With several natural ports, which became the sites of their cities, and an abundance of cedar and other trees for lumber, the Phoenicians began seafaring early. With their freedom from Egyptian rule in the 12th century, they built one of the largest trading empires in history over the next five centuries. Their goods were shipped all over the Mediterranean and even into the Atlantic to the Canary Islands and Britain. To what extent these commercial ventures were private enterprises and or were state-financed is unknown. Luxury items, such as jewelry, fine cloth, and perfumes, were among their trade items, but the most highly prized were metals. Thus they brought copper from Cyprus, iron from Crete, gold and lead from Morocco, and possibly tin from Britain. All of these imports were used in trade for food and other goods, many of which were traded in their turn.

Around 950 B.C.E. Tyre bought a large agricultural area from Israel, freeing the Phoenician city from having to import food. As a result, Tyre could use its full range of trading stock to enrich itself. It quickly became the wealthiest of the Phoenician city-states and, indeed, one of the wealthiest cities in the ancient Near East. The collapse of the Assyrian state around 600 B.C.E. freed the Phoenician city-states from having to pay tribute. The respite was temporary, for within a century the Phoenicians found themselves paying tribute to a new state, Persia.

THE PERSIANS

In the early sixth century B.C.E., under the Achaemenid Dynasty, Persia subjugated an even larger area than the Assyrians, ruling over the region from Asia Minor and the Mediterranean to India. Initially, as with the Assyrians, local economic institutions of the Persian Near East remained unchanged. Indeed, in Mesopotamia, for example, the distributive economy remained unchanged, and the labor tax remained in force; likewise, the Phoenician city-states continued their profitable trading. Throughout the entire Persian domain, payment in kind for taxes continued, even though currency in the form of coinage began to appear.

The Achaemenids divided their empire into provinces, called *satrapies*. The governor (satrap) of each was responsible for collecting taxes, some of which were sent to the Achaemenid capitals (Susa, Ecbatana, and Persepolis) as tribute. The tribute payment was partially in silver and partially in kind and was calculated on the basis of the affluence of the people and the agricultural yield of each satrapy. During the reign of Xerxes I (519–465 B.C.E.), for instance, the eastern satrapy of Media was assessed a tribute of 100,000 sheep in addition to a large sum of silver. The province also had to provide enough pasture for 50,000 royal horses. The king exempted the Persian heartland from this taxation, although Persians, like residents in the satrapies, were subject to a military *corvée*.

Trade was also an important part of the Persian economy, and since the state contained many important trade routes, the Persians controlled much of Near Eastern trade. To make it easier for traders and their goods to move along these routes, the Persian king Darius I (r. 522–486 B.C.E.) improved the roads by straightening and maintaining them, thus increasing the amount of trade traffic. He also posted soldiers along the roads to deter bandits who preyed on trade caravans.

Agriculture saw innovations that increased productivity and thus brought in more taxes to the royal treasury. The construction of underground channels brought water from the mountains to dry regions, thus enlarging the amount of arable land. Rice, imported from India, was planted in wet areas that previously had not been usable for agriculture.

Another important economic innovation during the sixth and fifth centuries B.C.E. was banking, which now appeared for the first time in the Near East. Two banking houses, Egibi and Sons and Murashu and Sons, operated in Babylonia at this time. These and other banks extended credit in the form of loans to individuals and to businesses that needed capital to pay taxes or to finance new commercial enterprises. Loans per se were nothing new. In both northern and southern Mesopotamia, *oikoi*, particularly temples, had always loaned barley, dates, or other food to their own members when necessary. The borrower would then repay the loan in kind at the next harvest. Most of these loans had no interest, though if a borrower failed to repay a loan, the lender might add a penalty of up to 25 percent to the loan.

The banks that appeared in the Persian-controlled Near East were private organizations that operated as profit-making businesses. They not only issued loans but also engaged in real estate transactions and underwrote promising business ventures. Still, loans were at the heart of this banking business, and these loans often carried high interest rates, sometimes 20 percent a month. With such high interest, the amount of a debt could rise quickly beyond an individual's ability to repay. When a borrower defaulted on a loan, a lender could take possession of the person's property. The banker could also seize the borrower and sometimes his or her family and sell them into slavery to help recoup the loan.

Loans became a necessity for many under Xerxes I, who raised taxes steeply. The Persian king also demanded that more of each year's tribute be paid not in kind but in gold and silver. The result of these royal measures was that merchants and landowners had to take out loans to pay their taxes. Often, in order to pay the exorbitant interest rates, borrowers had to allow lenders the right to work their land or run their businesses. It was then the lenders who reaped the profits and often gained possession of their clients' assets.

With the conquest of Persia by Alexander the Great (356–323 B.C.E.), Near Eastern economies, especially those along the Mediterranean coast, came increasingly under the influence of first the Greeks and eventually the Romans. But through the last centuries B.C.E. and the first centuries C.E. ancient Near

Eastern economies retained much that had emerged from the Sumerian cities of the fourth millennium B.C.E.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

A lack of written records makes it difficult to characterize the economies of ancient Asia and the Pacific. Writing arrived late in Oceania, in many areas not until the arrival of Europeans in the 18th and 19th centuries. Japan did not begin keeping written records until the 600s C.E. In China before the Han Dynasty (202 B.C.E.–220 C.E.) merchants and shopkeepers were considered insignificant people unworthy of including in government records, and the emperor Qin Shi Huangdi tried to have all historical records of China destroyed during his reign (221–210 B.C.E.) in order to have all history begin with him. The lot of peasants was of little concern to record keepers so long as they paid their taxes and served their overlords. In India records are confused before the Maurya Dynasty (321–185 B.C.E.) because the written language of the earliest civilization, the Harappan (ca. 2600–1500 B.C.E.), has yet to be translated, and the records of the succeeding Vedic culture were mostly oral tales; modern historians are still trying to sort out who ruled when and rely mostly on archaeological evidence for information about economic development.

People throughout eastern Asia, southern Asia, and the Pacific were originally hunter-gatherers; the rain forests of southern Asia offered plenty to eat. In Australia the climate was mostly dry, but hunter-gatherers found animals to eat. In the plains of northern China and Mongolia finding food became increasingly tough because the land was becoming desert. Nonetheless, prior to the introduction of agriculture, people could hunt big animals such as horses and deer; in Siberia people took to following reindeer herds on their migrations. These ancient peoples traded with one another, with seashells being traded to inland tribes and stone tools coming from central Asia. This trade resulted in the development of a new kind of economy, one in which people could acquire goods beyond their day-to-day needs as well as tools that would enable them to create more sophisticated products for use in their own societies and in further trade.

The seashells became particularly important for economic development, because some kinds became money that could be exchanged for goods or services. In China and India this was the beginning of the cash economies that would eventually make them the economic giants of ancient eastern Asia. There was not a big leap from bartering goods to using money. Instead, the shift was gradual, and bartering never entirely disappeared, especially in rural areas. In China government officials kept track of the use of barter, using its frequency as a sign of the health of the national and local economy: The more bartering, the less healthy the economy. Thus, Han Dynasty officials were alarmed when peasants shifted away from using coins to bartering in the first century C.E.

Bronze cast coin, Maurya Empire (which at its peak stretched from Kabul in Afghanistan to Nellore, near Madras, in southern India), third century B.C.E.; the Maurya Dynasty opened extensive foreign trade routes. (© The Trustees of the British Museum)

The first significant civilizations of Asia and the Pacific had agricultural economies. An agricultural economy is one in which the wealth of the nation depends on the productivity of farming. Agriculture began in eastern Asia around 6500 B.C.E. In the Yellow River region people began growing millet. Those people sometimes grew surpluses that they could trade for goods, thus raising their standard of living through being able to own more goods than could hunter-gatherers. In this way, some people gained more wealth than others and contributed to the development of upper and lower classes in society. Exactly when the ability to trade surpluses for wealth resulted in a shift to a full cash economy is not as yet known, but archaeological evidence from Chinese Shang Dynasty (1500–1045 B.C.E.) sites indicates that it had developed a strong cash economy. It was possible for people to build factories for manufacturing metal goods and pottery, to pay workers with coins, and to sell products for coins. This development gave the Shang a more efficient economy than one based entirely on barter, which was an advantage in its competition for power with its neighbors.

SHANG DYNASTY

An economy that depends for its wealth on products manufactured in factories is called an industrial economy. In Shang China were the beginnings of industry focused on the mass production of household goods and tools, but it nonetheless still depended on agriculture for most of its wealth. The center of the early Chinese economy was the Yellow River, where the Shang Dynasty was founded. Archaeological evidence is only beginning to reveal what economic life was like before the Shang. The people of the Yellow River were farmers. To their north were nomadic hunter-gatherers; to the south was the Yangtze River basin, where people grew rice; and farther south were people who lived in vast forests. The Yellow River people had begun farming in about 5800 B.C.E., several hundred years after rice was cultivated near the Yangtze. Instead of rice, they cultivated cereals such as millet.

The Yellow River people were actually several different cultures when the Shang united them through military conquest. The Shang Dynasty was warlike, and its economy grew in part because of the booty it acquired through conquest, moving mostly westward and northward. The peasants were the mainstay of the economy, because agriculture was still the primary source of wealth, and nearly everyone was a peasant. At first peasants owned their own land and were expected to give their loyalty to whoever was king. Almost nothing was recorded of their lives; their purpose was to serve the nobility. They formed the bulk of ancient Chinese armies and sometimes were killed in such huge numbers that the Chinese economy almost certainly was affected by the loss of food production.

Trade with the outside world was limited. There must have been some, because the techniques for casting bronze and manufacturing iron came from the west via trade routes through northern India. There may have been merchants and shopkeepers, but in the Shang world they were valued even less than peasants.

ZHOU DYNASTY

In 1027 the king of Zhou in western China overthrew the Shang king, beginning the Zhou Dynasty (1045–256 B.C.E.). As in the Shang Dynasty, peasants accounted for nearly all of China's population, and growth in the economy was fueled primarily by conquest. Merchants and shopkeepers counted for little more than they had during the Shang era, and their activities were little recorded. Potters and metalworkers seem to have been important, and they sometimes had homes nearly as fine as those owned by nobles. Depending on the wishes of the current king and immediate overlord, peasants alternately owned their lands and had their lands taken from them.

The remains of Zhou arts and crafts indicate that they developed a strong enough economy that even poor people could exchange their extra goods for small luxuries. An excavation of the city of Jin revealed a large bronze-working complex from about 450 B.C.E. It had smelting furnaces and 30,000 clay-casting molds. At Xinglong in Hebei Province a 36,000-square-yard factory for manufacturing iron farm tools has been discovered. These sites suggest that some Zhou people were able to specialize in the manufacturing of a particular kind of product and could exchange it for food, clothing, and housing without actually growing the food, making the clothes, or constructing the housing themselves. Goods owned by the small ruling class of royalty and nobles were elaborately decorated, indicating that there were craftspeople who survived by providing finely crafted products to the wealthy, but even ordinary pots owned by peasants had some decoration to make them pleasing to the eye or to endow them with magical properties. This suggests that the peasants lived slightly more prosperous lives than they had under the Shang.

The Zhou monarchs created a feudal society; they appointed nobles to rule provinces, and the nobles swore loyalty to the king. This meant that individual provinces could

vary considerably from one another in economic prosperity and the way in which they treated the people responsible for keeping the economy running: the peasants and tradespeople. In 770 B.C.E. the Zhou monarch moved his capital from the city of Xian in the far western province of Qin to Luoyang in the province of Zhou to be farther away from marauding barbarians. For this reason, the Zhou Dynasty's prestige fell so much that the nobles in the various provinces began vying for control of the country. Eventually the nation fell into ceaseless war among its provinces. This is often called the Warring States Period (4453–221 B.C.E.), during which the king had little power. At this time coins circulated widely enough to shift the economy from primarily one in which goods were bartered to one in which most goods were exchanged for money, resulting in a full-fledged cash economy.

QIN SHI HUANGDI

In about 228 B.C.E. an especially brutal but clever warlord, King Zheng of the state of Qin, began a war of conquest against the other Chinese nobles. He was able to do so in part because the economy of his province was stronger than elsewhere and its food production was high. He called himself Shi Huangdi. His political philosophy was called legalist, and it meant that everybody and everything should be governed by a mercilessly strict rule of law in which anyone could be punished, no matter what his or her social status. The laws were so numerous and confusing that almost everyone broke several of them without knowing, and commoners convicted of even petty crimes were sent to work themselves to death on the Great Wall in northern China.

He founded the Qin Dynasty (221–207 B.C.E.). This dynasty expanded trade with central Asia and India. To boost the economy of the nation, the Qin Dynasty also standardized China's currency, which made trade between different regions easier. In this way the economy became more efficient, which allowed wealth to accumulate faster. In 210 B.C.E. China's weights and measures were standardized as well; consumers' trust grew, and both merchants and the government could keep track of what goods were selling well and exactly how much was being paid for goods anywhere in the country. The Qin Dynasty also improved its bureaucracy for collecting taxes, keeping better records of what was paid. With standardized weights and coins, paying taxes became simpler, but the emperor's high taxes drove peasants and craftspeople into abject poverty.

HAN DYNASTY

So deep was the hatred for the Qin Dynasty that when it was overthrown in 206 B.C.E. every member of the emperor's family was murdered. Of the warlords who remained, a particularly able soldier named Liu Bang defeated his rivals and established the Han Dynasty. As emperor, he was known as Gaozu. Perhaps the most immediate effect on the economy came from the lowering of taxes. Taxation had to be fair, ac-

ording to the government's Confucian philosophy, and lowering taxes gave millions of Chinese the chance to improve their lives by investing money left over after paying taxes and purchasing their basic needs. This investing of money allowed people to pull their cash to develop business ventures jointly, which enabled those who could not have done so in the past to engage in trade with the world outside China.

This expansion of the Chinese economy had an effect on its neighbors, especially Japan. The merchants of the Han Dynasty pioneered sea routes, venturing along Asia's east coast; Chinese pottery was in especially high demand in the emerging civilizations to the south. To Japan, Han merchants brought silk, rice, iron, and bronze. By 200 C.E. the Japanese had become trading partners with China, exporting a high grade of silk coveted by Chinese merchants. Chinese copper coins became the only accepted money in Japan, aiding Japan's slow development toward a cash economy. In exchange for copper coins sent by China's emperor, Japanese rulers sent back tribute.

Foreign tribute was a complicated business in China; nearby foreign governments were often happy to give it to China because the Chinese government gave them valuable prestige by formally recognizing them. Furthermore, the Han custom was to send gifts back to those who sent tribute, sometimes of greater value than the original tribute. These gifts not only showed off China's economic prosperity but also encouraged local rulers to open their lands to Chinese traders. This began the great age of the Silk Road.

SILK ROAD

During the early Han Dynasty in northern China a nomadic tribe called the Xiongnu constantly conducted raids. The Xiongnu drove another tribe, the Yuezhi, westward and settled on China's main trade route to central Asia. In about 138 B.C.E. the Chinese emissary Zhang Qian was sent to sneak through Xiongnu territory to find the Yuezhi and form an alliance against the Xiongnu. He failed in this, but he returned to China in 126 B.C.E. with information about territories to the west. He also brought back grapevines and alfalfa.

Trading through central Asia was an important way to keep China's economy growing and healthy, by providing markets for Chinese goods. Furthermore, consumers in China were demanding foreign goods, putting pressure on the government to make trade routes secure. Using Zhang Qian's information, the Hans attacked the Xiongnu and drove them into central Asia. They continued into central Asia, where the local kingdoms were forced to agree to pay tribute to the Chinese emperor. This secured China's access to the Silk Road, which was actually several different routes that began in the city of Chang'an (now called Xi'an) in western China. These routes went through Persia to the city of Baghdad; from there the routes went to Syria and then to Mediterranean ports from which Chinese goods were shipped to southern Europe and North Africa. An important alternative route went down

the Indus River and then westward by sea. The first major Chinese caravan reached Persia in 106 B.C.E.

China imported wine, which was very popular, from the Near East and Europe. Foods imported from the west included figs and cucumbers, as well as sesame and safflower oils, which were used in cooking. Roman technology went east as well, including an improved potter's wheel for the manufacturing of ceramics. China exported peaches, apricots, ginger, and basil. China also exported silk cloth, which was held in high value; the Chinese carefully guarded the secret of the making of silk. Chinese merchants brought home piles of Roman coins, and Roman leaders worried that all their gold was going to China and India.

Under the Han Dynasty ordinary Chinese prospered as they had never done before. Not only could peasants and the working poor afford metal pots and pans for their cooking, they could also purchase a varied diet of foods. Wheat and barley cakes became common. Peaches, plums, melons, onions, turnips, yams, and beans were part of the everyday diet. Spices such as basil and ginger were used in everyday cooking. The middle class of merchants, craftspeople, and shop owners could afford to add meat, especially pork and chicken, to their everyday diets.

On the Korean peninsula in 108 B.C.E., to boost China's economy by making trade with Southeast Asia more efficient, the Han government established four trading cities that served as ports for commerce from Southeast Asia, as well as from Japan, the Philippines, and Indonesia. The governors of the cities kept records of who came and went, taking special note of tribute that was being sent to the emperor. By about 300 C.E. the Koreans and Japanese were imitating Chinese customs and adopting the Chinese diet.

THE HARAPPANS

The other great economic power of eastern Asia was India. Unlike China, which had a unified national identity for most of its development, India saw the rise and fall of many kingdoms. The first Indian civilization was the Harappan of about 2600–1500 B.C.E. It built cities and towns in the Indus valley and surrounding areas, northward into modern southwestern China, eastward beyond New Delhi, and west and south along the coast from the mouth of the Indus River. The Harappans' main crop was rice, probably grown on dry ground rather than in rice paddies, and they built irrigation canals to bring water to their crops.

Their major cities were Harappa and Mohenjo Daro, both of which seem to have been designed from the ground up, with each city laid out in a checkerboard pattern of streets and having underground sewers that were accessible through manholes. Each city had a huge granary. Some archaeologists characterize the granaries as banks, where the wealth of the local community was stored. In hard economic times Harappans could make withdrawals from these banks, thus enabling the population to feed itself. The wealth the grain represented also could be invested. This most often

took the form of exports; grain was traded to the Near East in exchange for consumer goods such as cookware as well as for luxury items such as decorative sculpture.

Harappan society seems to have been structured around an upper class and a lower class based on ownership of land. It may have had kings, but no palaces or other indications of royalty have been found. Some areas of the Harappans' cities and towns had large houses with big walls and spacious interiors, while other areas crowded together small houses along narrow streets. Based on differences in housing, some historians have theorized that the economy had a big division between rich and poor, with a small elite group controlling the wealth generated by the economy. Some also suggest that the division was so great that the lower class was made up of slaves of the upper class. Others speculate that the differences between social classes may have arisen from a difference between owners of large estates and owners of small farms, or they may have resulted from hereditary social status, with the upper class being nobility and the lower class peasants. In any case, the Harappans plainly had an economy advanced enough to have the means to pay people to care for the cities. Sewers, streets, walls, fortifications, and granaries were well maintained until about 1800 B.C.E., when the economy of the Harappan culture seems to have begun a decline, perhaps caused by natural disasters, invading nomads, or both.

The Harappans fueled an extensive trading empire and were well known to the Sumerians of the Near East, who called them Meluhha. Ships from the Harappans sailed to Dilmun, modern Bahrain, where they traded for goods made in the Near East. During the reign of Sumer's Sargon I (r. 2334–2279 B.C.E.) Harappan ships routinely sailed up the Tigris and Euphrates rivers to dock at major cities.

THE VAISHYAS AND SUDRAS

The next city-building culture did not arise in India until the 900s B.C.E., when the nomadic Vedic people began settling, though they did not become a fully agricultural society until about 500 B.C.E. By 1500 B.C.E. some of the nomadic peoples of central and northern Asia had developed the practice of waiting until after harvest time and then raiding towns and villages to steal food and other valuables. This behavior was a constant factor in weakening the ancient Asian economies of India, China, and Korea.

By 500 B.C.E. India was divided into numerous small kingdoms. Complex economies developed in northern India, giving rise to a cash economy, meaning an economy based not on barter but on the use of money to make purchases. The Vedic culture that dominated northern India had brought with it a system of social classes that became the castes of India. Under this system the third-highest caste was the Vaishya, who were in charge of money lending, agriculture, and trade. They paid higher taxes than the other castes because one of their duties was to create wealth to give to the higher castes—the Brahmins, or priests, and the Kshatriyas, or warriors and rulers. The Vaishyas resented

being third-class people and having to pay higher taxes than everyone else, so during the Maurya Dynasty many of them adopted Buddhism, which advocated social equality. The fourth caste was the Sudra, a group that included craftspeople. The men were blacksmiths, carpenters, and potters, while the women were basket makers and weavers of textiles. Perhaps either gender could have made garlands, which were important ornaments.

Farmers were of the Vaishya caste, and they led difficult lives, burdened by high taxes and usually allowed to work only small plots of land. The big estates tended to be owned by kings and temples, and they were worked by Vaishyas, who were little more than slaves. Their main crop was rice, but they also cultivated wheat, barley, and cotton mostly in northern India, and sugarcane, peas, and beans mostly in southern India. They raised sheep, cattle, and buffalo. Recognizing the importance of keeping their agricultural economies strong, Indian governments usually gave farmers seeds when the farmers needed them, and they lent farmers oxen, tools, and even money.

Large towns had public markets where farmers could sell their produce and where shops sold the products of the Sudras and goods imported by the Vaishyas. Merchants sold oil for lamps, perfumes, and spices. Some owned taverns, where government agents would spy on the patrons to see who was spending lavishly and therefore might not have paid all his taxes. The Mauryan government developed a bureaucracy devoted to keeping track of people and their wealth.

People paid for goods with gold and silver coins. Each coin was marked with a code that identified where it had been minted, which allowed governments to identify who might be minting underweight coins, which by law were supposed contain a certain weight of gold, silver, or copper. Underweight coins could cause inflation, because sellers would figure out that certain coins were underweight and would therefore demand more of them for their goods. A high number of underweight coins could cause people to lose faith in the coins, perhaps turning to bartering for their goods. This could lead to a collapse of the cash economy, which in turn would cause many businesses to go bankrupt. Governments also kept track of the movements of merchants and how they were treated. Villages, towns, and cities were expected to protect foreign merchants and sometimes were required to reimburse a merchant for the value of his goods if he was robbed by bandits while in their territories.

INDIAN FOREIGN TRADE

During the Maurya Dynasty, India opened up extensive foreign trade routes. The Mauryans traded with people from the east coast of Africa, the Near East, Greece, Rome, and China. Alexander the Great's invasion of northwestern India in 326 B.C.E. made wide-ranging contacts with Western cultures. Beginning with the reign of Augustus Caesar in Rome (27 B.C.E.–14 C.E.) Indian kingdoms sent ambassadors to the Roman court, seeking to expand and protect trade relations

with the Roman Empire, because the Roman Empire had become an important source of wealth, sending literally tons of gold and silver to India in exchange for goods India either produced or acquired from cultures farther east. Indian ships ranged westward and eastward, staying close to the southern Asian coast. They established trading posts on the Malay Peninsula and would land goods on the peninsula's west coast, then carry them overland to the east coast to be reloaded on ships. The island of Sri Lanka, off the southern coast of India, became famous for its big warehouses, extensive docks, and ships visiting from all over southern Asia. By charging docking fees and developing expertise in navigation, the Sri Lankans became wealthy.

With Greek and Egyptian crews, Indian merchants sailed as far as what is now southeastern China, and they traded in Java, Vietnam, Cambodia, and Thailand. On overland routes the Indians formed caravans, often consisting of the carts of several different merchants who had joined together for protection from bandits. Their caravans wended their way through the Western Ghats mountains to the west coast of India for loading onto ships or through the various roads called collectively the "Silk Road" that led northeastward to China as well as west into the Near East. In southern India this trade resulted in the development of trading empires, with governments devoted to fostering trade. How many people in southern India were reached by the wealth generated by the caravans is not known, but it seems that nearly everyone profited from the caravans by selling them food and goods or by providing them with services. So important was foreign trading that when the Roman Empire suffered an economic recession in about 170 C.E., the loss in trade lowered the standard of living of the Vaishya caste.

People in India imported and exported exotic animals, and they exported gems, metal, earthenware, and beads across Asia. This trade spread goods from many cultures across Asia, even bringing Roman pottery to Java. To Rome went spices, pearls, textiles, cosmetics, and a host of other goods. From Rome came wine, sculptures, ironware, and coins. By the end of the Maurya Dynasty, India had become one of the two great economic powers of eastern Asia, and it remained that way through wars and revolutions. The other great economic power was China.

EUROPE

BY PETER S. WELLS

Between the earliest human activity in Europe around a million years ago and the advent of writing around 200 B.C.E., we are dependent exclusively upon the evidence of archaeology for studying the economies of communities. The material evidence of archaeology enables us to examine in detail the three main categories of economic activity: subsistence (production of food), manufacturing (making of tools, weapons, ornaments, containers, and other necessary and desired goods), and trade (obtaining materials and products from

other communities, through exchange). During the final centuries B.C.E., and especially with the writings of Julius Caesar (100–44 B.C.E.) about Gaul, written sources in Greek and Latin begin to complement the evidence of archaeology. During the Roman Period in Europe—the first four centuries C.E.—a number of texts refer to the economy, though little written information pertains directly to the topic.

SUBSISTENCE

Before the introduction of agriculture and animal domestication around 6000 B.C.E. in the southeast of Europe, all peoples in Europe were hunter-gatherers, or foragers. They relied on plant foods they collected in their environment, such as fruits, berries, seeds, nuts, and roots, and on animals they hunted, fished, and collected, including eggs and shellfish. Bones of animals that people hunted and scavenged are often well preserved on archaeological sites. At sites of the Paleolithic Period, or Old Stone Age, from almost a million years ago to the end of the ice age that dates to about 12,000 years ago, such finds attest to the hunting of elephants, mammoths, woolly rhinoceros, reindeer, red deer, elk, bison, horse, and numerous small mammals, as well as birds and fish. Plant food remains are much less apparent on archaeological sites than animal bones. A wide range of plants were collected, processed, and consumed by Europe's early hunter-gatherers.

During the Mesolithic Period, or Middle Stone Age, roughly 8,000 to 12,000 years ago, the warming of the earth's climate melted the glaciers that had covered the northern parts of Europe, and the tundra that had occupied much of the continent was replaced by the forests and grasslands that comprise the natural vegetation of Europe in recent times. With the great climatic changes, the megafauna—the mammoths, woolly rhinoceros, and other large mammals—became extinct, and the lands were populated by new species of animals, such as red and roe deer, wild boar, aurochs (wild

Perforated part skull and antlers of red deer dating to the Early Mesolithic, about 7,500 B.C.E., from Star Carr, Vale of Pickering, North Yorkshire, England. © The Trustees of the British Museum

cattle), elk, and hare. Many Mesolithic communities made great use of shellfish along the coasts of northern Europe.

Agriculture was introduced into temperate Europe around 6000 B.C.E. from the Near East, where the cultivation of wheat and barley and the raising of cattle, sheep, goats, and pigs had been established by 8000 B.C.E. Agriculture is first evident in southeastern Europe, as at Nea Nikomedeia in Macedonia, and the practice spread gradually northward and westward, arriving at the coasts of the Baltic and North seas and the Atlantic Ocean around 4000 B.C.E. The transition from hunting and gathering to agriculture was not sudden. Many communities adopted farming to supply part of their diet while maintaining their hunting-gathering practices well into the Neolithic Period.

The process of the spread of agriculture from the Near East into southeastern Europe probably involved a number of different mechanisms. We know that communities that practiced hunting and gathering, as at Franchthi Cave in southern Greece, used boats to fish the deep waters of the Aegean Sea and to trade across the sea for materials such as obsidian (a natural volcanic glass used for making cutting tools). It is likely that some such communities learned the technology of agriculture and animal domestication and acquired the seeds and animals from farming peoples on the eastern side of the Aegean Sea in what is now Turkey. Also, some farmers from that region may have traveled across the Aegean with their seed grains and animals to settle fertile valleys in the southeast of Europe.

During the Neolithic Period, Bronze Age, and Iron Age, some communities tended to rely more on agriculture and others more on livestock, depending upon local climatic conditions and soils. Archaeological evidence shows that many fruits were eaten, including apples, pears, plums, grapes, raspberries, and blackberries, but it is not clear when these plants were fully domesticated.

Technological innovations contributed to the efficiency of food production. Metal sickles came into use during the Bronze Age. Traction plows, made of wood and pulled by animals, reduced the time and energy required for planting. In the Late Iron Age, after about 400 B.C.E., metal plowshares became common, enabling farmers to cultivate heavier and more fertile soils. In addition to cereals, oil-bearing plants, including flax and gold-of-pleasure, were commonly grown, as was the broad bean.

Following the Roman conquests of about half of Europe during the first century B.C.E. and the first century C.E., there was some shift in emphasis in crops grown in the new provinces, and new, often larger, breeds of animals were introduced. But for the most part farmers in the provinces continued tending the same crops and animals they had raised during the Iron Age. Rome introduced the villa system, and this pattern was widely adopted by local landowners. The villa included a residential building in which the owner and family lived. Around that building were gardens and workshops, and beyond them fields of wheat, barley, and other cereals.

Documents that pertain to subsistence in temperate Europe were written after the Roman conquest, and they describe how the villa system worked. The villa owner employed tenants who worked the land, and wealthy owners kept slaves. Villas were meant to be self-sufficient units of production. Each villa grew and manufactured what was needed by its little community, and it exported surplus produce to the urban centers to exchange for manufactured goods and luxury products. Villas varied greatly in size and wealth. Some were huge, with lavish residences decorated with mosaic floors and painted walls, and with hundreds of tenants and slaves working the fields and workshops. Others were modest, with the single family that owned the villa doing all the work.

Written documents from the Roman Period indicate that farmers had to pay tax on their produce, and the rate of taxes rose and fell with changing economic and political circumstances. Although we have no written records about taxes or tribute in the pre-Roman periods, it is likely that the political centers of the Iron Age maintained some kind of system that taxed the agricultural goods farmers produced.

In lands beyond the Roman imperial frontiers—east of the Rhine River, north of the Danube River on the Continent, and north of Hadrian's Wall in Britain—subsistence organization and practice were affected by the Roman presence but not as much as in the conquered lands. The Roman army had huge numbers of soldiers stationed along the frontiers—more than 100,000 along the Rhine and Danube rivers alone—and these troops placed a great demand on local resources for food and raw materials. Archaeological evidence shows that the Roman administrators traded for agricultural goods with peoples across the frontier. Places such as Feddersen Wierde on the northwestern coast of Germany demonstrate the effects of the Roman demand for goods from across the frontier. At that site the archaeological evidence shows an ever-increasing focus on the production of livestock during the first three centuries C.E., and at the same time an increasing flow of Roman luxury objects into the community.

MANUFACTURING

Among the earliest tools in Europe are those at Atapuerca in northern Spain; perhaps dating back as early as 700,000 years ago, they are called core and flake tools. Core tools are shaped by striking off flakes from the central portion of a large pebble or cobble. Flake tools are made from the flattish pieces that are knocked off. New during the Mesolithic Period, or Middle Stone Age (8,000–12,000 years ago), was an emphasis on manufacturing microliths—very small stone tools, many of which served as points on arrows. The bow and arrow was a new technology developed around the start of the Mesolithic Period as an adaptation to the hunting of the small and fast-moving animals of the forests that spread throughout Europe during the warming conditions after the end of the last ice age.

During the Neolithic Period people began to make pottery. Good potting clays are available throughout Europe, and most communities made their own pottery. Stone tools

during the Neolithic Period were similar to those of earlier times, with one significant innovation. Axes made by grinding one stone against another, rather than by flaking, became common. Modern experiments show that ground stone axes are more efficient for cutting down trees and chopping wood—both activities that Neolithic farmers carried out to clear their fields and to build houses and fences—than are axes made by flaking. More efficient tools meant that farmers could spend less time on the basic tasks of managing their farms and devote more effort to generating surplus produce. Surplus might take the form of foods such as grain and meat or perhaps other goods, such as leather and wool. Surplus products might then be used to exchange for materials made by other individuals or for goods that might arrive through trade with other communities.

The farming peoples of the Neolithic Period began to manufacture textiles on a regular basis, using wool from sheep and linen from flax grown in the fields. Only under exceptional circumstances do textiles survive to be recovered by archaeologists. Complete garments made of textile fibers have been found in many submerged settlements along the lakes of circum-Alpine Europe and in some bog environments in northern regions of the continent. The widespread distribution of ceramic spindle whorls (weights attached to spindles to help them maintain momentum) and loom weights attest to the production of textiles in many communities throughout the continent. Some communities produced the textiles they needed to make clothing for their own members, while others produced surplus textiles for trade with other communities, in exchange for which they would receive materials that the other communities produced.

Metalworking in Europe began during the sixth millennium B.C.E., when copper was hammered to form beads and simple pins. By the middle of fifth millennium B.C.E. metal-smiths were casting both copper and gold to produce more substantial objects than was possible through hammering. Bronze, a copper alloy that usually was about 90 percent copper and 10 percent tin, was coming into widespread use by the middle of the third millennium for tools and ornaments, representing an important technological advance over the softer copper. Neither copper nor tin is common in Europe, and both required complex underground mining to produce. Copper mines of the Bronze Age (2000–800 B.C.E.) have been explored in the Alps of Austria, and the evidence shows that the industry was relatively large in scale and highly specialized technologically.

Small quantities of iron were being processed during the Late Bronze Age, but it was not until iron began to replace bronze as the principal material for tools that we speak of the Iron Age. In central parts of Europe this change took place around 800 B.C.E., and in northern Europe a couple of centuries later. Iron is much more abundant on the earth's surface than are copper and tin, and so much iron ore was readily available on the surface during prehistoric times that underground mining was not required in many areas. While the

main advantage of iron over bronze was its greater availability, once blacksmiths had mastered the techniques of working with iron, the new metal also could yield sharper, harder, and more durable cutting implements. By the end of the Iron Age hundreds of different kinds of tools were being made of iron and of steel (an alloy of iron and carbon). Among the most common tools were knives of different kinds, axes, hammers, scythes for harvesting hay, and implements for use in wood-working, such as saws and chisels. Nails were first commonly employed for building houses and boats during the final two centuries B.C.E.

All of these tools made economic activity more efficient. Crops could be grown with less effort expended to prepare the soil and harvest the plants, and buildings and ships would be constructed faster and more sturdily. Thus, more time and energy became available for other economic activities, such as creation of surpluses for trade and engaging in trading expeditions. The overall scale of economic activity could increase, since these basic activities required a smaller proportion of a community's total resources and energy.

In the Roman Period the principal change in manufacturing was in scale, not in kind. In the politically unified landscape of the Roman Empire the production of some goods, such as pottery, could be organized on a larger scale than had been practiced earlier in temperate Europe. For example, large centers of manufacture at La Graufesenque and Lezoux in France and Rheinzabern in Germany produced great quantities of *terra sigillata*, the ornate red pottery that was favored both within the empire and outside it. In other materials also, including metal and glass, Roman Period manufacturing was carried out in greater quantities than was production in the pre-Roman context. But even with the emergence of some larger-scale industries, many of the manufactured goods that people used were still made in village or household settings.

TRADE

Trade is important not only because it enables people to acquire raw materials from far away and specialized products that their own communities do not produce but also because it inevitably brings people into contact and forces them to interact. Along with goods, information passes between trade partners. Evidence shows development of active trade by the Upper Paleolithic Period (12,000–40,000 years ago). Flint of exceptional quality and shells from the seacoasts are often found on sites at considerable distances from their sources, indicating that people were either trading with groups who had access to them or traveling distances to acquire them.

By the Mesolithic Period systematic trade in amber from the Baltic Sea region is evident throughout northern Europe. With the establishment of permanent settlements and the production of agricultural and animal goods, communities had the first opportunity to generate surplus products that could be traded for other goods. From this time on people traded for a wide range of materials, including amber, coral, gold, and jet, all of which they used to make ornaments and

to display their status and wealth. Trade continued in especially fine flint, as well as in some manufactured implements such as stone axes and pottery vessels.

Until shortly before the Roman conquest, we have no evidence for standards of value, such as coins. Instead of the market-based economy of today, early Europeans seem to have operated trade systems that were closely linked to social relations rather than to market exchange. Research on trade in Neolithic stone axes, for example, has shown how patterns in the distribution of these objects suggest that the objects played important roles in regulating social relations between the communities that were participating.

During the Bronze Age trade came to play an increasingly more important role in societies because many communities had to trade to acquire metal. Both copper and tin are relatively rare in nature. They occur in deposits in mountainous regions of Europe, such as the Austrian Alps and Cornwall, and not on the North European Plain, for example. Yet from the beginning of the Bronze Age on, communities all across Europe had bronze ornaments and tools. Copper mines at the Mitterberg near Salzburg in Austria show that hundreds of workers were involved in mining, smelting, and trading metal to communities throughout the continent. Along with bronze, many other materials circulated along the trade networks. Trade systems were complex and varied. Large and finely crafted items, such as swords and cauldrons, were transported great distances from their places of manufacture, while smaller and more common objects, such as decorative pins, were used near the places where they were made.

The Early Iron Age (800–450 B.C.E.) is distinguished by the appearance of trade centers, places where communities grew as a result of expanding systems of commerce. The best documented are a series of hilltop settlements, including Mont Lassois in France, the Heuneburg in southern Germany, Závist in Bohemia, and Belsk in Ukraine. At these locations communities grew to populations of perhaps 500 to 1,000, and they were actively engaged in trade with groups in different parts of Europe. Especially evident are objects that arrived into central Europe from the Mediterranean world. Greek pottery and ornaments, Etruscan bronze vessels, and branches of coral (to be cut and used for decoration on jewelry) are among the special imports that are found in considerable quantities at and around such centers during the sixth through fourth centuries B.C.E. Along with these luxury imports, more common objects circulated as well, such as bronze pins, glass beads, amber, and jet.

In the Late Iron Age, in addition to all the categories of trade goods that circulated earlier, bulk commodities came to play important roles in trade. Noteworthy are massive grindstones of basalt, quarried at different locations, such as in Bohemia and in the Middle Rhineland, and transported to still other locations where they were employed for grinding grain. In the final two centuries before the Roman conquest commerce intensified between communities in temperate Europe and the Roman world. Much of this commerce was centered

on the large, city-like settlements known as *oppida*, but many Roman imports occur at other sites as well. These imports included ceramic amphoras in which wine was transported, fine pottery, coins, medicinal implements, bronze vessels, silver vessels, and glass bowls. Some communities in temperate Europe began minting coins around the middle of the second century B.C.E., and they show that exchange flourished throughout Europe during the final two centuries B.C.E.

After the Roman conquest, which divided Europe roughly into a southern and western half that belonged to the Roman Empire and a northern and eastern half that remained unconquered, many new trade goods became available to communities in the provinces, including exotic foodstuffs from the Mediterranean world. Besides wine and olive oil, these included dates, figs, olives, and the tangy sauce known as *garum* that was a great favorite among Roman diners. Mass-produced Roman pottery circulated widely, both in the imperial lands and beyond it into far northern and eastern Europe. New infrastructure contributed to the expansion and intensification of trade during the Roman Period, with large cargo ships plying the Mediterranean shores and the major rivers of Europe, roads constructed over much of the Roman provinces, and bridges built across rivers where none had stood before, such as that across the river Thames in Roman London (Londinium).

Trade across the frontier into the unconquered regions of Germany, Scandinavia, Poland, and other lands was both extensive and intensive. The imperial frontiers on the Rhine and Danube rivers were no impediment to trade, as tens of thousands of Roman-made objects found north and east of those boundaries make clear.

GREECE

BY CHRISTOPHER BLACKWELL

The ancient Greek world, from the Bronze Age in the second millennium B.C.E. through the rise of Roman dominance in the Mediterranean in the second century B.C.E., consisted of independent city-states and kingdoms, dispersed across an area that had the Greek peninsula at its center but that extended from what is now southern France through the east coast of Italy, Sicily, parts of northern Africa, the west coast of Turkey, and around the Black Sea. These thousands of communities were united by a common language, worship of a more-or-less fixed set of gods, and certain shared customs. From time to time certain states would achieve political control over larger areas—the kingdom of Mycenae during the Bronze Age, Euboea during the eighth century B.C.E., Athens during the fifth century B.C.E., and Macedonia during the late fourth and early third centuries B.C.E. Even so, it is impossible to describe a single, unified “Greece” in any meaningful sense for any period of antiquity.

The economic history of the Greek world, then, must consider different places at different periods and is limited by the available evidence. For the Bronze Age, there survive

some bureaucratic records on clay tablets. For the so-called dark ages that followed, there are only archaeological remains, mainly burials. The best evidence for the Classical Period, the fifth and fourth centuries B.C.E., comes from Athens, from the speeches of Athenian orators, the writings of such philosophers as Xenophon and Aristotle, and the many inscriptions that the democratic Athenians erected to promulgate their public business. In the Hellenistic Period, after the fourth century B.C.E., the best evidence comes from Egypt, at that time ruled by Macedonian Greeks; the dry climate of ancient Egypt preserved many remains of documents written on papyrus and recording, in Greek, the day-to-day business of a complex civil administration, ruling over Egyptians but conducted mainly by Greeks and in the Greek language.

The English word *economy* derives from the Greek word *oikonomia*, a compound of the word *oikos*, “household,” and the word root *nom-*, which appears in many Greek words having to do with custom, opinion, belief, order, law, and regulation. We might translate *oikonomia* as “regulation of the household.” This interpretation gives some insight into the fundamentals of “economic” thinking among the ancient Greeks, which differs in important ways from the ideas that underlie modern economic institutions.

The vast majority of people in the ancient Greek world were rural peasants, living in small households and aspiring, at least, to be as self-sufficient as possible. The *oikos* of *oikonomia* does not refer to a structure but to the idea of a household; it includes all the people living together in a household, nuclear and extended family, servants, and slaves, as well as livestock, land, and any crops growing on the land. The most basic economy appears in the oldest surviving examples of texts written in the Greek, from the Bronze Age, and from Homeric poetry, from the period afterward.

EARLY EVIDENCE FROM THE BRONZE AGE

The oldest surviving examples of writing in the Greek language are the so-called Linear B tablets. These are clay tablets from the Greek Bronze Age (3000–1100 B.C.E.), inscribed with a script that predates the Greek alphabet. Deciphered in the 1950s, this script was revealed to be an early form of Greek, and the tablets were found to deal largely in the business of household management.

The tablets from the Bronze Age palace complex at Knossos, on Crete—over 4,000 of which have been found—contain mostly lists of material supplies. Stores of oil, wine, and grain as well as numbers of sheep and cattle—the food supply for a large, well-regulated community—were recorded and updated on clay. So certain tablets record the details of flocks of sheep: which areas they inhabited, who was responsible for them, their size, and what sort of sheep made up each flock.

More complex economic transactions appear on these tablets as well. One tablet, from Pylos in the Peloponnese (the southern peninsula of the Greek mainland), seems to record a donation of “ship bronze” to the king, from officials

of various temples and other religious sanctuaries. Scholars are uncertain as to what “ship bronze” may have been, but one explanation may be that the king at Pylos demanded contributions of metal from his outlying dominions to help construct a navy. Other tablets record payments to workers, such as a tablet, also from Pylos, that records the wages for the “bath-pourers,” who seem to have been paid in rations of wheat and figs.

ECONOMICS IN THE HOMERIC WORLD

Homer’s *Odyssey* describes in some detail the economic workings of the house of Odysseus. This hero left his estate on Ithaca to fight in the Trojan War, to return only after 10 years of fighting and another 10 years of wandering. While the poem is fantastic, filled with monsters, divine intervention, and mythological characters, the domestic world it describes must reflect, to a greater or lesser extent, the world familiar to the poet and his audience, during the 10th through seventh centuries B.C.E. It can thus provide some insight into the economy of a lord’s estate.

Odysseus’s household consisted of himself, his wife (Penelope), their son (Telemachus), and various slaves. One of these, the swineherd Eumaeus, recounts in the poem the extent of his master’s wealth. This wealth is described entirely in terms of livestock: “For surely his wealth was great beyond telling. . . he has twelve herds of cows on the mainland, the same number of flocks of sheep, the same number of pigs, and the same number of wide-roaming herds of goats, which are in the care of shepherds or pastured by strangers. Here, on Ithaca, he has eleven herds of goats grazing off in the distance, looked after by brave men.”

Several kinds of economic exchanges existed in the Homeric world. The most straightforward of these, the kind most purely “economic,” are trading and its more rough-edged cousin, piracy. When Odysseus arrives at various places on his wanderings, the people he meets invariably ask him, “Are you here for trade, or are you a pirate?” This question seems to reflect a new reality in the Greek world after the fall of the Bronze Age civilizations: increased economic activity across the Mediterranean, some of which was for mutual benefit (trade) and some of which was for more unilateral benefit (piracy).

The other kinds of exchange are less purely economic and are much more bound up in the social fabric. In the world described by Homer powerful people exchange gifts continually. A stranger coming to the house of Odysseus would be entertained and, upon his departure, offered gifts of material objects, such as silver bowls, shields, and gold cups. Such exchange establishes a social bond between guest and host, and the history of each gift-object was remembered and recalled forever. It was the mark of a wealthy and powerful person to give and receive such gifts. Giving precious gifts proved the wealth and status of the giver and put the receiver under an obligation.

Similar exchanges of valuable property attended marriages. The *Odyssey* suggests that a marriage involved both a

dowry—payment from the family of the bride to the groom—and bride-gifts—payment from the groom to the family of the bride. The latter established the status of the potential groom; a man who could not provide valuable bride-gifts would not be considered wealthy enough to deserve the bride. The former was insurance for the well-being of the bride. The dowry was paid to the husband but did not belong to him entirely; if he should send his wife back to her family, or if she should choose to leave, the dowry would have to be repaid.

Not everyone was a lord in the community like Odysseus, of course, and there were degrees of status among the more ordinary people. These degrees may seem surprising to modern readers, however. It seems that the status of a slave was higher than that of a hired man, for example, perhaps because a slave was a full-fledged member of the household while a hired worker did not “belong” in the community. Homer also identifies a category of *demiourgoi*, “workers for the community,” certain craftsmen, prophets, healers, builders, and singers of tales, who are not attached to a particular household but are nevertheless valued in the community. As the Greek world emerged from the dark ages and these household-based communities came to be organized into more structured city-states, more sophisticated economic practices and institutions came about.

Much of the literary evidence comes in the form of complaints—complaints from peasants about the oppression of the lords and from the lords about the presumption of the peasants. The poet Hesiod describes complaints about “bribe-devouring judges” who mishandled cases of inheritance, and the poet Theognis of Megara, in the sixth century B.C.E., details a complaint about how “those who previously did not know about courts and laws, but wore goatskins and held pastures outside the city” had come into political power, displacing the former lords. By the fifth century Greek society had produced enough evidence for modern scholars to describe in some detail the economic workings of a city-state, with the democratic and prosperous state of Athens providing the best evidence.

SLAVES

The best early evidence for the ancient Greek economy does not appear until the Classical Period (480–323 B.C.E.), and most of that evidence comes from the city of Athens. So Athens can serve as a representative case study of the ancient Greek economy. That economy depended on slaves. They provided labor in the house, on the farm, for public works, and, in dire circumstances, even for the conduct of warfare. Slavery in the ancient world generally was not based on race but was the consequence of war or piracy. Odysseus’s slave woman, Euryclea, describes how she was abducted by pirates as a child and sold into slavery. In the Classical Period it was common to sell into slavery the inhabitants of a defeated city. The children of slaves were also slaves and were often considered more reliable, never having known freedom.

The lot of slaves varied considerably. Slaves who worked in quarries or mines suffered terribly and had an extremely short life expectancy. Domestic slaves generally had an easier, but by no means easy, life. Even the most fortunate slave was still subject to the whims of the master and did not enjoy any real protection under the law. There are no accurate data on the number of slaves in Athens, and estimates vary widely. There may have been as many slaves as free Athenians, and the slaves may even have outnumbered the free by two to one or more.

No ancient writer discusses in any depth the extent to which the economy depended on slavery, though the dependence was well known. The historian Thucydides describes how, during the war between Athens and Sparta, the Spartans captured a fortress on the Athenian border, and he encourages Athenian slaves to flee there; according to Thucydides 20,000 slaves did so, damaging the ability of Athens to harvest crops and maintain public works.

FREEMEN

Some slaves could earn money and could hope to save enough to buy freedom. Masters could, and did, set free (or manumit) slaves in their wills. The most famous case is that of the slave Pasion in the fourth century. He was the property of a banker in Athens, and upon his master’s death he became free and the owner of the bank and eventually one of the wealthiest men in Athens. Through his generous gifts to the city, he even acquired Athenian citizenship and became an associate of the most prominent people in the city. This anecdote is extraordinary and certainly does not represent the usual experience of Greek slaves, but it does reveal the fluidity of economic status during the Classical Period.

RESIDENT ALIENS

Free people who were not Athenians and yet resided in the city were an important part of the economic life of the state. These were called *metics*, or *metoikoi*, which means “resident aliens.” They tended to be merchants or bankers, since as non-Athenians they could not own land. *Metics* were involved in industry, making and selling perfume and furniture; were traders in wheat, wine, or oil; and were bankers, loaning money at interest. *Metics* were acknowledged members of the community, enjoying protection of the laws, although each *metic* had to have an Athenian sponsor who would represent him in court, should the need arise. At the great festivals, when the Athenians celebrated their civic identity, the *metic* took part in the processions, a mark of formal status as part of the community. *Metics* were valuable to the community not only for the goods they brought to market and the services they may have provided but also for the taxes they paid to the city.

WOMEN

Women in classical Athens did not enjoy political rights, could not vote, and could not hold office of any kind. An Athenian woman could be said to be a “citizen” only in the

sense that her status determined the status of her children: To be a citizen of Athens during the fifth century B.C.E., one had to be a man born to an Athenian father and an Athenian mother.

Nevertheless, women were in charge of much of the fundamental economic activity that regulated daily life. Women were responsible for training and managing the slaves, ensuring that all members of the house were fed and clothed, and keeping track of the material goods and supplies of the house. In Xenophon's work *Oikonomikos*, his character Socrates states that a good wife is the partner of her husband; while he is the one who supports the family, "it is by means of the wife's economy and thrift that the greater part of the expenditure is checked, and on the successful issue or the mishandling of the same depends the increase or impoverishment of a whole estate." Xenophon expands on this philosophy as he has his character Isomachus (who is portrayed as a pompous fool) describe how he instructed his young wife regarding some of her duties: "Over those members of the household whose appointed tasks are conducted indoors, it will be your duty to preside; yours to receive the stuffs brought in; yours to apportion part for daily use, and yours to make provision for the rest, to guard and garner it so that the outgoings destined for a year may not be expended in a month."

CITIZENS

In Athens citizenship was limited to men born from two Athenian parents (during the fifth century B.C.E.) or to an Athenian father (during parts of the fourth century B.C.E.) or who had been granted citizenship by a vote of the democratic assembly. Economically, the most significant benefit enjoyed by citizens was the ability to own land, a right limited to citizens. In earlier centuries full political enfranchisement at Athens and in other cities was limited to citizens who met certain property qualifications, and even in the early days of the Athenian democracy certain political offices could be held only by citizens whose real property—land—yielded a certain value in crops; the citizen class of *pentekosmiomedimnoi*, the "500 bushel producers," could hold offices denied to the *thetes*, those citizens without property or with only a little.

Citizens were generally exempt from taxation, except in unusual circumstances, though the wealthy citizens were expected to support the city's finances in other ways. Citizens enjoyed full legal protection and full access to the courts. In fact, only (male) citizens had access to the courts, so when *metics* or women sought legal redress for some injury, they would have to find a male citizen willing to go to court on their behalf. Citizens could be fined by the state, and any Athenian man who had thus accumulated sufficient debt to the public treasury was prevented from holding political office and could even lose his right as a citizen, a process called *atimia*, or disenfranchisement. In the sixth century, before the legal reforms of the Athenian statesman Solon (ca. 630–ca. 560 B.C.E.), citizens who fell heavily into private debt could even be seized by their creditors and sold as slaves.

WEALTH AND COINAGE

The most durable and esteemed form of wealth was land, and even under the democracy those Athenians who owned large tracts of land constituted a *de facto* aristocracy, exerting the most political influence over the affairs of the city. But during the sixth century, as trade flourished in the Greek world and as city centers grew, more and more people made their living through means other than agriculture and accumulated wealth in ways other than growing crops, raising livestock, or renting land for others to do the same. Even large landowners rarely achieved the ideal of complete self-sufficiency. Such items as tools and furniture, clothing, and luxury goods had to be brought into a house from the outside, either acquired through exchange or purchased with money.

Money first appeared in the Greek world around 600 B.C.E. in the form of coins made of electrum, an alloy of gold and silver. By the Classical Period this alloy had fallen out of favor, mainly because the ratio of gold to silver, and therefore the value of each coin, could vary and was hard for people to determine by examining the coin. Coinage in antiquity did not derive its value by any institutional guarantee, as modern money does. It was simply a convenient way of exchanging small pieces of precious metal. So the names of ancient Greek coins refer to units of weight rather than value per se. The fundamental unit, the drachma, was a unit of weight, and a drachma in Athens might weigh more or less than a drachma at Corinth. A drachma of silver would be worth much less than a drachma of gold. Certain coinages were used more widely than others, as archaeological finds indicate, reflecting perhaps the relative strength of the economies of various cities. Athenian silver drachma coins from the fifth and fourth centuries B.C.E., displaying the owl of the goddess Athena, are widely found throughout the Mediterranean world, reflecting central role of Athens in commerce during the Classical Period.

At Athens the weights of coins and their relative values were as follows: Six obols equaled one drachma, 100 drachmas equaled one mina, and 60 minas equaled one talent. There were coins that weighed an obol, coins that weighed a drachma, and (the most commonly found coin) four-drachma pieces (the tetradrachm). There were no mina or talent coins; these terms were used to describe weights of silver or gold in tallying up values.

A juror serving in an Athenian courtroom was paid three obols per day, half a silver drachma; a citizen who rowed as part of the crew of a warship in the fifth century B.C.E. was paid one drachma per day. From this information, we can conclude that a drachma per day was a reasonable wage for labor—we know from literature that the jurors tended to consist of older men, those past their laboring years, for whom half a drachma might have represented a reasonable supplement to whatever resources they were living from. A talent of silver, then, was 6,000 drachmas, or approximately 16 years' wages (at one drachma per day). The former slave-turned-banker Pasion left an estate of 24 talents' worth of silver, indicating the vastness of his wealth.

PUBLIC FINANCE

Greek city-states did not, as a rule, regularly tax their citizens. They did regularly impose duties on imports and exports and freely imposed taxes on noncitizens, such as the *metoikion*, the fee that each *metic* had to pay for the privilege of living in Athens. *Metics* who performed extraordinary services to the state might be granted the right of *isoteleia*, or “equal taxation,” which amounted to a freedom from any fees or taxes, equal to that freedom enjoyed by citizens. During times of crisis the state could, by a vote of the assembly of citizens, impose taxes on its citizens, either calculated by head or based on the value of a citizen’s property. The state had many other ways of raising funds, however. War could produce income, from treasure plundered from defeated cities, from the sale of prisoners of war into slavery, or from the sale of captured ships.

The city owned property—public lands in its own territory or in territories captured in war. This land could be leased out for grazing or farming, and the products of any mines on public land would go into the city’s treasury, to be spent as the citizens saw fit. The most famous example of this practice was the discovery at the end of the sixth century B.C.E. of a vein of silver in Attica, the territory around Athens, at a place called Laurium. The initial plan for this windfall, reported to be worth about 100 talents, was to distribute it among the citizens equally—economic historians have noted this plan as evidence for the relative lack of sophistication in ancient economic thinking. Eventually, however, the citizens of Athens decided to use this new wealth to supplement their navy, a choice that proved wise a few years later when the Persian army of Xerxes invaded Greece.

Athens, which commanded a naval empire during the fifth century B.C.E., received tribute from its “allies” annually. These funds were supposedly to allow Athens to support its navy, which was to be used to defend its allies, but much of the income from this tribute went to glorify the city, being spent on the monumental building of the Athenian acropolis and on the city’s own fortifications. Thucydides reports that at the height of its power, Athens received 600 talents per year in tribute.

The most remarkable source of public revenue for the ancient city of Athens, and for other cities of the Greek world, was the *leitourgia*, or institution of “liturgies.” This was a system by which the wealthy citizens of the democracy were obliged to perform expensive public services from their own resources. The two most notable kinds of liturgy were the *choregia*, sponsorship of the performance of a play, either a comedy or a tragedy, during the public festivals, and the trierarchy, the private funding of a warship. The latter was extremely expensive; it could cost a talent of silver to keep a warship afloat, with a full crew, and in good repair for a year. Consequently, by the fourth century this duty was performed collectively, by groups of wealthy citizens. The benefit of liturgies for the state was obvious—costly services performed at no

public expense—and the benefits for the *euergetēs*, the person performing the liturgy, were real as well. He received public acclaim as well as an enhanced reputation as a good citizen and a man of wealth and prominence. To perform some liturgies poorly, resulting in a shabby production of a play, for example, brought shame from the community; in other cases, such as fielding an ill-equipped warship, the sponsor might be liable for legal prosecution.

The raising of public money was accomplished with as little public bureaucracy as possible. At Athens the nine archons, elected public officials, oversaw a small staff of secretaries who managed duties, fees, and rents. Major taxation was handled privately almost everywhere in antiquity, from democratic Athens to Egypt under the Macedonian Ptolemies, with the state auctioning off the right to collect taxes. People who bought these rights, the so-called tax farmers, would pay a fee up front and then collect taxes from those who owed them. The stability of a state could depend on how carefully the conduct of the tax collectors was managed and how diligently the public officials ensured that no one was compelled to pay more than the law required.

FINANCIAL SERVICES

Beginning in the Classical Period our evidence shows that financial services were offered by private banks and, very often, by religious institutions connected to particular temples. Banks and temples took deposits, offering to hold money securely on behalf of depositors. The evidence suggests that these deposits themselves did not earn interest. Banks would, however, both make and receive loans, charging interest in the former case and paying interest in the latter. The most profitable loans in antiquity were so-called bottomry loans, loans used to purchase goods to be transported by ship and sold. The return on such a loan could exceed 100 percent but could amount to nothing if the ship was lost. Loans of this sort were the basis for the banker Pasion’s wealth.

These financial institutions of the Classical Period continued to evolve and under the Greek rulers of Egypt during the Hellenistic Period reached a very high level of sophistication, including such seemingly modern services as spendthrift trusts, living trusts, annuities, and giro payments (a means of monetary exchange in which ownership of a bank deposit changes hands within the record-keeping system of the bank).

ROME

BY DAVID B. HOLLANDER

The Romans acquired and kept their empire in no small part because of their adept management of economic resources. According to Cicero, the first-century B.C.E. politician and writer, the Romans had often gone to war on behalf of merchants, but their economic policies went far beyond the mere protection of commercial interests. The Romans were masters at exploiting the resources of conquered territory though

taxation, confiscation, and enslavement. They developed highly efficient systems of taxation but also of redistribution to gather in wealth from their subjects and direct it to Rome and its increasingly far-flung armies.

The study of the Roman economy presents several obstacles. First of all, it is difficult to define the nature of the economy, which, at least in the late republic and early empire, seems to have been predominantly market based but still retained some elements of reciprocity (exchange through gifts and mutual obligations) and redistribution (a centralized economic system in which goods are collected by the government and redistributed at its discretion). A second problem is that there are very few prices or other statistics for an economic historian to study. Indeed, the surviving literary sources rarely discuss economic issues at all. Third, when Roman writers discuss economic life, they tend to present a highly distorted view of it. Cicero, like most Roman elites, regarded nearly every occupation aside from farming as demeaning and dishonorable. By definition, merchants were cheats, and laborers were little better than slaves as far as upper-class Romans were concerned. Cooks, fishermen, artisans, and performers were all beneath contempt, their economic activity rarely described.

Those who would understand the Roman economy must look elsewhere for evidence, and there are several profitable sources of information. Numismatics (the study of coinage) provides one such source. The volume, quality, and denominations of the coins produced as well as their distribution on sites and in coin hoards can reveal important aspects of the circulation and use of money. Thousands of inscriptions survive, and they, along with the many scraps of papyrus recovered from Egypt and writing tablets, such as those unearthed at Pompeii and Vindolanda, often record transactions, descriptions of careers, or parts of accounts. The excavation of houses, other buildings, and even shipwrecks also show archaeologists what was traded. Together these materials present a rich, if fragmentary view of the Roman economy.

THE REGAL PERIOD AND THE EARLY REPUBLIC

The evidence for the Roman economy in its first few centuries (753–300 B.C.E.) is rather poor. The tradition that the site of the city was occupied by shepherds suggests that initially Rome had a pastoral economy. The fact that the Latin word for money, *pecunia*, derives from the word for livestock, *pecus*, tends to support this conclusion, as does the fact that some early fines were imposed in terms of cattle and sheep. Nevertheless, Rome had good farmland and sat at the crossroads of two important trade routes: the Tiber River, which connected the interior of the Italian peninsula with the coast, and the river ford at Rome, which connected Latium (the territory occupied by the Romans and other Latin speakers) with Etruria (modern Tuscany), home of the wealthy and powerful Etruscans. No doubt agriculture and trade became important sectors of the Roman economy at a very early stage in its development.

Many Romans came to believe that Servius Tullius, the sixth king of Rome, created the city's fundamental economic institutions, including the census, direct taxation, coinage, the distribution of conquered land to citizens, and pay for soldiers. Servius, who allegedly reigned during the mid-sixth century B.C.E., certainly did not institute coinage (which the Romans would not begin minting until the late fourth century B.C.E.) or army pay (which other ancient sources associate with Rome's long conflict with the Etruscan city of Veii in the late fifth century B.C.E.), but some of the city's economic institutions may predate the start of the republic in 509 B.C.E. The census, regardless of its precise origins, would soon become Rome's central economic institution. At first the census seems to have been simply a survey of the wealth of Roman citizens conducted in order to assign men their appropriate military and political rights and responsibilities. Eventually, however, the censors, two magistrates placed in charge of performing the census beginning in 443 B.C.E, would wield a considerable amount of control over both the state's revenues and expenditures.

TAXATION AND OTHER FORMS OF REVENUE

The Roman state took in revenue from a variety of sources and in a multitude of forms. The earliest tax was the *tributum*, which was assessed, when necessary, on Roman citizens, who would have to pay some percentage of their assessed wealth. As the empire expanded, however, other forms of revenue became much more important, particularly indemnity payments from defeated enemies and provincial tax receipts. For example, at the end of the First Punic War in 241 B.C.E., Carthage agreed to pay Rome 320 talents of silver a year for 10 years. Since the talent, a Greek unit of weight, was approximately 57 pounds, this payment constituted a tremendous sum of money. The treaty ending the Second Punic War in 201 B.C.E. committed Carthage to pay 200 talents of silver each year for 50 years. As their power spread to the eastern Mediterranean, the Romans continued to exact these large indemnities from defeated nations. The Treaty of Apamea, which in 188 B.C.E. ended Rome's war with Antiochus III, ruler of the Seleucid kingdom in Asia, specified, among many other terms, that Antiochus pay Rome 1,000 talents per year for 12 years.

Provinces also paid taxes, though their nature and form are often unclear. Some communities paid in coin or bullion; some paid in commodities, like grain or olive oil. There were real estate taxes, poll taxes, and taxes that required farmers to turn over a portion of their harvests. Often the Romans simply kept preexisting tax systems in place following the incorporation of new territory into the empire. *Portoria* (customs duties) were exacted at the frontiers of the empire as well as on the borders between provinces. Other taxes that were levied at various times include a 5 percent tax on the value of manumitted (freed) slaves, a 1 percent tax on sales at auction, a 4 percent tax on the sale of slaves, and a 5 percent tax on some parts of inheritances. The emperor Vespasian

Gold bars with assayers' stamps, Roman, late fourth century C.E., found in Egypt and Romania; at the time, taxes were payable only in gold, which was considered the most valuable metal and the one easiest to transport long distances. (© The Trustees of the British Museum)

(r. 69–79 C.E.) even imposed a tax on Rome's urinals, since urine was sold to fullers for use in the washing of clothes. The government and its magistrates could also simply requisition both supplies and labor from Roman subjects. A provincial governor, for example, could demand food from local communities for himself and his staff or require cities to build roads or ships. This power was frequently abused, but it was difficult for provincials successfully to prosecute Roman officials. Victorious generals could also demand "gifts" of gold bullion from provincial cities.

Spoils taken in war often formed a substantial part of the state's revenues. Some of the spoils usually went to the soldiers involved in the campaign or financed the construction of a monument (usually a temple) commemorating the victory and thanking a particular god or goddess for assistance, but the rest went into the Roman *aerarium* (treasury). The spoils of war often included gold and silver coins and bullion as well as prisoners (who would be sold into slavery), livestock, and valuable works of art. It was customary for Roman generals to display some of this plundered wealth in their triumphs (victory parades held at Rome upon the conclusion of particularly successful military campaigns).

So much booty was acquired following the defeat of Perseus in the Third Macedonian War that the *tributum* was abolished for Italy in 167 B.C.E. The most notorious example of plundering in Roman history came at the end of this same conflict. The Senate decided to punish about 70 communities in Epirus (a region to the northwest of Greece along the east coast of the Ionian Sea), which had sided with Perseus.

Soldiers went to the towns (which had already surrendered), collected all the gold, silver, and other valuable goods, and then enslaved the inhabitants. As many as 150,000 people were led into slavery. Proceeds from the sale of the goods and people paid for bonuses for the soldiers who had served in the war.

The expansion of the empire also brought considerable amounts of land under the control of the Roman authorities. Some of this land was redistributed to veterans or colonists, but much of it was retained and designated public land (*ager publicus*). Most such land would be used for farming or grazing herds, but mines and saltworks could also be public property and thus be subject to various forms of rent. During the republic disputes over the distribution and use of such land frequently arose and could lead to political turmoil. For example, Tiberius Gracchus's proposal in 133 B.C.E. to enforce statutory limits on individual holdings of *ager publicus* met with considerable resistance from those in possession of large tracts of such land.

Fines also generated some revenue for Rome. The Augustan historian Livy reports that in 193 B.C.E. the aediles Marcus Aemilius Lepidus and Lucius Aemilius Paulus received so much money from fines levied against grazers that they were able to build a portico and wharf at Rome in addition to placing gilded shields on the temple of Jupiter. In 189 B.C.E. aediles (public officials in charge of public works and grain) again used money from fines, this time exacted from merchants convicted of hoarding grain, to erect gilded shields and statues commemorating their actions on behalf of the people of Rome. Violations of sumptuary laws (laws designed to limit excessive consumption or use of luxury goods) could also lead to fines.

GOVERNMENT EXPENDITURES

Although many aspects of the Roman government's budget must have changed over the centuries, the army almost certainly remained the single biggest expenditure. In addition to the salaries of the soldiers, who were not paid entirely in coin, there was the need for equipment, supplies, and retirement bonuses. Some payments could be made in kind, and requisitions could take care of some military needs, but cash was always essential. Rome's grain supply was another major item on the budget. Some grain was acquired through in-kind taxes (from Sicily, for example), but it was often necessary to purchase more.

Building projects could also be expensive, as were the games and shows that republican politicians and later emperors regularly put on. The maintenance of public buildings, spaces, and roads also required money. In 144 B.C.E., for example, Quintus Marcius Rex spent 45 million denarii to build and repair aqueducts. It is unclear how much money magistrates could expect to receive as allowances while governing provinces, but the sums were clearly substantial. Officials could requisition some supplies and labor, but the Romans often hired private companies to accomplish certain public

ends, such as building roads or feeding the sacred geese on the Capitoline Hill. One of the main jobs of the censors was to let out such contracts for public works. They also leased public land and auctioned off the right to collect some taxes.

TAX FARMING

One of the most lucrative businesses in the late republic was tax farming. Tax farmers, or *publicani*, purchased from the censors the right to collect certain taxes, ranging from the customs duties of a port to the harvest tithes of an entire province. To earn a profit, of course, the *publicani* had to collect more in revenue than they had promised to pay the Roman government. Because of the need for considerable amounts of capital to bid for such contracts and the need for big staffs to collect the taxes, the *publicani* formed large companies and even sold shares that could be traded. Although they were reviled in the provinces and even by some upper-class Romans, tax farmers came to wield considerable influence at Rome. Having bid too much for the right to collect taxes in Asia in the late 60s B.C.E., they successfully lobbied to have the sum reduced by a third. The *publicani* controlled a vast financial network and could help magistrates transfer large sums of money across the Mediterranean without physically transporting coinage or bullion. They also collaborated with governors in order to exploit the provinces fully. Corruption, provincial complaints, and the expansion of the Roman bureaucracy led to a gradual decline in tax farming under the empire.

ECONOMIC POLICY AND REGULATION

While the Romans may not have had a sophisticated conception of their economy and the rules governing it, they did attempt to regulate certain markets and formulate what one might call economic policies. In both cases their actions were primarily reactive and driven as much by social concerns as by economic ones. Sumptuary laws provide a good illustration of this approach. In the second century B.C.E., as wealth flooded into Rome, many people began to buy foreign luxury goods and serve expensive foods at dinners. Conservative Romans believed that this trend was dangerous and attributed it to the corrupting influence of military service in the rich and exotic East. In order to combat this perceived corruption, they passed a series of laws limiting the amount of money one could spend on dinners and the types of foods one could serve. Thus, moral concerns prompted economic legislation. Interest in such laws, which seem to have been fairly ineffective, continued down into the Imperial Period. Caesar, for example, taxed or banned certain foreign luxuries and is said to have seized such goods from both the market and even the dinner tables of private homes in which they were being served. Such strict enforcement does not appear to have been the normal practice, however.

At Rome and in other communities aediles were the magistrates normally charged with (among other duties) the oversight of markets. They prosecuted those who broke

market regulations and looked after the city's general food supply as well. The Roman Senate also had an important role in economic regulation. Before Clodius began in 58 B.C.E. the free grain distribution program that at times provided food for several hundred thousand Romans, the Senate arranged for the sale of subsidized grain in the city. Although the prices of basic foodstuffs seem normally to have fluctuated due to supply and demand, there were attempts to control the prices of some goods. For example, Suetonius, the imperial biographer, reports that Domitian (r. 81–96 C.E.) limited the price of eunuchs. Other measures sought to control prices by limiting production. According to Cicero, the Romans prevented the Gauls from cultivating vineyards and olive groves to protect the interests of Roman wine and olive oil producers.

THE DEVELOPMENT OF THE ECONOMY IN THE LATE REPUBLIC

The financial strain of the Second Punic War led the Romans to develop a new monetary system around 211 B.C.E. The main Roman coin became the silver denarius, which was minted in increasingly large quantities down to the end of the republic. Although some inflation occurred during this period, the growth in the money supply seems to have been balanced by an increase in monetization as more and more people came to rely on Roman coins for their transactions and as a store of wealth. Bullion and credit also contributed to the growth in the money supply, but since it is impossible to quantify the amount of bullion in circulation or the extent to which credit took the place of coin in transactions, it is difficult to estimate their significance.

The late republic witnessed a substantial increase in long-distance trade within the Mediterranean basin. Rome's newfound wealth allowed it to import many goods into Italy while continuing to export wine and other products. At the same time, Rome faced certain profound economic difficulties. An overreliance on slave labor, particularly for agriculture, led to a series of devastating slave revolts, most notably the one led by Spartacus in the 70s B.C.E. The provinces suffered too, from excessive taxation and corrupt Roman governors. Finding sufficient resources to reward Roman veterans also proved challenging.

Debt, however, more than anything else, constituted a perennial problem among farmers at the mercy of the weather, the urban plebs, and even aristocrats competing in the high-stakes and increasingly cash-intensive political arena. The Lex Poetelia Papiria, a law passed by the tribunes Gaius Poetelius Libo Visolus and Lucius Papirius Cursor in 326 B.C.E., helped ameliorate the consequences of indebtedness by outlawing debt slavery, but it could not do away with the underlying problem. Debt crises occurred frequently in the late republic and could even threaten the stability of the government. The conspiracy of Catiline, a failed plot to overthrow the state in 63 B.C.E., drew much of its support from the indebted. As dictator in the 40s B.C.E., Julius Caesar moved

to solve many of Rome's economic problems. He canceled some debts while creating a new mechanism to help debtors repay their obligations. He also reformed provincial taxation, removing the *publicani* as collectors in the east. In Italy he limited the number of slaves who could work as shepherds to help prevent slave revolts.

THE DEVELOPMENT OF THE ECONOMY IN THE IMPERIAL ERA

Under Augustus (r. 27 B.C.E.–14 C.E.), the first Roman emperor, the economy staged an impressive recovery, owing in no small part to the end of a series of disastrous civil wars. Nevertheless, Augustus did institute important economic reforms, such as giving salaries to provincial governors to prevent corruption and excessive exploitation. He took control of the finances of the army, creating a special treasury, the *aerarium militare*, to pay for retirement bonuses for soldiers. Cash sums began to replace grants of land and thus reduced anxieties concerning property rights. Many veterans were settled in colonies outside Italy, easing demand for Italian land. Augustus also reformed the management of the food supply, appointing a special official to oversee the transportation, storage, and distribution of grain at Rome. From the reign of Augustus on, the emperor's personal wealth came to play a substantial role in the state's finances. The use of Roman coins continued to spread throughout the empire, no doubt facilitating trade, but there was still no unified monetary system. Egypt had a separate system with its own special coinage, and many communities throughout the empire minted their own coins for local use. At the same time, gold coinage, first minted in quantity during the civil wars of the late republic, began to assume a larger part of the money supply, probably becoming the preferred means of exchange in long-distance commerce.

Although there were occasional crises, the Roman economy fared quite well during the first two centuries of the empire. Some emperors enjoyed sizable budget surpluses and could lavish expensive gifts on the army and inhabitants of Rome. Others emperors were less fortunate or more rapacious. They raised money through higher taxes, new taxes, or auctions of imperial property. According to Suetonius, Caligula (r. 37–41 C.E.) instituted a sales tax on food and a 2.5 percent tax on legal transactions. He may have also levied new taxes on porters and prostitutes. Although early in his reign Nero had lowered or abolished some taxes, he later became desperate for money and created a new tax on tenants and also raised funds through the manipulation of grain prices. Like many other emperors, Nero also confiscated the estates of his enemies. In the aftermath of the short-lived but destructive civil war of 69 C.E., the emperor Vespasian raised some taxes while creating new imposts as well. He was also accused of raising money by creating monopolies of some commodities and then charging inflated prices for them.

Many emperors worked to promote the economic development of the empire (although they would not have con-

ceived of their behavior in these terms) and the welfare of their subjects. Claudius (r. 41–54 C.E.) sought to secure the city's grain supply by insuring merchants' ships, offering cash incentives for the construction of new vessels, and building a new harbor and lighthouse at Ostia, Rome's port city at the mouth of the Tiber. He also drained the Fucine Lake in central Italy, creating new farmland. Following the eruption of Vesuvius in 79 C.E., the emperor Titus (r. 79–81 C.E.) created a relief fund by appropriating the property of those who had died in the disaster and had left no heirs. Several emperors, starting with Nerva (r. 96–98 C.E.), created foundations to distribute money to poor boys and girls in Italian communities so that they could buy food.

Emperors typically financed large construction projects in the city of Rome. Vespasian, for example, began construction of the Colosseum, which his son Titus dedicated in 80 C.E. Such buildings beautified the city, but their construction and maintenance also provided jobs for the lower classes at Rome. Some emperors simply gave gifts of money to the people, and by tradition gifts of cash were occasionally made to the soldiers. Increasingly in the second century C.E. emperors would patronize other communities in Italy and elsewhere in the empire in addition to Rome. The stationing of army units in various locations in the provinces also contributed to the economic development of these regions, since soldiers had money to spend and many military supplies would be purchased locally.

In the latter half of the second century C.E. the empire began to experience economic as well as military and political difficulties. The silver coinage was repeatedly debased. (That is, its silver content was reduced.) As the intrinsic value of the coins declined, prices began to rise. Although Trajan's (r. 98–117 C.E.) conquest of Dacia and its rich gold mines in the first decade of the second century C.E. helped feed Rome's mints, precious metals seem to have been in increasingly short supply. Part of the problem was that there were few rich territories left for Rome to conquer, and it was expensive to defend what Rome already possessed. Imports, particularly from the east, also drained the empire of some gold and silver. In the first century C.E. Pliny the Elder claimed that millions of denarii were exported each year to the East to pay for spices, gems, textiles, and other luxury goods.

Although the Crisis of the Third Century, the massive breakdown of the imperial system from 235 to 284 C.E., was primarily a military and political crisis, it had severe economic ramifications. Warfare disrupted trade and the further debasement of the silver coinage brought about considerable inflation. Taxes were also raised. The empire began to recover under the emperors Diocletian (r. 284–305 C.E.) and Constantine (r. 306–337 C.E.), but economic problems persisted. Diocletian's Prices Edict of 301 C.E. attempted to deal with inflation by setting maximum prices for all goods and services. The law specified execution as the punishment for those who charged too much. The measure failed, as did Diocletian's two

At its height in 200 C.E. the Roman Empire stretched from the Rhine and Danube rivers on the north to Britain and the Iberian peninsula on the west, northern Africa on the south, and Mesopotamia on the east.

attempts to reform the currency. A reform of the empire's tax system was somewhat more successful. It created one system of taxation for the entire empire. In theory, it was more consistent and fair than the patchwork of local and regional taxes it replaced.

Constantine continued many of Diocletian's policies. He was able to introduce a new gold coin, the solidus, which was not debased and became the preferred means of exchange in late antiquity. Nevertheless, economic conditions remained grim, and the government attempted to regulate more closely the movement and professions of its citizens, creating a new class of rural serfs known as *coloni* while continuing to tax the population heavily to pay for the large imperial army and bureaucracy. These policies, along with a series of civil wars, left the empire ill prepared to deal with the Germanic invasions of the later fourth century C.E.

THE AMERICAS

BY MICHAEL ALLEN HOLMES AND TOM STREISSGUTH

By about 2000 B.C.E. the foundations of agricultural civilization were being laid throughout the Americas. Maize, beans, and gourds sustained many cultures in North and Central America, while South American societies relied on the potato. Economic activity beyond trade at the village level, however, did not occur on a substantial scale until the advent of political organization, which went hand in hand with expanded trading networks. Complex economic structures evolved steadily over time, leading to greater contact between regions and the sharing of technologies, resources, weapons, and tools. Barter and trade provided an essential point of contact, allowing tribes to gather scarce goods without foraging or warfare.

NORTH AMERICA

In North America a long-distance system of exchange was developing by about 4000 B.C.E. As nomadic peoples learned to plant and harvest, they began to gather resources needed for a more settled life. They traded for goods such as obsidian, chert (a rock with characteristics of flint), turquoise, copper, silver, and the shells that served as a medium of exchange in many regions, including the coasts of the Pacific Ocean and the Gulf of Mexico. In times of drought, when crops often failed, many native North Americans relied on trade to maintain a settled life and avoid a return to a nomadic, uncertain life of hunting.

In Arctic regions the people depended on hunting almost exclusively. This life demanded constant movement to follow herds of musk ox and caribou and track the seasonal migration of seals and walrus. This lifestyle demand mobility and restricted bands to just a few individuals. Game taken in summer had to be dried and stored for the spare months ahead, particularly because people's diet consisted almost exclusively of meat. The long nights of the Arctic winter forced these groups to band together, and some historians speculate that they may have entered a state of semi-hibernation in order to survive the lack of food, heat, and light.

People of the Pacific Coast had access to a wide variety of plant and animal resources. Settled agriculture was rare, emerging only in southern California under the influence of southwestern cultures that raised maize, beans, gourds. To protect the valuable oak trees that provided acorns, the people sometimes set planned fires to burn off underbrush, which was easily ignited by lightning strikes. Areas of heavy salmon and coho runs in the Pacific Northwest allowed coastal communities to flourish. Offshore fishing was carried out in canoes; the coastal tribes also lived off seals and walrus that lived along the coast. Populations flourished where it was easy to access the sea and where streams ran perennially to their mouths.

Trade routes between the coast and the inland western regions allowed the exchange of shells, baskets, acorns, salt, fish, and clothing. Obsidian was a valued resource, and beads made of clamshells were sometimes used as a form of currency. Eastern Oregon was an important source of raw obsidian, which went into tools and spear points. By 500 C.E. the artisans of the Northwest were greatly diversifying their production of tools, fishhooks, basketry, clothing, and weapons. A highly stratified population emerged along with important signifiers of wealth and status within the clan or tribe. An abundance of food resources resulted in surpluses that came under the control of elaborate hierarchies.

In the arid Southwest a network of trails linked the desert basins and mountain valleys with the Pacific Coast. Knowledge of pottery making, irrigation, and agriculture moved along these trails, and many historians speculate that the advanced societies of Mesoamerica were an important source of goods as well as technical know-how. Large structures known

as *kivas* served as centers for both religious activities and trading. The southwestern tribes may have also held regular market days, when traders could meet to exchange goods and information.

On the Great Plains the most important medium of exchange was the buffalo hide. The vast bison herds of the grasslands were also a source of food, clothing, shelter, tools, and weapons. In eastern North America, important exchange centers grew along the principal rivers, including the Illinois, Mississippi, and Ohio. Copper and silver were obtained from the Great Lakes region. Appalachian tribes exchanged their quartz and mica; flint was a vital resource of Illinois and Indiana; pipestone came from deposits in Ohio and Minnesota. The villages of the Hopewell culture that prospered along the Mississippi and Ohio valleys imported these raw materials and then manufactured finished goods, reexporting them throughout North America along the network of long-distance trails.

MESOAMERICA

Owing to its antiquity and its absence of a substantial written record, the Olmec civilization remains shrouded in mystery. Stone figures, many of which were found buried at ceremonial sites, suggest that Olmec society revolved around a cult of jaguar worship. Rulers who derived their power from religious authority directed economic activity and physical labor, which was needed to plan ceremonial centers and obtain stone from distant sites to build structures and public sculptures, such as the colossal heads that are believed to represent rulers.

At the site of San Lorenzo, settled by about 1500 B.C.E., large gangs of workers quarried and transported massive basalt boulders from 50 miles away to raise the ceremonial heads that glorified their rulers. Basalt stone was also used to create elaborate irrigation and drainage systems. The Olmec society at San Lorenzo was divided into farmers and rulers, the latter claiming more fertile land along the banks of rivers and streams. The Olmec elite imported obsidian from distant points in Mexico and Guatemala and also obtained nodes of iron ore, which was polished to a mirrorlike surface. Sometime around 1200 B.C.E. violent events brought about the fall of San Lorenzo. The monumental heads were damaged and buried, either by outsiders or by a peasantry discontented by their subservient lot.

One of the best known Olmec centers is La Venta, an island of sand and clay surrounded by swampland in the modern eastern Mexican state of Tabasco. Among the products of *corvée* (forced labor) were several giant stone heads some six feet tall and a 110-foot clay pyramid. Archaeologists speculate that the pyramid, which has never been excavated, may have been used as a tomb. The priesthood at La Venta is believed to have lived in a fair degree of luxury, making them among the Western Hemisphere's first elite class. Burial sites, in some of which even infants were given riches to accompany them to the afterlife, indicate that shamanistic privileges and wealth

were inherited. As religious subjects provided not only labor for the construction of temples but also food and other goods, priests ate well and wore elaborately tailored ceremonial dress.

Priests routinely buried the figures that middle-class artisans carved from stone and jade. The demand for jade probably fueled commercial relations from central Mexico to the Isthmus of Tehuantepec and as far as modern El Salvador. Other important trading goods were salt, chert, basalt, obsidian, and hard materials from which tools could be fashioned. Some luxury goods remained the property of the elite. Rubber from the Gulf Coast was made into balls used in ritual games, jaguar skins and scepters were traded among rulers, and the priestly caste dealt in jade jewelry and figurines. The elite also collected iron ore, cotton, cacao, shells, and exotic feathers, such as those from the quetzal.

With respect to the economic activity of the masses, a request for a single monolithic stone head would have required countless man-hours of peasant labor. Historians estimate that it took 800,000 man-days to raise the massive La Venta pyramid, the largest structure of its time in ancient Mexico. Thus, given the degree of domination the priesthood achieved, subjects must have been spiritually devoted or fearful of the wrath of their gods, or of the rulers themselves. The oppression of the lower classes and the system of forced labor may have brought about discontent and the violent ends met by the communities at both San Lorenzo and La Venta.

THE MAYA

While scattered cultures developed in the more hospitable regions of Central America throughout the centuries following the rise of the Olmec, none attained a level of societal and economic complexity comparable to the Maya. The Mayan civilization began developing around the same time as the Olmec were flourishing on the Gulf Coast, and by 300 C.E. Mayan city-states were evolving throughout eastern-central Mesoamerica. The Maya came to occupy the Yucatán Peninsula and modern Mexican land south to the Gulf of Tehuantepec, as well as modern Belize, Guatemala, El Salvador, and the western half of Honduras. As such, they found themselves in an ideal position to benefit from trade between the Olmec and other Mesoamerican cultures to the west and the remainder of Latin America to the southeast. In general, Mayan society was never explicitly unified by political means; rather, commerce served as the most significant regional unifying factor.

The regions inhabited by the Maya, particularly the tropical lowlands, were not exceptionally fertile. Water resources were relatively scant, with few rivers and lakes providing uninterrupted supplies. One early irrigation canal was constructed in Kaminaljuyú, in the southern highlands, by 700 B.C.E. Around Edzná, on the Yucatán Peninsula, a more substantial system of canals and reservoirs was developed by 100 C.E. This system spanned some 14 miles, allowed for canoe traffic, and facilitated the farming of fish. Throughout the

lowlands the Maya used wells and *aguadas*, smaller reservoirs lined with clay. The *aguadas* around Tikal were substantial enough to provide water for 70,000 people over a dry period of 120 days. Underground reservoirs called *chultunes* were also carved into bedrock and into the bottoms of natural depressions, further expanding water-collection capacities.

Mayan farmers increased production by cutting ditches for drainage and raising the level of the fields with the excavated soil. To prevent the erosion of soil on sloping farmland, terraces and platforms were carved into hillsides. Household refuse was used as fertilizer to replenish the nutrients in the soil, and crops with different chemical properties were regularly rotated; beans were typically planted alongside maize, so that in the course of harvesting and replanting nitrogen produced by the beans could be extracted and used by the maize. Most basically, ancient Mayans intensified crop production through mass contributions of labor. Only stone tools were then in use, so farmers had to be more sensitive to annual climatic cycles—plants were easiest to cut at the ends of dry seasons, when they were more brittle.

Among the Maya trade in agricultural goods began as individuals and communities achieved surplus production. At first, exported crops were simply the excess supplies of foodstuffs, largely maize, which were delivered to regions lacking their own surpluses. The transportation of foodstuffs, however, was limited by the food's perishability and also by the fact that those doing the transporting would need to consume portions of the load during their journey. Historians have calculated that when traveling by land, food carriers would have been able to travel at most some 90 to 170 miles. By canoe the feasible ratio by weight of foodstuff to person would have been higher, allowing greater distances to be covered.

A number of products other than farmed foodstuffs were valued and traded in ancient Mesoamerica and beyond. Cotton and cacao beans, in particular, were major crops exported from the Mayan region. Cotton grew in fair proliferation on the relatively dry Yucatán Peninsula as well as in other locales throughout eastern Mesoamerica. Both a brown and a whiter variety were spun to form thread, which was dyed and woven into highly marketable textiles, some featuring embroidery. Cacao beans, which grow especially well in warm tropical regions where the soil is rich and the rainfall is heavy, bore particularly high economic value throughout Latin America. While they were originally used simply to brew chocolate drinks consumed by the elite classes, over time, thanks in part to their convenient size and countability, cacao beans became used as currency. Cacao beans of extraordinary quality were produced in the Soconusco lowlands, along the Pacific coastal region in modern southeastern Mexico.

An additional crop grown largely for export was hemp, derived from the agave plant, from which textiles and also sandals were fashioned. Clothes produced with hemp were almost exclusively worn by peasants, as the elite classes wore only clothes produced with finer, softer cotton. (Peasants also would have used cloth made from pounded bark.) Obsidian

scrapers were used to depulp the leaves of the agave plant, especially the henequen variety, to produce rope and twine. Tobacco was another locally produced commodity that was valued both within and outside the Mayan region. Unlike in modern times, however, the tobacco was not cut and processed for mass consumption; instead, acting as a hallucinogen in its purest form, tobacco was smoked in cigars or in pipes during religious ceremonies and perhaps also served medicinal purposes. The tobacco smoke, like incense, may have also been deemed “food” fit for consumption by supernatural beings.

The extensive and accessible coasts of the Caribbean Sea and the Gulf of Mexico provided basic sustenance as well as export resources. Fishing communities near the coast used nets fitted with ceramic weights to collect lobsters, shrimp, and shellfish, while other fish were caught using nets and bone hooks. Given the abundance of marine life relative to the size of the coastal population, coastal Mayans were able to salt excesses, preserving them for as long as several years, and occasionally trade them inland. At a burial site at Lamanai, fewer than 50 miles from the coast, archaeologists determined from the skeletal remains of an elite couple that only the male had eaten seafood, such that it must have been considered a delicacy.

The salt that was used to preserve fish was also derived from the sea. One settlement, Komchén, at the northwestern tip of the Yucatán, evidently existed almost solely to facilitate the production and exportation of salt. Other sites throughout the peninsula's northern flats produced the most highly coveted salt in Mesoamerica; dubbed “white salt,” it was valued enough to be shipped to the elite in the central Mexican highlands. Along the coast, seawater was collected in shallow pans, from which it evaporated under the tropical sun, leaving masses of salt behind. Elsewhere, including on the coast of the Pacific and at certain springs in the highlands, saltwater had to be boiled.

Honey was another valued commodity throughout Mesoamerica, especially because no other purely sweet substances were locally available. The Yucatán produced substantial quantities of honey, with its importance reflected in the fact that throughout the region a divine being in the form of a bee was worshipped. Hives were provided for the small, stingless bees located there in the form of tree trunks that were hollowed and filled in at the ends, with small holes drilled into the sides to allow the bees entry.

The intensification of agricultural production and the rise of export trade allowed the population density in given areas to increase. This in turn fostered the rise of large urban and ceremonial centers, where an artisanal class depended on the production of coveted goods that further fueled the trade economy. These artisans included painters, whose primary medium was ceramics; weavers, who employed both cotton and hemp; and sculptors, who worked with either stone or jade. Many of these high-quality goods were given to leaders in the form of tribute, while others were deemed valuable

enough to be traded over longer distances than more commonly available commercial goods.

While the ruling classes maintained much of the administrative control over trade, middle-class merchants were responsible for most of the actual exchanges of goods and currency. Merchants conducted business at marketplaces in their home cities. Markets were likely set up in large plazas and other open spaces. Any structures that served as marketplace shelters were constructed of materials that would not have left behind any traces over the centuries, such as wooden poles and thatch.

In effect, trade heightened the power and prestige of the Mayan elite. In fact, whereas the ruling classes of the Olmec evolved primarily through spiritual and religious dominion, the royal families at the heads of Mayan cities likely attained their power by amassing and controlling wealth. Accordingly, the cities stationed on trade routes flourished as goods and wealth passed along those routes; when trade routes shifted, cities suddenly prospered or faded into regional irrelevance. The rarest and most exotic goods, such as feathers, shells, and the most elaborate garments, seem to have belonged to and been buried with noble families alone, indicating that laws may have banned the possession of such items by commoners. Likewise, only the elite would have consumed certain foodstuffs, like drinks produced with cacao beans; indeed, peasants likely would have been disinclined literally to drink what money they might have had.

Currency, which emerged at an unknown time, facilitated the exchange of goods. A trader bearing goods was no longer obligated to seek out trading partners who both wanted his goods and possessed goods that he desired. In both Central and South America, cacao beans emerged as an important form of currency. As no hieroglyphic records of financial transactions survive, details regarding the value of cacao beans are available only for the time of Spanish conquest in the 16th century. The market value of the beans may have simply been determined on a day-to-day basis by those engaged in trade. Counterfeiting did occasionally take place, with the flesh of the beans removed from the pod and replaced with soil or the rinds of avocados.

Through ancient times, certain trade routes rose and diminished in importance. With no dominant political center, haphazard and complex trade networks developed along the coasts and rivers of Central America. Goods were distributed from the primary cities to the larger towns, then from the larger towns to the smaller towns, and so forth. Meanwhile, canoe trade routes to the north, particularly along the coast of the Yucatán, seem to have prospered throughout ancient times, spurred by the north-south salt trade. Trade was conducted both within the Mayan region, particularly with respect to perishable, bulky foodstuffs, and between the Mayans and neighboring cultures, especially the city of Teotihuacán, in south-central Mexico. Trading was carried out with South America via the Gulf of Ecuador, which provided both sheltered harbor and a center of exchange between the

Andean civilizations to the south and the lowlands of Central America.

SOUTH AMERICA

In South America a great variety of natural environments imposed their particular demands on the Chavín and Moche cultures that preceded the Incan empire. On the arid Pacific coast, settlement was concentrated in a series of valleys that run down to the sea from the steep Andes highlands. The mountains themselves are further divided into high plateaus known as the Altiplano and the Puna, a grassland region stretching from southern Peru into Bolivia and northern Argentina.

In these highlands little rain fell, soil was thin, and temperatures were low, and the often steep Andean slopes prevented the use of much land for planting. As a result, settlement was scattered over a large area and economic life tended to be isolated. Farming and herding went together; family groups often undertook both vocations in places where pasturage and fertile land lay close together. Some clans held land in different locations and at different elevations to exploit a greater variety of resources. They migrated from one holding to the next to cultivate and harvest crops with different growing seasons. Andean farmers also made widespread use of terraces, which extended the cultivable land and made more efficient use of the available water.

In the Andes storage was vital, and crops often failed altogether through lack of rainfall, hailstorms, and frost. Crops also had to be rotated each year to avoid depleting the less-fertile soil. Alpaca and llama provided all-purpose work animals, transporting goods on the mountain trails and providing wool for clothing and blankets and meat for storage and use in the years of crop failure. In the high Puna region, above the zone where farming is possible, these animals were essential to survival. While both men and women worked the fields, children were given the task of herding and watching the animals.

Because their agriculture was undependable, the mountain settlers acquired beans, maize, cocoa, cotton, salt, and fish by trading along the valleys leading to the seacoast.

In coastal regions, people and entire communities tended to specialize in a single type of productive activity, such as fishing, farming, or herding. Some fishing communities specialized in a certain kind of marine life. Farming along the coast was made difficult by sparse rainfall; crop fields demanded complicated irrigation systems using streams flowing down from the Andean highlands. Irrigation canals demanded large and centralized labor forces. The system gave rise to seasonal work periods; farmers worked at maintaining the irrigation works when their fields were lying fallow and unused.

► education

INTRODUCTION

The need for the adult community to educate its youth runs deep into history. In preliterate cultures, the elders of a community educated young people in the skills they needed to survive and to be contributing members of their society. Generally, this type of education was gender specific. Boys were taught to hunt, build fires, tend fields and livestock, fight with weapons, and so on, and they often learned a trade or craft from their fathers. Girls were taught to cook, sew, take care of children, and other domestic chores. All were taught the history and values of their community through songs, legends, and stories, and all were schooled in the arts of cooperation with others, necessary for survival under usually harsh conditions. Knowledge about the world was hard won, and it was

important for elders to preserve and transmit that knowledge for future generations.

In later, literate cultures more formal schooling was common, at least for boys and for members of royal and upper classes. In ancient Rome, there was a legislated system of universal education. Egypt, China, India, Mesopotamia, Greece, and Rome all had formal school systems; the oldest of these schools operated in Mesopotamia and date back some 4,000 years. In most of these schools a primary purpose was to teach literacy. Children were drilled in reading and writing, often having to learn complex writing systems based on pictographs or ideograms, such as in China. In some cultures, emphasis was placed on mathematics as well. As time progressed, some school systems allowed older students to specialize in such fields as medicine, history, astronomy, rhetoric (public speaking and argumentation), and other fields. Young people who successfully completed their education were often able to secure positions as scribes, or writers of documents for the court; as civil officials; and, in the case of those adept at mathematics, as architects and builders. Formal educational systems also became more selective, as exams were administered and students were selected for their desire and aptitude.

Early education systems, though, focused on more than career education. Formal schooling also existed to teach young people the norms, values, and proper behaviors of their culture. In ancient China, for example, students were drilled in the teaching of Confucius, the ancient Chinese philosopher. A major function of many ancient schools was the teaching of religion. In ancient India, for instance, students spent a great deal of time memorizing verses from the Vedas, the ancient Hindu scriptures. In general, students were taught about the deities that were worshipped in their religious tradition and became familiar with the basic religious texts.

School was generally not easy. In some cultures students were taken away from their homes and even communities to study in isolated schools, where they had no distractions. The conditions tended to be austere, and schoolmasters were often harsh and unforgiving. Further, much education tended to consist of rote memorization. Students had to memorize written characters, and when they studied texts, such as works of literature or scripture, they learned those texts by heart. Even the study of rhetoric often consisted of little more than the memorization of formal exercises.

AFRICA

BY DIANNE WHITE OYLER

Education in the African society and culture of the ancient world was designed to prepare children for their lives as competent, responsible, contributing adults in the community, thus prolonging the life of the community for posterity. In both preliterate societies and a large segment of literate societies, indigenous education was the norm and was controlled by the family or community leaders. In literate societies not

all members of the community were literate. Those who were educated in the literate tradition also received the same primary education as those in preliterate societies but received additional formal schooling that enabled them to read and write and occupy positions as leaders in government and business.

In the preliterate community the educational leaders achieved their position by the status conferred on them from respect for the knowledge they had gained over a lifetime—by benefit of longevity. These were elders at the head of each family or clan, who worked together to govern the community. Even in the context of a community that existed as part of a larger political unit of chiefdom or kingdom, educating children remained the responsibility of the community elders. The elders taught children how to be adults. In some communities this meant being an apprentice to the parents—daughters learned how to carry gourds of water from the river and how to farm, and boys learned how to carry loads of tree branches for fuel to the compound and how to hunt. For most communities, however, there was more control over establishing what was taught as the norms of knowledge and behavior. For example, in West Africa “secret societies” and in South Africa “age grade systems” established the curriculum for boys and girls to learn the requirements of their place as adults in their communities.

For the most part, boys and girls were educated separately, with respected elders as their tutors. As early as age 10 children might be removed from the community and isolated for this intensive process, which could last three to four years. The student would leave the community as a child and return as an adult who, in some cases, had a new name. Boys learned how to be an adult hunter, husband, and father, and girls learned how to be an adult farmer, wife, and mother. This education included step-by-step instruction in a curriculum of ethnic and family history, community values and relationships, religion and cosmology, songs and dances, and acceptable behavior for all expected roles. Specialized instructions as a priest, diviner, healer, tailor, weaver, and so on were received within the family, where the new adult would learn skills that had been handed down from father to son. Alternatively, he would apprentice to another family member or a member of the community. The curriculum was delivered through oral literature, including folktales and legends that communicated the group’s history, dilemma tales that honed decision-making skills, riddles and proverbs that exercised the thinking processes and taught community mores and appropriate behavior, and praise songs, stories, and dance.

When the new adults entered the community, they became members of the male or female “secret society” or “age set” because they now possessed the “secret” information of adulthood. Similarly to members of a graduating class, they had a common bond that enabled them to form significant cooperative groups for economic and social needs. While these new adults might have been ready for marriage, depending upon the community, the males were restricted for a period of

time from the next step in the life cycle by the elder men, who controlled younger men's labor, but some of the new adult females married older men.

After the advent of Christianity, education in religious texts in indigenous and foreign languages and scripts became the priority for Christians as African groups converted to Christianity. The first educational institutions were monasteries and convents. The monks and nuns taught novices the scripture, giving them a religious education, and also how to read and write. King Ezana converted the kingdom of Axum to Christianity in the fourth century of the Common Era, and scripture was translated into the Ge'ez language and writing system and taught in the monasteries that became centers of education. Saint Augustine of Hippo established the first monasteries in North Africa's Maghreb region at Tagaste and Hippo, where third- and fourth-century Donatist and Gnostic Christians studied the Bible in Greek and Latin. Finally, Christian monks and traders introduced Coptic Christianity to Nubia in the fifth and sixth centuries C.E.; with conversion of the rulers and people by the seventh century, the monastic tradition continued in the teaching of its clergy.

In the ancient African world indigenous, preliterate education trained the next generation to be responsible contributing members of the community. Those who were preliterate and those who were literate lived together in the urban areas, and those who received formal schooling for jobs using literacy also received the same training as their preliterate neighbors. The two levels of instruction provided scribes with an elementary level and a secondary level of education that corresponded to an apprenticeship. Thus, scribes were educated to live in the community of their peers and to become leaders in an ever-growing civilization that required their skills.

EGYPT

BY AMY HACKNEY BLACKWELL

Most ancient Egyptian children did not go to school. For much of the ancient period, schools were rare or nonexistent. Instead, children stayed at home and helped their parents with daily tasks, in the process learning skills they would need as adults. Girls worked with their mothers, learning to weave, sew, cook, and take care of babies. Boys helped their fathers hunt, build houses, or gather wood. The sons of warriors might learn from their fathers how to use weapons. Boys and girls both worked in the fields with their parents, learning the complicated rhythms of the seasons and the Nile's flooding. Children sat with adults during religious rituals and evening storytelling, learning about their culture and religion.

Many children served as apprentices for several years, learning a craft such as metalworking, glassblowing, or embalming through practical experience. If a father practiced a craft, he would teach it to his sons starting when they were four or five years old. Many children were apprenticed to craftsmen who were not their fathers. Their parents had to pay their masters for the training. At the end of training an

apprentice might have to pass a test to show that he had mastered his trade.

Some ancient Egyptian children studied academic subjects, such as reading, writing, and mathematics. The children of the Egyptian rulers were taught in the palace by tutors. The Egyptian temples ran schools for the sons of wealthy parents; students attended from the age of four to their midteens. Most students who attended school were boys. Very few girls were educated, though daughters of wealthy and noble families often did learn to read and write. A successful performance at a temple school could mean that a boy would be qualified to take a prestigious government position or to serve as an army officer. Many graduates of temple schools became scribes, professional writers who could be hired to compose documents for those who could not read or write. Educated boys might also become priests, entrusted with the rituals of Egyptian religion.

During the heyday of Egyptian rule, before Greeks entered the country, Egyptians did all their writing with a pictographic written language. A pictogram is a picture that represents a concept or an object. Egyptian pictograms are known as hieroglyphs. It took many years for students to learn all the hieroglyphs they needed to know. They also had to learn how to make paper from papyrus, a reed that grew in the marshes.

Much of the Egyptian curriculum came from volumes that are now called "books of instruction." These books contained verses of advice given by a father to his son or a king to his heir. They admonished their young readers to tell the truth, to treat others with fairness, to avoid boasting, and generally to behave with prudence and wisdom. These documents resemble the admonitions in the Old Testament book Proverbs. Students learned these lessons by copying their texts over and over until they memorized them.

Students also studied mathematics and medicine. Egyptians were very good at mathematics, using a decimal system to make the calculations they used to build pyramids and to trade with neighboring peoples. They also used mathematics to create a calendar that would allow them to predict when the Nile River would flood. Students who studied medicine benefited from the knowledge of anatomy gathered by embalmers who made mummies. They learned about incantations, prayers, and the use of amulets, or charms, to ward off evil, but they also studied the effect of diet on human health. Young doctors often specialized in particular diseases, gaining their expertise by working with older doctors.

From 332 B.C.E. until 641 C.E. Greek was the official language in Egypt. Although commoners continued to speak their native dialects, Greek was the language of education, and all upper-class Egyptians learned it. Egypt's government needed a large number of educated scribes and officials, and many Egyptians saw education as a means to social advancement. Under Greek and then Roman rule, literacy became widespread, even among peasants, who needed to read in order to engage in commerce. People moved from the country-

side to the cities, where they found more teachers and more social mobility based on education.

Egyptian education in this period was similar to education in Greece. Younger students learned reading, writing, arithmetic, music, gymnastics, and athletics. They memorized poetry, especially that of Homer. Older students might engage in specialized study of composition, philosophy, rhetoric, astronomy, history, medicine, or mathematics. In addition to classes, students were expected to compete publicly in tests of academic achievement.

Some students went to schools where they studied with groups of children of about the same age. Others studied at home with private tutors. Parents had to pay for their children's education, which meant that the poorest people could not send their children to school. Tutors were usually slaves purchased by parents to teach their children. Teachers of all sorts were held in fairly low esteem; elementary teachers received the least respect, while secondary-level teachers were somewhat more highly regarded. During this period girls studied too, though education was still less common for girls than it was for boys.

Egypt became a center of learning during the Classical Period (480–323 B.C.E.). Alexander the Great founded the city of Alexandria in 332 B.C.E., modeling it on Athens and recruiting citizens from all over the ancient world. Among the new citizens were many scholars, and Alexandria became an important destination for those seeking advanced study. One famous Alexandrian scholar was the mathematician Euclid (ca. 325–ca. 265 B.C.E.), who greatly advanced and also systematized the study of geometry. Many educated Jewish settlers came to Alexandria and taught their religion there; the Septuagint, a Greek translation of the Hebrew Bible, was written by Jewish scholars in Alexandria.

Alexandria was especially famous for its library, which was the largest collection of writing ever assembled at the time. The library had an excellent collection of texts by Homer as well as works by other famous authors and scholars. Scholars came from everywhere to read and study in the library. In ancient times it could be difficult for a student to find the works he needed to read, and texts often existed in various versions in different places, so the Alexandria library's collections were invaluable to serious students. The library functioned as an early university, its resources attracting scholars who in turn learned from one another.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Ancient Mesopotamians were among the first people in the world to create schools. Archaeologists have found lists of vocabulary words dating to about 3000 B.C.E. at the Sumerian city of Uruk; this is the earliest evidence of formal schooling in the region. By 2000 B.C.E. Mesopotamians had a well-regulated school system, with scribal schools created by royal edict

and students doing work in many major cities, including Ur, Uruk, Nippur, Shuruppak, and Abu Salabikh. Between 2000 and 1500 B.C.E. Mesopotamian students did enough school exercises to leave archaeologists hundreds of clay tablets containing their work with directions from and corrections by their teachers.

Mesopotamian schools had several purposes. The most basic was to create scribes by teaching children how to read and write. The government, the temples, and businesses all needed people who could read and write letters and inventories and do arithmetic. A more philosophical purpose was to create an educated, thoughtful citizenry. Mesopotamian writers are the first in the world to mention the concept of “humanity” as a condition of people who have been elevated above the animals by learning to think. Another reason to educate children was so that they could read of past events, interpret them in the present, and in their turn write down the events of their lifetimes and thus leave a record for future generations.

Sumerian schools were private, not public. Only wealthy parents, such as government officials, businessmen, scribes, priests, and military officers, sent their children to school. Almost all students were boys; the only female students were the daughters of royalty and girls being prepared to become priestesses. Still, most Mesopotamian boys and girls never went to school at all, instead spending their childhoods helping their parents and learning the tasks they would perform as adults. Schools met from sunrise until sunset, and students ate lunch at school. Students attended for several years, finishing in their teens. A school would typically contain students of many different ages and levels of academic achievement. The older students helped instruct the younger ones; they were called “big brothers.” All the pupils called themselves their school’s “sons.”

Teachers were scholars in various fields, including mathematics, language, and surveying. They took their salaries from the fees parents paid as tuition. Parents would sometimes try to persuade teachers to give their children favorable treatment; in one ancient Sumerian school story, a lazy boy’s parents invite their son’s teacher to dinner and give him a ring as a present, whereupon the teacher lavishes praise upon the lad. Most schools had a disciplinary officer who beat unruly students with a stick. Infractions were similar to those in modern schools; they included speaking without permission, standing up or leaving without permission, not speaking correct Sumerian, and dressing inappropriately.

The first thing Mesopotamian students learned was the cuneiform writing system. This system was extremely complex and required readers to recognize subtle differences in patterns of tiny triangles made with a reed pen, or stylus, on clay tablets. It took years to memorize all the characters and learn to read quickly. Writing cuneiform presented its own difficulties. Students had to learn how to make clay tablets by mixing and molding the clay and how to fire the clay tablets so they hardened.

Teachers taught reading and writing by writing a sentence at the top of a tablet and requiring their students to copy it over and over. The teacher or an older student would review the work and correct it, and all the students were expected to study their day’s work at home that night. The next day they had to write the previous day’s lesson correctly, after which they would receive a new writing exercise. Archaeologists have found numerous clay tablets containing these exercises, including teachers’ corrections; one tablet was apparently so disastrous that the teacher crossed out everything the student had written. Older boys wrote out longer texts than younger ones. Sometimes teachers gave lessons based on stories, some of them humorous. As students grew more advanced, they began reading and reciting their lessons aloud. Students might specialize in various fields, including architecture, engineering, astronomy, botany, geography, medicine, and zoology.

Mathematics was very important to Mesopotamians, who were expert architects and carefully collected and distributed their people’s grain. Students practiced mathematical skills with word problems that presented situations a professional man might face, such as plotting the movements of the stars, calculating the supplies needed for a military campaign, collecting taxes, determining how many bricks were needed to build a palace, or measuring plots of land and estimating how much grain they would produce.

Sumerian schools also taught languages. Students were expected to learn Sumerian. As time went on, people stopped

Cuneiform tablet with schoolwork, Old Babylonian, about 1900–1700 B.C.E., probably from southern Iraq. (© The Trustees of the British Museum)

speaking Sumerian. but Mesopotamian students kept learning it; they used it much as Latin was used in medieval Europe, as a dead but stable language that marked people of learning. After about 2500 B.C.E. students also learned Akkadian, the language of the Akkadian people.

The ancient Jews in the Levant also developed an elaborate system of education. They believed that education was important for transmitting knowledge from generation to generation, for increasing the entire body of knowledge, and for defining culture and acceptable behavior. The three branches of education were military training, occupational skills, and religious education; the latter was generally considered the most important. Jewish people considered study to be a form of prayer. Both boys and girls were educated, and most ancient Jews were literate. Parents were supposed to teach their children the Torah at home. Children at the age of five began learning about ritual purity and how to pray. At age 10 children studied the oral law. They completed their primary education around the age of 12 or 13.

Boys in their early teens spent time at the Bet Midrash, or “House of Study,” where rabbis taught them Jewish law and history, including the scriptures in Old Testament and the Talmud, the Jewish book of law and scriptural commentary. They progressed through several stages; at age 15 they were considered ready to study the works of wise Jewish scholars and at age 20 were prepared to pursue a vocation. The Bet Midrash functioned as school, place of prayer, and communal library. Teachers included scribes and Pharisees. Scribes were literate men who worked as administrative officials and teachers. The Pharisees came from the ranks of the scribes, but they were more specialized scholars, teachers, and professional writers in charge of transcribing and interpreting the Torah, the Jewish holy text. Jewish people continued to pursue education throughout their adulthoods. Thirty was considered the age at which one was mature enough to enter the ministry, and by age 50 a person was educated enough to advise others.

In ancient Persia priests called magi were trained to interpret dreams and other omens and to predict the future. The rank of magi was hereditary, so only boys born into magi families could undergo the necessary training in scripture, ritual, and astrology. One of the best-preserved accounts of education in Persia is *Cyropaedia* (*The Education of Cyrus*), the Greek historian Xenophon’s fictional account of the life and education of Cyrus the Great (585–529 B.C.E.). This book recounts Cyrus’s process of learning political philosophy and spreading his ideas among the Persian people. Herodotus, a Greek historian of the fifth century B.C.E., described the education of Persian boys. Noble boys spent the first five years of their lives with their mothers and then the next 15 years learning to hunt, ride, shoot arrows, and throw spears. A few learned to read and write; some of them became scribes. Although the Persians revered wise and educated men, most noble Persians restricted their philosophical education to the rudiments of ethical behavior.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Most children living in Asia and the Pacific region in ancient times had no formal education. They stayed at home with their parents and learned the skills they would need to function as adults. Fathers taught their sons how to hunt, build houses, and perhaps fight with weapons. Mothers taught their daughters how to make cloth, cook, sew, and tend children. Both sexes helped their parents in the fields. Children would have joined adults for storytelling sessions and religious rituals in which they learned the specifics of their culture and their own ethnic mythologies.

China developed a very complex education system during the ancient period. Much of Chinese educational philosophy was based on the teachings of the ancient thinker Confucius (551–479 B.C.E.). Confucius claimed that all people had the potential to act properly and that education was the best way to help people grow up to behave correctly. Chinese students spent years learning to read and write the Chinese script. Chinese writing consisted of ideograms, or characters—patterns of brushstrokes that represented images or concepts. Each character was painted by brush or, for inscriptions, cast with molds or incised into materials like bone or bronze. While the order of strokes was meant to be predetermined or regular, calligraphers often violated that protocol. The characters were seen as graceful images as well as written words, and beautiful handwriting was considered a valuable skill. The advantage of this system of writing was that it did not depend on spoken language for comprehensibility, so people who spoke different dialects could understand each other’s writing. The disadvantage was that was difficult to learn to read and write; students had to memorize thousands of characters before they could be reasonably literate. This took many years.

The Han Dynasty emperor Wu Ti (r. 140–87 B.C.E.) founded a state educational system in 124 B.C.E. His chief purpose in educating young boys was to train them to be civil servants who could work in the government bureaucracy, creating a highly selected and trained body of government officials loyal to the emperor. (All students in China were boys. Girls could not become civil servants, and their families preferred to keep them home to work. Some girls in the nobility were instructed at home and learned to read, but they were the exception.)

Wu Ti built provincial schools all across China and founded an academy for advanced students. Admission was competitive; students had to pass a difficult examination to get in. Once students were admitted, the government provided food and housing for them. The Han Dynasty introduced a system of examinations as a way of identifying the best students on the basis of ability, rather than allowing professors to pick and choose their favorites.

Han emperors believed that the Confucian approach to education would produce a new class of educated aristocrats

Yue ware water dropper in the shape of a frog drinking from a cup, from Zhejiang Province, southern China, Six Dynasties, third to fourth century C.E.; such items were made for the scholar's desk and used in calligraphy. © The Trustees of the British Museum

who would be more loyal to the state than the hereditary nobility was. Consequently, the ancient curriculum consisted largely of Confucian philosophy and ethics. Professors were experts in the Confucian Five Classics, which included works on history, rituals, poetry, and divination (foretelling the future or discovering hidden knowledge through omens). Confucian philosophy emphasized loyalty to the state above all. Students also studied mathematics, music, and painting among other subjects.

Confucius thought that all social classes should be educated, even the poor. As a practical matter, most of the poor did not have the time or the resources to go to school, so most boys who went to school came from wealthy families. There were nonetheless many exceptions. The Han emperors set up their system to find talented boys, not wealthy boys, and this gave many poor young men an opportunity they would not otherwise have had. A number of boys from humble backgrounds did rise up through the system to take important jobs high in the governmental bureaucracy.

As Chinese culture spread throughout eastern Asia, the people in Southeast Asia, Japan, and Korea adopted Chinese educational practices. Korea, for example, created an education system during the Three Kingdoms Period (57 B.C.E.–668 C.E.) that was very similar to the Chinese system, with a heavy emphasis on Chinese classics, Confucian philosophy, and preparation for government service.

In India education was inextricably tied to religion. Hindu students were expected to learn Hindu scriptures, rites, and rituals as a preparation for higher knowledge. Every student studied with a teacher called a guru. In ancient times a guru was considered a god in human form. Students were expected to choose a single guru and stay with him until their education was complete. To study with a guru, a student would go to a *gurukula*, a sort of school that was often located

in the forest, away from cities and students' families. Entering a *gurukula* was not easy; a student had to convince the guru that he was serious about wanting to study and that he was intelligent enough to learn the material. Gurus believed that there was no point in teaching those who were not interested or mentally capable of learning, and tradition forbade the acceptance of unqualified students. Once in the *gurukula*, students studied the Hindu scriptures, or Vedas, memorizing verses and reciting them in order; a student could not move on to a new verse until he had recited all the preceding verses perfectly. Although scriptures were important, students could also study practical subjects such as mathematics, medicine, music, magic, or the art of warfare.

Discipline was strict and living conditions austere; students had to observe a stringent diet, meditate, practice yoga, remain chaste, and perform menial jobs for the guru. Sometimes students traveled with the guru to perform rites. When a student finished the several-year course of study, he paid the guru for the instruction.

Almost all students in *gurukulas* were boys. Girls were not allowed to study; a few royal women were educated, but ordinary women were not. For the most part, lower-caste people were not allowed to study either; education was restricted to the upper classes. People in lower castes were allowed, however, to receive training in their occupations. Members of castes that specialized in various crafts, such as weaving, pottery, or building, would train their children in the traditional practices of their specialty. After the fifth century B.C.E. Indian students also studied Buddhism. Buddhism placed more emphasis on practical living techniques that would pave the way to enlightenment. Communities of Buddhist monks and nuns functioned as schools of Buddhism.

EUROPE

BY JUSTIN CORFIELD

Throughout Europe during ancient times there were formalized systems of childhood education involving parents, relatives, and village elders who taught lessons in farming and hunting and various other adult occupations. Indeed, education largely took the form of initiation into adulthood, and this process varied across the continent and gradually changed and adapted over time until the Romans extended their rule over much of western, southern, and central Europe.

The tradition among Celts was for boys to be handed over to "foster fathers" at the age of seven (as was the case in Ireland) to 10 (as was practiced in Scotland). The foster fathers, often uncles or longtime family friends, were then responsible for the academic, artistic, and physical training of the boys. This responsibility was regarded as a great honor, with accounts that in Ireland "five hundred kyne [cattle] and better" were often given for the training of the son of a "great man." A Celtic youth was supposed to have "four and twenty" skills. Among these skills were the "six feats of activity": hurling weights, running, leaping, swimming, wrestling, and rid-

ing a horse. There were also the “four exercises of weapons”: archery, use of the javelin, use of the quarter-staff, and use of the sword and the sword and buckler. Then there were the “three rural sports”: hunting, fishing, and hawking. Last there were the “seven domestic games”: poetry, heraldry, diplomacy and musicianship, and four board games. Although the foster father oversaw this training, particular aspects were taught by skilled individuals; spiritual training, for example, was often performed by Druids.

Many of the skills that Celtic boys had to learn were concerned with war, and the Bronze Age in which they flourished was not only prosperous but also violent. The Germanic tribes tended to prefer boys to use the bow and arrow, while the Gauls, in the region that is now France, tended to favor the javelin. To encourage them in warlike pursuits, the Romans recorded that Celtic boys were, from a young age, served meat on the point of a sword. Many early sporting pursuits, such as tossing the caber (a pole or tree trunk) for the Picts (in Scotland) or juggling swords, were important for developing skills useful for battle, where agility rather than armor made the difference between life and death. In parts of Europe where there were no major pressures of population, skills related to hunting and trapping animals were given priority. Upon being trained, the boys would be asked to prove themselves in terms of valor and skill at arms to be acknowledged publicly as achieving adulthood.

In parts of Europe some men, especially mercenaries, had specialized occupations. The slingers from the Balearic Islands were used extensively by the Carthaginians, and Roman writers mention them in some awe and trepidation. To achieve the level of skill they had, boys on these islands were trained from an early age in the use of the sling. One writer notes that the boys were trained to hit bread with a stone and were not allowed to eat until they hit the target; it is also noted that boys were trained by their fathers, who gave them a sling as their first toy. Similarly, the Huns trained their sons from a young age to ride horses.

As the Roman Empire expanded, many well-to-do families wanted their sons to be educated in the Roman style. Many boys in towns and cities were taught by schoolmasters, who opened a room or more of their houses and tutored a number of students at the same time. Salaries were low, but there were encouragements, such as that teachers were exempted from military service by the emperor Constantine (r. 306–337 C.E.). The wealthy often used an educated slave known as a *paedagogus*, who would act as a tutor. A significant number of these slaves, especially around the Mediterranean, were Greeks.

Small schools followed an unregulated Roman system of education with rote learning of grammar as well as poetry and rhetoric, or the effective use of speech and writing. The system also involved learning how to read, often both Latin and Greek, depending on the town or city in which the school was located. The works of Homer were regularly used to teach history, to explain problems with life and morals, and also to teach rhetoric. The study of rhetoric sometimes involved

repeating imaginary speeches from such historical figures as Alexander the Great, Hannibal, and Julius Caesar. Children would write on slate, with many committing information to memory, reinforcing the oral tradition used by the Celts, the Dacians, and others.

Agricola, the Roman governor of Britain from 77 to 84 C.E., brought with him from Tarsus to Britain a Greek schoolmaster called Demetrius. Other similar situations occurred. Indeed, Saint Patrick spoke some Latin from a young age. During the height of the Roman Empire the system of education, though it did not follow any set curriculum, was probably fairly uniform throughout the empire. It was not uncommon for children of the very wealthy to go to Athens or Rhodes for the best schooling available at that time. The Roman elite families certainly availed themselves of these opportunities, and it would seem likely that other rich families across the empire might have done the same.

Apart from some from wealthy families who would have had tutors, the Celts seem to have paid little attention to girls' education, which would have been conducted largely at home. It is also possible that the male Roman writers did not choose to record the education of Celtic girls, whose treatment may not have been much different from that of girls in villages in Italy. The names of very few women survive from this period, and even for those about whom much is written, such as Boudicca, who fought the Romans in Britain in 60–61 C.E., little is known about their early life and training. After the growth of the Christian church from the early fourth century, churches became places of learning, and boys (and probably a few girls) started getting their education—religious and academic—from the local priest and gradually at monasteries.

GREECE

BY CHRISTOPHER BLACKWELL

Before the fifth century B.C.E. there is little evidence for formal, organized schools in the Greek world. The education of aristocratic children would have been handled by their nurses when they were very young or by slaves, but schooling was probably left to informal instruction by peers and older mentors. In Homer's *Iliad*, we read that Achilles' father, Peleus, retained an older man, Phoenix, as a companion and tutor for the baby Achilles. Phoenix talks of teaching Achilles to eat with a spoon, and later he instructs him to play games and use weapons. Young Achilles was also said to have attended a “school” run by the centaur Chiron—the mythological nature of this schoolmaster may suggest that formal education was so rare as to seem magical, the privilege only of those aristocrats descended from gods. In the most ancient Greek world the aristocracy tended to assume that their superiority was inborn, a matter of blood and not of education.

For all Greek boys and young men in the centuries before the Classical Period (which began in the fifth century B.C.E.), informal and formal athletic competitions would have been the center of their development. These games involved

strength and endurance training, various foot races (including races while wearing armor), and the acquisition of military skills such as boxing, wrestling, archery, swordplay, and the use of the spear and javelin.

Before the widespread adoption of the Greek alphabet, “literary” and cultural education would have come through public rituals. The shared theology and mythology, a cultural heritage that more than anything else united the independent and scattered communities of Greek speakers, passed from generation to generation through sacrifices and festivals, each associated with a myth or in celebration of the origin of some cultural institution. Thus, Athenian children would learn of the history of their legendary king Theseus at the festival of the Deipnophoria and of the political unification of Athens at the festival of the Synoikia. Many festivals featured the performance of Homeric poetry, and all young Greeks would thereby have come to know of the legends about the Trojan War and the heroes who fought in it.

At some time, and over a period of time, before the fifth century B.C.E., the Greeks adopted a new alphabet, modified from the Phoenician alphabet, which allowed a true culture of literacy to arise and which spurred the invention of formal programs and institutions of learning. An anecdote from the fifth century B.C.E. historian Herodotus illustrates this change.

In Book 6 of his history, Herodotus describes an incident that occurred around 496 B.C.E. on the island of Chios, where a roof collapsed on a group of 120 boys as they were being taught their letters; only one boy survived. Herodotus calls this an omen, anticipating the overall political disaster that was about to befall the community of Chios, specifically an invasion by a Persian army. Herodotus mentions another disaster that happened at the same time: A chorus of 100 young men from Chios, officially sent to Delphi for a performance at a festival there, fell victim to a plague that killed 98 of them. Only two of the boys returned alive to Chios. This double tragedy serves, for us, to illustrate two parallel institutions of learning: one private and literate—an indoor school where boys quietly studied written texts—and one public and preliterate—a chorus trained to sing poetry.

In Athens during the fifth century B.C.E., we have evidence for a fully developed system of education for boys, while the education of girls seems to have continued to be a private, ad hoc affair managed, if at all, by mothers inside the home. For all Athenian boys, there was a compulsory program of public education during the years of adolescence, the *epebeia*, designed to train young citizens of the democracy. This program included military training but also training in civic responsibility. Apart from these years, however, schooling was optional and required payment to private teachers.

Young Athenian boys learned under three kinds of teachers. A boy might begin the day with the *paidotribēs*, the gymnastics teacher, working on physical fitness and the vigorous games that formed the basis of public competition and prepared young men for war. Afterward he might go to

HOMWORK IN ANCIENT GREECE

The dry sands of Egypt have preserved tens of thousands of documents that were part of the day-to-day lives of people. Because the ruling classes of Egypt after the fourth century B.C.E. were Greek, we have a vast number of receipts and recipes, personal letters, and business contracts written in Greek by ordinary people. Among these are school exercises from students as they learned to read and write the Greek language, the universal language of business, politics, science, and art from the fourth century B.C.E. until well into the period of the Roman Empire.

Some of these surviving exercises are extremely basic. A fragment from the fourth century B.C.E. shows a series of letters written well and clearly, followed by the same letters written in a very clumsy hand; clearly the teacher did the first row, and a beginning student tried to copy them, working on the shapes and attempting (unsuccessfully) to write between the lines scratched on the fragment.

A scrap of papyrus from the second century B.C.E. has the student’s name at the top—Apollonius—and a list of the Athenian names for the months, followed by a list of the Macedonian names of the months. The writing is unsteady, and there are a number of misspellings. Other fragments show students copying the names of Greek gods and goddesses, or the names of the heroes in Homeric poetry.

After learning their letters, students went on to learn grammar. One student was set to writing the phrases “the good father,” “the appropriate warning,” and “the philanthropic attitude” in each of the grammatical cases of the Greek language—the teacher was clearly trying to add some moral instruction to the lesson in grammar and syntax. These fragments are a wealth of evidence for teachers and learners in the ancient Greek world, though the stories behind them—the students’ successes and failures—are now lost.

the *kitharistēs* to study music—singing and playing the lyre, a stringed instrument like a harp. Music was considered important for teaching balance and moderation, for developing aesthetic sensibilities, and for providing a certain amount of mathematical study. And later still he might go to the *grammatistēs* to learn letters, read Homeric poetry, and study arithmetic and geometry. Apart from any examinations these teachers might give to their students, study was motivated by the prospect of festivals, at which boys would be expected to compete in games, to recite the poetry they had learned, or to dance as members of a chorus.

Athens is not the only model, however. The poetry of Sappho (sixth century B.C.E.), from the island of Lesbos, not only shows great literary accomplishment by the poet herself but also suggests an intellectual community among the young women of Sappho's acquaintance; during the Victorian era English scholars liked to imagine that Sappho ran a prep school or finishing school for women. There is little evidence for this, but there is no denying the evidence for some formal literary training of women at that time.

In Sparta during the Classical Period girls were educated beside boys, with the whole program of education focusing on the skills necessary in a military state—athletics, gymnastics, and war games but also music, poetry, and dancing, all of which were deemed necessary for young warriors as well as for the future wives and mothers of warriors.

During the fifth century B.C.E. a number of professional intellectuals came to Athens—then the cultural, economic, and political center of the Greek world—and set themselves up as professional teachers of rhetoric and philosophy. These men were known as *sophistēs*, or sophists, and they introduced new ideas about the gods, human ethics, and the role of reason in public life. They often promised to help young men achieve prominence in the democratic state of Athens by teaching them to speak persuasively. As with most new intellectual movements, this “sophistic revolution” was met with some suspicion and often ridiculed, but it was also highly influential. Pericles, a figure who dominated Athenian politics in the middle of the fifth century B.C.E., was greatly influenced by the Sophists.

The heritage of this sophistic revolution were a number of schools of philosophy and rhetoric—Isocrates' school of rhetoric, Plato's Academy, and Aristotle's Lyceum being the most famous—and the lasting position of rhetoric, public speaking, as the centerpiece of education for wealthy young men, a movement that survived throughout the Hellenistic Period (323–31 B.C.E.) and into the Roman Empire. Indeed, long after Athens ceased to be a military or political power, it remained an intellectual center. We have a number of letters from the Roman statesman Cicero (106–43 B.C.E.), written to his son whom he sent to study in Athens. These letters confirm the lasting legacy of the Athenian model of education, and they also suggest that the challenges faced by young people going abroad for higher education, and by their parents back at home, transcend time.

ROME

BY ROBIN BARROW

In the sixth and fifth centuries B.C.E. education was a family matter. There were no schools and no formal program of study. A father had absolute legal authority over his children and took prime responsibility for their upbringing, which consisted mainly in developing character, particularly the Roman virtues of dignified bearing (*gravitas*), sense of duty (*pietas*), and respect for tradition (*mos maiorum*). The mother

also played an influential role in the children's early years, and she went on to initiate her daughters into the customs, practices, and skills associated with a conventional female role. These skills were chiefly those suited to the running of a household. The sons would conclude their education by being apprenticed to the father's trade or, in the case of the wealthier classes, by entering military service and being inducted into the business of political life by the father or a close family friend.

Reading and writing played little or no part in education at this early date, but they had become part of the education of the families of senators and *equites* (“knights”) by the end of the fourth century B.C.E. By the middle of the second century B.C.E. Roman education was increasingly influenced by Greek example. Greek tutors had been popular for some time, but now Romans began to study Greek language and culture.

The orator and statesman Cicero (106–43 B.C.E.) maintained that Rome did not have a uniform system of education; there was no centralized system, no compulsory formal schooling, no common curriculum, and no state funding (though later emperors and other wealthy individuals did sometimes endow schools and professorships). But there were schools by this date. These were generally very small and often consisted of nothing more than a small room in a tavern or even a spot in the open air. A fee-paying school was opened in the second half of the third century B.C.E., but there were a few schools of an informal nature the century before that, where payment would have been by gift or in kind, though the wealthy never ceased to employ tutors.

There was no formal requirement of attendance and no regularized curriculum even by the end of first century B.C.E., but by then students did by and large follow a basic pattern of schooling. At about the age of seven, they were taught basic literacy and numeracy by the *litterator*, being escorted to and from school by a slave. Letters were learnt by copying; once the child could form sentences, he would copy out improving phrases and sayings, such as *laborare est orare* (“to work is to pray”), intended at the same time to improve his character. Writing generally involved inscribing letters on a wax board with a *stilus* (“stylus” or “nib”). Calculation was done on the fingers, on an abacus, or in the head. At about the age of 12, the boy went to the *grammaticus* to study literature. Girls could receive a formal education but did not commonly do so; it is not clear whether boys and girls were ever taught together.

In studying literature the emphasis was on analysis and memorization, and the presumption was that the study would also be uplifting and contribute to character development. Students had to recite from chosen authors and compose commentaries on them. The material was largely poetry and initially Greek (for example, Homer). By the first century C.E., following the emergence of poets such as Virgil (70–19 B.C.E.) and Horace (65–8 B.C.E.), Romans were able to study their own literature, though Greek authors never lost their appeal.

Fragments of painted plaster, Roman Britain, first or second century C.E., from Otford, Kent, England; these fragments from a frieze that decorated a corridor at a Roman villa are inscribed with a line from Virgil's *Aeneid*, showing widespread knowledge of classical Roman literature. (© The Trustees of the British Museum)

At about the age of 15, students passed to the third and final stage of formal education under the rhetor. Rhetoric was first taught in the second century B.C.E., once again using Greek materials that were gradually replaced by Latin material. The rhetor taught the art of public speaking, which was important in relation to political advancement in a society that encouraged widespread debate, developed a legal system that still affects us today, and expected participation in civic affairs. In its heyday the study of rhetoric was a practical form of legal training. Romans such as Cicero and Quintilian (ca. 35–ca. 100 C.E.) wrote sophisticated treatises on the subject; Cicero, in particular, shows by his career (and in his many extant speeches) the high quality that such a training could achieve.

The study of rhetoric, however, involved a somewhat mechanistic training, consisting for the most part in a number of repeated routine exercises. For example, students were called on to argue for or against some course of action; to compose eulogies or criticisms of historic figures; to debate the merits of epigrams and other famous sayings. The student was expected to focus on selecting a suitable subject matter, arranging or organizing the argument appropriately, delivering it clearly, and adopting an appropriate tone. The study culminated in the practice of comparing imaginary speeches and presenting them to fellow students (*declamatio*). There were two kinds of *declamatio*: one (*suasoria*) involved the attempt to justify (or condemn) some course of action, usually historical; the other (*controversia*) consisted of an attempt to argue for or against a specific legal case.

By the end of the first century B.C.E. many Romans completed their education by studying rhetoric and philosophy abroad, almost invariably somewhere in the Greek world and

particularly at Athens. But what started well and flourished for a while eventually went into decline under later emperors when, with political freedom being very limited, the practical significance of rhetorical ability lessened and artifice and mannerism began to overshadow substance. (Hence, today *rhetoric* is generally a critical term, suggesting a triumph of presentation over real argument).

The three stages of education outlined correspond roughly to the Greek model of schooling. However, the Romans did not share the Greek passion for either music or physical education. Generally speaking, the *litterator* and *grammaticus* were held in low repute and were poorly paid. The rhetor commanded more respect and is thought to have earned something like five times the salary of the *litterator*; a few acquired considerable fame. Holidays seem to have been quite common, taking place on festival days, market days, and any day when there was a gladiatorial show or a military triumph as well as during a lengthy summer vacation. The school day began early (often before daylight in winter); discipline was strict and included corporal punishment.

The key features of Roman education were schooling in the basic skills of reading, writing, and arithmetic; character development; and training in the art of public speaking or advocacy. In the process there was a great deal of drill, rote learning, and skill practice; the focus was on seriousness of purpose and material was chosen for its moral value rather than its intellectual interest or artistic quality, still less its entertainment value. It is perhaps sometimes difficult to see how it did so, but this system of education could produce great humanists and cultured individuals such as Cicero, Virgil, and Quintilian.

THE AMERICAS

BY ANGELA HERREN

For the ancient Americas archaeological evidence provides no indication of formalized education in schools. One can assume that parents or community members trained their children at a young age to perform the activities of daily life. Later cultures divided major tasks between the genders. Men often hunted, fished, grew crops, constructed buildings, sculpted, painted, made ceramics, and at times engaged in warfare. Women typically maintained the home, raised children, prepared food, and wove textiles. During the first millennium B.C.E. early cultures grew more complex and began to build elaborate ceremonial sites. With the stratification of society, knowledge must have become more specialized as hierarchical class distinctions between elite groups, commoners, and ritual practitioners took root. Early sculptural works and monumental constructions indicate an interest in astronomical phenomena, the cosmos, deities, genealogy, and rulership. In addition to these public monuments, ritual performances and royal ceremonies educated the populace on the history, religion, and developing power structures that provided the foundation for communal society.

Created by the Adena (ca. 1000 B.C.E.–ca. 200 C.E.) and Hopewell (ca. 200 B.C.E.–ca. 400 C.E.) cultures in the area around southeastern Ohio, the art of the Woodlands Period (ca. 1000 B.C.E.–ca. 1000 C.E.) demonstrates keen observation of nature and perhaps the development of religious practices. The Serpent Mound in Adams County, Ohio, represents one of the most striking monuments created by the Adena. A monumental earthwork, the dimensions of the serpent form measure 4 feet high, approximately 20 feet wide, and 1,254 feet long. The mouth of the serpent appears to bite an egg, while the body undulates across the landscape, terminating in a spiral form at the tail. The Adena created other earthworks depicting birds, bears, mountain lions, and various predatory animals. Such monuments may mark sacred sites and could have educated local communities on the power of these creatures or the deities they represent. Like the Adena, the Hopewell buried their dead with small artworks and effigy pipes. In their stone pipes, the Hopewell artists include certain identifying characteristics, such as beak, tail, or teeth, that make the particular species more easily recognizable. Hopewell artists must have taught their protégées how to recognize and represent these traits in the restrained naturalism so characteristic of the culture.

In South America many early ceremonial centers mark basic movements of the sun, moon, and stars; represent important cosmological concepts; and demonstrate the increased importance of shamans, intermediaries between the spiritual and mundane worlds. Shamans who directed rituals at the Old Temple and New Temple at the highland Andean site of Chavín de Huántar (ca. 900–200 B.C.E.) educated their followers on the east-west trajectory of the sun, the cardinal directions, and the axis mundi, or fifth vertical direction that connected the heavens, earth, and underworld. Art and architecture underscore themes of duality and complementarity that formed bedrock cultural beliefs, passed down through generations of Andeans.

Archaeological excavations prove that the Moche (ca. 1–600 C.E.) on the north coast of Peru practiced an important ceremony called the “Sacrifice Ritual” for hundreds of years. Moche priests and priestesses enacted their rites, educated their apprentices, and spread their practices to neighboring settlements. They recorded the protagonists, costumes, and activities of the ritual on painted ceramics and murals.

The highland site of Tiwanaku (ca. 300 B.C.E.–1100 C.E.), near Lake Titicaca in western Bolivia, contained a ceremonial core filled with highly symbolic monuments visible to the surrounding community. One of them, a huge stone portal called the Sun Gate, depicts a relief carving of a supernatural being or shaman surrounded by bird- and human-headed attendants. Associated with the puma, this figure carries arrows and a spear thrower. The people of Tiwanaku represented the spiritual beliefs that tied their community together in permanent stone monuments. They disseminated their ideas by copying images from ceremonial architecture in portable textiles.

Ancient Mesoamericans also used monumental sculpture, architecture, and artwork to transfer communal knowledge. Unlike contemporaries in North and South America, however, they developed pictorial writing systems and complex calendar notations to record and store information. The earliest evidence of these developments appears on carved stone sculptures and monuments.

Dating to the first millennium B.C.E. a stone block discovered in a quarry in Veracruz, Mexico, in 2006 may represent the earliest forms of glyphic, or symbolic, writing in Mesoamerica. While the glyphs remain undeciphered, they resemble forms found on art of the Olmec culture (ca. 1200–400 B.C.E.). Lightly incised glyphic marks often cover three-dimensional carved celts, or axes, and stone sculptures depicting human and animal composite figures. Many glyphs seem to represent deities or cosmological information. These art objects, often found near ritual and ceremonial structures, may indicate that Olmec villagers relied on priests or shamans to maintain and transmit spiritual knowledge on their behalf. Late Formative and Proto-classical stone sculptures from the southern Maya region (ca. 400 B.C.E.–250 C.E.) record extensive glyphic notations and calendric dates.

Priests, artists, and elite persons probably commanded the greatest knowledge in ancient Mesoamerica, training those with aptitude and interest. Commoners may have called upon these individuals to impart their knowledge when needed.

► empires and dynasties

INTRODUCTION

When people think about history, it is likely that kings and queens, emperors and empresses, as well as vast empires will soon come to mind. In empires one can often see the great sweep of history, especially when great empires extend their realms by conquering their neighbors. It is important when studying empires and dynasties to remember on whose backs the empires were built. For instance, the empires of ancient China consisted mostly of peasants who had little or no say in how they lived their lives. When there were wars to be fought, the peasants made up almost the entire military force of soldiers, and when they went away into battle, they seldom returned home. The food they produced fed the empire, and the battles they fought made emperors powerful.

On the other hand, the Zhou Dynasty (ca. 1045–ca. 256 B.C.E.) accomplished something remarkable: It created a sense of common nationhood among the many ethnic groups that lived within its territory, so that even when the empire splintered among petty warlords, everyone believed that China should be one nation. Even when barbarians seized control of parts of China, the barbarians began thinking of themselves as Chinese. During the Six Dynasties era (220–589 C.E.), when China was embroiled in many civil wars, there was an abiding belief among its people that all within China were one nation.

The success or failure of an empire can be gauged in part by how successful it was in creating among its population a sense of being one people who stand apart from others. The term *barbarian* or variants of it usually signified that one set of people were part of an empire and other sets of people belonged outside it; the outsiders were considered barbarians because they did not practice the customs of the insiders. Perhaps the world's first empire was that of the Old Akkadian Dynasty (ca. 2350–ca. 2100 B.C.E.), created by Sargon I in the Near East. It suffered from ill-defined borders and a size greater than a central government could manage at that time, but it also eventually failed because most of those within it did not see themselves as Akkadians but instead as conquered peoples, as outsiders. The rulers of the Neo-Assyrian Empire (1000–626 B.C.E.) tried resettling entire populations from their homes into parts of the empire where the rulers could keep an eye on them. When Babylon and Judah revolted and the Medes invaded in about 615 B.C.E., Assyria was full of people who did not think of themselves as Assyrian. Thus, the Assyrians were overthrown, and they had few places to hide even in their own lands.

Perhaps no one was more aware of the importance of making people feel part of their empire than were the Romans. From the time of Julius Caesar's conquest of Gaul, the Romans tended to let their conquered peoples live in peace, just as long as they paid their taxes. Human sacrifices were forbidden, but religions were mostly left alone, and wars among the peoples of the empire were forbidden,

despite Rome's occasional civil wars. What Rome did was bring the benefits of the *Pax Romanum*, the Peace of Rome, to bear in conquered lands. There were well-built roads for communication and trade. Services on the roads included a postal system in which a letter mailed in Britain could arrive in Egypt in about four weeks. Trade along the roads was protected by soldiers in stations or forts that appeared frequently. Wealth and power could be attained by anyone who made use of Rome's opportunities, and conquered people quickly began sending their children to school to learn Latin and Roman customs, so that they could share in the wealth of the empire.

Furthermore, Romans often settled in large groups in newly conquered lands. This was crucial in the Romanization of North Africa after Rome's victory over Carthage. Roman-style cities were built from the ground up and populated by Roman soldiers, who were encouraged to marry local women. Prosperous, bustling, and exciting Roman cities made the Roman way of life very attractive, and the Romans' marriages with local people made the cities seem welcoming. It was by luring people into living like Romans that the Roman Empire became the standard for civilization among its multitude of ethnic groups.

A sobering counterpoint was the German rebellion of 9 C.E. The Germans near the Elbe had been under Roman domination since about 9 B.C.E., and they were already becoming Romanized by wearing Roman clothing, speaking Latin, and following Roman laws. All this was ruined by a governor who abused the Germans, overtaxing them and brutally repressing them. The result was a rebellion in which three Roman legions were wiped out. The Romans had to withdraw. This lesson was reaffirmed in Britain, where even allies of the Romans were subjected to rape and other brutalities, and rebellion in 60–61 C.E. resulted in the killing of tens of thousands of Romans. A lighter hand in Britain later Romanized the Britons.

The practice of sharing social benefits worked in other cases. Egypt was aided by its geography, which tended to set it apart from other cultures, helping create an "us against them" mentality among all who lived there. Still, Egypt did absorb disparate peoples into its way of life. Libyans, Sea Peoples, and Semites all invaded at one time or another, and even when they lost they were sometimes allowed to settle in Egypt. They tended to adopt Egyptian culture rapidly, probably within a few generations. Even the Kushite dynasty (the Twenty-fifth Dynasty, ca. 770–ca. 657 B.C.E.) was accepted, because its rulers behaved like Egyptians and considered themselves to be part of the Egyptian culture.

Another way to judge an empire's success is by how long it lasted. The Chinese empire lasted from about 1500 B.C.E. to 1911 C.E.; the Egyptian empire lasted from before 2950 B.C.E. to 30 B.C.E. Another way to look at the success of empires is by how much they influenced later people. The Chinese empire still influences the written languages and laws of modern people. The Greeks created most of the modern

sciences and empirical reasoning. The Romans have left their alphabet, their language, and their laws in numerous modern languages and legal systems. The Mesopotamians left metallurgy and the concept of national government. In terms of achieving a national identity, the Chinese are rivaled by the Mayans, who even after the collapse of their civilization remained in language, religion, and culture one people, to the present day.

AFRICA

BY MICHAEL J. O'NEAL

In ancient times much of the African continent was sparsely populated. The entire reach of the continent below the Sahara was populated largely by small nomadic hunter-gatherer tribes until about 200 years before the start of the Common Era. No one knows why the people of the sub-Saharan region remained organized in nomadic groups. The most likely explanation is that they had sufficient resources, so they had no need to turn to a more settled agricultural life. Another is that geography kept these groups isolated and protected. As a result of both these factors, the people of the sub-Saharan remained relatively immune from both invasion and migration. The result was that the sub-Saharan region was not home to any noteworthy empires or dynasties until much later.

The people of ancient sub-Saharan began to lay the groundwork for empire and more advanced civilizations during the last millennium or so of the ancient period. One of the peculiarities of ancient sub-Saharan is that it essentially skipped the Bronze Age, which played such an important role in Europe, the Middle East, and other parts of the world. Around 1400 B.C.E. the region seems to have passed directly from the Stone Age into the Iron Age. In East Africa people began to use furnaces to produce carbon steel at about this time. By about the sixth century B.C.E. people in such regions as Nigeria, Tanzania, Ethiopia, and the Great Lakes area of East Africa (which includes most prominently Lake Victoria, the world's second-largest freshwater lake in surface area, and Lake Tanganyika, the world's second-largest lake in volume of water) were also producing steel. Over the next 500 years steel technology spread throughout the continent, primarily as a result of what are called the Bantu migrations.

Bantu refers to a family of languages. These languages, the largest language family of Africa, are closely related. In the last century before the start of the Common Era, people who spoke Bantu began to migrate from north-central Africa, a process that continued throughout the first 1,000 years of the Common Era. To the south they migrated into the rain forests of the Congo. To the east they migrated to the East African highlands. This migration was no trickle. It was a flood of people who imposed their language and culture in the regions where they settled, often resulting in hybrid tongues and hybrid cultures. In time, the earliest immigrants were themselves pushed farther south and east under the pressure of new waves of migrants, continuing the process. Eventually

these new people would give rise to the Great Zimbabwe civilization, sometimes called the Mwene Matapa civilization. Along with iron smelting and steel production, the Bantu migrants also spread knowledge about farming. Under their influence, indigenous peoples learned to grow such important crops as plantain, yams, and bananas.

The result was a significant growth of population as people turned from hunting and gathering to a more sedentary village life. In comparison with much of the rest of the ancient world, urban life was a late development in sub-Saharan Africa. Although there are archaeological remains of towns in Mauretania that date back almost 4,000 years, such formal settlements were an exception. But beginning in around 600 B.C.E. and over the next 800 years, the Sahel, a dry, hot savanna just south of the Sahara, became the site of numerous urban centers with large populations. Some of these included Kumbi, Gao, and Djenné, as well as the later capital of the kingdom of Ghana, Kumbi Saleh. By the early medieval period and for the next 1,000 years, these and other urban centers throughout sub-Saharan Africa became the center of important kingdoms whose roots extended back into the ancient world.

Meanwhile, the empires of the African continent lay to the north. During the ancient period the most significant of these empires was, of course, that of the Egyptians, which lasted for over three millennia and was ruled by dynasties of kings who built some of the world's greatest monuments to civilization. In addition to Egypt, three other empires of note left their mark on ancient Africa. The first was the Carthaginian Empire, which was founded in the ninth century B.C.E., reached the height of its power in the third and second centuries B.C.E., and was eventually destroyed by the Romans in 146 B.C.E. Farther south, and much earlier, was the kingdom of Kush, which reached the height of its power between 1700 and 1500 B.C.E. The third was the kingdom of Axum, which was thriving in the first century C.E.

CARTHAGE

Carthage, a name derived from the Phoenician words for "new city," was founded in 814 B.C.E. by Phoenician traders from the city of Tyre in Lebanon. (Other Phoenician settlements were also given the name Carthage, but these were all smaller towns and outposts.) Over the next centuries it grew into a large political and economic empire. As one of the major world powers at the time, it was a rival to the Roman Empire, which dominated Europe and the eastern Mediterranean. Primarily because of the strength of its navy and its trading prowess, it reached the height of its power in the third and second centuries B.C.E.

In texts the term *Carthage* can refer to both a city and a civilization. The city of Carthage, the capital of the empire, was in North Africa on the east edge of the Lake of Tunis, in modern-day Tunisia. Some historians believe that it was the world's second-largest city during Hellenistic times, or the era when the Greek Empire was at its height; only Alexan-

dria was larger. It was protected by massive walls that were 23 miles in length. The city also had marketplaces, towers, a theater, a council house, an area for religious worship, a huge, elaborate cemetery, four residential areas, and, in the center, a tall citadel called the Byrsa. *Carthage*, though, can also refer to the civilization that spread across North Africa to dominate the western Mediterranean Sea from the border of Egypt on the east to Morocco on the west.

The roots of the Carthaginian Empire extend back to the 10th century B.C.E. and the eastern Mediterranean Sea. The Phoenicians' most important cities were first Tyre and then Sidon, but to protect their trading interests, they founded and controlled several trading posts around the region. Among them was the city of Carthage, which provided a safe harbor for ships. This network of trading cities also helped the Phoenicians protect their monopoly on natural resources used for trade. Additionally, the early Phoenicians needed funds to pay tribute to the larger empires that dominated them. They also feared that in time the Greeks would gain control of the entire region. Because the Phoenicians were few in number and their cities were small, they embarked on a project to colonize cities throughout the Mediterranean region.

Their project was successful. During the three centuries that followed its founding, Carthage became the center of the empire as Tyre declined and was eventually destroyed by the Greek conqueror Alexander the Great. Leadership of the Phoenician Empire then passed to Sidon, but in time Carthage became the most dominant city. The Phoenicians established 300 colonies in Algeria, Morocco, Tunisia, and Libya. In 509 B.C.E. Carthage signed a treaty with Rome that in essence divided the region into two spheres of influence, with Rome retaining its hold over the eastern Mediterranean. The Carthaginian Empire included not only the north coast of Africa but also important Mediterranean islands, such as Sardinia, Malta, Cyprus, portions of Crete, Corsica, and the western portion of Sicily. The Carthaginians also founded important colonies on the Iberian Peninsula (that is, Spain and Portugal), as well as the Balearic Islands, islands off the eastern coast of Spain that included Majorca, Minorca, Ibiza, and Balears. The Carthaginians appointed magistrates who directed the activities of the colonies.

Eventually Carthage became too much of a threat to Rome. Accordingly, Rome launched a series of wars called the Punic Wars, from the Latin word for Phoenician, *Punicus*; many older history texts use the word *Punic* rather than *Carthaginian*. The First Punic War broke out in 264 and dragged on until 241 B.C.E. The outcome was indecisive. War broke out again in 218 B.C.E. The Second Punic War remains famous because of Hannibal (247–183 B.C.E.), the Carthaginian general who marched his troops from Spain over the Alps and won convincing victories against the Romans. The war ended only when the Romans invaded Carthage itself and the Carthaginians sued for peace. The Third Punic War erupted in 149 B.C.E. Unlike the First and Second Punic Wars, the Third Punic War was relatively brief. The Romans invaded, laid siege

to the city of Carthage, and then finally destroyed it, killing its occupants or selling them into slavery. Thus, in 146 B.C.E. the Carthaginian Empire came to an abrupt end.

The destruction of Carthage has posed a significant problem for historians. The Romans wiped out virtually every aspect of Carthaginian civilization, razing the city and destroying its documents. Accordingly, historians have few primary documents to examine and study. These include Greek and Latin translations of Carthaginian texts, but most of what is known about Carthage comes from Greek and Roman writers, including Livy, Appian, Plutarch, Herodotus, and others. But Rome and Greece were in competition with Carthage, so the objectivity of these sources is questionable. More information has become available as a result of recent archaeological excavations of Carthaginian sites, but much of the new information still fails to provide a clear picture. The basis of Carthaginian power and empire was its massive navy, which included up to 350 warships that continuously patrolled the Mediterranean. Additionally, Carthage maintained a large fleet of merchant ships, each capable of carrying 100 tons of goods, all protected by two large harbors. No nation would match Carthage's naval fleet in size and tonnage until 18th-century Europe. Unlike its rivals, Carthage did not typically maintain a standing army. When the empire needed to protect itself, it raised an army, such as that commanded by Hannibal, or hired mercenary armies.

Much of the empire's trade was based on the Iberian Peninsula, the source of large amounts of lead, silver, and tin ore. Tin ore was especially important, for numerous ancient civilizations mixed tin with copper to make bronze. The Carthaginians also traded tin with Britain and possibly the Canary Islands, giving Carthage a monopoly on the tin trade and therefore on bronze. Trading rivals were eager to obtain a portion of this tin, but the Carthaginians were so bent on protecting their monopoly that ship captains would deliberately crash their ships rather than allow other nations to learn where and how to approach the rocky shores of the British Isles. Further, Carthage's strategic location between Sicily and the African coast allowed it to control the supply of tin to the east.

Nearly as important as tin were the silver mines in North Africa and Iberia. These mines were so productive that the Carthaginians were able to provide Hannibal with 300 pounds a day. Another important commodity was a dye called Tyrian purple—a product so valued that a pound of it was equal in value to up to 20 pounds of gold. Other important commodities included textiles (silk, wool, and cotton), spices, perfumes, pottery, incense, glasswork, wood, bronze, alabaster, precious stones, plows, mirrors, cabinetry, household items (pillows and bedding, for example), slaves, and weapons. Food commodities included fish as well as a range of agricultural products, such as wine, olives and olive oil, grapes, dates, nuts, and fruits. Carthage's agricultural system was so efficient that after the Third Punic War, the Romans ordered that a Carthaginian agricultural treatise written by

Mago in about 350 B.C.E. be translated for Rome's use. The Carthaginians also bred and traded prized Arabian horses. Much of Carthage's wealth came from brokering trade in these goods.

Carthage's influence also spread southward. The empire sent caravans into the African continent, where they traded for such goods as ebony, ivory, salt, timber, gold, and hides, and such animals as apes and peacocks. To the north they obtained amber from the Scandinavian countries. In summary, the Carthaginians traded in just about every commodity that anyone wanted in the ancient world. Their efficiency in storing, transporting, buying, and selling goods (they invented the auction) was the source of the empire's wealth and power.

According to legend, Carthage was founded under the leadership of Queen Elissar, sometimes spelled Elissa or Alissa. In the *Aeneid* of the Roman writer Virgil, the queen is called Queen Dido. Details of the queen's life are sketchy, but according to such sources as the Roman writer Justin, her father was King Matten, known also as Belus II or Muttoial. At his death the throne passed jointly to Elissar and her brother, King Pygmalion. She then married Acherbas, her uncle, a man of great wealth. Her brother, though, was a tyrant and wanted to gain control of Acherbas's wealth, so he killed Acherbas. Elissar escaped and founded the city of Carthage. Little is known of her subsequent fate, though according to Virgil she committed suicide.

Some details survive about the rulership of Carthage. Through most of its history the empire was ruled by an oligarchy of judges known as suffets, from the Hebrew word *shofet*, meaning "judge." (The Phoenicians were a Semitic-speaking people, meaning that their language was similar to that of the ancient Jews.) Early in the empire's history was a governing body of judges called the Hundred and Four, whose primary role was to oversee the military. Additionally, the city of Carthage was ruled by a governor.

A supreme council made up of the empire's most influential and wealthy families exercised power in the empire. Additionally, two judges with both judicial and executive powers were elected, though historians do not know whether they were elected by the people or by the council. While this oligarchy ruled the empire, Carthage had elements of a democracy, including a constitution (written about by the Greek philosopher Aristotle), workers' unions, and elected representatives. A council of elders acted in an advisory capacity. One Greek historian, Polybius, notes that the Carthaginian people had more power over their government than the Roman people had over theirs. Separate from the civil administration was a class of appointed admirals and generals.

One of the most important oligarchic families of ancient Carthage was the Barcid family, best known as tenacious opponents of the Roman Empire. The family name Barcid is an invention of historians for a family whose original name was Barca or sometimes Barcas, meaning "lightning" in the Semitic languages. According to legend, the Barcids descended

from Queen Elissar, though Rome's destruction of Carthage makes it unlikely that the true origins of the family will ever be known. The Barcid family was the closest thing to a ruling dynasty that Carthage produced.

The Barcids rose to power in the third century B.C.E. They saw that the Roman Republic was expanding and foresaw that Rome could eventually eclipse Carthage and put an end to Carthage's power on the sea. Accordingly, the Barcids were the driving force behind the First Punic War and led preparations for the Second Punic War. Moreover, they founded in Iberia a number of cities whose names still survive, including Barcelona and Cartagena, which evolved from Carthago Nova, or New Carthage.

Some of the most famous members of the Barcid family include Hamilcar Barca (270?–228 B.C.E.), a military commander during the First Punic War. Hasdrubal the Fair (?–221 B.C.E.), Hamilcar's son-in-law, followed in his father-in-law's footsteps and continued Carthaginian expansion in Iberia. Hannibal Barca was Hamilcar's son and became one of the most famous military commanders in history when he led his troops over the Alps from Spain and crushed the Roman forces in the Battle of Cannae in 216 B.C.E. His brother Hasdrubal (?–207 B.C.E.) defended Iberia in Hannibal's absence, then led reinforcements to Italy in 207 B.C.E. Their youngest brother, Mago Barca (243–203 B.C.E.), not to be confused with the Mago who wrote the agricultural treatise mentioned earlier, was also an able military commander.

KUSH

In the fourth millennium B.C.E. the ancient Egyptians colonized a region around the first cataract of the Nile River. (Along its length the flow of the river's waters is interrupted by cataracts, or shallow areas with rocks, islands, and rapids. These cataracts are conventionally numbered from south to north, since this is the direction in which the Nile River flows.) This region was called Nubia, divided into Upper Nubia to the south and Lower Nubia to the north (again, because of the direction of the river's flow). Because Egypt maintained control of these regions to the south, Egyptian civilization was spread southward into the interior of the African continent. A kingdom grew up along the Nile, in the floodplain between the first and third cataracts. The Egyptians called this kingdom Kush. Thus, *Nubia* refers to the region, roughly modern-day Sudan; *Kush* refers to the people and their kingdom.

The kingdom of the Kush functioned as a major center for trade. Goods from the southern part of Africa, including gold, ebony, ivory, exotic animals, and slaves, passed through Kush on the way to points north. While at various points in their history the Kush ruled their own independent kingdom in Upper Nubia, at other points they were an Egyptian colony, and Lower Nubia remained a colony through most of its history. Throughout their history, the Kush thought of themselves principally as Egyptian, and their religion, architecture, government, and other aspects of their culture were essentially Egyptian.

As trade with Egypt increased, the region's power grew, but during the Middle Kingdom (2040–1640 B.C.E.) Egypt expanded into Nubia. The region remained politically disorganized until the first in a series of three kingdoms was established. The kingdom of Kerma lasted from about 2400 to 1500 B.C.E. Kerma's kings accumulated enough power to build large walls, tombs, and other structures. Kerma is the name of the modern city on which the kingdom was built; the name used at the time is unknown. During the New Kingdom (1550–1070 B.C.E.), Egypt expanded further into Nubia and built a new capital at Napata, which lasted from 1000 to 300 B.C.E. and which was powerful enough to turn around and conquer Egypt, with its kings ruling Egypt as Egypt's 25th Dynasty in the eighth century B.C.E. until Assyria invaded Egypt in the seventh century B.C.E.

The Assyrian invasion pushed the Kushites southward. The result was that much of their contact with Egypt, as well as with the Middle East and Europe, was closed off. In 591 B.C.E. the Assyrians conquered Napata, so the Kushites relocated their capital to Meroë. The Meroitic Kingdom lasted to about 300 C.E. Rather than focusing its attention northward, to Egypt, the Meroitic Kingdom looked southward. During the Napata and Meroitic kingdoms, the Kush embarked on a program of pyramid building that rivaled that of the Egyptians.

Establishing the chronology of Kushite dynasties has posed particular problems for historians and archaeologists. In most cases, they have to estimate dates. The principal evidence they use consists of inscriptions from tombs and pyramids. On this basis, historians have determined that the first ruler of the Napata Kingdom was Alara. He was followed by Kashta, who ruled from about 770 to 750 B.C.E. The first ruler of the Meroitic Kingdom was Aspelta, who was followed by a long succession of kings and even several queens, particularly after the start of the Common Era. Knowledge about the line of succession ends at about 355 C.E.

The most noteworthy dynasty that ruled the Kushites was the succession of monarchs who made up the 25th Dynasty of Egypt (770–657 B.C.E.). This dynasty included five Kushite pharaohs, all successors to Kashta: Piye (r. 750 to 712 B.C.E.), his brother Shabaka (r. 712–698 B.C.E.), Shebitku (r. 698–690 B.C.E.), Taharqa (r. 690–664 B.C.E.), and Tantamani (r. 664 to 657 B.C.E.). The ruling dynasties of Kush resembled those of Egypt, with several exceptions. First, the pharaohs of Kush ruled according to law rather than divine right. This law was created and interpreted by priests. The pharaoh, then, was elected from the royal family, with descent following the mother's rather than the father's line. For this reason Kush produced a number of queens, in contrast to most of the other civilizations of the world at that time.

The Meroitic Kingdom remained powerful through the second half of the first millennium B.C.E. It went through a period of decline until it was defeated and its commercial and trading power was taken over by the kingdom of Axum to the east.

AXUM

The kingdom of Axum rose in power as that of the Kushites declined, and in about 350 C.E. Kush's reign as a major power in the area essentially ended when Axum conquered the Kushites. The Axumite Kingdom occupied the highlands of Ethiopia near the Red Sea, along with parts of modern-day northern Ethiopia, Eritrea, Yemen, southern Saudi Arabia, northern Somalia, Djibouti, and northern Sudan. Axum was a mixture of indigenous Kushitic-speaking people and immigrants from the southern Arabian Peninsula, who settled in the region in about 500 B.C.E.

Unfortunately, historians know little about the Axumite Kingdom. Much of what is known comes from Greek and Roman writers as well as from modern archaeological excavations. It is known that the Axumites developed their own alphabet, called the Ge'ez alphabet, and that Ethiopia, Axum's modern successor state, has one of the world's longest continuing traditions of literacy. Axum was the first African state to mint its own coins. The kingdom had large, cosmopolitan cities, including the cities of Axum, Yeha, Hawulti, Matara, Adulis, and Qohaito, which were among the most culturally advanced cities in the ancient world at that time. Axum was a crossroads for people from numerous parts of the world, including India, the Middle East, Sudan, and Egypt, and the kingdom accommodated a range of religious adherents, including Jews, Christians, and Buddhists. The Ethiopian Christian Church, created in roughly 325 C.E., when the kingdom converted to Christianity, is among the oldest Christian churches in existence.

The source of Axum's power, like that of the Kushites, was trade. The region occupied a strategic position that linked Africa with the Arabic countries, Rome, India, and later Byzantium, the capital of the Eastern Roman Empire (present-day Istanbul in Turkey). Through trade, primarily in such commodities as silk, spices, ivory, tortoiseshell, gold, and emeralds, the kingdom became immensely wealthy. With the help of a powerful navy on the Nile River and the Red Sea, Axum was able to extend its imperial power by establishing colonies throughout the region in the decades after the start of the Common Era. Axum remained a major power until the rise of Islam in the seventh and eighth centuries C.E.

The official title of the Axumite kings, found on numerous royal inscriptions, was "king of kings." While little is known about the earliest Axumite kings, it is known that they claimed to trace their lineage back to the biblical King David, King Solomon, and the Queen of Sheba. Somewhat more is known about later kings, particularly those who ruled in the centuries after the start of the Common Era, when Axum reached the height of its power. Most of this knowledge comes from coins minted during the kings' reign. Among the most important of these kings was 'Ezānā, who ruled in the fourth century C.E. and converted the empire to Christianity.

EGYPT

BY KIRK H. BEETZ

In modern works Egyptian history is subdivided into three kingdoms—Old, Middle, and New—and 31 dynasties. However, the ancient Egyptians did not divide their history into kingdoms or dynasties; instead, they recorded one continuous line of kings. The modern subdivisions are derived from those of Greek historians of the later first millennium B.C.E., who may have been inspired by Egyptian hieroglyphic lists that are now lost. Although the Greek historians made some significant mistakes, historians and archaeologists still use their list of dynasties. They also continue to use the labels *Old Kingdom*, *Middle Kingdom*, and *New Kingdom* for convenience, because at the end of each was a period in which the succession of kings was muddled, usually because two, three, or even more people were claiming to rule Egypt at the same time.

PREDYNASTIC ERA

Egyptians were forming large communities for cooperative farming by 5000 B.C.E. Based on artifacts discovered by archaeologists, it appears the southern part of Egypt had formed a single culture by 4000 B.C.E. This is known as the Naqâda I Period, named for an ancient settlement on the west side of the Nile River. By 3500 B.C.E. the Naqâda II Period had begun. Artifacts from that time indicate a common culture had spread from southern Egypt throughout northern Egypt. Burials indicate that by 3000 B.C.E. Egyptian society was forming an elite class. At this time they also were building small cities.

EARLY DYNASTIC PERIOD (CA. 2920–CA. 2575 B.C.E.)

Sometime between 3200 and 2900 B.C.E. Egypt was united under the rule of a single king. He was called Meni by the Egyptians of later ages and Menes by Greek historians. Menes is credited with founding the First Dynasty (ca. 2920–ca. 2770) and creating the capital city of Memphis. Supposedly, he was the king of Upper Egypt, or southern Egypt, and he conquered the kingdom of Lower Egypt, or northern Egypt. The double crown worn by Egyptian pharaohs represented a combination of the crowns of the two kingdoms, and Egyptians called their rulers dual kings. Archaeologists now believe Menes was a mythical figure and that Lower Egypt was not a kingdom when it was absorbed by Upper Egypt.

Historians continue to dispute the names of the First Dynasty kings. The first king for whom there is evidence is Narmer, who appears in written artifacts from his own time. He became king of all Egypt in about 2950 B.C.E. He either founded a dynasty of kings whose names are lost in mythological Egyptian tales, united Egypt without founding a dynasty, or founded the First Dynasty. Some historians name Narmer and Aha as two separate kings, and some assert that

Aha was the legendary Menes, calling him Aha Men; others say Narmer and Aha were the same person. Before Narmer's rule, there may have been six leaders who were kings of parts of Egypt, including Ip, the legendary Scorpion King.

The kings of the First Dynasty developed a centralized government and established the belief that the king of Egypt ruled as a god on earth. All government officials derived their authority from the king, and they had to attend the king at his court periodically to show they served only at his whim. The term for king was *nyswt*. The word *pharaoh* did not come into use until late during the New Kingdom. Second in command to the king was a vizier, who during the Old Kingdom remained at the king's court.

The Second Dynasty (ca. 2770–ca. 2649 B.C.E.) had seven kings of uncertain date. Because these kings came and left quickly, some historians believe there was a civil war during the Second Dynasty, though archaeological discoveries reveal no disruptions during this time. Perhaps the number of kings is incorrect, or the kings' names represent palace coups that did not disturb the common people.

The most famous king of the Third Dynasty (ca. 2649–ca. 2575 B.C.E.) was Netjerykhet (r. ca. 2630–ca. 2611 B.C.E.), better known in later times as Djoser, meaning something like “the special one.” Until Djoser's reign a king's tomb consisted of underground chambers, often carved out of solid rock, topped aboveground by a platform of mud brick called a mastaba. When the mastaba for Djoser's tomb at Saqqara was built, either he or his vizier, Imhotep, decided to make it grander. Imhotep designed the resulting Step Pyramid, Egypt's first great stone pyramid, which is built of limestone blocks and was coated with polished white limestone. The Step Pyramid is surrounded by a temple complex where spirits could roam.

OLD KINGDOM (CA. 2575–CA. 2134 B.C.E.)

The Old Kingdom consisted of the Fourth through Seventh/Eighth Dynasties. Imhotep's grand design marked the beginning of the age of the giant pyramids, the most characteristic structures built during the Old Kingdom. The foremost public work of each royal reign was the king's tomb, and Egyptians devoted parts of each year to working on its construction. Contrary to popular myth, slaves were not used. The building of a pyramid served to unify Egyptians by focusing them on a project to honor their god-king. The biggest of these works was the Great Pyramid built near Giza for Khufu (r. ca. 2551–ca. 2528 B.C.E.), a ruler of the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.).

The Fifth Dynasty lasted from about 2465 to 2323 B.C.E. and the Sixth Dynasty from about 2323 to 2150 B.C.E. The last king of the Sixth Dynasty was Pepi (or Pepy) II (r. ca. 2246–ca. 2150 B.C.E.). His was the longest reign of any Egyptian ruler, and his was the last great pyramid built on the Giza plateau. During his reign, Pepi II solidified Egypt's domination of the Nubians of the south, but the king's central authority diminished for unknown reasons.

The Greek historians mention a Seventh Dynasty, perhaps dominated by the northern city of Memphis, or Mit Rahina. Most modern historians believe that there was no Seventh Dynasty, noting the unlikely description that it had 70 kings in 70 days. The Eighth Dynasty may have lasted from about 2150 to 2134 B.C.E., with 18 or more kings.

FIRST INTERMEDIATE PERIOD (CA. 2134–CA. 2040 B.C.E.)

The Greeks erred in identifying two separate Ninth and Tenth Dynasties by duplicating the kings in their lists, though the Greek historians may have found the dynasties listed this way in Egyptian sources. The Ninth and Tenth were only one dynasty, lasting from ca. 2134–ca. 2040 B.C.E. Later Egyptian writings characterize this period as one of chaos, with people forsaking their old gods and proper worship. These accounts may have been written more to justify contemporary kings' absolute power rather than to provide an accurate commentary of the First Intermediate Period. However, it is known that a civil war began between the Tenth Dynasty kings of Lower Egypt and the Eleventh Dynasty kings of Upper Egypt, with an army of the Tenth Dynasty looting and desecrating tombs at the town of Abydos, north of Thebes. This attack would have been regarded as a terrible offense against religion and morality.

Modern historians are uncertain about the exact events that occurred during this civil war. Because the battles were between two different dynasties, most historians classify the first half of the Eleventh Dynasty as overlapping with the end of the Tenth Dynasty. There is also some consensus that the Theban king Mentuhotep (or Montjuhotep) II (r. ca. 2061–ca. 2010 B.C.E.) defeated the northern kings of Heracleopolis in about 2040 B.C.E., thereby reunifying Upper and Lower Egypt and establishing the relative calm of the Middle Kingdom. Other historians identify Mentuhotep I, the Theban governor Wast, as the founder of the Eleventh Dynasty, followed by Intef (or Inyotef) I, II, and III. Some believe Mentuhotep I and Mentuhotep II were the same person.

MIDDLE KINGDOM (CA. 2040–CA. 1640 B.C.E.)

After defeating the northern kings, Mentuhotep II spent the remainder of his reign strengthening the reunification of Egypt. He kept most government officials in their posts, replacing some who were not loyal to him, and his administration worked to reintegrate provinces into a single government. Mentuhotep II proved to be an exceptional administrator, and by the time of his death he had succeeded in bringing war-torn Egypt together as one nation.

The Twelfth Dynasty (ca. 1991–ca. 1783 B.C.E.) began when Mentuhotep IV (r. ca. 1998–ca. 1991 B.C.E.) was succeeded by his vizier Amenemhet I (r. ca. 1991–ca. 1962 B.C.E.). The transfer of power was peaceful. Amenemhet I was a reformer who tried to restore Egyptian government to the form it had during the Old Kingdom. He moved his residence from Thebes to the town of Itjtawy, near Saqqara, where sacred

pyramids such as that of Djoser were located. Amenemhet I became an absolute ruler, and all government authority came from him. During the Middle Kingdom, beginning with Amenemhet I, eldest sons sat beside their fathers on the throne, sharing in royal authority, and wives and daughters of kings also were considered divine.

The Twelfth Dynasty was a period of great prosperity. The government pursued large public works projects, including building great tombs for kings and impressive tombs for regional governors. Beginning with Mentuhotep II, the Twelfth Dynasty's army extended Egyptian dominance in Nubia, reaching its fullest extent under Senusret III (r. ca. 1878–ca. 1841 B.C.E.), securing major trade routes into southern Africa that brought much wealth to Egypt. The last ruler of the Twelfth Dynasty was Sobeknefru (r. ca. 1787–ca. 1783 B.C.E.), a female king.

Her reign was followed by the Thirteenth Dynasty (ca. 1783–ca. 1641 B.C.E.), which was composed of a series of perhaps 33 kings, most of them with unknown names and dates. The early king Neferhotep I and others were powerful rulers of a central government, but during the middle of the Thirteenth Dynasty the kings' power waned. In the Nile Delta many small principalities became independent; their governors often called themselves kings.

SECOND INTERMEDIATE PERIOD (CA. 1641–CA. 1550 B.C.E.)

The Second Intermediate Period is a confusion of dynasties that overlapped because they ruled different parts of Egypt. There was the Fourteenth Dynasty, Fifteenth Dynasty, Sixteenth Dynasty, and Seventeenth Dynasty (ca. 1641–ca. 1550 B.C.E.). Of these dynasties, only the Seventeenth Dynasty has a coherent history of kings, all ruling Upper Egypt. The Fourteenth Dynasty had 76 kings, possibly more, and the Sixteenth Dynasty had 32 or more kings. These kings probably do not represent family lineages, as Egyptian historians of the 1200s B.C.E. may have included the kings of even small territories in these dynasties. The Fifteenth Dynasty consisted of six kings of the city of Avaris, located in the northeastern Nile Delta. They were prosperous because of trade with the Near East, and Avaris was a well-defended fortress city. These kings are known as Hyksos, and historians still debate their origins. According to Egyptian records, they were Asiatic kings from the Near East who were remembered as cruel overlords.

The kings of the Seventeenth Dynasty ruled from Thebes. They saw themselves, not the Hyksos, as the true inheritors of the Thirteenth Dynasty kings and believed that Egypt should be one country. They focused on boosting the economy by freeing up trade routes that were blocked both to the north and south. The last king of the Seventeenth Dynasty, Kamose (r. ca. 1555–ca. 1550 B.C.E.), succeeded in recovering southern territory all the way to Elephantine, then known as Abu. This was just north of the region of Wawat, which was the focus of trade routes. Kamose attacked Avaris in about 1540 B.C.E. but did not breach its walls.

NEW KINGDOM (CA. 1550–CA. 1070 B.C.E.)

The 18th Dynasty (ca. 1550–ca. 1307 B.C.E.) began with Ahmose (r. ca. 1550–ca. 1525 B.C.E.), a brother (or perhaps son) of Kamose. He believed that he was the true heir to Egypt's throne and attacked Avaris possibly five different times. His army finally overwhelmed the defenses of Avaris, probably killing the last Hyksos king, Khemudy (unknown period of reign). The Hyksos used the fortified town of Sharuhén, in northeastern Sinai, southwest of Gaza, to control trade routes from the Near East into Egypt. Ahmose laid siege to Sharuhén, which fell after three years. The Egyptians massacred the inhabitants, and Egyptian dominance in the region was restored. Ahmose's son Amenhotep I (r. ca. 1525–ca. 1504 B.C.E.) was the last of the family line; a courtier, Thutmose I (r. ca. 1504–ca. 1492 B.C.E.), succeeded peacefully to the throne.

The New Kingdom was an era in which queens became coreulers with their husbands, wielding both political and military power. The female king Hatshepsut (r. ca. 1473–ca. 1458 B.C.E.), the wife of Thutmose II (r. ca. 1481–ca. 1479 B.C.E.), ran Egypt during the early rule of her stepson, Thutmose III (r. ca. 1479–ca. 1425 B.C.E.). She tried unsuccessfully to have one of her daughters succeed her as king; later Egyptians believed that she had tried to upset the lawful line of kings. Other queens were very powerful, notably Nefertiti, the primary wife of Amenhotep IV (r. ca. 1353–ca. 1335 B.C.E.). In 1330 she was declared the co-king and took the royal name of Neferneferuaten (r. ca. 1330–ca. 1327 B.C.E.). Her husband was called a heretic by later Egyptians because he believed there was only one god, the disk of the sun, and changed the state religion accordingly. During the reign of Tutankhamun (r. ca. 1333–ca. 1323 B.C.E.), the old pantheon of gods was restored.

During the Eighteenth Dynasty, Egypt became one of the most prosperous nations of the ancient world. It dominated most of Nubia and expanded its influence to the east coast of North Africa. It controlled the Mediterranean coast of the Near East into Syria, as well as the Sinai. After military victories, the central Egyptian government would leave a local ruler in charge of the conquered area. This ruler was expected to follow edicts from the central government, although the local people were allowed a certain degree of autonomy in deciding their own affairs. The Egyptian government consistently required that trade routes be left open and caravans be allowed to pass unmolested; anyone who interfered with these two requirements was put to the sword. Many Egyptian military campaigns involved no fighting. Kings would lead armies all the way into Syria or deep into Nubia just to make clear that, if Egypt wished, it could crush these areas.

The Nineteenth Dynasty (ca. 1307–ca. 1196 B.C.E.) was an era of great national wealth and military power. Its kings were intelligent, strong-minded, and hard working. The word *pharaoh* came into use to describe the king. The most famous of the Nineteenth Dynasty kings is Ramses II (r. ca. 1290–ca. 1224 B.C.E.), whose reign was the second longest of the Egyptian kings; he became the model ruler for his successors.

He was brash and a megalomaniac. He was also intelligent, an excellent military leader, and one of the greatest builders among Egypt's kings. His military campaigns prevented the Hittites of the northern Near East from taking control of trade in northern Palestine, and he built impressively huge monuments all over the lands he controlled. These monuments, often depicting Ramses II, were intended to show local people the power and geographical range of the Egyptian government.

The Twentieth Dynasty (ca. 1196–ca. 1070 B.C.E.) continued the strong rule of the Nineteenth Dynasty until its last 30

HATSHEPSUT, FEMALE KING

During the New Kingdom the Chief Royal Wives of the kings were partners with their husbands in ruling Egypt. Their status seems to have reflected a general social attitude in Egypt about the rights and responsibilities of husbands and wives as partners, and women and men were equals before the law. The wife of the king often ran Egypt's bureaucracy and economy. She sometimes even participated in battles, though warfare seems to have been primarily the husband's responsibility. Occasionally, a woman would become a female king, meaning she had the duties and powers of the male part of kingship.

The first such female king may have been Sobeknefru (r. ca. 1787–ca. 1783 B.C.E.), who ruled during the Middle Kingdom. The most powerful female king was probably Hatshepsut (r. ca. 1473–ca. 1458 B.C.E.), who was the daughter of Thutmose I and had been the wife of Thutmose II. When her husband died, she became the regent for her stepson, Thutmose III, but in about 1473 B.C.E. she made herself the co-king. This shift in her status was reflected in the art of the time: She was depicted wearing a beard which was a traditional symbol of kingship.

Hatshepsut was responsible for opening up new sources of trade for Egypt. In about 1460 B.C.E. she sent an expedition through the Red Sea to discover the location of Punt, with which Egypt had traded through intermediaries since the Old Kingdom. The expedition found Punt to be a region on the east coast of Africa, and it began direct trading with people in Punt. Children of chiefs from Punt were raised in the Egyptian court. Hatshepsut also established links with tribal peoples south of the kingdom of Kush, sometimes entertaining delegations from southeastern Africa in her palace. Her efforts significantly increased the prosperity of Egyptians, bringing into Egypt gold, ebony, ivory, exotic incenses, and other goods from new foreign sources.

Colossi of Ramses II and his wife at entrance to Karnak Temple; Ramses II completed this complex of temples and monuments, which was begun and developed by rulers of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.) to glorify the god Amun-Re. (© Board of Regents of the University of Wisconsin System)

or so years, during the reign of Ramses XI (r. ca. 1100–ca. 1070 B.C.E.). In about 1087 B.C.E. the governor of Nubia rebelled and attacked Upper Egypt, driving all the way to Thebes. Ramses XI and his army made a vigorous counteroffensive, driving the rebel army back south of Elephantine, perhaps to the town of Miam in Wawat. Even so, Egypt did not regain control of Nubia, a land that had been part of Egypt for about 500 years, and the loss of access to southern trade routes seriously damaged Egypt's economy.

THIRD INTERMEDIATE PERIOD (CA. 1070–CA. 712 B.C.E.)

Ramses XI died without an heir, resulting in the founding of the Twenty-first Dynasty (ca. 1070–ca. 945 B.C.E.). The first pharaoh of the new dynasty, Smendes (r. ca. 1070–ca. 1044 B.C.E.), was a vigorous ruler, and he led military campaigns in the Near East to enforce Egyptian dominance in that re-

gion. His successors found it increasingly difficult to hold the nation together. The Twenty-second Dynasty (ca. 945–ca. 712 B.C.E.) was founded by a man of Libyan descent, Shoshenq I (r. ca. 945–ca. 924 B.C.E.), who peacefully succeeded to the throne. The Twenty-second Dynasty saw the development of conflicts among governors of different regions, and some governors disputed the authority of the central government. Shoshenq III (r. ca. 835–ca. 783 B.C.E.) tried to maintain control of the country by appointing members of his family to be governors and giving each of them the title of king. Thereafter the family members bickered with one another and the country continued to fragment.

The last pharaoh of the Twenty-second Dynasty was Osorkon IV (r. ca. 735–ca. 712 B.C.E.), who ruled from the city of Tanis, in the Nile Delta. By this time Egypt had broken apart. The Twenty-third Dynasty (ca. 828–ca. 712 B.C.E.) ruled from the city of Leontopolis, which was at that time called Taremu, and the 24th Dynasty (ca. 724–ca. 712 B.C.E.) ruled from the city of Sais, both in the Nile Delta.

For a short time Egypt was reunited by the Twenty-fifth Dynasty (ca. 780–ca. 657 B.C.E.), which was composed of kings from Kush, the Nubian kingdom to Egypt's south. These kings followed Egyptian traditions of religion and government, and they saw themselves as Egypt's only rightful remaining royal line. The dynasty probably was established by Alura (r. ca. 780–ca. 770 B.C.E.) in the Nubian city of Napata. His successor, Kashta (r. ca. 770–ca. 750 B.C.E.), began the Nubian takeover of Egypt. Kashta's son Piye (r. 750–712 B.C.E.) led an army into Egypt to secure Thebes so that the Nubian kings could worship there. Piye continued beyond Thebes to Hermopolis, then known as Wenu, where he met the army of the Twenty-fourth Dynasty pharaoh Tefnakht (r. ca. 724–ca. 717 B.C.E.) and defeated it. Tefnakht withdrew to Sais in the Nile Delta, and Piye secured his dominance all the way north to Heliopolis, then known as On, northeast of Memphis. Local rulers swore fealty to him and he took on all the regal trappings, duties, and titles of an Egyptian pharaoh.

LATE PERIOD (712–332 B.C.E.)

The Late Period traditionally starts with the reign of Piye's successor, Shabaka (r. ca. 712–ca. 698 B.C.E.), a dynamic pharaoh who united the Nile Delta with the rest of Egypt. He and his successors tried to rule Egypt as traditional pharaohs. They defended the country's interests in the Near East, built a great fleet to patrol the Mediterranean, and constructed great public works. When Assyria became a formidable military power, the Twenty-fifth Dynasty tried to find ways to oppose it. In about 674 B.C.E. Assyria attacked Egypt and was defeated by the forces of Taharqa (r. ca. 690–664 B.C.E.), but around 671 B.C.E. Assyria attacked again, driving its way into Memphis. Taharqa withdrew into Nubia. The last pharaoh of the Twenty-fifth Dynasty was Taharqa's heir, Tantamani (r. ca. 664–ca. 657 B.C.E.), who recaptured all of Egypt before being soundly defeated by the Assyrians, who exacted cruel reprisals all the way to Thebes.

The first pharaoh of the Twenty-sixth Dynasty (ca. 672–525 B.C.E.) was Neko I (r. 672–664 B.C.E.) of Sais. He was an Assyrian puppet who was killed by Tantamani. His successor was Psamtek I (r. 664–610 B.C.E.). Although he began as an Assyrian vassal, during his long reign Psamtek I slowly rebuilt the Egyptian government. With Assyria distracted by wars elsewhere in the Near East, Egypt reoccupied part of Palestine in 630 B.C.E., and in 616 B.C.E. Psamtek's army invaded Syria. After Babylon overcame Assyrian dominance, its new king, Nebuchadnezzar II, attacked Egypt in 601 B.C.E. and again in 581 B.C.E. These invasions were repelled decisively by the pharaohs Neko II (r. 610–595 B.C.E.) and Apries (r. 589–570 B.C.E.). The Egyptian general Amasis (r. 570–526 B.C.E.) deposed Apries in 570 B.C.E., but Apries returned to Egypt at the head of a Babylonian army to reclaim his throne. He was defeated and probably killed by an army led by Amasis. Amasis and his successor, Psamtek III (r. 526–525 B.C.E.), were shrewd statesmen who won many friends in other nations, but they were outmatched by Persia.

Persia defeated Babylon in 539 B.C.E. and, when Amasis died, invaded Egypt, defeating the forces of Psamtek III. These events began the Twenty-seventh Dynasty (525–404 B.C.E.), which consisted of Persia's kings, who treated Egypt as a province of Persia. The Persian kings Cambyses (r. in Egypt 525–522 B.C.E.) and Darius I (521–486 B.C.E.) ruled somewhat benevolently, spending long periods in Egypt while behaving like traditional pharaohs; thereafter the reign of Persians in Egypt was notable for its brutality. Around 404 B.C.E. Amyrtaeus (r. ca. 404–ca. 399 B.C.E.), the ruler of Sais, succeeded in driving out the Persians. Amyrtaeus was the only pharaoh of the Twenty-eighth Dynasty.

The Twenty-ninth Dynasty (ca. 399–ca. 380 B.C.E.) and the Thirtieth Dynasty (ca. 380–ca. 343 B.C.E.) ruled an Egypt that was slowly regaining its influence in the Near East and Mediterranean. When Persia invaded in 374 B.C.E., it was defeated. When Persia invaded again in 351 B.C.E., it was defeated again, but the cost of the war nearly bankrupted the Egyptian government. When Persia's Artaxerxes III Ochus (ruled Egypt 343–338 B.C.E.) invaded in 343 B.C.E., he not only conquered Egypt but also desecrated its sacred sites. The last pharaoh of the Thirtieth Dynasty, Nectanebo II (r. 360–343 B.C.E.), briefly clung to power in Upper Egypt. He was the last native Egyptian pharaoh. The Thirty-first Dynasty (ca. 343–ca. 332 B.C.E.), known as the Second Persian Period, consisted of Persian kings (Artaxerxes III, Arses, Darius III) who were despised by the Egyptians.

GRECO-ROMAN PERIOD

When Alexander the Great's army drove the Persians out of Egypt in about 332 B.C.E., the Macedonian king was greeted as a hero. He cultivated his hero status by honoring Egyptian gods and following Egyptian customs, and the Egyptians gave him the status of pharaoh. When Alexander the Great died in 323 B.C.E., his empire broke into pieces, and one of his generals, Ptolemy Soter, eventually took over Egypt from the Mace-

donian kings and made himself Ptolemy I (r. 304–284 B.C.E.). He and his immediate successors (almost all named Ptolemy) tried to force Egypt to adopt a Greek-style culture. Ptolemy I changed the names of cities and gods to Greek ones, and he enforced laws that reduced women from partners of men, as had long been the Egyptian practice, to mere servants of men. The language of government became Greek, and using Egyptian was discouraged. As a result, the Egyptians viewed the Ptolemaic Dynasty (304–30 C.E.) with resentment.

Nonetheless, the Greek pharaohs viewed Egypt as an independent nation, and they reasserted Egypt's ancient claim to domination of Palestine. Ptolemy III (r. 247–221 B.C.E.) conquered territory all the way to Syria and Babylon, and by the end of his reign Egyptian ships ruled much of the Mediterranean. The Greek pharaohs negotiated treaties with the Nubian kingdom of Kush, thereby regaining Egypt's access to trade in both the Near East and Africa. The Greeks also introduced new farming techniques that increased the yield of crops.

Rome began to interfere in Egyptian politics when its Senate nominated Philometer to become the pharaoh, which he did under the royal name Ptolemy VI (r. 180–144 B.C.E.). In 51 B.C.E. the Senate named two coregents, Ptolemy XIII (r. 51–47 B.C.E.) and his sister and wife, Cleopatra VII (r. 51–30 B.C.E.). Ptolemy XIII was succeeded by Cleopatra's other brother and second husband, Ptolemy XIV (r. 47–44 B.C.E.), and then by her son with Julius Caesar, Ptolemy XV (r. 44–30 B.C.E.). Courtiers tried to exclude Cleopatra VII from rule, but Julius Caesar and Marc Antony championed her cause, and she became the dominant political figure in Egypt. Rather than submit to the rule of the Roman emperor Augustus, she committed suicide. With her death came the end of the Egyptian empire and its dynasties.

THE MIDDLE EAST

BY KIRK H. BEETZ

EARLY SETTLEMENTS

By 3500 B.C.E. there were many cities in Mesopotamia, the lands around the Tigris and Euphrates rivers. Eventually, these became the city-states of Sumer. The residents of these cities spoke a common language and worshiped the same gods, and they recognized themselves as all being part of the same culture. People who lived in the cities and those who lived in land around the cities were passionate about their love for their particular city, often treating their entire city as a sacred entity with a life of its own. The cities were governed by a chief administrator, and there is evidence for the existence of city councils as well.

The invention of writing in about 3400 B.C.E. allowed city governments to become more centralized because writing gave them the means to keep track of large amounts of goods, taxes, and population. As the city-states grew, they competed with one another for good farmland, and they fought wars, for which they needed good leaders. The chief city adminis-

trators became kings, regarded as chosen by the gods to rule. Archaeologists and historians have divided ancient Mesopotamia into two geographical areas: southern Mesopotamia, which includes the lands south of Baghdad, and northern Mesopotamia.

EARLY DYNASTIC PERIOD (CA. 3000–CA. 2350 B.C.E.)

In southern Mesopotamia the period of the early, city-based dynasties referred to in the Sumerian King List, an ancient text on clay tablets (dating to ca. 2125 B.C.E.), is called the Early Dynastic Period. Uruk (biblical Erech and modern-day Warka) grew to be some 500 acres, with a massive city wall. By 2700 B.C.E. it may have had over 50,000 residents and was ruled by King Gilgamesh, who became the mythologized hero of an early literary work, the Epic of Gilgamesh. The Sumerian King List mentions the names of many kings belonging to dynasties at various cities such as Uruk, Umma, Lagash, and Ur. By 2500 B.C.E. King Mesilim of the city of Kish established himself as the first-known lord over all the other kings of Sumer. King Eannatum of the city of Lagash overthrew the dominance of Kish around 2400 B.C.E. About 50 years later King Lugalzaggisi of the city of Umma brought all of Sumer under his rule. This was the first regional state in southern Mesopotamia that unified and held an area larger than that of a single city and its hinterland.

AKKADIAN DYNASTY (CA. 2350–CA. 2100 B.C.E.)

The Akkadian Empire was, however, the first true empire based in Mesopotamia that ruled over an area extending beyond the borders of this region. Founded by Sargon of Akkad (r. ca. 2334–ca. 2279 B.C.E.), the Akkadian Empire at times extended from the Mediterranean to the Persian Gulf. Campaigns were conducted into the Zagros Mountains to the north and east of southern Mesopotamia as well. Sargon began as cupbearer to the king of Kish, but he established a new imperial city, Agade, which has yet to be rediscovered. Sargon I probably took power through a coup.

A grandson of his, Naram-Sin (r. ca. 2254–ca. 2218 B.C.E.), added territory to the empire from what is now western Iran and southern Anatolia, in modern-day Turkey. The more the Akkadian Empire grew, the more vulnerable its borders became and the more discontented the former city-states of Sumer were. Practically every time a new king ascended to the throne, an insurrection arose in the cities of the south. In addition, nomads from the desert and tribes from the Zagros Mountains invaded Mesopotamia. Sometime before 2100 B.C.E. the Gutis from the northern Zagros took power, and the world's first empire was no more.

THIRD DYNASTY OF UR PERIOD (CA. 2112–CA. 2004 B.C.E.)

Eventually, Ur-Namma of the city of Ur managed to establish his rule over territory that was about one-third the size

of the Akkadian Empire at its largest. He was the founder of Ur's Third Dynasty of kings. This mighty dynasty lasted for a century, but in 2004 B.C.E. the Elamites, led by their king Kintattu, conquered the city of Ur itself, ending its brief empire. The Elamites came from what is now southwestern Iran.

FIRST DYNASTY OF BABYLON (CA. 1894– CA. 1595 B.C.E.)

A nomadic people called the Amorites had settled in parts of Mesopotamia during the late third millennium B.C.E. Their descendants would found dynasties both in Babylon and in Assyria. The one in Assyria was founded by King Shamshi-Adad (r. 1813–1781 B.C.E.). He conquered northern Mesopotamia, but after his death his kingdom was divided between his two sons, one who was lazy and one who was foolhardy. One of Shamshi-Adad's vassals was the king of Babylon, Hammurabi (r. 1792–1750 B.C.E.), who took advantage of the foolishness of Shamshi-Adad's sons. He had already conquered the cities of Uruk and Isin, both outside Assyria's dominion, and he had proved himself an able civic leader, improving Babylon's irrigation system and constructing temples. In each city he conquered, he made a point of building temples to show the local people that he was favored by the gods.

In 1764 B.C.E. Hammurabi conquered Elam. Then, in 1761 B.C.E., Hammurabi defeated Rim-Sin of the city of Larsa, in battle and seized control of all Sumer. From 1757 to 1755 B.C.E. he conquered northern Mesopotamia. He was a clever military leader. To defeat one city—Eshnunna (modern-day Tell Asmar) along the Diyala River—instead of assaulting the city, he diverted its water supply; this caused the city to surrender. He attracted to the city of Babylon artists from throughout the Near East, who added to the city's luster as the center of Mesopotamian culture. He is famous for his code of laws, which are carved on a stone stele now in the Louvre Museum in Paris. Curiously, though Hammurabi's laws were intended to impress the gods with his good rule, they are never cited in the thousands of legal documents in cuneiform that have survived from ancient Mesopotamia.

The First Dynasty of Babylon lasted until 1595 B.C.E., when the Hittites under Mursilis I (r. ca. 1620–ca. 1590 B.C.E.) sacked Babylon. Thereafter, a people from the Sealand (the marshes of southern Iraq) took control of the south. They were followed by the Kassites, who are often thought to have originated in the Zagros Mountains of what is today western Iran.

BABYLON'S KASSITE DYNASTY (CA. 1500–CA. 1155 B.C.E.)

The Kassites appeared in Babylonia during the reign of Samsuiluna (r. 1749–1712 B.C.E.), Hammurabi's successor, who defeated their army. With Samsuiluna's consent, the Kassites settled near the Diyala River. In 1475 B.C.E. the Kassite king Ulamburiash drove the Dynasty of the Sealand out of Mesopotamia and reestablished the city of Babylon as the center of an empire, called "Babylonia." Babylonia was a major mili-

tary, economic, and cultural power under the Kassite kings. It was often at war with Assyria to its north, but it was allied by ties of marriage with the ruling house of Elam to its east, with the Hittites to the north, and with the distant Egyptians in a web of diplomatic relations. In about 1154 B.C.E. the Elamite king, feeling that he was the rightful successor (through marriage and his Kassite mother's lineage) overthrew the Kassite Dynasty when his petition to ascend the Kassite throne was rudely rejected. The Elamites carried to Susa, a large site in southwestern Iran, the statues of Babylon's chief god Marduk, symbolizing Babylon's loss of independence.

A king of the Second Dynasty of Isin (ca. 1158–ca. 1027 B.C.E.), Nebuchadnezzar I (r. ca. 1124–ca. 1103 B.C.E.), drove the Elamites out of Babylonia. Isin was a city to the southeast of the city of Babylon. Nebuchadnezzar I conquered Susa and brought the Marduk statue back to Babylon, which was once again the seat of government. Nebuchadnezzar I was a patron of the arts and commissioned many literary works, especially ones about himself. His efforts to expand Babylonian control to cities in northern Mesopotamia led to retaliation by the Assyrians, who destroyed a few of the cities in Babylonia.

The Second Dynasty of Sealand (ca. 1026–1006 B.C.E.) in Babylon was begun by a former member of the Assyrian army. Little is known about Babylon from 1026 to 732 B.C.E. Apparently, a new dynasty arose, perhaps in 979 B.C.E. Its kings occasionally tried to break the dominance of Assyria. In 689 B.C.E., after King Marduk-apla-iddina II (r. ca. 700–690 B.C.E.) tried to break away from Assyria, the Assyrians sacked the city of Babylon. Marduk-apla-iddina II was a Chaldean, a Semitic tribe that had settled near the southern Euphrates River. After his defeat, Babylonians waged a guerrilla war against the Assyrians. From 654 to 648 B.C.E. Shamash-shum-ukin, the Assyrian governor of Babylonia, waged war against his rival brother, Assyria's king Ashurbanipal. After defeating the revolt, Assyria appointed a puppet, King Kandalanu (r. 648–627 B.C.E.), to rule Babylon.

NEO-BABYLONIAN DYNASTY (CA. 625–539 B.C.E.)

A Chaldean leader, Nabopolassar (r. ca. 625–605 B.C.E.), led a successful revolt against Assyria. He expanded the Babylonian Empire, and in 605 B.C.E. he sent his son Nebuchadnezzar to lead an army against Egyptian forces in Palestine. He died that year, and the ascension of his son Nebuchadnezzar II (r. 605–562 B.C.E.) marked the beginning of the Neo-Babylonian Empire. Nebuchadnezzar II successfully took control of most of Palestine, yet the Egyptians defeated him when he tried to invade Egypt in 601 B.C.E. When the kingdom of Judah in Palestine rebelled against Babylon in 587 B.C.E., the forces of Nebuchadnezzar II sacked Jerusalem. Nebuchadnezzar II repaired and rebuilt ziggurats and other public structures in his empire and built the Hanging Gardens of Babylon, supposedly to please his wife, who missed the Median mountains (in western Iran) where she had grown up.

Nebuchadnezzar II's first three successors had trouble keeping control of the throne. The last of them was assassinated. A commoner named Nabonidus (r. 556–ca. 539 B.C.E.) became king but was unpopular, and he went into exile in about 539 B.C.E. His son Belshazzar (r. ca. 539 B.C.E.) replaced him but was not fully accepted as king because his father was regarded as still king. In 539 B.C.E. Cyrus the Great invaded and put an end to the Babylonian Empire.

ELAMITE DYNASTIES (CA. 2900–539 B.C.E.)

The history of Elam is customarily divided into three eras: Old Elamite Period (ca. 2900–ca. 1500 B.C.E.), Middle Elamite Period (ca. 1500–1000 B.C.E.), and Neo-Elamite Period (1000–539 B.C.E.). During the third millennium B.C.E. the Elamites established towns in what is now southwestern Iran. Their kings ruled from the city of Susa. Elam was a vassal state of the Akkadian and later Ur III empires, but in 2004 B.C.E. Kindattu of Elam sacked Ur. In 1764 B.C.E. Hammurabi of Babylon conquered Elam, but Elam successfully rebelled against Hammurabi's son Samsuiluna.

In 1154 B.C.E. the Elamites conquered Babylon, but in about 1126 B.C.E. King Nebuchadnezzar I of Babylon conquered Elam. In the 700s and early 600s B.C.E. Elam supported Babylonian rebellions against Assyria. In about 646 B.C.E. Assyria destroyed Elam's capital city, Susa, but despite its destruction a late Neo-Elamite kingdom arose, and it was in this context that Cyrus the Great, called "king of Anshan" (the name of an ancient Elamite city and region near modern Shiraz) arose and finally claimed Babylonia in 539 B.C.E.

OLD ASSYRIAN PERIOD (CA. 1900–CA. 1700 B.C.E.)

Assyria was a region of northern Mesopotamia, centered on the area of modern-day Mosul along the Tigris River. The first notable Assyrian king was Shamshi-Adad (r. ca. 1813–1781 B.C.E.), who built an empire partly by war and partly by diplomacy. Weaker kings of city-states voluntarily submitted to his rule in the hope that he would use his power to protect them. He left in place those kings who submitted to him, allowing them to run their territories and practice their own customs just as long as they paid their taxes to him. This made for a weak administration, and he had to constantly patrol his lands to keep them in order. His capital city was Shubat-Enlil. His sons Yasmah-Addu and Ishme-Dagan, who divided Shamshi-Adad's kingdom between them, failed to keep a strong presence in their territories, and the empire collapsed when Hammurabi of Babylon invaded it. Assyria then became a vassal state of Babylon.

MIDDLE ASSYRIAN PERIOD (CA. 1390–CA. 1076 B.C.E.)

In about 1500 B.C.E. the shadowy kingdom of Mitanni was the dominant power in northern Mesopotamia, with its territory extending from the northern reaches of the Tigris River to the Mediterranean Sea; after the sack of Babylon by the Hittites

in 1595 B.C.E., Assyria became a vassal state of Mitanni. In the 1300s B.C.E. Mitanni became part of the Hittite Empire, creating an opportunity for Assyria to reassert its independence under King Ashur-uballit I (r. ca. 1365–ca. 1330 B.C.E.). He established the Assyrian capital in the city of Ashur and gained dominion over several cities located near the confluence of the Great Zab River into the Tigris River. King Adad-nirari (r. ca. 1307–ca. 1275 B.C.E.) campaigned westward into the heart of Mitanni. Shalmaneser I (r. 1274–1245 B.C.E.) attacked deep into central Anatolia, securing Assyria's northern frontier.

Tukulti-ninurta I (r. 1243–1207 B.C.E.) attacked Babylonia in 1220 B.C.E. and occupied the city of Babylon until 1213 B.C.E. He adopted Babylonian titles of kingship and transported Babylonians to Ashur, resulting in a spreading of Babylonian culture. His forces drove eastward to the Zagros Mountains. His numerous building projects included a new temple of Ishtar in Ashur and a new town north of Ashur for his residence, called Kar-Tukulti-Ninurta. In 1208 B.C.E., during a palace coup, one of his sons assassinated him. His empire immediately began to fall apart.

It was Tiglath-pileser I (r. ca. 1115–ca. 1077 B.C.E.) who again pulled the Assyrian Empire together. His conquests extended south to Babylonia, northwest to the Hittite Empire, and west across the Euphrates River, through the Syrian Desert, and through Palestine to the Mediterranean Sea. The borders of his new empire were ill defined, and nomads raided the empire's territories. By about 1000 B.C.E. the Assyrian Empire had withdrawn to the territory that had been ruled by Ashur-uballit I.

NEO-ASSYRIAN EMPIRE (CA. 100–CA. 626 B.C.E.)

After Tukulti-ninurta I there seems to have been an unbroken line of kings who kept Assyrian cities and temples in good repair, but it was Ashur-dan II (r. 935–912 B.C.E.) who began Assyria's climb back to preeminence. He reformed Assyrian agriculture, making it more productive, and he developed a strong military to protect Assyria's frontiers. Adad-nirari II (r. 911–891 B.C.E.) developed Assyria into a military powerhouse and reconquered most of the territory held during the Middle Assyrian Period. In the 870s B.C.E. King Ashurnasripal II (r. 883–859 B.C.E.) conquered most of Syria. After the death of Shalmaneser III (r. 858–824 B.C.E.), Assyria foundered on internal conflicts and some its conquests became independent.

During the reign of Tiglath-pileser III (745–727 B.C.E.) Assyria reasserted itself. Tiglath-pileser III founded a postal service that would continue to serve later empires into Roman times. To break up hostile groups of subjects, Assyrian governments deported them to Assyrian territories, where they could be both watched and put to work. In this way, Tiglath-pileser relocated more than 200,000 people from their homelands. In 722 B.C.E. Shalmaneser V (r. 726–722 B.C.E.) was overthrown by Sargon II (r. 721–705 B.C.E.). When Babylon rebelled, Sargon II took away the sacred cult statues of the

Babylonian gods, in about 711 B.C.E. In 705 B.C.E. the city of Nineveh, one of the most ancient of Assyrian cities, became Assyria's capital. When Esarhaddon (r. 680–669 B.C.E.) became king, he returned the captured cult statues to Babylon and undertook the rebuilding of shrines in the empire in an effort to build goodwill. He was succeeded by Ashurbanipal (r. 668–627 B.C.E.), famous for the immense library discovered in his palace. He was brutal and inflicted horrifying torture and suffering on victims throughout his empire, inspiring hatred of him and Assyria. In about 615 B.C.E. Babylon and Judah revolted, and the Medes invaded from the east. Ashur was leveled by the Medes, not to rise again. Nineveh fell in 612 B.C.E.; in 609 B.C.E. the last Assyrian resistance was eradicated.

HITTITE EMPIRE (CA. 1650–1205 B.C.E.)

In the third millennium B.C.E. the Hittites were one of a number of Indo-European-speaking groups living in Anatolia. In the late 18th century B.C.E. King Anitta conquered the small kingdoms of Zalpa, Hattusas and Puruskhanda and succeeded in establishing the first central Anatolian state, stretching from the Mediterranean to the Black Sea. In about 1650 B.C.E. Hattusilis I (r. ca. 1650–c. 1620 B.C.E.) made the city of Hattusas his capital, and the Hittite written record (in cuneiform) began. The Hittites were pillagers of other peoples and used their superior iron body armor and military tactics to subdue their neighbors. In 1595 B.C.E. Mursilis I (r. ca. 1620–ca. 1590 B.C.E.) led a daring raid down the Euphrates River to attack Babylon, and the Hittites sacked the city. Mursilis I was assassinated in about 1590 B.C.E., and the Hittites' warrior elite fell to killing one another. Hattusas was captured by the Kaskas, a tribe from the north. Mitanni, a kingdom in Syria, dominated much of the rest of Hatti.

Exactly when the Hittites reunified has yet to be clarified, but around 1500 B.C.E. Telipinus succeeded in restoring political, religious, and military order. Tudhaliyas I (r. ca. 1420–1400 B.C.E.) campaigned against the Mitanni in Syria, but the rise of the kingdom of Hattusas really occurred under King Suppiluliumas I (r. 1355–1320 B.C.E.), who not only retook Hattusas but also sacked Washukanni, the capital of Mitanni, during a remarkable campaign. He created a strong central government. Mursilis II (r. 1318–1290 B.C.E.) pushed the empire to its maximum size, stretching from the Aegean Sea to eastern Syria and south into Palestine.

The trade routes in northern Palestine were valued by several Near Eastern peoples, and keeping those trade routes free from bandits and marauding nations became national policy for Egypt. After fighting several battles over who should control northern Palestine, the Hittites and Egypt made a peace treaty in about 1258 B.C.E. that defined the border between them and made them allies against the Assyrians. The cause of the demise of the Hittite Empire around 1200 B.C.E. is unclear. Marauders called the Sea Peoples by modern historians but who were actually several groups of people who had been displaced from their homelands in and around the Mediter-

anean Sea have sometimes been credited with the fall of the Hittites, but internal troubles seem to have been more significant, and several vassal states had already succeeded in breaking free under Suppiluliuma II (after 1215 B.C.E.).

ISRAEL

Although Palestine was dominated by Egypt for much of its ancient history, Egypt in general did not meddle in local politics. Its primary concern was keeping open and free from danger the trade routes that linked Palestinian seaports with the Near East and Egypt. Most historians believe that Hebrews settled in Palestine in about 1200 B.C.E. and that they were a nomadic people. Biblical accounts say that they left Egypt, and accounts left by Egyptians on their monuments indicate that the Hebrews had lived in Egypt in a region in the eastern Nile Delta. This was not unusual, because at other times Egypt allowed Libyan tribes and even some of the notorious Sea Peoples to settle, all of whom were absorbed into the Egyptian culture.

Palestine was a land of city-states and experienced a flow of different peoples through it. Some of the Sea Peoples who had attacked the Hittites settled in Palestine, becoming the Philistines. Wars with the Philistines and other tribes seem to have driven the Hebrews to organize their tribes into a nation. Their first king was Saul (r. ca. 1020–ca. 1000 B.C.E.), who conquered territory well north of the Sea of Galilee, much of the land around the Dead Sea, and eastward beyond the city of Ammon, but he died while fighting the Philistines. His successor, David (ca. 1000–ca. 962 B.C.E.), decisively defeated the Philistines and extended the empire of the Hebrews northward into Syria and southward to the Gulf of Aqaba, and he claimed much of the Mediterranean coastline of the region. The extent of his eastward conquering has yet to be established by archaeologists. King David conquered the city of Jerusalem and made it his capital.

David's son Solomon (r. ca. 961–ca. 921 B.C.E.) was the last to rule over a united Hebrew nation. The power of his nation was great enough to create vassal states in Syria. During his rule, the empire was a powerful economic force in Palestine. With the nation's wealth he undertook many public building projects, the most famous of which was a temple in Jerusalem. After his death the kingdom split into Israel, with its capital in the city of Samaria, and Judah, with its capital in Jerusalem. Israel lasted until around 722 B.C.E., when Shalmaneser V of Assyria destroyed it. He had the Hebrews resettled elsewhere in his empire to separate them from their homeland and relocated Mesopotamian peoples to Israel. Judah lasted until about 587 B.C.E., when Babylonia burned Jerusalem and resettled the people in Mesopotamia.

PERSIA

The Medes were a people in western Iran (between the Caspian and the Zagros mountains) who are spoken of in Assyrian sources and participated in the sack of Nineveh in 614 B.C.E. Although they were credited by the historian Herodo-

tus with having a powerful empire, there is little evidence of this outside the literary sources. Indeed, the first great Persian Empire (538–331 B.C.E.), also known as the Achaemenid Empire, arose not from Median but from Elamite roots. Cyrus the Great (r. 558–529 B.C.E.), who entered Babylon in 539 B.C.E. and is credited with subsuming Media before going on to conquer Lydia, emerged from an Elamite milieu. Cyrus established a new capital at Pasargadae, not far from the ancient city of Anshan (modern-day Tal-e Malyan), northwest of Shiraz.

Cyrus was killed while campaigning near the Aral Sea in Central Asia and was succeeded by his son Cambyses II (r. 529–522 B.C.E.), who conquered Egypt in 525 B.C.E. After the death of Cambyses during the return journey from Egypt, Darius I (r. 522–486 B.C.E.) came to power. It is with him that the true Achaemenid Dynasty began, since Darius was of the house of Achaemenes, whereas Cyrus was not. Darius's conquests stretched from the Indus River valley in the east to Thrace in southeastern Europe. He reorganized the Persian Empire into 20 provinces, called satrapies, and he improved the postal system that had been created by Assyria. He built the Royal Road, extending 1,600 miles from Susa in Iran to Sardis in Lydia

Portion of a relief in the tomb of Darius I showing his throne bearers; all 28 throne bearers represent the 28 nations of his empire. (Courtesy of the Oriental Institute of the University of Chicago)

(Asia Minor) and created an efficient intelligence service. He determined how much each province could pay in taxes and then taxed half that amount. He built major palaces at the ancient city of Susa and the new capital of Persepolis.

After putting down a rebellion of Greek city-states in Asia Minor, Darius launched an attack on Athens in Greece, which had supported the rebels. His forces were defeated at Marathon in 491 B.C.E. His son Xerxes (r. 486–465 B.C.E.) campaigned against Greece in 480–479 B.C.E., but the Persians were defeated by an alliance of Greek city-states. In 401 B.C.E. a civil war broke out between the Persians of Artaxerxes II (r. 404–359/358 B.C.E.) and Greek mercenaries commanded by his brother, Cyrus the Younger. Cyrus was defeated, but the Greek mercenaries fought their way out of the Persian Empire, as recounted by Xenophon.

SELEUCID KINGDOM (CA. 311–CA. 140 B.C.E.)

The last Persian monarch was Darius III (r. 336–330 B.C.E.). In 336 B.C.E. Alexander the Great invaded the Near East with a well-trained army of Greeks and Macedonians. He fought a series of battles against superior numbers, first taking the cities of the eastern Mediterranean, then Egypt, Assyria—where he defeated Darius III at the battle of Gaugamela—and Babylonia and finally Iran. It took until 328 B.C.E. to secure the Persian Empire, after which Alexander conquered part of northwestern India in 326 B.C.E. He seemed to take on the role of a Persian emperor after that and had plans for an invasion of Arabia, but after an arduous overland journey through Baluchistan and eastern Iran and following the burning of Persepolis, he died at Babylon of a fever in 323 B.C.E. Thereafter, the empire he had briefly created broke into smaller kingdoms ruled by two of Alexander's generals, Seleucus I (r. ca. 311–281 B.C.E.), who founded the Seleucid Kingdom, and Ptolemy I (r. ca. 323–285 B.C.E.), who founded the Ptolemaic Kingdom (322–168 B.C.E.). These kingdoms, centered on Syria and Mesopotamia (Seleucid) and Egypt and Cyprus and the southern Levantine coast (Ptolemaic), eventually succumbed to the superior strength of Parthia in the east and Rome in the west.

PARTHIAN EMPIRE (CA. 250 B.C.E.–226 C.E.)

The Parthians originally lived in what is now northeastern Iran and adjacent parts of central Asia. The kingdom of Parthia, as known from coin issues, began with the reign of Arsaces I (r. ca. 250–ca. 248 B.C.E.), whose capital was at Nisa in what is present-day Turkmenistan and after whom the dynasty is sometimes referred to as Arsacid. Mithridates I (r. 171–138 B.C.E.) conquered southwestern Iran and pushed the western frontier across most of Mesopotamia. The Arsacid kings established a more centrally located capital at Ctesiphon, near Baghdad, and for many years the Euphrates formed the border between Rome's eastern provinces and the Parthian Empire. Artabanus V (r. ca. 213–226 C.E.), the last Parthian king, was overthrown by Ardashir I (r. 226–241 C.E.) from Ispahan, near Persepolis, who established the Sasanian Empire (226–651 C.E.), Iran's last great pre-Islamic state.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

HARAPPAN CIVILIZATION

Harappa and Mohenjo Daro were the two largest cities of the Harappan civilization, and both were close to the Indus River. The civilization included numerous towns and villages scattered over an area that extended from central Asia to south of the Himalayan Mountains and along the seacoast west and south of the mouth of the Indus River. Its size was enough to qualify it as a large nation for its era, 2600–1500 B.C.E. Its government is a mystery because its written language has yet to be deciphered, and the Near Eastern civilizations with which it traded give it only brief mentions in their surviving records.

In about 1900 B.C.E. natural disasters began to undermine the main Harappan cities and towns. Rivers often flooded and sometimes changed their courses, inundating cities and towns and forcing the Harappans to repeatedly repair or even rebuild them. By 1500 B.C.E. Harappa was in steep decline as its people abandoned their cities, probably because of floods and bad harvests. In about 1500 B.C.E. Aryan tribes from central Asia invaded the Indus valley and the rest of northern India. Even so, some Harappan villages and towns survived in northern India and passed on their art and religion to later generations.

VEDIC INDIA

The word *Vedic* refers to the Vedas, the oldest sacred writings of Hinduism. Passed on orally until they were first written down in the 500s B.C.E., they recount the wars of the Aryan tribes and the sources of their religious beliefs. Vedic India dates to about 1500 to 600 B.C.E. Vedic society was stratified into groups called castes. There were four principal castes: At the top was that of priests, called Brahmins; second was that of warriors and political rulers, called Kshatriyas; third was that of merchants, money lenders, and farmers, called Vaishyas; fourth was that of craftspeople, servants, and minor government officials, called Sudras. Below all these people were the people without a caste. Castes were hereditary, meaning a person's caste was the same as that of his or her parents. This social system set the pattern for the rest of India's history.

The Aryans were originally nomads who directed sheep and cattle to different grazing grounds according to the season. Some of their descendants in northern India continued to practice the old way of life into the 21st century. Most of the Vedic people began to settle down as they spread eastward and southward. By the 800s B.C.E. they had formed many small tribal territories called *janapadas* across northern India. The *janapadas* were constantly at war with one another, and the stronger ones absorbed the weaker ones until 16 were left in the late 700s B.C.E. These territories were called *mahajanapadas*. Their power extended south to the Godavari River, which flows west to east, almost bisecting India.

MAGADHA

One of the *mahajanapadas* was Magadha, the kingdom that would create the first Indian empire (684–26 B.C.E.). By 400 B.C.E. Magadha and another *mahajanapada*, Koshala, were conquering their neighbors. Both King Bimbisāra (ca. 543–491 B.C.E.) of Magadha and King Prasenajit of Koshala became patrons of Siddhartha Gautama (ca. 563–ca. 483 B.C.E.), who became the Buddha. When Bimbisāra died, he was succeeded by his son Ajatashatru, who spent the first few years of his reign fighting off challengers to his rule. In the meantime, one of Bimbisāra's widows died; she was a daughter of Prasenajit. Land that Prasenajit had given to Bimbisāra as a dowry was reclaimed by Prasenajit. Ajatashatru went to war to reclaim the land and was defeated. Later, Prasenajit was overthrown by his son and fled to Magadha's capital of Rajagriha, where he died of exhaustion outside the city gates. Ajatashatru swore to avenge the fallen king, and through good luck and intelligence he led a successful military campaign that put a permanent end to Koshala. Ajatashatru went on to wage war against Licchavi, a republic ruled by several thousand knights. He lost some battles, but eventually he conquered Licchavi, and he made Magadha the dominant power in northern India. Dates are very uncertain for India in the 300s, but Ajatashatru died probably sometime between 380 and 330 B.C.E.

Ajatashatru's death was followed by chaos in Magadha's government. Apparently, numerous people claimed the throne. The man who eventually made the kingdom his own was Mahapadma Nanda, who in about 424 B.C.E. founded the Nanda Dynasty, which lasted only until about 321 B.C.E. Mahapadma Nanda was the son of a barber, a member of the Sudra caste. This made him intolerable to the warriors of the Kshatriya caste, who tried to kill him. Nanda retaliated by defeating his enemies in many battles. He built an army of more than 200,000 troops and used it to establish himself as the supreme power in northern India.

INDIA'S MAURYA EMPIRE

In 326 B.C.E. Alexander the Great (356–323 B.C.E.) of Greece entered northwestern India, where he won over some Indian leaders as allies and defeated in battle those who opposed him. He was poised to battle the army of the Nandas when his own army refused to continue to fight. It is unlikely that Alexander gave up his ambition to conquer India, but he died in 323 B.C.E., before he could reasonably build a new army for a war.

By then Aggrames, son of Mahapadma Nanda, was the Nandan king. His government was very wealthy, and its riches became legendary in its time. Its taxes were high, creating resentment throughout his kingdom and making him very unpopular. Also, there was the matter of his father being a Sudra. Thus, in 321 or 320 B.C.E. one of his generals, Chandragupta Maurya (r. ca. 321–ca. 297 B.C.E.), overthrew him and founded the Maurya Empire, which lasted from 321 to 185 B.C.E.

Chandragupta had spent the previous few years in Greek-controlled territory, planning his revolt. He was not only a

careful planner but an inspiring leader. By 305 B.C.E. he had conquered all of northwestern India, including the Indus River valley and lands to Bactria, in modern Afghanistan. He established a government bureaucracy that kept tight control of the empire's subjects. His government increased trade by building roads and improved crop yields by building irrigation systems.

He was succeeded by his son Bindusāra, who reigned from 297 to 272 B.C.E. Bindusāra conquered lands south of the Godavari River, leaving only the southern tip of India unconquered. His son Asoka, who reigned until 233 B.C.E., expended the empire farther by conquering the southeastern coastal kingdom of Kaling in 261 B.C.E. Asoka was deeply troubled by the suffering he had caused in Kaling, and this resulted in his conversion to Buddhism.

Asoka spread Buddhist values throughout his empire. He built tens of thousands of monuments to the Buddha all over the land. He reorganized the government to be less oppressive and made edicts on how government should conduct itself in a moral way. He had these edicts carved on monuments scattered about the country. Declaring that the Maurya Empire would embrace peace, Asoka assured his neighbors that he would do them no harm. He sent Buddhist missionaries into China, southeastern Asia, and the island of Ceylon. His reforms of government, his advocacy of peace, and his sending of Buddhist missionaries to foreign lands made him one of the most influential and remarkable rulers in India's history.

He had hoped to rule by moral authority rather than military authority, but this meant that after his death more militant people encroached on Mauryan territory. In 185 B.C.E., when the Maurya Empire was overthrown, its territory had shrunk to about the same as that of Magadha in 320 B.C.E. India would not see another empire until 320 C.E.

INDIA'S GUPTA EMPIRE

The Gupta Empire lasted from 320 to 499 C.E. It was founded by Chandragupta I (r. 320–ca. 330 C.E.), who was unrelated to Chandragupta Maurya. During his reign he conquered enough territory to form a new nation in the heart of what had been the Magadha kingdom. He gave himself the title Maharajadhiraja, meaning "great raja of rajas." His son Samudragupta was the great empire builder in the family. During his reign from 330 to about 380 C.E. he conquered the rest of northeastern India and drove his territory south through the eastern half of India. He established a feudal government in which he allowed some of the kings he had conquered to rule their lands while paying him tribute. Thus, he made most of central India acknowledge his supremacy over them and exacted tribute from them, but he chose not to absorb them into his empire. His government built roads that improved trade within the empire.

He was succeeded by Ramagupta, whose military ineptitude caused him to be replaced by his brother Chandragupta II (r. ca. 380–415 C.E.). By 409 C.E. he had conquered much of northwestern India and had forced the rest of northwestern India to pay him tribute. Chinese visitors recorded

his reign as a golden age for the arts, while noting that most Indians had good lives. He was succeeded by Kumāragupta (r. ca. 415–455 C.E.), whose rule was weakened by a rebellion in Malwa, in central India. The next Maharajadhiraja was Skandagupta (r. ca. 455–467 C.E.), who faced an invasion by the Hunas, the Huns. During his father's reign he had put down the rebellion in Malwa, and as the Gupta ruler he drove out the Hunas. He was succeeded by his nephew Budhagupta, whose reign seems to have been brief. The Hunas returned and defeated the Gupta army, ending the Gupta Empire.

CHINA'S LEGENDARY DYNASTY

Almost nothing is known about the politics of the region of China before the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.). Ancient Chinese legends say that the first Chinese king was Huangdi, also called the “Yellow Emperor.” *Huang* means “august sovereign,” and *di* means “high god.” During the Shang and Zhou dynasties, *di* would come to mean “divine ruler.” Huangdi supposedly lived sometime between the 2900s and 2600s B.C.E., with 2698 B.C.E. sometimes being asserted as the year he made himself king.

According to Chinese histories from the Han Dynasty (202 B.C.E.–220 C.E.), the first Chinese dynasty was the Xia, said to have been founded in 2205 B.C.E. This dynasty has long been thought to be a myth, but so was the Shang Dynasty until the early 20th century, when archaeologists began finding proof of its existence. In fact, one Han historian, Sima Qian of the second century B.C.E., made a list of Shang rulers that closely matches a list created by archaeologists from Shang writings, and he made a list of Xia rulers, too, so perhaps ancient Xia just remains to be discovered.

CHINA'S SHANG DYNASTY

Since the 1910s archaeologists have found cities of the Shang Dynasty and tombs of some of its rulers. Chinese legend says it was founded in about 1700 B.C.E. by King Tang. Modern archaeologists and historians are more comfortable with the date 1500 B.C.E. for the founding of the Shang Dynasty along the Yellow River, probably by a historical King Tang. The Shang were warlike, and they conquered territories to the north and west of the Yellow River.

By 1050 B.C.E. the Shang kingdom was remarkable. The Shang conquerors had absorbed into their kingdom a variety of different ethnic groups who spoke several different languages and had instilled in most of them the idea that they were one people, living in a kingdom given to them by gods. The cultural influence of the Shang reached south beyond the Yangtze River, north into what is now Inner Mongolia, west to the Qin Mountains, and east to the ocean. The Shang Dynasty's strong central government held the country together for centuries, but it began to weaken in the 1100s and 1000s B.C.E. because it could not keep track of its increasingly far-flung territories, and its borders were constantly fluctuating with the ebb and flow of barbarian invasions and Shang counterattacks.

CHINA'S ZHOU DYNASTY

During the 1100s or 1000s B.C.E. the rulers of the province of Zhou began calling themselves *wangs*, meaning “kings.” There is some doubt about exactly when the Zhou overthrew the Shang Dynasty, with the earliest date being 1122 B.C.E., but the year was probably 1045 B.C.E. The Shang government had fallen into disarray, with its kingdom's provinces tending to rule themselves. Although the Zhou were not as technologically advanced as were the Shang, they had a better-disciplined military. King Wu of Zhou defeated the Shang army and sacked the capital city of Anyang.

Historians divide the history of the Zhou Dynasty into two periods: the Western Zhou, when the capital was in the city of Xian in the Qin province, and the Eastern Zhou, when the capital was in Luoyang in the province of Zhou, to the east of Xian. The Western Zhou era lasted from 1027 to 771 or 770 B.C.E. Its first monarch, King Wu, declared that the Shang Dynasty's divine energy had disappeared and that he had been chosen by the gods to found a new dynasty.

To later Chinese, the Western Zhou era was a golden age because the Zhou government maintained the peace. Instead of creating a strong central government, the Zhou monarchs solved their problems with ruling a large nation by creating a feudal system in which they appointed family members and close friends to rule dozens of small provinces. No one had a large enough province to have the manpower necessary to overthrow the government, and the Zhou Dynasty had a series of strong leaders who traveled the country with their army. The army was so magnificent when it marched that enemies were overawed by the sight of it.

During the 800s B.C.E. nomadic peoples from the west of China raided the Qin province and threatened Xian. Thus, in about 770 B.C.E. the Zhou king moved his capital east, away from the threats from barbarians. This resulted in a great loss of prestige for the king, and the rulers of provinces began ignoring the Zhou government. This began the Eastern Zhou, which historians divide into two smaller periods: the Spring and Autumn Era (722–481 B.C.E.) and the Warring States Era (453–221 B.C.E.). These names were given because the first period is covered in an ancient history book called *Spring and Autumn Annals*, and the other is covered in *The Strategies of the Warring States*.

During the Eastern Zhou the king had almost no political power and ruled only a tiny territory. He did have important ceremonial significance, and rulers of the provinces consulted him as a matter of fulfilling protocol. This protocol may have annoyed the provincial rulers, but they held their stations as rulers because they received the blessings of the king, who ruled by divine right and passed that right to them. To kill the king and be done with him would take away their own justifications for being rulers. Meanwhile, the different provinces waged war against each other.

The Shang Dynasty dominated ancient China between 1500 and 1045 B.C.E.

CHINA'S QIN DYNASTY

One of history's most remarkable people is the emperor Zheng (r. 221–210 B.C.E.), who ruled the Qin province from 246 B.C.E. in the west of the Zhou empire. Public works projects, such as irrigation systems, by Zheng's father and grandfather had enabled Qin to have a thriving economy, which could feed and equip a large army. They had dispensed with the tradition of using heredity to appoint public officials, instead using merit. This meant that they had an army run by able men who were often commoners who had risen through the ranks because of their accomplishments. Clever and ruthless, Zheng defeated the other provinces in battle.

In 246 B.C.E. he declared himself Qin Shi Huangdi. He chose "Huangdi" to tie himself to the mythical first king and also because *huang* outranked *wang*, because by then it meant "emperor," and *di* meant that he had the divine right to rule. *Shi* meant he was the "first" emperor of China. He ordered the destruction of historical records so that all history would begin with him as well as to eliminate what he thought was the corrupting influence of past governments. He had about 40,000 Confucian scholars buried alive to prevent their teaching about the past. He imposed the legalist philosophy of government, under which every aspect of life was governed by laws, and punishment was severe. When he died in 210 B.C.E. his government began to collapse. So loathed were Qin Shi

Huangdi and his family that when they were deposed soon after his death, every last one was executed. Qin Shi Huangdi had bragged that his dynasty would last 10,000 generations. In fact, in 206 B.C.E. the Han Dynasty took power.

CHINA'S HAN DYNASTY

The Han Dynasty was founded by Liu Bang (r. 206–195 B.C.E.), a commoner who had risen through the ranks to become a general. He had little idea of how to rule a country, but he had the good sense to know that to establish a stable government he had to do away with the legalist way of governing. On the advice of scholars he established Confucianism as China's governing philosophy. The precepts of Confucian philosophy were modified to make clear that everyone had to obey the emperor, but otherwise the Confucian idea that a government should serve its people rather than the other way around was made national policy. The lowering of taxes and easing of laws were popular and had the desired effect of making Liu Bang and his descendants popular for the next 200 or so years.

Trade with the outside world was expanded during the Han Dynasty, which lasted until 220 C.E. China spread southward and northwestward and extended its northern Great Wall to cover part of the so-called Silk Road, the trade routes over which China exported and imported goods to and from Europe, Rome, Persia, and India. Even peasants began to share in some of the nation's wealth. An educational system was begun in the 140s B.C.E. to teach boys Confucianism and a basic understanding of geography and the sciences. This system served to indoctrinate the barbarian provinces into the Chinese way of life, and it provided the government with a pool of people it could appoint to government offices based on their merits.

During the last 100 years of the Han Dynasty eunuchs gained control of much of the central government, and they enriched themselves and manipulated governments officials. Angry and resentful, some Han generals rebelled and slaughtered the eunuchs. One of the generals, Dong Zhuo, put the last Han emperor, Xian (r. 189–220 C.E.), on the throne. Dong Zhuo failed to control his troops, who went on a rampage in the capital city, Luoyang, sacking the city and burning government buildings, including the national library. In another age Xian might have been a great emperor, but it was all he could do just to hang on to his throne until he abdicated at sword point in 220 C.E.

CHINA'S SIX DYNASTIES ERA

The Six Dynasties Era lasted from 220 to 589 C.E. and takes its name because, except during one brief period, it was ruled in pieces by different governments. After 220 C.E. China was divided into three kingdoms: Wei in the north, Wu in the southeast, and Shu in the southwest. In 264 C.E. Wei conquered Shu, and in 280 C.E. it conquered Wu, briefly reunifying the nation under the Jin Dynasty. By 304 C.E. northern barbarians had pushed the Jin Dynasty south into the Yangtze River valley. From 304 to 535 C.E. 17 different dynasties, 14 of them non-Chinese, ruled in the north. The barbarians

adopted Chinese customs and Chinese Buddhism. Throughout the Six Dynasties Era the Chinese leaders wished to reunite China under one government. It was General Sui who succeeded, establishing the Sui Dynasty in 581 C.E. and conquering most of China by 589 C.E.

FUNAN

Funan began as a trading city in the Mekong Delta of what is now South Vietnam. According to the Chinese of the time, an Indian merchant named Kaundinya, meaning "king of the mountain," wooed Liu-ye, meaning "willow leaf," who was a local queen, probably the leader of a tribe, perhaps a priestess. Between 100 and 200 C.E. they married and founded a royal dynasty. Funan adopted an Indian-style government and embraced Hinduism. Funan was notable for the Hindu temples it built, mostly of bricks. By conquering other tribes, by the 300s C.E. it controlled territory from Camranh Bay in the east to central Cambodia. To its north were the Chams and the Khmers. The Khmers conquered the Chams, creating the kingdom of Chen-la, which became a vassal state of Funan. In the mid-500s the Khmers conquered Funan.

NAM VIET

The ancient history of Vietnam is murky, colored by myths. In about 500 B.C.E. there was a Viet kingdom south of the Yangtze River in what is now China. The Chinese conquered it in 333 B.C.E. Many of the Viets moved southward to get out of the way of China's expansion, displacing through war a culture that may have been related to Indonesian tribes of the time. Other Viets remained in China and assimilated into the Chinese culture. In about 207 B.C.E., while Liu Bang was establishing his control of China, a Chinese general created a kingdom called "Nam Viet," meaning "Southern Viet." This kingdom reached from 40 miles south of the city of Hue in modern Vietnam to a region west of the modern city of Canton in China. In 111 B.C.E. China conquered Nam Viet, ruling it until 938 C.E., when a Viet general, Ngo Quyen (ca. 896–944 C.E.), drove the Chinese out.

KOREA'S THREE KINGDOMS

Much of ancient Korea was under no one's particular rule, and its three main kingdoms did not have clearly definable borders. These kingdoms were Silla (57 B.C.E.–935 C.E.), Koguryo (37 B.C.E.–668 C.E.), and Paekche (18 B.C.E.–660 C.E.). It was Silla that united Korea in 668 C.E. Previously, Silla ruled much of southeastern Korea, Koguryo ruled northern Korea, and Paekche ruled southwestern Korea.

Koguryo was founded by King Tongmyongsong (r. 37–19 B.C.E.) and migrants from Manchuria. After a successful military campaign by King Mich'on (r. 300–331 C.E.) in 313 C.E., Koguryo ruled much of southern Manchuria. In 612 C.E. the army of King Yong-yang under the command of General Ulchimumdok decisively defeated an attacking Chinese army in a series of battles in southern Manchuria.

Paekche had been started by tribes from Manchuria that migrated farther south than had the people of Koguryo. Its

first king was Onjo (r. 18 B.C.E.–28 C.E.). Paekche was heavily influenced by China, which had trading colonies in it. The kingdom sometimes needed help defending itself against Koguryo, and it was aided by the Japanese and sometimes by Silla. The first king of Silla was Hyokkose (r. 57 B.C.E.–3 C.E.). For much of its early history Silla was the weaker of the three kingdoms.

In 372 C.E. the Chinese introduced Buddhism and Confucianism to Koguryo. Buddhism's influence spread to the other two kingdoms, and the monarchs of the three kingdoms encouraged its adoption by their people, hoping that Buddhism would help their kingdoms prosper by making their societies more harmonious, as well as by repelling evil spirits. Scholars from Paekche brought Confucianism to Japan, perhaps in the late 300s C.E.

JAPAN

Very little is known about the rulers of ancient Japan. Although there were lists created during the Middle Ages of monarchs going back to 660 B.C.E., Japanese historians proved these to be false in the 1600s C.E. Some historians cite Jimmu as the first ruler of Japan because he is named in Japanese mythology, but he did not exist. The first ruler for whom there is any evidence is Queen Himiko. She is found in several Chinese records of her era, which note how she lived and her relationship to China. She was China's only important ally in northeastern Asia and was a valued ally of the Chinese kingdom Wei after the fall of the Han Dynasty.

Her exact dates have not been established, but Chinese records show her active for a long time; she was probably alive from the late 100s to the late 200s C.E. In 247 C.E. Himiko asked her Chinese allies for help during a period of unrest in her kingdom, and an ambassador named Zheng Zhang was sent. The Chinese record her being succeeded by a man who, in turn, was replaced by a 12-year-old girl. Like Himiko, she was a sorceress, but little else is known about the young queen. Even her name is in dispute, though it was probably Ichiyo.

During the reigns of Himiko and Ichiyo Japan moved from illiteracy toward literacy. The extensive road building that would connect the island of Honshu, north and south, probably began during their era, and they probably introduced Chinese building techniques for public buildings.

CEYLON (SRI LANKA)

It was probably the first king in Ceylon, Dutthagamani (r. second century B.C.E.), who established the capital of ancient Ceylon in the city of Anuradhapura in the northern part of the island. He and his successors were Buddhists, and they were expected by their subjects to rule according to the Buddha's teachings of modesty and compassion. They endured invasions from southern India and were ruled by southern Indian Tamils from 104 to 89 B.C.E. and again from 433 to 459 C.E. During the rule of King Dhatusena (r. 459–477 C.E.) Ceylon was famed for its large ports, huge warehouses, and cosmopolitan life.

EUROPE

BY KIRK H. BEETZ

Empires and dynasties did not emerge until relatively late in ancient Europe. An empire is a state that not only controls the territory that surrounds its capital but also seeks to expand its territory by colonization or military conquest. Thus, the leader of an empire is not just the king of his own territory but also the emperor of a much larger realm. A dynasty is a succession of hereditary rulers, a royal line. Typically in the ancient world, the rulers of kingdoms and empires passed their positions to their sons (occasionally, to their daughters) upon their deaths. In the chiefdoms, kingdoms, and small states of the Bronze and Iron Ages after about 2000 B.C.E., hereditary leadership was probably practiced, but not until the emergence of Imperial Rome and the smaller states that formed around its periphery did a true major European empire develop with its own dynasties along with the royal lines of the kingdoms that existed on its borders.

Our knowledge of empires and dynasties in ancient Europe is limited by the sources available to historians. Some modern accounts of the ancient world just skip the history of Europe outside Greece and Italy, covering most of the rest of the world without hinting at why Europe is missing. Sometimes a history of the ancient world will try to come to terms with the problem: Ancient Europeans were illiterate until the conquest by the Romans from 58 to 50 C.E., meaning that they left no written histories of themselves. What little is known of names of people and places comes from foreigners, mostly Greeks, who visited them. Thus, kingdoms may have risen and fallen, and kings and queens may have accomplished great deeds, but their names are lost to history. Archaeology can help, but without even written names, it cannot tell modern readers what the ancients called themselves or the names they had for the lands in which they lived, unless a Greek or Roman recorded the names, and surviving Greek or Roman records provide only a little of the oral history of the Celts, Germans, Slavs, and others who existed in most of Europe.

In the 1100s B.C.E. the Phoenicians began their centuries-long exploration of the Mediterranean and Atlantic coasts of Europe. They brought back home silver, tin, exotic foods, and other goods as well as information about the geography of European coasts. In about 670 B.C.E. literacy returned to Greece following a dark age after the collapse of the Mycenaean culture in about 1250 B.C.E. The Greeks adapted the Phoenician alphabet to their own language and seem almost immediately to have begun writing down everything they could remember about themselves, their politics, their religion, and their history as well as whatever they could learn about other peoples. Most of these writings have been lost, but they are sometimes quoted in later writings that have survived. There were other cultures that developed written languages, notably the Etruscans and the Romans, but most of Europe remained illiterate until conquered by Rome, and therefore much of what is known about European kingdoms and rulers comes secondhand, often from very biased Greek and Roman writers looking at other Europeans from the outside.

ETRUSCANS

Studying the ancient Etruscans can quickly make clear the problems historians have in reconstructing Europe's past. The Etruscans had their own written language, and they were for a time the rulers of Rome. The Romans wrote many histories about themselves, so it would be reasonable to assume that there would be plenty of information about the Etruscans, yet they are still a mysterious people. Their language is strange; it does not fit with Celtic, Latin, or Greek languages, making it hard to translate. Most histories were written by outsiders—the Greeks, who regarded the Etruscans as enemies because the Etruscans had allied themselves with the Carthaginians to limit Greek trade in the western Mediterranean, and the Romans, who had fought wars against the Etruscans and typically characterized Etruscans as indolent and obese.

The empire of the Etruscans began to develop around 900 B.C.E. in Etruria, a region of northwest-central Italy. Called the "Villanovan" culture by archaeologists, it encompassed several towns and stretched from the west coast to the east coast across Italy. By 600 B.C.E. the towns had become the Etruscan League, a federation of city-states that cooperated in foreign and military affairs. Their empire extended south past Salerno, west into Corsica, north to the Alps, and east to the northwestern Adriatic Sea.

An Etruscan city-state was governed by *zilaths*, who were members of an assembly, perhaps like community elders or like Roman senators. These cities belonged to 12 divisions of the Etruscan League, each division ruled by a king. Kingships seem to have been hereditary, but succession practices are not clear. The Etruscan League also had a general assembly where the *zilaths* would meet to select a "first *zilath*," who could lead the entire league, especially during wars. These general assemblies seem to have selected the first *zilath* once a year, but some first *zilaths* were reelected several times.

A prominent Etruscan king was Porsena, ruler of the city of Clusium. When the city of Rome deposed its Etruscan king Tarquinius Superbus in 510 B.C.E., Porsena provided the army that was intended to put Tarquinius Superbus back on Rome's throne. According to Roman histories, Rome was saved by heroic stands of small groups of Roman soldiers against the advance of the mighty Etruscan army. Some historians doubt that the Roman histories tell the truth, suggesting that Porsena's army actually defeated the Romans. In any case, Porsena seems to have been regarded as one of the Etruscans' great kings. After Porsena's time Etruscan power waned while the Etruscans lost wars to Carthaginian, Greek, Roman, and Celtic rivals. The Etruscan city-states retained their cultural identities even during Roman rule. The Etruscans received Roman citizenship in 88 B.C.E.

NORICUM

Noricum was a Celtic kingdom east of the Alps and north of Italy, founded around 500 B.C.E. Under the influence of the Romans, the people of Noricum developed a stable economy and existed mostly in peace with the Romans. Not much is

known about their rulers, though they seem to have followed the typically Celtic practice of appointing new kings or queens rather than having a hereditary kingship. The people of Noricum originally wore trousers but adopted Roman dress. By the time the Romans invaded Gaul, Noricum had adopted so many Roman customs and laws that it was absorbed into the empire with little disruption to its people's lives.

GAUL

Until the Germanic invasions of the fifth century C.E., the Celts were the dominant ethnic group in Europe. They were given the name Celts by the Greeks; they were called Gauls by the Romans. They had what historians call a "heroic culture," meaning a warrior culture in which great military deeds are exalted. The Gauls usually did not see themselves as a single political nation. They were divided into numerous tribes, and they were very mobile. Entire tribes of tens of thousands of people would sometimes take everything they could carry and march to settle somewhere else, sometimes pushing out the people who already lived there, who themselves would move into a new area, driving people out. This movement is how the Celts came to the Romans' attention as a danger in 390 B.C.E. Celtic tribes had been driven out of their homes and had settled in northern Italy. From northern Italy they raided into other territories, and in 390 B.C.E. they sacked Rome. This attack made them a military target for the Romans.

Most Celtic tribes were ruled by kings. The kingship was not hereditary, though the kingship tended to remain in one family. At a king or a queen's death, the elite class of the Celts, the warriors, would choose a replacement. Rulers were much more often men than women, but tales recorded by Greek writers and Roman experiences with Celtic women suggest that there were formidable women rulers among the Celts.

The Celtic tribes were forever fighting one other. When Rome's Julius Caesar invaded Gaul in 58 B.C.E., he took advantage of this Celtic trait, playing one tribe against another. Some Celtic leaders thought that they could use the Roman army to good advantage and allied themselves with the Romans in the hope of having the Romans destroy a particularly hated enemy.

Out of the Celtic tribes of southern Gaul arose Vercingetorix, a member of the Averni tribe. His father had been chief of the Averni but had been executed for being too ambitious, perhaps meaning that he had tried to become a tyrant rather than rule by the consent of the tribe's warriors. In 53 B.C.E. Celtic tribes rebelled against Caesar, and Vercingetorix had urged the Averni to join the rebellion. For this rebellion he was expelled from the tribe, yet he continued to agitate for war and drew to him many disgruntled young warriors and other warriors who were leaderless. With their assistance, he seized control of the Averni government.

The rebellion had begun under the leadership of Indutiomarus, chief of the Treveri tribe, who had led a winter attack on a Roman camp. His army was defeated, and he was hunted down and killed in 53 B.C.E. Vercingetorix's most remarkable

achievement at that time was to convince many of the fractious Celts of Gaul that they should think of themselves as one people and unite to fight for their freedom, and he was made chief of the war effort. He learned in an engagement at Noviodunum that his army was no match for the Romans' superior tactics and discipline in a pitched battle, so he resorted to guerrilla warfare. He burned farmlands to deny the Romans access to food. Even so, Julius Caesar managed to track down his army and trap it in the fortified town of Alesia, where the Celts starved until they surrendered. Vercingetorix was sent to Rome, imprisoned, and publicly humiliated, and in 46 B.C.E. he was executed by strangulation.

These events did not end ambitions for the independence of Gaul. Now and then tribes would try to take a stand for Celtic freedom, but little came of their efforts until 259 C.E., when Gaul seceded from the Roman Empire. Gaul had three emperors: Postumus (r. 259–268 C.E.), Victorinus (r. 268–270 C.E.), and Tetricus (r. 270–274 C.E.). After seizing power in Gaul in 259 C.E., Postumus declared the existence of the Gallic Empire in 260 C.E. In 261 C.E. Britain, Spain, and the Germanic territories in central Europe joined Gaul as part of his empire. The Gallic emperors defeated attempted invasions by Germanic tribes from outside of Gaul. In 274 C.E. the Roman emperor defeated Tetricus's army and ended the Gallic Empire.

Among the Germanic tribes who periodically attacked Gaul were the Franks. In 418 C.E. King Pharamond (r. 418–428 C.E.) began what became the Merovingian Dynasty (418–751 C.E.). He was succeeded by Clodio (r. 428–447 C.E.), who in turn was succeeded by Merovech (r. 447–458 C.E.), for whom the dynasty is named. When the Huns under Attila attacked the city of Orleans in 451 C.E., the Franks joined the Gauls, and the Goths and the Burgundians, Germanic tribes under the command of a Roman general, rescued the city and later defeated the Huns in battle.

Merovech was succeeded by Childeric I (r. ca. 458–482 C.E.). Childeric expanded the power of the Franks in Gaul, but it was his son Clovis I (r. 482–511 C.E.) who made the power long lasting through his military prowess, his conversion to Christianity (496 C.E.), and his establishment of the city of Paris his capital. In 486 C.E. he defeated in battle Syagrius, who was the last official Roman governor of Gaul.

IBERIA

Iberia is the peninsula where Portugal and Spain are now. Iberia was settled at least 30,000 years ago by modern humans. By 5000 B.C.E. West Mediterranean peoples were migrating from the east coast into Iberia. Some ethnologists believe that descendants from both these populations still live in Iberia, especially in Portugal and the Basque provinces of northern Spain. The Greeks gave them the name Iberians. Phoenician merchants were visiting Iberia by 1100 B.C.E., and in the 700s B.C.E. the Phoenicians had colonies on the east and south coasts of Iberia. Along these coasts cities arose with their own governments, probably out of a desire to protect resources, such as tin mines, that were important in trade. These cities

were ruled by warriors and priests. In the rest of Iberia people lived in small tribes that were often at war with one another.

About 750 B.C.E. the Iberian tribe the Tartessians established the kingdom of Tartessos (called Tarshish in the Bible), probably to protect their rights to copper mines in southern Iberia. By 600 B.C.E. it encompassed the lower half of the Guadalquivir River and had four cities, Osuna, El Carambolo, Niebla, and the capital, Huelva. Tartessos was not only a key source of copper but also an important way station for merchants sailing to the Atlantic coast of Europe and to Britain because its ports were on the Atlantic side from Gibraltar. In the 200s B.C.E. it was conquered by the Carthaginians.

The first wave of Celtic migration into Iberia from Gaul occurred in the 800s B.C.E. A second wave followed in the 600s B.C.E. At first the Celts settled in northern Iberia, but during the second wave they spread throughout Iberia, except for the southern and eastern coasts, which remained under the control of native Iberian cities until they were conquered by Carthage in the 200s B.C.E. The Celts did not drive out the local tribes but instead mixed with them, creating a group now known as the Celtiberians. They were ruled by warriors, and the Celtiberian tribes frequently clashed with one other. In the 200s B.C.E. the Celtiberians began living in *castros*, or fortified towns.

Greeks and Carthaginians often fought over control of the western Mediterranean. In 264 B.C.E. Rome came to the aid of Greeks in Sicily, beginning the First Punic War (264–241 B.C.E.), which Carthage eventually lost. Having lost much of its influence among the Mediterranean's islands, Carthage compensated by conquering the southern and eastern coasts of Iberia. Carthage tried to conquer the Celtiberians of the interior but was mostly unsuccessful; however, through diplomacy, Carthage built alliances among the Celtiberians, allowing Carthaginians some control over events in central Iberia. During the Second Punic War (218–201 B.C.E.) the Carthaginians used Iberia as a landing ground for their armies, and for this reason Rome invaded Iberia, inflicting defeats on the Carthaginians and winning allies. Still, many Iberians resisted Roman rule, and Rome did not have complete control of Iberia until 19 B.C.E. Thereafter the peoples of Iberia adopted Latin as their primary language and adopted the Roman way of life.

The Germanic tribes the Suevi and the Vandals invaded Gaul in 405 C.E., but another Germanic tribe, the Visigoths, drove them out. They fled to Iberia. The Suevi numbered about 60,000 and chose to settle in northwestern Iberia. The Vandals conquered part of southwestern Spain, which came to be called Andalusia, in reference to the Vandals. The Visigoths were a well-organized tribe that had adopted many Roman customs. Their king Ataulphus (r. 412–415 C.E.), cooperating with the Romans, overcame the Suevi and drove most of the Vandals out of Iberia in 411 C.E. The Vandals fled to North Africa.

The Visigoths ruled Iberia as their kingdom from 412 to 711 C.E. Kingship was not hereditary. Instead, the warrior elite elected the member of the royal family whom they considered most fit to lead them. Many Visigoths became farmers, but the warriors were the nobility, serving as knights. They spoke

Latin and followed many Roman customs; although they made Iberia an independent kingdom, for diplomatic matters they acknowledged loyalty to the Roman emperor in Constantinople. The Visigoths were Arian Christians, meaning they downplayed the divinity of Jesus Christ, a practice that led to conflicts with the Roman Catholic Iberians, who believed in the divinity of Jesus Christ. In 486 C.E. King Alaric (r. 484–507) established the nation's capital in Toledo.

BRITAIN AND IRELAND

The Celtic peoples of Britain and Ireland were known to the Romans as fierce savages. When Julius Caesar first led Roman troops to Britain, they were met by nearly naked warriors who waded into the ocean toward the Romans' ships to do battle. They were no match for the discipline and superior armaments of the Romans and were scattered. What Caesar later discovered was a land of petty kingdoms with fairly stable governments. He was even able to establish trade agreements that survived until the Roman emperor Claudius (r. 41–54 C.E.) invaded in 43 C.E.

When Claudius invaded Britain, the governments of southern Britain were used to trading with Romans, and a few of the small kingdoms allied themselves with Rome, believing that they would benefit from a close relationship with the Romans. The Romans viewed the Britons as savages and treated them as such. In particular, human sacrifice in religious rituals as practiced by the Druids was appalling to the Romans, who tried to end it. The Romans became cruel overlords, even mistreating their allies. Among these allies was the kingdom of Icenia. In 61 C.E. the Roman soldiers raped two Icenian girls, an act that outraged Queen Boudicca and her subjects.

Boudicca was a sorceress as well as a leader, and when she painted herself in her war colors, she was said to be terrifying. She led a revolt against the Romans that nearly expelled the Romans from Britain. A Roman legion was wiped out in one ambush. Roman settlements were sacked. The Romans were driven out of Londinium. When Boudicca's army faced that of the Roman governor Suetonius Paulinus, it probably outnumbered his forces more than 20 to one. However, the traditional Celtic fighting style of the Britons, which emphasized individual heroism, proved to be their undoing, because they attacked in an uncoordinated mass, and the Romans responded with discipline, skill, and cool efficiency. The Romans killed between 60,000 and 80,000 British warriors and drove the rest to flight. Boudicca followed Celtic tradition by committing suicide rather than being captured.

After that time the Romanized Britons always retained some independence in dress, customs, and tastes from Rome, though they loved Roman-style country villas. In 410 C.E. the Roman emperor Honorius (r. 395–423 C.E.) told the Britons that he could not help defend them. Little is truly known about what events actually followed because the few written records that have survived are short on names and dates. Germanic tribes invaded Britain. The Roman governor or perhaps a regional king may have asked Germanic mercenaries

to help defend Britain from other Germans, possibly in exchange for land. The mercenaries turned on their employers, taking slaves, looting, and killing.

In the last years of the Roman Empire governorships were divided between a political governor and a military one, called a *dux bellorum*. The *dux bellorum* of Britain in the mid-400s C.E. may have been the original King Arthur, a man nicknamed *Ars*, meaning "bear" in the local dialect. His true name is much debated and is probably permanently lost. There is some archaeological support for one of the achievements attributed to him. Ancient chroniclers say that he defeated the Anglo-Saxons in a great battle around 460 C.E. and that thereafter there were about 50 years of peace. This peaceful period seems to have occurred.

GREECE

BY CHRISTOPHER BLACKWELL

In antiquity there was no single nation known as "Greece" or even "Hellas," as the modern Greeks call their own country. Hellas was an abstract idea, and the "Greek world" described by the historian Herodotus in the fifth century B.C.E. encompassed "all those people speaking the same language, sharing the same customs, and worshipping the same gods." In the time of Herodotus this Greek world included the Balkan Peninsula, where the modern nation of Hellas (Greece) is today, and settlements in Sicily, on the coast of Italy, in southern France, along the north coast of Africa, on the west coast of what is now Turkey, and around the Black Sea in what is now southern Russia. In this area and at different times individual cities governed themselves, came together under alliances and confederacies, and enjoyed a variety of forms of government, including monarchy, oligarchy, tyranny, and democracy.

We have evidence from mythology, poetry, and archaeology for empires during the Bronze Age (3000–1100 B.C.E.), which faded before the historical period, the period for which we have written accounts. During the so-called Archaic Period (600–480 B.C.E.) a succession of dynasties of tyrants arose in assorted cities. These dynasties tended to give way to various forms of democracy during the Classical Period (490–323 B.C.E.). The latter period came to an end with the first true "empire" of historical Greece, the rule of the Macedonians Philip (r. 359–336 B.C.E.) and Alexander the Great (r. 336–323 B.C.E.). After Alexander's death Macedonian Greeks set up dynasties that ruled portions of the eastern Mediterranean world, in European Greece, Asia Minor, and Egypt, until these regions came under the power of Rome.

BRONZE AGE CIVILIZATIONS

When Sir Arthur Evans excavated the island of Crete in the late 19th century, he uncovered the remains of a rich civilization dating from the third and second millennia B.C.E. He found large, sprawling palaces, elaborately decorated with wall paintings—scenes of dancing, games, and marine life. He also noted that these palaces lacked defensive walls. From

this last fact he concluded that the long-dead inhabitants of these structures were confident in their security, and he speculated that such security must have come from a solid military command of the sea. These speculations led him to think of the legendary king Minos, who was said to have ruled the Aegean Sea and eastern Mediterranean, and he named the civilization he uncovered “Minoan.” We know very little of this period apart from what archaeology can tell us, but we know that these palaces had a complex bureaucracy and great wealth.

Archaeologists have also uncovered the remains of an “empire” on the southern mainland of Greece, dating to the second millennium B.C.E. Marked by immense, strongly fortified palaces, this civilization is known as “Mycenaean,” after Mycenae, one of the principal settlements of the period. Mycenae was also the home of Agamemnon, the mythological king who, according to the Homeric *Iliad* and *Odyssey*, was the chief *basileus*, or “king,” of all the Greek kings who went to war against Troy. Historians are quick to point out that Homeric poetry is not history and that there is no archaeological evidence that Agamemnon was a historical figure.

Still, mythology, poetry, and archaeology tend to support each other on broad points: The cities mentioned in the *Iliad* and *Odyssey* were major settlements during the Mycenaean Period (1600–1100 B.C.E.); the king of Mycenae claims supremacy in the *Iliad* and *Odyssey*; and the network of roads between Bronze Age settlements in southern Greece seem to converge on Mycenae. It is therefore reasonable to assume that Mycenae was politically central and thus perhaps the center of something we can call an empire.

The palace at Mycenae was destroyed by forces unknown around 1150 B.C.E. During the next few centuries the Greek world entered a “dark age,” so called because of the modesty of the archaeological remains and the lack of written sources. Between 750 and 700 B.C.E. the Greeks adapted the Phoenician alphabet for their own use, and the historical period began. The archaeology of this period and accounts of oral traditions written centuries later point to an empire of sorts during the dark ages. Around 800 B.C.E. Greeks from Euboea, the long island that runs along the east coast of the Greek mainland, founded a trading colony at Al Mina, in what is now Syria. Later in the eighth century B.C.E. they founded another colony near the Bay of Naples. During this period widespread finds of Euboean pottery throughout the Mediterranean suggest that the Euboean cities of Khalkis and Eretria were significant economic powers, and later accounts of a war between the two—the so-called Lelantine War that involved many other Greek cities—would suggest political and military power as well. But the Lelantine War seems to have brought an end to Euboean power, and Euboea ceased to be a political force after around 680 B.C.E.

TYRANTS

In 776 B.C.E. the first Olympic Games were held in the Peloponnese, in southern Greece. This marks a clear beginning

of a consciousness among Greek speakers that despite their political disunity they were in some sense a single people. The eighth through sixth centuries B.C.E. were the so-called Archaic Period of Greece, and during this period many city-states underwent political revolutions. At Corinth, Sicyon, Megara, Miletus, Mytilene, Sámos, and finally Athens, the rule of aristocratic families was overthrown, to be replaced by rule by tyrants.

According to the philosopher Aristotle, who wrote on political systems in the fourth century B.C.E., tyranny in Greece was a step away from monarchy and aristocracy and toward democracy. The common people of a city, unhappy with their aristocratic rulers, would choose a “champion” and give him (they were always men) absolute authority; this new *tyrannos* (the Greek word that gives us “tyrant”) would enact economic and social reforms.

An example of this trend was the establishment of tyranny at Corinth around 650 B.C.E. This city had long been ruled by the aristocratic family of the Bacchiadae. Cypselus (r. ca. 657–627 B.C.E.) himself was the son of a Bacchiad woman, Labda. When the common people of Corinth revolted against the perceived injustice of Bacchiad rule, Cypselus emerged as their champion. Ancient sources differ on the nature of his rule, with some saying that he was bloodthirsty but others noting that he never employed bodyguards, which would indicate that he enjoyed popular support. Like many tyrants, he founded a dynasty, with his son Periander (r. 627–586 B.C.E.) following him in rule. As was often the case, the second generation of a tyrannical dynasty was less benign, and ancient sources universally describe Periander’s rule as one of violence and oppression. Periander passed the tyranny to his son Psammetichus, who called himself Cypselus II. This man was murdered, bringing an end to tyranny and ushering in a period of constitutional government with many democratic features.

At Athens tyranny came later, at the end of the sixth century B.C.E., after at least two close calls earlier. In 632 B.C.E. a man named Cylon attempted to set himself up as tyrant after winning fame at the Olympic Games. His efforts were thwarted by members of the aristocratic family of the Alcmaeonidae, and Cylon was murdered in a temple—a scandalous violation of religious laws that would haunt the Alcmaeonidae for centuries. Around 594 B.C.E. a period of conflict between the aristocrats and the common citizens could easily have led to tyranny, following the pattern at Corinth. But in this case both sides of the dispute agreed to allow Solon (ca. 630–ca. 560 B.C.E.), a prominent Athenian, to reform the constitution along more equitable, if not fully democratic, principles.

Then, in 546 B.C.E., Peisistratus established himself as tyrant in Athens by “taking the people into his party,” according to Aristotle, and disarming the aristocrats. As with Cypselus, ancient writers disagree on the nature of Peisistratus’s reign, but Aristotle states that he ruled according to the laws. Peisistratus also entertained dynastic ambitions, leaving power to his sons Hippias and Hipparchus. These men, like

their father, were patrons of the arts, but this was not enough to protect them from popular ill will, and Hipparchus was murdered by Harmodius and Aristogiton in 514 B.C.E. These men were forever after hailed as the “tyrannicides,” and the Athenians drove Hippias into exile in 510 B.C.E.

When the tyranny at Athens ended, the Athenians adopted a new constitution that instituted a radical democracy. At this same period the tyrannies in the Greek cities of Asia Minor came to an end due to the conquest of that territory by the Persians. The Great King of Persia, Cyrus the Great (r. 558–ca. 529 B.C.E.), established friendly puppet governments in these cities and soon came into conflict with the Greeks of Europe. There followed the so-called Persian Wars, which provided the occasion for Herodotus’s great work of history, the first in the European tradition, and the first significant test of the democracy at Athens, the city that found itself playing a central role in defending the Greek world from Persian ambitions.

THE FIFTH CENTURY B.C.E.

Against all reasonable expectation, the Greek cities that joined Athens and Sparta in resisting Persia were successful in defeating first the armies of Cyrus and then the massive invasion of his grandson, Xerxes (r. 486–465 B.C.E.). By 479 B.C.E. the Greeks had beaten the Persian fleet at Salamis, defeated the Persian army at Plataea, and chased down and destroyed the retreating forces at Mycale.

After the defeat of Persia, an alliance of Greek cities, including many of those on the islands of the Aegean Sea, came together for mutual defense against future Persian threats. Initially the Spartans, the preeminent military force of the day, led this coalition. But the Spartans proved to be overbearing, and Athens gradually took over leadership of this league, which came to be known as the Delian League, because its treasury was on the island of Delos.

Athens’ power was based on its naval fleet, as Sparta’s was based on its infantry. In 482 B.C.E., just before Xerxes invaded Europe with his army, the Athenians had discovered a rich vein of silver in their territory, at Laurium. Their initial plan was to distribute this wealth among the citizens, but a certain Themistocles (ca. 524–ca. 460 B.C.E.) persuaded his countrymen to use this treasure to build up the navy. When the Persians invaded Greece and entered and sacked Athens, the Athenians were able to evacuate to the island of Salamis, thanks to their fleet, and then to defeat the Persians at sea. With his advice thus vindicated, Themistocles assumed a position of prominence—not by virtue of any particular office, but merely by force of character and persuasion. After the Persian Wars, he planned a series of walls around the city of Athens that connected the city to its harbor. Athens was thus safe from invasion and could use its fleet to wage war and provide food from abroad in time of war.

After Athens assumed leadership of the Delian League, the Athenians gradually turned this confederacy into an empire, with themselves at its head. They persuaded the member

states to cease providing ships for the common defense and simply to provide funds, which the Athenians would use to build up their own navy, ostensibly to protect all the Greeks against Persia. By the first third of the fifth century B.C.E. this “league” had become an *archē*, an “empire,” and the “dues” for the common good had become tribute paid to Athens. In 454 B.C.E. the treasury of the league was moved from Delos to Athens, ending all pretence, and in 440 B.C.E., when the island of Sámos tried to excuse itself from the league, the Athenians sent military forces to enforce their rule.

The rise of Athenian power alarmed the rest of the Greeks, and particularly Sparta, which began collecting allies to oppose Athens. In 431 B.C.E. war broke out between Athens and its allies and between Sparta and its allies. This war, called by the Athenians the Peloponnesian War because Sparta was in the Peloponnese, is the subject of the historical account by Thucydides. The war lasted 25 years, though there were a few periods of truce.

The most prominent Athenian at the outbreak of the war was Pericles (ca. 495–429 B.C.E.), who was a descendant of the aristocratic Alcmaeonidae, who had ruled Athens before the time of Solon and prevented Cylon from becoming tyrant. Like Themistocles, Pericles’ prominence had less to do with any particular political office than with his qualities as a leader, but his aristocratic lineage, even in Athens of the radical democracy, almost certainly added to his authority.

Pericles was most active in persuading the Athenians to rebuild the temples on the Acropolis, a building program that resulted in the monumental architecture visible there today—the Parthenon, the Propylaea, and the Erechtheum. He was also a staunch advocate for war with Sparta. The Spartans knew this, and in public debates among the ambassadors from cities of Greece, Spartans and their allies made frequent references to “the accursed” leader of the Athenians. This was a reference to Pericles’ aristocratic lineage and his Alcmaeonid ancestors who had killed Cylon after the would-be tyrant had taken refuge in a temple. War between Sparta and Athens came, to the satisfaction of Pericles, but in its second year he died of the plague that devastated the urban population of the city. According to the historian Thucydides, the Athenians who assumed leadership after his death were not aristocrats but demagogues, rising to power through championing the people and playing on their prejudices, and the city’s policies suffered for it.

By the end of the century the Athenians had squandered many of their advantages, having launched a disastrous expedition against Sicily in 413 B.C.E. and experienced a short-lived oligarchic coup d’état in 411 B.C.E. The Spartans, in the meantime, had begun receiving monetary and military support from Persia. The Spartans finally ambushed and destroyed the Athenian fleet at Aegospotami in 405 B.C.E. After a prolonged siege, the Athenians surrendered. The Spartans dismantled the Athenian empire, nullified the democratic constitution of Athens, and instituted an oligarchy of 30 rulers, chosen from the Athenians friendly toward Sparta.

Athenian democracy was not undone for long, however, nor was Athenian power at a permanent end in the Aegean. The Thirty Tyrants proved to be so oppressive at Athens that the Spartan general Lysander, who had instituted them in the first place, himself helped to overthrow them and restore the democracy. Athens remained an economic power in the Greek world and soon reemerged as an influential force. The rise of the city of Thebes, which allied itself with Athens, kept Sparta in check, and by the beginning of the fourth century B.C.E. Athens and Thebes had fought Sparta to a standstill in the so-called Corinthian War, Athens had reestablished an Athenian Confederacy, including many cities and islands in the Aegean, and Spartan power was fading.

MACEDONIA: PHILIP AND ALEXANDER

During the first two-thirds of the fourth century B.C.E. the main powers in the Greek world were Athens, Thebes, and Sparta, which spent these years struggling for supremacy. First, Thebes and Athens united to resist Sparta. Later, Athens and Sparta united to resist Thebes. In the 350s B.C.E. a war broke out over control of the sanctuary at Delphi, the site of a temple of Apollo. Thebes took one side of this conflict and Athens and Sparta the other. This was called the Third Sacred War, and it went on for four years without any resolution until the Thebans called for help from a new power in the Greek World: Philip, king of the Macedonians.

Philip had become king of Macedonia in 359 B.C.E. and spent the decade of the 350s unifying the small, semiautonomous principalities of northern Greece. He expanded Macedonian territory by seizing from Athens some territories in the north, including Amphipolis, which had rich gold mines. He also reformed the Macedonian military, making it a formidable fighting force. By 352 B.C.E. all the Greeks recognized that Philip's army would be decisive, and his entry into the Third Sacred War was enough of a shock to bring about a truce.

Philip settled that conflict reasonably and became increasingly involved in political affairs among the cities of the Greek mainland. In 348 B.C.E. he seized Olynthus, another territory that the Athenians considered to be theirs, causing alarm in Athens and Thebes. The Athenian orator Demosthenes (384–322 B.C.E.) gave a series of speeches to the democratic assembly urging the city to oppose Philip with all its power. In these speeches, the "Olynthiacs," the orator describes the relative strengths and weaknesses of Athens, a democracy where decisions were made collectively, comparing it with Macedonia, a military autocracy in which Philip could move and strike where and when he saw fit, with no cumbersome process of deliberation.

In 338 B.C.E. Athens and Thebes joined forces to oppose Philip's power. Their armies fought a battle at Chaeronea, near Thebes. Philip won a complete victory, with his 18-year-old son Alexander leading a unit of cavalry. For the first time since the Bronze Age, if ever, a single military power was dominant in Greece. Philip established the League of

Corinth, ostensibly a kind of United Nations to manage international affairs among the cities of Greece, its charter being a Treaty of Common Peace. In reality, however, this league was the instrument of Philip's will and the means by which Macedonia exerted authority over all the cities of the Greek mainland. Philip's first plan was to expand his power and remove a significant threat by invading Asia and going to war with the Persian Empire. As plans for this invasion were under way in 336 B.C.E., Philip was assassinated, leaving rule over the Macedonians and the Greeks to his son, Alexander.

The Greeks saw this as their opportunity to throw off Macedonian rule, and once again Athens and Thebes came together to fight for their freedom. Seeing their opportunity when Alexander took his army north to put down an uprising of the Illyrians, the Greeks moved to march toward Macedonia and bring an end to the Treaty of Common Peace and the League of Corinth. Alexander proved as capable a leader as his father. He moved south faster than anyone could have expected, defeated this rebellion, and destroyed the city of Thebes. The next year, 334 B.C.E., Alexander led his Macedonian army across the Hellespont into Asia to go to war with the Persian king Darius III.

Alexander's campaigns in Asia lasted from 334 until his death in 323 B.C.E. They mark the beginning of a period when Macedonian Greeks ruled over much of the Greek-speaking world east of Sicily and over much of the Near East. After defeating Darius at Issus in 333 B.C.E., Alexander took control of Egypt in 332 B.C.E. and then all of the Persian Empire between 331 and 324 B.C.E., having marched to the Punjab in India, having sailed down the Indus River to the India Ocean, and having marched across the deserts to the former Persian capital of Susa.

Alexander seems to have sought to create a multicultural empire. Upon returning from his march to India, he arranged for the marriage of hundreds of his officers with Persian brides and sought to unify his Macedonian forces with his newly acquired Persian army. These specific plans went unfulfilled. Alexander died of a fever, leaving only an infant son, born of a Bactrian woman named Roxana, and a group of experienced and ambitious Macedonian generals. According to the historian Arrian, when asked on his deathbed to whom he would leave his empire, Alexander replied, "To the strongest." In the decades that followed, Alexander's goal for a mingling of Greek and eastern cultures in a long-lasting Macedonian dynasty was fulfilled, piecemeal, by his successors, but not without a great deal of intrigue and warfare.

THE SUCCESSORS, ROME, AND AFTER

Alexander had left his general Antipater (ca. 397–ca. 319 B.C.E.) behind to rule over the Greek mainland. This Antipater did with some effort, having to fight and win a war against the Spartan king Agis III and having to deal with a certain amount of Athenian intransigence. Upon news of Alexander's death, the Athenians once again made an effort for their freedom, launching a war northward against Antipater and his

son, Cassander. This so-called Lamian War can be seen as the last event of the Classical Period of Greek history, the last act of an independent city-state. The Athenians lost, the Macedonians executed the most outspoken of the public orators, and Athens was never again to act as an autonomous state.

After Alexander's death, his general Ptolemy acted quickly to secure a kingdom for himself, taking control of Egypt and resisting efforts by his former colleague Perdiccas. Seleucus seized the eastern parts of the former Persian Empire around Babylon. Lysimachus took the territories north of the Aegean, in Thrace, and Antigonos (called "the One-Eyed") took the western territories of Asia Minor. Cassander succeeded his father Antipater in control of Greece. By 311 B.C.E. this new order had stabilized, and Greek-speaking Macedonians had founded dynasties that would last until the rise of Rome.

Of these new dynasties, that of Ptolemy was the most stable. Affecting the style of Egyptian rulers for millennia, these Macedonian kings and queens reused the same names, Ptolemy for men and Cleopatra—a traditional Macedonian name (Alexander the Great had a sister and an aunt named Cleopatra)—for women, and they tended to marry brothers and sisters. The line lasted from 305 until 44 B.C.E., from Ptolemy I to Ptolemy XIV and his sister, Cleopatra VII, whose alliances with Julius Caesar and Mark Antony make her the most famous member of the Ptolemaic Dynasty. Under the Ptolemies, Egypt became a center of culture and learning. The city of Alexandria, founded by Alexander in 332 B.C.E., became the focus of learning for the western world, its library boasting scholars like Euclid, the mathematician, and Aristarchus, the great editor of the Homeric poems.

Pergamum (modern-day Bergama, Turkey), which came to be ruled by the Macedonian dynasty of the Attalids in the third century B.C.E., also vied with Alexandria as a cultural center to the extent that the Ptolemies issued an embargo on the export of papyrus to Pergamum. Faced with a lack of paper for books, the scholars of Pergamum, then under the rule of Eumenes, began using animal skins: this "Pergamum sheet," or *pergamena charta* in Latin, evolved into the word *parchment*. The dynasties of Macedonian rulers made the Greek language the universal tongue of politics and commerce in the eastern Mediterranean world. This lasted long after the Seleucid, Ptolemaic, and Antigonid dynasties had fallen from power in the face of the expansion of Rome.

The patronage that the Ptolemies and Attalids showed toward scholarship helped make Greek the language of culture and learning as well. Added to this was the continued influence of Athens, which may have lost its political and military empires after the fourth century B.C.E. but continued to rule over an intellectual empire. The classical tragedies of Aeschylus, Sophocles, and Euripides; the philosophy of Plato's Academy and Aristotle's Lyceum at Athens; the histories of Herodotus and Thucydides; the oratory of Lysias and Demosthenes, all these continued to set the standard for literary art well into the Roman Empire. Roman aristocrats sent their sons to Athens to study and become cultured.

The combination of an Athenian cultural empire with the political dynasties of the Macedonian successors to Alexandria explains why Greek culture was so ubiquitous throughout the Mediterranean world. The great Roman Julius Caesar, in moments of stress, naturally spoke Greek—upon crossing the Rubicon he exclaimed a line from the Greek poet Menander, and his dying words, according to the Roman historian Suetonius, were not "Et tu, Brute?" (Latin for "You too, Brutus?") but the words "*Kai su, tekne?*" (Greek for "You too, child?"). Likewise, Saul, who became the early Christian apostle Paul, a Jew from Tarsus in Cilicia (modern Turkey) and a Roman citizen, wrote fluent Greek, as did all the Jewish authors of the books of the Christian New Testament.

Roman rule eventually absorbed these Greek dynasties or reduced them to subordinate status as client-kingdoms. But in the late third century C.E. the emperor Diocletian (r. 284–305 C.E.) split the Roman Empire into parts for more efficient governance. By the fourth century C.E. the most active site of Roman rule was in the emperor Constantine's city of Constantinople, formerly the city of Byzantium. By the sixth century the Roman Empire had given way to a Byzantine Empire that was more Greek in culture and spirit than it was Roman—in 628 C.E. the Eastern Roman Empire officially stopped using Latin terms for political offices, in favor of a return to much older Greek terms. This last empire of the ancient Greek world would last until the Turks seized Constantinople in 1453 C.E.

ROME

BY KIRK H. BEETZ

THE FIRST KINGS (CA. 753–CA. 510 B.C.E.)

The earliest years of Rome's existence are mysterious. The names of kings and when they ruled are taken from Roman historians of the first century B.C.E., whose sources may have been only oral tradition. According to the ancient Romans, the city of Rome was founded in 753 B.C.E. by Romulus, who was supposedly descended from Aeneas, a refugee from the Trojan War.

Graves from the mid-800s B.C.E. have been found around Palatine Hill, where Rome began as a village. Also on Palatine Hill are the remains of a house dating from the 900s or 800s B.C.E., showing that the area was inhabited before the traditional date given for the founding of Rome. The traditional dates for Romulus's reign are 753 to 717 B.C.E. The reign of the next king, Numa Pompilius, was 715 to 673 B.C.E. He and his successors were probably real people, and he is remembered as a peaceful king. By the reign of Tullus Hostilius (r. 673–642 B.C.E.), Rome was growing from a village to a small town. Tullus Hostilius waged military campaigns to enlarge Rome's territory, and his successor Ancus Marcius (r. 642–617 B.C.E.) continued to expand Rome's lands until they stretched to the mouth of the Tiber River in the west.

Ancus Marcius was Sabine by ancestry, and his successor, Tarquinius Priscus, also called Tarquin I (r. 616–578 B.C.E.), was Etruscan. The Etruscans were the dominant military and political power in the region of Italy where Rome was situated. Tarquinius Priscus undertook major public works in Rome, which was expanding because of trade. The city was the best place to cross the Tiber River, and many merchants passed through it. Tarquinius Priscus drained the swamp at the base of Palatine Hill and built the Roman Forum on the newly dry land. He also built the Capitol, in which temples to Rome's patron gods would be housed, and in it he built the temple to Jupiter, Rome's chief god.

By the time of Tarquinius Superbus, meaning Tarquin the Proud (r. 534–510 B.C.E.), Rome had about 40,000 residents and had formed an aristocracy of wealthy people, called patricians. In 510 B.C.E. Sextus, a son of Tarquinius Superbus, raped an aristocrat's daughter, Lucretia. This enraged the aristocrats, and under the leadership of Lucius Junius Brutus they rebelled and threw the Tarquin family out of Rome. They established the Roman Republic, which was ruled by the Senate, composed of aristocrats. Tarquinius Superbus returned with an Etruscan army to retake Rome but was stymied by the Romans. Probably under the leadership of Brutus, Rome formed an alliance with other cities in the region; united, they defeated the Etruscans at Aricia in 506 B.C.E. and formed into independent city states.

THE REPUBLIC (CA. 509–27 B.C.E.)

Although ultimate political authority rested with the Senate, the new constitution for Roman government called for two executives, called consuls, to run the government jointly for one year at a time, with an annual election of consuls by the Senate. One of the first of the early consuls was Brutus, who served in 509 B.C.E. In times of war the Senate could appoint a dictator who would rule with almost absolute power. Lucius Quinctius Cincinnatus, who was dictator in 458 B.C.E., set an important precedent by voluntarily relinquishing his power after defeating Rome's enemies, even though he could have used the army he commanded to make himself king.

Marcus Furius Camillus may have been dictator as many as five times. He may have first been declared dictator in 390 B.C.E., when Gauls sacked Rome. Perhaps he rallied the spirits of the Romans and persuaded them to rebuild their city. In 367 B.C.E. he was declared dictator when the Gauls threatened to invade Rome, again. He seems to have followed the precedent set by Cincinnatus by relinquishing his dictatorships when his tasks were done.

For the dictatorship of Quintus Fabius Maximus Verrucosus in 217 B.C.E. archaeology has found evidence to support the basic events found in Roman accounts. Fabius served as consul in 233, 228, 215, 214, and 209 B.C.E. and was named dictator in 217 B.C.E. He was sarcastically nicknamed "Cunctator," meaning the Delayer, because of his policy of avoiding direct confrontations with Hannibal's army, always trying to draw the Carthaginian army away from attacking the city

of Rome. Later, after other commanders suffered disastrous losses in direct confrontations with Hannibal's forces, the nickname became one of honor, in recognition of the wisdom of his delaying tactics.

Fabius opposed the plans of Publius Cornelius Scipio, also known as Scipio the Elder. Scipio served as consul in 205 and 194 B.C.E. In 205 B.C.E. Rome was still at war with Carthage. Scipio wanted to take the war overseas by attacking the city of Carthage. Fabius and other senators regarded this plan as too dangerous, and the Senate refused to fund Fabius's military plans. Scipio went to Sicily and raised and equipped an army. In 204 B.C.E. the Senate refused financial and military support to Scipio's venture but gave its consent to his invading North Africa. Scipio succeeded in leading his forces to victory and ending the war.

An office representing the plebeians, or common people, in government had evolved, called the "tribune." Tiberius Gracchus and his younger brother Gaius Gracchus tried to use the office of tribune to reform Roman society. When the Senate blocked his reforms, Tiberius Gracchus took the matter to the popular assembly, the Concilium Plebis, which passed his reforms. He ran for reelection as tribune, and on election day he and hundreds of his supporters were murdered by followers of the Senate. Gaius Gracchus served two terms as tribune (123–22 B.C.E.) He tried to enact his brother's reforms and was mostly successful. After he was defeated for a third term, Gaius Gracchus and his supporters were set upon by henchmen of the Senate; about 3,000 of them were murdered in a day, with Gaius Gracchus either committing suicide or being murdered by bounty hunters eager to collect a reward of gold.

Powerful individual leaders gradually gathered to themselves the power to run Rome. Among them was Gaius Marius, who served as consul seven times between 107 and 86 B.C.E. He was a political and social reformer as well as a military leader, and he was willing to use the threat of his troops, who were more loyal to him than to Rome, to enforce his wishes over opposition by the Senate. Much of his work was undone by Lucius Cornelius Sulla, who was dictator from 82 to 79 B.C.E. He was a successful general who championed aristocratic dominance of society and government. He ruled with almost absolute power and condemned to death without trial thousands of people, with his soldiers enforcing terror in the streets of the city of Rome. He set a precedent for Roman military commanders by taking control of the city by military force. In an effort to shore up the privileges of the Senate, he rewrote Roman laws, placing courts under patrician control and granting patrician jurists immunity from prosecution for taking bribes. So thorough was he in restructuring Roman law that later Romans confessed that even though they disliked some of the laws, they did not know how to change them all and keep Roman society intact. Sulla chose to retire in 79 B.C.E.

JULIUS CAESAR (100–44 B.C.E.)

The next powerful figure was Gnaeus Pompeius Magnus, later known as Pompey the Great. As a military commander he

had won significant victories in the Near East and had added Syria to Rome's domains. In 62 B.C.E. he entered into a contest for power against the wealthy Marcus Licinius Crassus and Gaius Julius Caesar. In 60 B.C.E. the three of them divided the rule of Rome, forming the First Triumvirate (60–53 B.C.E.). Pompey championed the rights of commoners and was immensely popular. Crassus was not only wealthy but clever, a master of the workings of government. In Caesar they faced one of history's most remarkable people: a brilliant writer, an artful propagandist, a master planner, and an outstanding military leader.

In 59 B.C.E. Caesar served as consul and then he took charge of Rome's provinces in southern Gaul, in modern southern France. He conquered most of Gaul, making the Rhine River Rome's new northern boundary. He marched into Italy with his army in 49 B.C.E. Crassus had already died, in 53 B.C.E. This left Pompey to face Caesar. Pompey formed an army near the Adriatic Sea, north of Greece. Caesar chased Pompey's army south to the city of Pharsalus, where he defeated Pompey, who fled across the Mediterranean Sea to Egypt, where he was murdered. Caesar became dictator of Rome (49–44 B.C.E.), where his popular reforms angered senators. It was clear that he could become king if he wanted to do so, but he chose to retain the institutions of the Roman Republic in order to give the outward appearance of honoring Roman traditions. On March 15, 44 B.C.E., while conducting public business, he was murdered by a group of senators.

JULIO-CLAUDIAN DYNASTY (27 B.C.E.–69 C.E.)

Caesar had an adopted son, Octavian (later called Augustus, 63 B.C.E.–14 C.E.), who was nearly as remarkable as he was. Octavian and one of Caesar's generals, Marcus Antonius (now known as Mark Antony, ca. 82–30 B.C.E.), joined forces to fight the senators who had murdered Julius Caesar. In 42 B.C.E. their army decisively defeated the army of the assassins, and they formed the Second Triumvirate (43–36 B.C.E.), in which Octavian controlled the western part of the empire, Antony controlled the eastern part of the empire, and Marcus Aemilius Lepidus controlled the rest of Rome's North African territory. In about 36 B.C.E. Lepidus tried to overthrow Octavian but failed. He lived until 13 B.C.E., known as the incompetent member of the Second Triumvirate.

Antony became fascinated by Egypt's Cleopatra VII. She was not physically beautiful, but her exceptional intelligence and charming personality were attractive to powerful men. Her influence on Antony was resented in Rome, and her meddling in Roman politics may have been one of Octavian's motivations to go to war against Egypt in 32 B.C.E. Another motivation was that Antony had married Octavian's sister, making his relationship with Cleopatra an insult to Octavian's family. In 31 B.C.E. the Roman and Egyptian navies battled at Actium, a port on the west coast of Greece. Octavian had more ships, and Antony and Cleopatra poorly

led their forces. After the Egyptians were soundly defeated, Antony and Cleopatra fled back to Egypt. In 30 B.C.E. Antony and then Cleopatra committed suicide, and the entire empire was Octavian's.

Like his adoptive father, he chose to retain the outward appearance of the Roman Republic. From 31 to 23 B.C.E. he held the title of consul. In 27 B.C.E. the Senate proclaimed him Augustus, meaning First Citizen, instead of emperor, and he made a point of appearing to consult with the Senate and government officials. Nonetheless, all knew he was emperor, and during his reign (27 B.C.E.–14 C.E.) he reshaped the Roman government into an imperial one. He sponsored massive construction projects throughout the empire and especially in Rome. He personally took on the responsibility of feeding the poor and the homeless.

When he died, he was succeeded by a successful general, his stepson, Tiberius (r. 14–37 C.E.), who had little taste for government and spent most of his reign living outside Rome. He was succeeded by Caligula (r. 37–41 C.E.), a nickname based on the name for his favorite kind of coat. He began well and had much popular support, but he was self-indulgent and cruel to a level that became intolerable to some of the patricians, who assassinated him.

The Praetorian Guard, the bodyguards of the emperor, proclaimed Claudius (r. 41–54 C.E.) emperor. He seemed an unlikely choice, chronically ill and a stammerer, but he was a strong ruler. He undertook important public works projects, such as widening the port at Rome, and he succeeded where Julius Caesar had not, by leading an invasion of Britain that resulted in bringing the southern half of what is now England into Roman domination. It is possible that he had reason to believe the young man he adopted as his successor would be a good ruler. This was Nero (r. 54–68 C.E.), who started out well. He listened to his advisers and engaged in valuable building projects, and he was popular at first. He was cruel, however, and he lost the support of the patricians. In 65 C.E. some senators conspired to kill him, but they failed. In 68 C.E. leaders in Spain and Gaul rebelled against him. Even though the rebellion in Gaul was put down, Nero had lost all support in government, and a leader from Spain, Servius Sulpicius Galba (r. 68–69 C.E.), was a dire threat. Nero committed suicide in 68 C.E.

FLAVIAN DYNASTY (69–96 C.E.)

Galba was assassinated in January 69 C.E., at the hands of Marcus Salvius Otho (r. 69 C.E.), who succeeded him. Otho was deposed by the Roman legions from the Rhine, and their general, Aulus Vitellius (r. 69 C.E.), became emperor. Roman legions in the eastern empire declared General Vespasian (r. 69–79 C.E.) emperor, and those in the Danube soon followed suit. The legions from the Danube, led by General Antonius Primus, defeated Vitellius's army in September 69 C.E., making Vespasian emperor. He was succeeded by his sons Titus (r. 79–81 C.E.) and Domitian (r. 81–96 C.E.). They consolidated Rome's hold on its territories.

ADOPTIVE EMPERORS (96–197 C.E.)

The Adoptive Emperors Era was one in which the Roman emperors rejected the idea of emperors being succeeded by natural-born sons. Instead, they each adopted a man they considered to be an able leader, thereby making that man next in line to the throne. Thus, Emperor Nerva (r. 96–98 C.E.) adopted a man from Spain, Trajan (r. 98–117 C.E.).

Trajan was an empire builder. The kingdom of Dacia, in present-day Romania, posed a threat to Rome. The Dacians had fought and defeated the Romans in the past. From 101 to 102 C.E. Trajan's legions fought Dacia to an apparent stalemate. Trajan tried to negotiate a settlement with the Dacian king, but the king ended negotiations in 105 C.E. Trajan invaded Dacia, overcame its army, and made it a province of the Roman Empire. From 114 to 115 C.E. Trajan conquered Armenia and much of northern Mesopotamia, adding them to the empire. His legions fought the Parthian Empire and advanced through southern Mesopotamia to the Persian Gulf, then withdrew back to northern Mesopotamia.

Trajan was succeeded by Hadrian (r. 117–38 C.E.). Rather than follow up on Trajan's gains against the Parthians, Hadrian chose to pursue peace. He had a 75-mile stone wall built across the northern frontier of Rome's territory in Britain and a 350-mile wooden one built between the Rhine and Danube rivers, each intended to keep enemies out. The purpose of the Roman army shifted from being aggressive to defensive. Historians often mark Hadrian's reign as the era in which the Roman Empire's decline began, because Roman policy had shifted from seeking out enemies and defeating them to waiting for attacks and then repelling them. This gave Rome's enemies the choice of when and where to fight.

The next emperor began the Antonine Age (138–92 C.E.). He was Antoninus Pius (r. 138–61 C.E.). Whereas Hadrian had traveled all over the empire to meet with people and discuss their problems, Antoninus Pius stayed in Italy. Through diplomacy and threats, he avoided major wars. On his death he was succeeded by two men who seem to have gotten along well with each other: Lucius Verus (r. 161–69 C.E.) and Marcus Aurelius (r. 161–80 C.E.).

In 162 C.E. the Parthians invaded the Eastern Roman Empire, and Lucius Verus led an army against them. In 165 C.E. the Roman army had penetrated to the heart of the Parthian Empire and sacked the Parthian capital, Ctesiphon. In 169 C.E. Lucius Verus died of an illness, perhaps from a plague that carried off thousands of Romans. This left Marcus Aurelius as sole ruler. He was a Stoic, a follower of a philosophical discipline in which he did not allow himself to show outward emotion or allow emotion to overcome his thinking. His personal journal, known as *Meditations*, is still studied for its wisdom. In 170 C.E. the Germanic tribes Quadi and Marcomanni crossed the Danube and attacked Italy. Rome managed to repel the invasion, and Marcus Aurelius spent much of the last decade of his reign unsuccessfully trying to expand Roman domination beyond the Danube.

He was succeeded by Commodus (r. 180–92 C.E.), who paid little attention to the day-to-day business of government. Perhaps as a consequence, government corruption grew to a level that angered the Roman public. Commodus loved gladiatorial combat and sometimes participated as a gladiator himself. He was planning to participate in New Year's gladiatorial contests when he was murdered on the final day of 192 C.E., first poisoned and then strangled.

After Commodus's death, Rome quickly went through three emperors. Publius Helvius Pertinax (r. 193 C.E.) was an elderly statesman and general who was murdered by the Praetorian Guard. Marcus Didius Julianus (r. 193 C.E.) was overthrown and killed by the general Lucius Septimius Severus (r. 193–211 C.E.). Severus faced two rival emperors. One was Pescennius Niger (r. 192–94 C.E.), whose army Severus defeated in three battles in the Near East; Niger was murdered in Antioch. The other was Decimus Clodius Septimius Albinus (r. 193–97 C.E.), who took four years to dispose of. Although he was originally from North Africa, Albinus was the governor of Britain. He had the support of much of the Senate. Severus defeated his army near Lyon, in modern France, in 197 C.E.

SEVERAN DYNASTY (193–268 C.E.)

The founder of the Severan Dynasty, Severus was from North Africa. He was married to a Syrian priestess, Julia Domna. Severus was a dynamic and aggressive leader who tried to shift the Roman Empire back to attacking its enemies rather than defending against them. From 195 to 198 C.E. he seized territory from the Parthians, founding a pair of new provinces in the captured lands, and he established a new province in North Africa while extending Roman authority southward. He tried but failed to expand Roman rule northward in Britain, to encompass modern Scotland. He left his empire to his sons, Caracalla (r. 211–17 C.E.) and Geta (r. 211–12), who was murdered by Caracalla. Caracalla granted Roman citizenship to all free men in the empire in 212 C.E.

The succeeding Roman emperors had to deal with multiple threats from within and outside the empire. From within came assassination conspiracies; from without came attacks from the Alemanni Germans across the Rhine, the Goths who had settled in Ukraine, and the Parthian Empire, now under the rule of a new Persian Dynasty, the Sassanids. In 260 C.E. Emperor Valerian (r. 253–60 C.E.) was captured and killed by the Sassanids. Valerian's son Gallienus (r. 253–68 C.E.) tried to use diplomacy to hold the empire together and stave off its enemies, but Gaul seceded to form its own nation, and provinces in the east tried to become more independent of Rome.

The breakaway nation of Gaul had three emperors: Postumus (r. ca. 258–68 C.E.), Victorinus (r. 268–270 C.E.), and Tetricus (r. 270–274 C.E.). In 260 C.E. Postumus created the Gallic Empire, and in 261 C.E. he had control of Spain, Britain, and the Germanic territories in central Europe as well as the Gallic provinces. The Gallic Empire issued coinage and held off the

Germanic tribes that wanted to loot Gaul. After about four years of war, Tetricus's reign was ended in a battle in northern Gaul by Roman emperor Aurelian (r. 270–75 C.E.).

ILLYRIAN EMPERORS (268–305 C.E.)

The Illyrian emperors were primarily army officers from the Balkans. For most of their reign they tended to be murdered by their troops and replaced by another officer. The first Illyrian emperor was Claudius II (r. 268–70 C.E.), who was also called Gothicus. He defeated the Goths and drove them back beyond the Danube. His successor, Aurelian, recovered the lost territories in the east and reclaimed Gaul. Eventually Carus (r. 282–83 C.E.) invaded the Parthian Empire, and again the Romans sacked the Parthian capital, Ctesiphon.

The most important of the Illyrian emperors was Diocletian (r. 284–305 C.E.). He established elaborate royal ceremonies that kept him remote from the general populace, perhaps to lessen the opportunity for assassination. To make the Roman Empire more secure internally, he separated the military from the civil authority in the provinces, making it harder for a governor to declare himself independent of Rome. Further, he broke Rome's provinces into many smaller provinces to make sure no single province could become powerful enough to challenge the central government. To make the Roman Empire more secure externally, he increased Rome's standing army by about 100,000 troops to more than 400,000. In addition, he made sure soldiers were paid well, in full, and on time.

THE TETRARCHY (284–337 C.E.)

In 285 C.E. Diocletian decided to share power because he was overwhelmed by all the work that needed to be done to preserve the Roman Empire. That year he appointed Maximian (r. 286–305 C.E.) to be a junior emperor, but in 286 C.E. he made Maximian a senior emperor, placing Maximian equal to himself. When they added two junior emperors who had separate responsibilities for the eastern and western parts of the empire, their government became a tetrarchy, meaning four rulers.

In 305 C.E. Diocletian and Maximian chose to retire, leaving governance to their junior emperors, who then became senior emperors. One of them was Constantius I (r. 305–6 C.E.). He had been in charge of the Western Roman Empire, and when he died the western provinces expected his son Constantine I (r. 306–37 C.E.) to become emperor. In 306 C.E. Maxentius (r. 306–12 C.E.), the son of Maximian, declared himself emperor. This resulted in a series of civil wars that ended the Tetrarchy and concluded in 324 C.E. with Constantine I as sole emperor.

HOUSE OF CONSTANTINE (306–364 C.E.)

Constantine I became known as Constantine the Great. In 312 C.E. he invaded Italy and fought and defeated the army of Maxentius at Augusta Taurinorum, modern-day Turin, and Aquileia, modern-day Verona, but Maxentius was a tough opponent with an army that was determined to win.

Before the climactic Battle of Milvian Bridge in central Italy, Constantine I had a vision of the Christian cross and heard a voice that said he would win if he carried the cross into battle, which he did. Although he waited until he was on his death bed to be baptized, he considered himself a Christian from that time on. Thousands of Christians had been slaughtered as enemies of the state during the reign of Diocletian, making Constantine's conversion very dramatic.

He agreed to allow Licinius (r. 308–24 C.E.) to rule the eastern empire, including Egypt, while he ruled the rest of North Africa as well as the western empire. In 316 C.E. Constantine I seized the Balkans and Greece, which had been under Licinius's rule. In 324 C.E. he advanced into Thrace, where he decisively defeated Licinius's army at Adrianople, present-day Edirne, and won the rest of the Roman Empire.

During his reign Constantine I strengthened the empire's army and defenses, especially along the Danube, where he built defensive earthworks. He was deeply involved in Christian affairs, even joining in theological meetings about the future course of Christianity. He built churches in Jerusalem at holy sites, such as the cave where Christ had been interred. In 330 C.E. he moved the capital of the empire to Byzantium, modern-day Istanbul, and renamed it Constantinople.

Constantine I left his empire to his sons, Constantine II (r. 337–40 C.E.), Constans I (r. 337–50 C.E.), and Constantius II (r. 337–61 C.E.), as well as to Flavius Iulius Dalmatius, the son of his stepbrother. His sons murdered Dalmatius. Constantine II was killed fighting Constans; Constans was killed by the self-proclaimed emperor Magnentius (r. 350–53 C.E.); Constantius II died of an illness. Their cousin Julian (r. 361–63 C.E.) seized power. Before Julian challenged Constantius II for the throne, he had distinguished himself with victories over Germanic tribes at the Rhine. Julian believed in the traditional Roman gods and tried to suppress the Christian faith. In 363 C.E. he invaded the Parthian Empire, but he was killed in battle.

HOUSE OF VALENTINIAN (364–395 C.E.)

In 364 C.E. the Roman Empire was divided into west and east. The west was ruled by Valentinian I (r. 364–75 C.E.), and the east was ruled by his brother Valens (r. 364–78 C.E.). In 357 C.E. the Germanic tribe the Visigoths fled the Huns into the Balkans of the empire. In 378 C.E. Valens tried to drive the Visigoths out of the empire, but he was killed and his army defeated at Adrianople. In the west Valentinian I had been succeeded by his son Gratian (r. 375–83 C.E.), who appointed the general Theodosius I (r. 379–95 C.E.) ruler of the eastern empire. In 382 C.E. Theodosius I and the Visigoths made a peace treaty that allowed the Visigoths to settle in the Roman Empire. From 394 to 395 C.E. Theodosius I ruled both east and west of the empire.

HOUSE OF THEODOSIUS (379–565 C.E.)

The Visigoths tried invading Italy in 401 C.E., during the reign of Theodosius I's son Honorius (r. 395–423 C.E.), but

they were defeated in battle by Honorius regent Stilicho. Honorius ruled the western empire while his brother Arcadius (r. 383–408 C.E.) ruled the eastern empire. Arcadius was succeeded by Theodosius II (r. 408–50 C.E.), whose eastern part of the empire prospered. Another Germanic tribe, the Vandals, invaded the empire in 406–9 C.E., raiding all the way to the southern coast of Spain. In 410 C.E. the Visigoths again invaded Italy and sacked Rome. Honorius lost control of Spain, much of Gaul, and Britain.

In 429 C.E., during the reign of the western emperor Valentinian III (r. 425–55 C.E.), the Vandals crossed the Mediterranean Sea and invaded North Africa. In 439 C.E. they conquered Roman Carthage. That Valentinian III managed to hold together fragments of his empire was remarkable. Even more remarkable was his defeat of the army of Attila the Hun in 453 C.E. His successors became dependent on Germanic generals and kings to protect them. In 476 C.E. the last western emperor, Romulus Augustulus (r. 475–76 C.E.), was forced to resign by the dominant Germanic tribe in Italy, the Ostrogoths.

THE AMERICAS

BY J. J. GEORGE

The concepts of *empire* and *dynasty* usually imply a state-level society with organizational and administrative features tied to decision making and hierarchy. Scholars focus on different traits to establish a definition of state, and exact definitions are hard to apply. Territory, use of force, the presence of an overarching government, well-developed divisions of labor, the underlying structural features of decision making and authority, and the mechanisms that enhance and preserve the privileges of certain social groups are some of the criteria scholars focus on to classify a type of societal structure. The Americas of the ancient period was replete with social units that ranged downward from complex, hierarchical societies to intermediate units with seasonal subsistence groups coalescing at temporary villages to basic units of hunter-gatherers.

Anthropological definitions of the state as well as its material indicators in the archaeological record are closely linked to the theoretical framework in which the concept of the state is developed. Definitions that focus on political power and social classes tend to define states broadly, with many archaeological cases fitting the definition. Some scholars have even argued that the existence of social classes in and of itself is the defining feature of state organization. Other scholars have argued that the existence of any monumental construction elaborate enough to necessitate coordinated labor above the household is evidence for state organization.

Assuming that some of the basic social, economic, and political criteria defining the state are present in a given society, empires are then the result of a process of state expansion that encompasses peoples who previously had separate ethnic or state identities. Empires can express a variety of relationships and spatial forms, where distant realms may

be conquered or absorbed even though the local institutions and often the local royal line are kept in place in return for fealty, tribute, or other special concessions. The opposite also may be true, whereby strong reorganizational efforts occur, including the resettlement of populations to the capital, thus dramatically altering the previously existing system of society, rulership, and authority.

RULERSHIP

Rulership in the Americas took the form of family or kin group leaders, tribal chiefs and petty princes with little authority and small domains, or powerful kings and emperors commanding tens of thousands of subjects, supervising impressive bureaucracies, and enforcing their will through military might. By 500 C.E. rulership conformed to the general pattern of early states elsewhere in the world. Kings, often thought to be divinely ordained or even godlike, were supreme, hereditary rulers of complex societies with the legitimate authority to enforce their decisions. As occupants of the highest-status position they were responsible for all state functions—administrative, military, religious, judicial, and redistributive—although the relative importance of these functions varied from one culture to another.

Dynastic rule and kingship rarely followed a strict rule of primogeniture, or the exclusive right of inheritance belonging to the eldest son. Dynastic election usually involved choosing the next ruler from a range of eligible persons, almost invariably from close relatives already in high positions of authority. However, there is also strong evidence of patrilineal descent at specific sites that suggests a dynastic genealogy of more immediate, familial succession. For example, among the later Maya it was of great importance to be able to trace one's ancestry along both patrilineal and matrilineal lines to an ancient ancestry, because society was divided into strict classes. Therefore, tracing a line of noble lineage was socially more advantageous than tracing a line with commoner roots. The situation varied, of course, as the institutions of kingship and power varied from region to region over time.

NORTH AMERICAN SOCIETIES

Direct evidence of empire and dynasty is scarce for ancient North America and generally supports sociopolitical structures more in line with hunter-gatherer societies, chiefdoms, associated villages, or interaction spheres. Although it is difficult to tell chiefdoms from empires archaeologically, the material footprint of many early North American sites suggests sociopolitical mechanisms less pervasive than an empire. It appears, then, that more localized, indigenous florescences were characteristic, as opposed to a centrally operated, state-supported expansion.

For example, the Adena and Hopewell cultures of the Early and Middle Woodland periods (1000 B.C.E.–500 C.E.) spread throughout the central United States over a number of sites in proximity to the Missouri, Mississippi, and Ohio river systems. There mortuary ceremonialism, the presence

of earthen mounds, interregional exchange, and artistic development clustered loosely affiliated villages under an umbrella of regional extent. The lack of a centralized administrative, bureaucratic, or militaristic complex prohibited the sort of cohesive growth and expansion evidenced in empire states elsewhere. Although these mound builders apparently gathered periodically for funeral ceremonies and construction, most of the year the population was widely dispersed in small, temporary villages. Given the light trace of archaeological data and a complete absence of written history, evidence of dynastic history and major political leaders is impossible to infer. Compared with their Mesoamerican neighbors, a North American example of an empire or dynasty is virtually nonexistent in the ancient period.

THE OLMEC

The Olmec civilization represented the first successful kingdom in Mesoamerica, flourishing in the tropical lowlands of Mexico's Gulf Coast of modern-day Tabasco and Veracruz, a water-logged region of meandering rivers, from around 1500 to 400 B.C.E. Although the causes of the evolution from rank societies to kingdoms remains to be determined, it is clear that the subsequent flowering and spread of Olmec civilization for the next half millennium was intimately tied to the creation, display, and manipulation of monumental and portable art objects.

The Olmec had novel governmental practices based upon social stratification and kingship. Their earliest monumental sculptures included stone thrones weighing several tons and naturalistic, three-dimensional depictions of rulers, carved as either colossal heads or full figures. Between the ninth and fifth centuries B.C.E. stone carving shifted from three-dimensional forms to high- and low-relief narrative carvings, much of which is thought to portray divine kings dressed in the costume of corn deities. Other small stone statuettes are thought to depict kings in shamanic transformation. The distribution of Olmec painted pottery and figurines outside the heartland suggests not only the spread of the Olmec artistic canon but possibly also accompanying practices of governance, the nature of which is still debated. Attempts to designate the Olmec tend to shift between classification as a civilization, complex chiefdom, kingdom, state, or empire.

The major Olmec sites—San Lorenzo, La Venta, and Tres Zapotes—all contained large ceremonial structures. San Lorenzo was the largest site and was thought to yield a population of between 10,500 and 17,000 persons. Olmec public-works projects that were probably kingdom-sponsored activities include the mining, transport, and subsequent fabrication of colossal stone monuments from as far as 60 or 70 miles away; the construction of massive terraces, plazas, elite residences, platforms, and systems of elaborate stone drains; significant activities related to dragging the stones, including cutting paths through the jungle or building roads and bridges; the production of enough food for the thousands of persons necessary to transport the stones from distant work-

shops; long-distance trade; and the production of goods for export. It is also believed that San Lorenzo was the capital of a kingdom that had secondary centers and tertiary villages, hamlets, and special-function sites, probably administered by princes. Individual rulers, however, have not been secured from the data, nor is it known why each of the sites was eventually abandoned.

THE ZAPOTEC

Farther south, in the Valley of Oaxaca, evidence suggests that the Zapotec hilltop site at Monte Albán was the center of an empire whose imperial aspirations began around 600 B.C.E. One of the most compelling lines of evidence for its imperial conquests comes from the site itself, in the form of one of its buildings, referred to as Building J, which is shaped roughly like an arrowhead. On this building are 50 carved stone slabs depicting dead rulers of towns thought to be subjugated by Monte Albán. It is thought that these towns define the territorial limits of Monte Albán's empire. However, evidence supporting Zapotec dominance over the full range of towns has not yet been conclusively demonstrated.

An abundance of evidence is highly suggestive of Zapotec conquest and imperial influence well beyond their immediate heartland. Evidence includes the violent destruction and abandonment of local villages; the presence of objects of intimidation, including skull racks thought to be for the display of defeated warriors; village relocation, thought to reflect Zapotec-imposed resettlement for more effective agricultural production; evidence of a frontier garrison where the Monte Albán overlords were housed; the imposition of Zapotec architecture; the elimination of ceremonial facilities and trappings; and the disappearance of products previously imported from Monte Albán and elsewhere, interpreted as resulting from the termination of reciprocal exchange.

At least three models of interaction can be used to describe the political and economic interaction of the Zapotec with their neighbors following the imperial scheme. The first model suggests that the Zapotec exacted tribute from conquered polities and allowed for local political autonomy. The second suggests an economic and imperial model of exploitation under imposed, centralized Zapotec governance. The third model suggests reciprocal economic exchange in the form of intensified trade, falling short of conquest and colonization, between independent polities. Further research is necessary to clarify the exact nature of Zapotec relations to its neighbors, though current information indicates the presence of definite imperial qualities. Although it is unclear exactly why Monte Albán fell, it seems to have done so gradually and uneventfully, its authority petering out and fragmenting as other towns in the valley became settled.

TEOTIHUACÁN

No discussion of empire in the Americas is complete without a look at Teotihuacán, 40 miles northeast of contemporary Mexico City. Between 100 B.C.E. and 700 C.E. Teotihuacán

rose and became an immense city. Its early growth was rapid, tied to advances in irrigation agriculture, and by the second century it covered about eight square miles with a population estimated between 60,000 and 80,000. Subsequent growth slowed and reached a maximum population of about 125,000, making it the fifth-largest city in the world for its time. Its great surge in urban growth around the turn of the millennium seems to signify the influence of strong-minded rulers. Moreover, it is about this time that virtually the entire population elsewhere in the Basin of Mexico disappeared, as people were evidently resettled in Teotihuacán. No other Mesoamerican city had such a large and dense urban concentration before the Aztec capital of Tenochtitlán in the late 1400s.

Territory under immediate Teotihuacán control by the fourth century B.C.E. covered at least 9,600 square miles, a radius of about 55 miles, though it may have reached considerably farther. Beyond the primary radius Teotihuacán probably concentrated on controlling key settlements and routes between them as opposed to controlling blocks of territory. Its immense prestige certainly exceeded its political sphere, but little is yet known about specific outposts. Teotihuacán moved to control the Valley of Morelos to the southeast, where cotton could be grown, a key resource for a textile industry and maintained a presence at Tula to the northwest, Cholula to the southeast, Cantona to the northeast on the route to the Gulf lowlands, and Alta Vista in Zacatecas. The Zapotec state, centered at Monte Albán in Oaxaca, maintained diplomatic relations with Teotihuacán, and there was even a barrio at Teotihuacán that is now referred to as the Oaxaca Barrio because it is believed to have exclusively housed craftsmen from Oaxaca.

Connections are also known to have run to southern Veracruz, Mirador in Chiapas, sites in highland and Pacific coastal Guatemala, and Belize. Connections are especially strong at Tikal in northern Guatemala and reflect the adoption of a limited number of Teotihuacán-related symbols by local elites for their own purposes. The influence of Teotihuacán at Tikal is secure by 360 C.E. thanks to a ruler referred to as Curl Nose in hieroglyphic inscriptions found at the site. Curl Nose was apparently a collaborationist ruler who accepted military and political advisers from Teotihuacán, which gave Tikal an edge over rival Mayan centers and allowed for further expansion.

The exact form of rule is unclear and might have shifted over time. Supreme political authority may not always have been strongly concentrated in a single person or lineage. A major apartment compound at Teotihuacán has been interpreted as residences of the heads of state, though it is unlike better-known royal palaces, such as those in Tenochtitlán when the Spaniards arrived. It seems to fit a pattern wherein the head of state controls fewer resources and can command construction projects less for his own glorification than for the glorification of the state, leading some scholars to suggest that rulership took the form of an oligarchic republic (one

ruled by a small group), which is not necessarily democratic or egalitarian. Scholars have also suggested a corporate or collective model of leadership, which may explain why there is an apparent lack of self-glorifying rulers and consequently why dynastic history is thus far unknown. Yet most of the major constructions happened early and quickly, which indicates at least a few very powerful, able, and imaginative rulers.

Far afield the military certainly played a role in securing interests as Teotihuacán gained preeminence. Scholars disagree on the exact nature, role, and extent of the military, but it is unlikely that Teotihuacán's influence over trade would have been possible had it not been able to overcome armed resistance from rival centers. Reflecting a lack of consensus, it has been suggested both that the emphasis on war was largely symbolic and that it was very real. It has been argued convincingly that the army of Teotihuacán was highly effective, efficient, and organized. Military symbolism was adapted in the lowland Maya regions, and even though conquest of the Maya seems unlikely, the city's military prestige traveled well.

In its last century the population of Teotihuacán declined significantly. Many factors might have contributed to the decline, including a failure to adapt to new styles of government, commerce, or religion developing elsewhere; a lack of income from conquests; crises from outside threats or rulers; and possibly environmental problems. The state itself was largely destroyed by fire, especially in the central part of the city. It is unknown who was responsible for the destruction, but its focused and selective results suggest to some scholars that it was an inside job. One theory proposes that a combination of dissident insiders and members of surrounding societies who had gained power could have defeated a weakened and no longer well-led city.

THE MAYA

The Maya created the most sophisticated civilization of ancient America. Their achievements in art, architecture, writing, astronomy, and calendrical notation were unsurpassed. Maya civilization developed along several lines that are continuously redefined and debated. Although development varied from site to site over time, by 150 C.E. many criteria of urbanism were present, including relatively higher population density than the surrounding countryside, a stratified society, nonfarming occupational specializations, formalized religion, markets, and a bureaucracy or civil service supported by a social surplus. The levels of organization necessary for these developments indicates the complexity of regional centers and state-level society, though they appear to have lacked the highly centralized structures typical of imperial centers. By the end of the Late Formative Period and the beginning of the Classic Period, around 150 C.E., a number of Maya sites had become large and complex, including Tikal and Mirador, and dynastic histories were recorded in combination with the advanced Maya practice of writing.

In early Classic times population growth continued, and competition among neighboring centers increased. Concentrated urban development converted regional market and administrative centers to cities. Similarly, social structural changes took place that shifted lineage heads to hereditary aristocracy. A basic feudal system developed with an aristocracy based on control of land and water and the labor to work it. By about 350 C.E. Tikal was one of the largest and best-organized centers, probably in some form of alliance with the outside imperial influence of Teotihuacán. It appears that Tikal had moved far beyond its feudal political system to more a centralized bureaucratic state, somewhat along the lines of Teotihuacán. At its height around 750 C.E. the population of Tikal reached approximately 72,000.

Dynastic lineage is known at Tikal, because ceremonial elite burials and monumental stone stelae commemorating rulership are evident in the material record. Beginning in 376 C.E. Tikal witnessed a succession of uniquely named rulers that favor the notion of lineality, with an unbroken chain of parent-child links over 11 generations. (The beginning of the lineage according to one source is as follows: Jaguar Paw, Curl Nose, Stormy Sky, Kan Boar, Bu. 160, Jaguar Paw, Bu. 195, Man from Southeast, and so on.) It is possible, therefore, that there were actual ruling lineages, and succession would have been restricted to members of a particular ruling lineage, which would favor a sociopolitical structure of rule by hereditary dynasty.

Succession at Tikal favored the patrilineal line, where the office in question passes to the son of the previous holder; in some instances, however, authority transferred through the woman's side even though a woman was never a ruler. This happened when there were no patrilineal heirs (sons or brothers) available. It appears that this happened at Tikal at least four times in the 11 documented successions, in which case the favored transition seemed to favor the husband of the daughter of the previous ruler. Ultimately, most likely the result of necessity, the rulers of Tikal were willing to suspend the rules of patrilineal succession in favor of orderly succession. Tikal maintained a prominent role in the hierarchy of Maya centers until its collapse around 900 C.E.

THE INTERMEDIATE AREA

The so-called Intermediate Area, comprising most of Ecuador, highland and coastal Colombia, western Venezuela, and Central America east of Honduras, is a region of vast environmental diversity. There was little in this area comparable to architecture on the scale of Tikal or the urban complexity of Teotihuacán, though the population achieved a high level of artistry in craft production, particularly in ceramics and metallurgy. The level of sociopolitical organization did not match anything to the north or south, and small chiefdoms of a tribal level probably developed in small villages; small chiefdoms may have developed in coastal Ecuador as early as 2200 B.C.E. More complex societies, such as at La Tolita in Ecuador and San Agustín in the highlands of southern Co-

lombia, developed between 400 B.C.E. and 200 C.E., though evidence of any dynastic history is absent and the prospects of empire far off.

THE ANDES

The central Andes region comprises modern-day Peru, western Bolivia, northern Chile, and Ecuador. It includes rugged mountains, highland grasslands, low forests, and some of the world's driest deserts. It is a particularly difficult region in which to succeed, yet the earliest and most advanced civilizations in South America managed to develop and flourish in this region. Atypical in comparison with their Mesoamerican neighbors, in western South America monumental architectural construction precedes state development. Nonstate societies are fully capable of amassing sufficient labor to build large monuments, usually through religious means. The Inca civilization, typically held as the supreme example of the South American empire model, did not evolve until the 15th century. Some scholars, however, favor a definition of empire in which a major center or capital is supported by other cities, a definition that would disqualify the Inca because of the absence of cities, despite the fact that they controlled and administered territory—militarily, politically, economically—stretching more than 3,000 miles. This example is cited to reinforce the idea that not all definitions and models are equally applicable, especially in the ancient period, and that the South American example offers its own possibilities. Nevertheless, true empires did not exist in the ancient period, even though at least two early civilizations, Chavín and Moche, provide examples that correlate with imperial tendencies.

Agriculture began in the Andean highlands of Peru by 5500 B.C.E. At the beginning of the fourth millennium B.C.E. all peoples in South America lived in small hunting, gathering, and horticultural camps or, on rare occasions, in semipermanent villages. On the coast there is evidence of nonegalitarian societies that did not rely on agriculture for a significant portion of their diet, practically unknown in other regions of the world. The consensus in the literature is that the Late Preceramic Period (until about 2000 B.C.E.) represents at most the development of ranked society typical of simple chiefdoms. No single site was the center of a regional polity. Andean sociopolitical development at this time may have had more in common with the interaction spheres of the North American Hopewell and Adena, with a network of chiefdoms linked in alliance and exchange relationships.

By the Early Horizon (800–200 B.C.E.) along the north coast of Peru, Chavín de Huántar was the apparent center of an interaction network and stylistic diffusion, which some archaeologists have interpreted as a marker of some form of interregional social or political integration. The widespread distribution of the Chavín style poses the same sort of problem as does the occurrence of Olmec figurines and ceramics in the highlands of Mexico. What degree of social, economic, political, or ideological unification is represented by the rapid diffusion of an art style? It is generally thought

that the spread of Chavín art was a reflection of the expansion of a religious cult.

Moche is the name given to the site, river valley, culture, style, and state that dominated the north coast of Peru for the first 600 years C.E. The site of Moche comprised two enormous adobe structures, the Huaca del Sol and the Huaca de la Luna. The former was the largest structure in the Americas, constructed of roughly 130 million adobe bricks. Much information on the Moche is known through the iconography of painted pottery and murals, including the division of society into specialized classes reflecting rulers, nobles, priests, warriors, slaves, messengers, servants, hunters, fishermen, and farmers. Marked differences in wealth can be inferred from the grave goods that accompany burials, suggesting a stratified society, and scenes on painted pots offer clear proof of hierarchical organization. Images of warfare, prisoner sacrifice, and portraits of important individuals leave little doubt that the Moche were a highly militarized people led by strong individuals.

The Moche mounted an expansive conquest campaign around the fourth century C.E. over neighboring valleys and subordinated those areas to the state. While the Moche clearly had a firm grip over state organization, uniting several valleys under one administrative network, the lack of expansive trade, interaction spheres, or control of distant lands, as in other empires, such as Teotihuacán and the later Inca, largely prohibit defining the Moche as an empire even though they clearly had imperial designs. Similarly, evidence

from realistic portrait vessels hints at a dynastic form of authority, but lacking further coordinating data the images remain isolated and enigmatic reminders of a once-burgeoning state. There is evidence of great floods followed by extensive droughts that not only may have interrupted what was a campaign for imperial rule but also may have led to the collapse of the Moche. At the same time the Wari Empire, the first true empire of the Andes, was growing. Although there is no evidence that the Wari conquered the Moche, their presence on the outer boundaries may have contributed to the Moche collapse around 600 C.E.

Africa

~ The Selection of Aspelta as King of Kush, ca. 600 B.C.E. ~

Now the entire army of his majesty was in the town named Napata, in which Dedwen, Who presides over Wawat, is God—he is also the god of Kush—after the death of the Falcon [Inle-Amon] upon his throne. Now then, the trusted commanders from the midst of the army of His Majesty were six men, while the trusted commanders and overseers of fortresses were six men. . . . Then they said to the entire army, “Come, let us cause our lord to appear, for we are like a herd which has no herdsman!” Thereupon this army was very greatly concerned, saying, “Our lord is here with us, but we do not know him! Would that we might know him, that we might enter in under him and work for him, as It-Tjwy work for Horus, the son of Isis, after he sits upon the throne of his father Osiris! Let us give praise to his two crowns.” Then the army of His

Majesty all said with one voice, “Still there is this god Amon-Re, Lord of the Thrones of It-Tjwy, Resident in Napata. He is also a god of Kush. Come, let us go to him. We cannot do a thing without him, but a good fortune comes from the god. He is the god of the kings of Kush since the time of Re. It is he who will guide us. In his hands is the kingship of Kush, which he has given to the son whom he loves. . . .

So the commanders of His Majesty and the officials of the palace went to the Temple of Amon. They found the prophets and the major priests waiting outside the temple. They said to them, “Pray, may this god, Amon-Re, Resident in Napata, come, to permit that he give us our lord, to revive us, to build the temples of all the gods and goddesses of Kemet, and to present their divine offerings! We cannot do a thing without this god. It is he who guides

us. Then the prophets and the major priests entered into the temple, that they might perform every rite of his purification and his censuring. Then the commanders of His Majesty and the officials of the palace entered into the temple and put themselves upon their bellies before this god. They said, "We have come to you, O Amon-Re, Lord of the Thrones of It-Tjwy, Resident in Napata, that you might give to us a lord, to revive us, to build the temples of the gods of Kemet and Rekhyt, and to present divine offerings. That beneficent office is in your hands—may you give it to your son whom you love!"

Then they offered the king's brothers before this god, but he did not take one of them. For a second time there

was offered the king's brother, son of Amon, and child of Mut, Lady of Heaven, the Son of Re, Aspalta, living forever. Then this god, Amon-Re, Lord of the Thrones of It-Tjwy, said, "He is your king. It is he who will revive you. It is he who will build every temple of Kemet and Rekhyt. It is he who will present their divine offerings. His father was my son, the Son of Re, Inle-Amon, the triumphant. His mother is the king's sister, king's mother, Kandake of Kush, and Daughter of Re, Nensela, living forever, He is your lord."

The Middle East

~ *The Legend of Sargon of Akkad, ca. 2300 B.C.E.* ~

1. Sargon, the mighty king, king of Akkadê am I,
2. My mother was lowly; my father I did not know;
3. The brother of my father dwelt in the mountain.
4. My city is Azupiranu, which is situated on the bank of the Purattu [Euphrates],
5. My lowly mother conceived me; in secret she brought me forth.
6. She placed me in a basket of reeds; she closed my entrance with bitumen.
7. She cast me upon the rivers, which did not overflow me.
8. The river carried me; it brought me to Akki, the irrigator.
9. Akki, the irrigator, in the goodness of his heart lifted me out;
10. Akki, the irrigator, as his own son brought me up;
11. Akki, the irrigator, as his gardener appointed me.
12. When I was a gardener, the goddess Ishtar loved me,
13. And for four years I ruled the kingdom.
14. The black-headed peoples I ruled, I governed;
15. Mighty mountains with axes of bronze I destroyed.

16. I ascended the upper mountains;
17. I burst through the lower mountains.
18. The country of the sea I besieged three times;
19. Dilmun I captured.
20. Unto the great Dur-ilu I went up, . . .
21. I altered. . . .
22. Whatsoever king shall be exalted after me,
23.
24. Let him rule; let him govern the black-headed peoples.
25. Mighty mountains with axes of bronze let him destroy;
26. Let him ascend the upper mountains;
27. Let him break through the lower mountains.
28. The country of the sea let him besiege three time.;
29. Dilmun let him capture;
30. To great Dur-ilu let him go up.

Greece

~ Herodotus: "On the Kings of Sparta," ca. 430 B.C.E.
 (The History of the Persian Wars, Book 6, 56–60), extract ~

These are the royal rights which have been given by the Spartans to their kings, namely, two priesthood—of Zeus Sparta and Zeus Uranios—and the right of making war against whatsoever land they please, and that no man of the Spartans shall hinder this right, or if he do, he shall be subject to the curse; and that when they go on expeditions the kings shall go out first and return last; that a hundred picked men shall be their guard upon expeditions; and that they shall use in their goings forth to war as many cattle as they desire, and take both the hides and the backs of all that are sacrificed. These are their privileges in war, and in peace, moreover, things have been assigned to them as follows: if any sacrifice is performed at the public charge, it is the privilege of the kings to sit down to the feast before all other, and that the attendants shall begin with them first, and serve to each of them a portion of everything double of that which is given to the other guests, and that they shall have the first pouring of libations and the hides of the animals slain in sacrifice; that on every new moon and seventh day of the month there shall be delivered at the public charge to each one of these a full-grown victim in the temple of Apollo, and a measure of barley-groats and a Spartan "quarter" of wine; and at all the games they shall have seats of honor specially set apart for them. . . .

The kings alone give decision on the following cases only, that is to say, about the maiden who inherits her father's property, namely who ought to have her, if her father have not betrothed her to anyone, and about public ways; also if any man desires to adopt a son, he must do it in presence of the kings: and it is ordained that they shall sit in council with the elders, who are in number twenty-eight, and if they do not come, those

of the elders who are most closely related to them shall have the privileges of the kings and give two votes besides their own, making three in all.

These rights have been assigned to the kings for their lifetime by the Spartan state; and after they are dead horsemen go round and announce that which has happened throughout the whole of the Spartan land, and in the city women go about and strike upon a copper kettle. Whenever this happens so, two free persons of each household must go into mourning, a man and a woman, and for those who fail to do this great penalties are prescribed. . . . A certain number of the *perioiki* are compelled to go to the funeral ceremony: and when there have been gathered together of these and of the helots and of the Spartans themselves many thousands in the same place, with their women intermingled, they beat their foreheads with a good will and make lamentation without stint, saying that this one who had died last of their kings has been killed in war, they prepare an image to represent him, laid upon a couch with fair coverings, and carry it out to be buried. Then after they have buried him, no assembly is held among them for ten days, nor is there any meeting for choice of magistrates, but they have mourning during these days.

When the king is dead and another is appointed king, this king who is newly coming in sets free any man of the Spartans who was a debtor to the king or to the state; while among the Persians the king who comes to the throne remits to all the cities the arrears of tribute which are due.

► employment and labor

INTRODUCTION

Among the most ancient civilizations “employment” or “labor” as an institution would have been an entirely foreign concept. The daily goal of early peoples was to ensure survival by having enough to eat. Accordingly, most labor involved the search for or production of food. Other chores were probably done communally, such as the building of huts for shelter or the construction of a boat or raft. In agricultural societies it would have been impossible for one person or one family to carry out the labor-intensive tasks necessary for agricultural production. Thus, ancient societies learned to pool their efforts in such public works projects as terracing agricultural land, building canals and dikes, irrigating fields, and draining swamps. As civilizations advanced and as farmers were able to produce surplus food, systems of employment and labor became more organized and advanced. In time specializations developed, including architects, stonemasons, plasterers, and sculptors. Meanwhile, a peasant class continued to produce food.

“Labor” was not something that was particularly valued in the ancient world. Laborers frequently occupied nearly the lowest rung of the social order, and because they often lacked skills, they were not held in high esteem. In some societies, such as ancient Greece and Rome, slaves and prisoners of war provided most of the physical labor. In ancient Egypt slave labor may have been used to construct such monuments as the pyramids. Additionally, large numbers of workers would have been involved in the quarrying, cutting, and transportation of the stones used to build the pyramids and other stone monuments throughout the world.

As urban societies became more complex and sophisticated, additional job categories began to emerge: mechanics, carpenters, artists, weavers, bakers, butchers, fishmongers, pottery makers, clothes washers, barbers, physicians, and even candy makers. Women might have found employment as seamstresses, and in places like ancient Rome they also found work as prostitutes.

In most cultures educated workers who could read and write were employed as civil servants, tax collectors, accountants, scribes (writers of documents, such as legal documents), directors of public works, and the like. Those involved in

trade and commerce had to be able to keep accounts, so they needed a background in mathematics, and workers had to be organized for the storage and transportation of goods. Others became artists, astronomers, or priests. Much like today, education was a way for people to acquire the skills they needed to avoid backbreaking manual labor.

The earliest workers were not paid for their work. Rather, they were entitled to their share of food and other commodities. Over time systems of barter were developed to compensate people for labor. In ancient Egypt, for example, copper was used as a unit of measurement for valuing goods, and such commodities as grain, oil, and fish were “priced” relative to copper. In turn, workers were compensated with commodities according to their value measured by copper. Later still, systems of currency, including coins but also paper money and even money made with leather, were used to compensate workers. In ancient Rome salt was highly valued because it was used in food preservation. The Roman Empire mined a considerable amount of salt, and salt was often used as a form of payment. The modern word *salary* is derived from the word *salt*.

AFRICA

BY KIRK H. BEETZ

The earliest peoples of Africa were hunter-gatherers, and most of what is known about them comes from paintings on rocks in southern Africa and the Sahara. The purpose of many southern rock paintings may have been to illustrate adult behavior for youngsters during their initiations into adulthood and, therefore, may be depictions of everyday behaviors. For instance, paintings show people in small boats fishing with spears, and others depict humans hunting animals with bows and arrows as well as spears, labor that grown-ups would have been expected to do.

In general, in a hunter-gatherer society everybody has to be able to do all tasks, because an individual person’s survival may depend on his or her being able to identify food plants, hunt animals, make tools and pots, weave baskets, and so on. Anthropologists by and large believe that specialization in particular tasks occurred only when people developed agriculture and began making enough surplus food to allow some people to forgo producing food so that they could focus on a specific job. In this case, many African societies did not allow for distinct jobs because the San (or “Bushmen”) and the small-statured groups that have been termed Pygmies who occupied most of central and southern Africa until after the 200s C.E. were hunter-gatherers until the 20th century.

Each individual was responsible for the well-being of everyone else in their nomadic group. Although disabled people and the elderly were cared for, everyone else was expected to contribute to the work of staying alive. There was a division of labor between men and women, with men hunting animals, which often took them far from home, and the women and children searching for plants to eat. The manufacturing

of vessels and utensils for cooking might have been done by either gender, with actual preparation of meals at the base camp being the responsibility of women and children. Men prepared their own meals while on the hunt. The San traded with other people, so that San in an area rich in clay would make pottery to trade with others who might have woven baskets or made other basic goods.

For most of Africa the big change in this way of life came with the invasion of the Bantu-speaking people from West Africa. The Bantu speakers may have included descendants of people who had lived in the Sahara when it was a fertile grassland before 3000 B.C.E., migrating south as the Sahara dried and bringing with them the knowledge of how to care for herding animals, such as cattle, goats, and sheep, and of how to raise cereal crops. Rock paintings from the Sahara date back to about 27,500 B.C.E. and reveal the development of the ancient Saharans from hunter-gatherers to herders in 5095 B.C.E. and then to adopting a horse-based culture in 2780 B.C.E. and beyond. This evolution meant that their descendants among the Bantu speakers would have had a division of labor into different jobs and would have had customs regarding employment and labor.

Even without writing, their rules about employment were complex by the time they began making substantial inroads on the ancient territories of the San and the so-called Pygmies. People were bound to one another by family, clan, village, and personal obligation. Becoming an employee was considered a personal obligation in which labor was exchanged for training, goods, or money. At first the Bantu speakers were slash-and-burn agriculturalists, but they slowly changed from that practice to a more renewable form of agriculture. The first step toward renewable agriculture may have begun in the 200s C.E. when several hundred Bantu speakers migrated up the Congo and established farms. Their success attracted others, who became farmhands. The manufacture of iron was well known to them, and ironmasters set up business and attracted apprentices. This growth in employment represented an increase in prosperity and, with it, a rise in disputes over the proper distribution of wealth among employers and employees. To resolve labor disputes, both employers and employees consulted female shamans, a priestess skilled in magical arts.

Women were usually the ones who conducted trade among the Bantu speakers. Their knowledge of trading made them experts in the value of goods and, therefore, probably in the value of labor. In that context, having female shamans, whose religious status put them in positions of authority, settle labor disputes seems natural. It is likely that the shamans put their judgments in supernatural terms, with certain labor practices angering supernatural forces or drawing bad luck. The shamans would have settled questions of how much someone was to be paid, how long an employee had to work for his or her boss before becoming free to work elsewhere or to set up his or her own business, and who owned which part of a business.

In eastern and northeastern Africa complex civilizations arose, partly because of influences from Asia. The most significant nations were Karmah (ca. 1900–ca. 1550 B.C.E.), Kush (ca. 900 B.C.E.–ca. 350 C.E.), and Axum (ca. 500 B.C.E.–ca. 900 C.E.). Little is known about employment and labor in these cultures, even though Kush and Axum left written languages. The languages have yet to be translated, leaving inscription written in foreign languages as the only readable records. Karmah did a lively business in logging and animals skins, with its products being traded to Egypt. Karmah had metalsmiths, jewelers, cabinetmakers, and potters. Somewhat more is known about Kush because of its extensive contacts with Egypt.

Farming was the most important industry in Kush, because Kush's sovereignty depended on having its own, secure supply of food. Most of its wars were fought against nomads who tried to steal crops and livestock. Caring for Kush's fields was shared labor, with families or clans cooperating in the use of water, especially during the dry growing season when the pouring of water from the Nile into irrigation ditches had to continue day and night. Cooperative families probably did this in shifts.

Kush's economy had to be intricate, and from about 700 B.C.E. to about 250 C.E., it was probably equal in complexity to the economies of Egypt and Near Eastern countries. Scribes and priests were the elite workers in Kush, though the laws governing their behavior are not known. For a time during the 600s B.C.E. some priests could order a king to commit suicide, and the king would do so. In about 590 B.C.E. a king had those priests slaughtered, ending their political ascendancy, though later priests remained important in religious life and were in general well paid.

Axum was built on trade between Africa and Asia, with contacts extending to India and perhaps to China. Its society was a mix of ethnic groups that formed a unique culture. Axum had intricate laws governing trade, mostly to make sure that people did not cheat one another, and it seems that there were specialists in the laws who were in charge of what traders did in Axum's ports and marketplaces. Axum had complex businesses that employed many people. Construction workers and scribes seem to have been particularly important, but until the written language of the Axumites can be translated, little about its employment and labor practices prior to the medieval era is likely to be known.

EGYPT

BY CHARLOTTE BOOTH

In ancient Egypt it was common for people to work to sustain their families or to increase their personal wealth. A monetary system was introduced by Alexander the Great in 332 B.C.E.; before this time wages were paid in produce or services. Goods, however, were given a relative value according to weight or volume. For example, grain was measured by the unit kher, which was roughly equivalent to 20 gallons, and

the unit deben, a little over 3 ounces of copper, was used as a general value for many items.

Most of the available information regarding wages and income are records from Deir el-Medina, the village of the royal workmen at Thebes. These records show the middle-class residents were paid three times that of an ordinary field hand. The workmen at Deir el-Medina would have worked eight-hour days and had one day off in 10. Despite this long workweek, these people were able to take as many days off as they needed for a variety of reasons, including making libations (offerings) at tombs of relatives, illness, and arguments with spouses. These absentee records have been discovered at the site and are very enlightening regarding the lives of the villagers. In addition to their wages, the workmen were provided with housing, firewood, fish, vegetables, water, and oil—all the essentials of daily life. There was also a resident doctor at the village to deal with ailments; the doctor's services were paid for by the state. Within the community itself the income levels varied depending on responsibility and status. Foremen were paid the highest rate at $7\frac{1}{2}$ kher of grain per month; ordinary workmen were paid $5\frac{1}{2}$ kher; scribes earned less than half the foremen's wages at about $3\frac{3}{4}$ kher; porters were paid the lowest wage at $1\frac{1}{4}$ kher.

There were also extra rations awarded to the workmen by the king, as a reward for their labor. During the reign of Merneptah (r. 1224–1214 B.C.E.) some of these extra rations were noted by the scribe Anupemheb, who recorded 150 donkey loads of provisions brought to the village, consisting of 9,000 fish, a large amount of salt for drying, and 10 oxen ready for slaughter. Such extra rations would have provided enough for a few meals per person. Also recorded were four donkey loads of beans and sweet oils, eight donkey loads of barley malt (enough for four pints of beer per person), 9,000 loaves of bread (enough for 150 per household), and eight donkey loads of natron used for soap.

An average family of 10 members would consume $5\frac{1}{2}$ kher of grain per month, so many of the workmen would have earned enough to live on but may have had little left over for the market. For the richer members of the Deir el-Medina society, their wages and additional rations would have been enough to feed their families and also would have provided some excess that could be used for purchasing other goods.

It was, however, possible to earn money outside the working environment, and many of the workmen at Deir el-Medina earned additional income. For example, the scribe Harshire adorned three coffins for a songstress of the deity Amun, for which he received 329 deben of copper. Another workman, Bekenwenero, received 91 deben for an order of coffins, beds, chairs, boxes, and tables. Excess wealth would, therefore, have depended on personal initiative and the willingness to make salable goods. These spare goods would then be taken to market by both the men and women. In the Theban tombs of Ipuw and Kenamun, market scenes depict men and women seated under canopies selling their goods, which include linens, sandals, and foodstuffs. The marketplace was

visited so frequently that some villagers from Deir el-Medina invested in huts and chapels near the river on the east bank so that they could stay overnight rather than make the journey back. Although there was no currency, everything would have had a relative value that was of common knowledge to Egyptians. Household goods, livestock, and even servants would have been exchanged for an equivalent value of copper within a barter system.

It would have been difficult for a simple workman at Deir el-Medina or a field hand elsewhere to save enough to make expensive purchases, as $5\frac{1}{2}$ kher of grain, more than many people earned in a month, would be equal only to a small amount of purchasing power—enough, for example, to buy a simple wooden chair. The workmen of Deir el-Medina were supposed to get paid on the 28th day of each month, but on some occasions these payments were late. In Year 29 of Ramses III there were six months of delays. The workmen went on strike, making protests at the funerary temples of Thutmose III, Ramses II, and Seti I, where the grain stores were situated. One text describes this event: "It is because of hunger and because of thirst that we come here. There is no clothing, no ointment, no fish, no vegetables. Send to Pharaoh our good Lord about it and send to the vizier, our superior that sustenance may be made for us." In this instance the workmen received their rations, but later that same year Djhutymose, a village scribe, had to go with two bailiffs to collect the grain rations himself from the local farmers and the temples, as the rations again had not arrived.

Although the ancient Egyptians have a reputation for slave labor, the evidence suggests that there was a positive employment program with health care and a bonus scheme. There was also the possibility of making extra income after work hours, ensuring that the workmen were well fed and had opportunities to acquire wealth.

THE MIDDLE EAST

BY TOM STREISSGUTH

As the people of the ancient Near East tamed wild cattle, sheep, goats, and pigs, their society changed from a nomadic life of hunting and gathering to farming. Their most important occupations were raising livestock and growing crops, mainly wheat and barley. Hunting wild game became the privilege of the nobles and royalty, while fishing became the occupation of the lower classes. In the rivers and along the seacoasts of Persia, Arabia, and the Levant small vessels made of wood or reeds served as fishing trawlers. In coastal areas and river valleys fish provided a vital source of protein to supplement the daily fare of grains, vegetables, and fruit.

Mesopotamia remained a largely agricultural land, even as cities and urban society developed on its plains and river valleys. Mesopotamian farmers settled and lived in one place throughout the year. They had to build homes and villages, collect their harvests, and bring their produce to market. Because rainfall was scarce, they also had to assure a steady wa-

ter supply to their fields. This meant building irrigation dikes, ditches, and canals to draw water from the two main rivers of the region—the Tigris and Euphrates—and their tributaries. Irrigation works demanded central planning and collective labor, giving rise to more complex systems of government and a ruling class of government officials.

The annual cycle of farming began with the spring rains. Farmers allowed their fields to flood with the rains and with water directed from the rivers. Bulls and oxen were released to roam in the fields to stamp down weeds and fertilize the ground, after which plows, picks, and mattocks were used to break apart the soil and prepare a seedbed. In the fall the crops were harvested. The farmers cut sheaves of grain, threshed the grain stalks to separate the heads of the plants, and then winnowed the grain to separate edible portions from the chaff. The grain was stored and allowed to dry and then ground into flour in mills. The work of milling grain was carried out by humans and strong draft animals, who dragged heavy stones across the grain to pulverize it.

The work of the farmer followed an annual calendar, attuned to the growing season and to the regular spring floods. Survival became less precarious, though famine was still an ever-present danger in years of poor harvests. The rise of a market economy also allowed farmers to trade their produce for needed tools and land. The Mesopotamians became cultivators and traders and lost their former attributes of nomadism and skill in the hunt. Gradually, the Mesopotamian plains saw the rise of an urban civilization. Cities grew at strategic river crossings, at trading ports, and at market towns. People who moved into the cities began to specialize in artisanal crafts, such as pottery and tool making. In the Uruk III–IV Period (3300–2900 B.C.E.) of Mesopotamian history, new occupations emerged: baker, brewer, jewelry maker, brick maker, and weapons smith.

In the Hittite realm of Anatolia farmers raised grains, fruits, vegetables, and livestock, including cows and goats for milking. Oxen helped with plowing, horses pulled chariots, and mules helped carry goods to market. Hittite craftsmen had a ready supply of copper and iron ore as well as gold and silver deposits. Most metalsmiths, weavers, and stone carvers worked in the service of the king or lived within a temple precinct. Throughout the Near East the growing demand for luxury goods—jewelry, fine clothing, and other adornments—provided a market for artisans and their apprentices. In Persia and the Levant the difficult craft of glassmaking rose to new heights as artisans developed techniques of molding and coloring glass. Syrian glassmakers learned how to shape and score (decoratively cut) finished glass in the eighth century B.C.E. By the first century C.E. they had discovered glassblowing, which allows the artisan to create thin-walled vessels in a great variety of shapes and sizes.

As the cities grew in Mesopotamia and Persia, government began to levy workers for road building and the construction of palaces and monuments. For farmers and many city dwellers work became an obligation owed to the state for a

fixed number of days every year. The labor *corvée* was a heavy burden, as it often took the head of a family away from his home. To avoid unrest, the *corvée* often took place in winter, after the harvest but before the plowing and planting season of spring. Forced laborers worked grain fields owned by the state, the produce of which was meant for armies or for state warehouses. They dug irrigation works and removed the river silt that was constantly clogging the canals. They helped build royal palaces, city walls and, in Mesopotamia, the stepped temples known as ziggurats. In the 10th century B.C.E. King Solomon of the Israelites decreed monumental construction projects for his army of 30,000 laborers, who had to work four months out of every year. Throughout the Near East the wealthy classes were usually exempt from the *corvée*, or they were able to replace their work with taxes paid in money or goods. However, by one of the law codes of Hammurabi, the king of Babylon (r. 1792–1750 B.C.E.), a commoner attempting to escape a labor *corvée* was subject to the forfeit of his lands and property.

The work of women remained largely domestic. Women ground grain and spun flax and wool to make clothing. Many wives of landowners and the wealthy had a large staff of laborers to run their households. These servants spun clothing, made pottery, prepared food and drink, cooked and cleaned, and handled the management of lands and urban estates. In the Hittite realm independent women worked as millers, weavers, and innkeepers. They attended to childbirth as midwives or entertained royalty as musicians, dancers, or singers.

In the Near East regular wages were paid to laborers in the form of grain or silver. A system of training or apprenticeship prepared workers for skilled jobs. Some workers were bound by labor contracts to a period of work, and, at the end of their service, they were rewarded with grants of land. Others paid their taxes through work or borrowed money against their labor. Their loan was considered paid when the work was completed. In Persia and Babylon slavery became a more important means of providing labor to the state and to wealthy households. Slaves were subject to the tyranny of their owners; there were no laws regarding their treatment. There was a very limited commercial trade in slaves, but captured fugitives, refugees from foreign countries, convicted criminals, and prisoners of war often were forced into slavery. The slave could be freed from his status after a period of time or for merit, but escape from slavery was very rare. There was no refuge in foreign countries, and anyone found harboring a runaway was subject to arrest, the loss of their property, and execution.

ASIA AND THE PACIFIC

BY DAVID KELLY

The records of social and economic interactions in the nations of ancient Asia vary greatly. Records of the activities of many Pacific Islanders, for instance, were kept only after westerners began to arrive in the 18th century. In contrast,

much more is known about China and India for millennia before the Common Era began.

By late in the third millennium and into the second millennium B.C.E., China already had well-established divisions of labor. Cities were separated into sections where different economic functions dominated. Some areas were devoted specifically to religious and ceremonial functions, but in industrial sectors skilled workers fabricated goods, both practical and decorative, out of such materials as clay, jade, bronze, and bones. A merchant class was also well established, and young men from the lower classes were able to enter this class through apprenticeships.

A turning point in the economic growth of China was the start of the Zhou Dynasty near the end of the second millennium B.C.E. Farming was organized under a semifeudal system not much different from the feudal system that was to appear in Europe centuries later. The first ruler of the Zhou Dynasty (ca. 1045–256 B.C.E.) was King Wu Wang, who claimed that his authority was granted by God under the Mandate of Heaven, a claim that future Chinese emperors were to invoke. Land was owned by nobles, who doled it out to serfs in exchange for a percentage of the harvest. Similarly, the means of production, such as the smelting process that provided bronze for making tools and weaponry, was directed by nobles. Most of the items used in daily life were produced in individual households and were therefore not subject to barter.

The vast majority of Chinese peasants during the Zhou Dynasty were farmers or soldiers, but by the time the dynasty ended in 256 B.C.E. China had also developed a complex governmental bureaucracy. In this feudal society land was controlled by a number of territorial princes, who collected taxes from the peasants who did the actual farming on the land. The transfer of wealth that taxes required spurred the use of money for exchange, so that a distant centralized state could reap the benefits of labor without being burdened with amassing goods from all over its lands.

The later Qin Dynasty (221–207 B.C.E.) and Han Dynasty (202 B.C.E.–220 C.E.) was a period of great prosperity. Many people were employed by a large bureaucracy that controlled the economic activities of China's 36 districts. Labor became more efficient with the introduction of standardized weights and measures, roads, and even axle widths for wheeled vehicles. During the short-lived Qin Dynasty, hundreds of thousands of laborers were used to construct the first of China's great walls to keep out invaders and a massive mausoleum for the emperor. During the Han Dynasty the country underwent great economic expansion as well as an expansion of trade and commerce along the so-called Silk Road, which extended all the way to Europe. This expansion provided opportunities not only for merchants and traders but also for the many thousands of craft workers that provided goods for trade. Farm laborers were given better tools with the expansion of the Chinese iron industry. These processes continued during the subsequent Three Kingdoms Period (220–263 C.E.) and the Jin Dynasty (265–420 C.E.), though a series of military crises and internal instability worsened the condition of Chinese workers.

During the Han Dynasty, Emperor Wu Di (140–87 B.C.E.) designated Confucianism as China's official philosophy and code of ethics of the state. Confucianism focused on three elements that directly affected areas of employment and wages. One was the teaching of moral precepts to the uneducated. The second was the establishment of a clear social hierarchy. The third was that those who held prominent social positions must behave in a way that provided proper examples for the rest of society. The social hierarchy Confucius had in mind permitted movement through the ranks of society. By passing an examination, a person could become a government officer, with the potential to gain wealth and honor. Initially, the exam was offered to those who were summoned to the capital because the emperor had heard of their moral excellence, though over the centuries it became more open to anyone.

Cowrie shells, the earliest form of money in China, Shang and Zhou dynasties, 16th to eighth centuries B.C.E. (© The Trustees of the British Museum)

This system both offered possible social advancement and institutionalized the government bureaucracy.

In contrast to China's extensive recorded history, there is no reliable record of Japanese development before 400 C.E. From the first signs of civilization in 10,000 B.C.E. to the cultivation of rice that began in the Yayoi Period starting around 300 B.C.E., Japan was in a Neolithic phase, characterized by tribes of hunters and gatherers who shared chores and responsibilities related to basic sustenance. There is evidence of the use of pottery in this period but no evidence that the making of pottery was specific to any one group of dedicated professionals. At the start of the Yayoi Period, Japan was made up of hundreds of tribes, with chores within each tribe divided equally among its members. By the end of the period, however, a large class of advanced potters was making pottery on wheels. Iron was being used to produce tools and weapons, and bronze was being used to make weapons, bells, mirrors, and similar objects—all requiring classes of trained workers. In agriculture village labor was becoming more varied, with villagers weaving cloth and constructing buildings. Landowners gained wealth through the efforts of rice growers in irrigated lands.

As the tribes bonded together over centuries, forming alliances against each other, military professionalism came into existence. The Kofun Period that began in 250–300 C.E. and extended into the sixth century was marked by a central government, with regional control in the hands of families or clans, called *uji*. The *uji* were frequently identified as members of professions, such as religious *uji* or military *uji*. The growth of the clan structure created the need for subsidiary workers, called *be* or *tomo*, to work for the families. The people in this category were on the lower rungs of the labor ladder; sometimes foreigners but more often skilled Japanese laborers, they provided valuable services to the lords. Below this class was a class of common laborers and slaves who were acquired in warfare to do unskilled work.

The centralization of government services that gave Japan a stable system for workers had already been in effect in India for hundreds of years by the time that the Kofun Period emerged. The Indus Valley civilization, which flourished from 3000 to 1600 B.C.E., had a thriving economy in which people worked as farmers, herders, metalsmiths, and traders. They also worked on public works projects, building streets, drainage systems, and waterworks. The caste system, which divided people into social classes based on birth and which arose from Hinduism, created classes of workers, leading to division of labor and the development of the apprentice system for training workers.

The Maurya Empire came to power in India in 312 B.C.E., when the country was a collection of warring states that taxed workers and conscripted them into armies. Mauryan culture was organized under principles laid out in the Arthashastra, a treatise on statecraft generally attributed to a minister of Chandragupta Maurya, who founded the dynasty. In the Arthashastra rules are laid out that provided stability to the

merchants, farmers, and traders who made up the civilian economy. They were freed from the oppressive taxes that had been levied on them by multiple governing bodies when the country was fragmented, and a unified economy across India allowed for increased productivity, as workers were able to move freely from district to district. One distinct benefit Mauryan culture had was that of privately held corporations, which pooled capital to create trade, craft, and artisan businesses with more international power than the family-oriented businesses that had been traditional for the country. The later Gupta Empire (240–550 C.E.) continued the expansion of trade and was a kind of golden age of Indian culture. The productivity of the country's labor force created surplus wealth that supported writers, poets, craft workers, artisans, architects, scientists and mathematicians, and philosophers.

Many of the smaller countries of the Asian mainland followed the social and economic pattern of China, with whom they had been trading for centuries. While China and the surrounding countries that it influenced (Vietnam, Cambodia, and Korea, for example) supported a steadily growing bureaucracy that, in turn, supported a centralized government, the social structures of the Pacific Island countries was less complex. While the islands, like China, tended toward large populations, they were confined to limited geographical terrain, which meant a greater population density than on the mainland.

The remotest of the islands in the Oceanic region, between Asia and America, were colonized by people from Southeast Asia in about 2000 to 1500 B.C.E., relatively late compared with the thousands of years in which civilization had already spread across Asia, but their populations grew quickly. The resulting societies tended to be as stratified as the society established in China, but they were less complicated. There were still rulers and tax collectors and tradespersons and peasants. The vulnerability of the island nations, however, tended to drive the citizenry toward the protection of the government that controlled the military. While mainland nations were ruled by governments that conquered their citizenry and imposed taxation on them, the island nations tended toward more close-knit, cooperative, and voluntary support of their leaders.

EUROPE

BY MICHAEL J. O'NEAL

The concepts of employment and labor, as they are understood in the modern world, were in many respects unknown in ancient Europe. In early hunter-gatherer societies, the chief occupation of nomadic tribal cultures was finding food. Any additional goods that people had—clothing, pots, tools—they probably produced themselves, though some bartering for goods took place, and services were provided by the family, clan, or community as a whole. The basic economic unit was the family, clan, and tribe, so there were no businesses, no commerce or trade, no large public works. In this type of eco-

conomic system, no one was “employed” in the modern sense of the word, though daily life demanded “labor” just to ensure survival and protection from the elements.

In was not until the advent of agriculture, with the more settled communities that could support it, that anything like employment and labor began to emerge. Even then, however, the concept of hiring a worker to perform labor in exchange for a wage was largely unknown. Most people were farmers, growing their own crops or tending their own livestock, and again the family was the basic economic unit, with most goods being produced in the home. The development of agriculture, though, enabled communities to produce food surpluses that could be stored for the future. This enabled communities to begin to support a class of nonagricultural workers, including civil servants, priests, artisans, and the like.

Meanwhile, the work of the community proceeded. Ground had to be tilled; ditches dug; swamps drained; grain stored; livestock tended; fabrics woven, dyed, and turned into clothing; salt and ore mined, shoes sewn, barrels manufactured, the dead buried, and primitive roads built. By about the second century B.C.E. coinage was introduced, creating the beginnings of a money economy. But until then and even afterward, the economy was based on barter and in-kind transactions.

Roughly several hundred years before the beginning of the Common Era, further specialization began to take place. The Celts, in particular, began to develop an economic system and to engage in trade, primarily with the Roman Empire and the civilizations around the Mediterranean Sea. Accordingly, there emerged a more specialized class of crafts workers, who produced pottery, glasswork, and particularly metalwork, some of it for trade. Archaeological remains from northern and north-central Europe include a large number of metal objects—not just domestic goods, such as wine flagons and bowls, but also swords, scabbards, helmets, and other objects used in war. These metalworkers were adept at using not only bronze and iron but also gold and silver. A highly valued artisan was one who could make “prestige goods” for the nobility, allowing them to enhance their power and status. These goods included clothing and weapons. One highly valued craft was that of the wheelwright. The Celts were skilled carriage makers, and their wheelwrights produced wooden wheels bound with a hooped iron “tire” that were highly durable, making transport much easier.

In some parts of ancient Europe communities were a beehive of economic activity. Particularly in the Celtic Hallstatt community, in and around modern-day Austria, archaeological findings show that communities would have been alive with the hammering of smiths, the grinding of grain on millstones, the clatter of looms, and the mining of salt (a valuable commodity used for food preservation). Not only did the salt have to be mined from deep within the earth, but it also had to be stored, brought to a usable degree of concentration, baked in oven, packaged, and shipped. All of this shows a high degree of organization, with large numbers of laborers

carrying out the necessary tasks. In the same region nearly every Celtic town was the site of a metal foundry and smelting forge, as well as slag heaps, suggesting the mining of ore and the production of metal was a widespread activity.

In some areas of ancient Europe land was regarded as communal property, so farmers could, for example, graze their livestock anywhere. No one person was regarded as the owner of the land. In much of early Europe, however, there emerged something like the feudal system of the Middle Ages. Historians often use the phrase “embedded economy” to refer to the system of production and land ownership that prevailed among the ancient Celts. In Celtic civilization a class structure emerged, consisting at the top of tribal chiefs, followed by the warrior nobility and then a class of craftsmen and artisans and, finally, the peasantry. While the aristocracy did not own the land, livestock, and so forth, they were entitled to receive a share of the community’s production. In return, the aristocracy provided common people with protection, primarily from neighboring tribes.

The closest institution to employment is referred to as clientage. The source of wealth in ancient Europe came from warfare (and seizure of an enemy’s goods and means of production), trade, and agriculture. One way that the aristocracy accumulated wealth was by acquiring clients. These clients were obligated to provide services for their noble patrons. These services could include fighting or the production of prestige goods, either through manufacture or trade; wine was such a valuable prestige good that a slave would sometimes be exchanged for a single flagon of wine. In exchange, nobles provided their clients with protection. Sometimes a noble could gain a client from another tribe, often by forging personal alliances with nobles in the tribe. In effect, the patron-client relationship was a sort of barter system in which labor and other services were provided in exchange for protection. These patron-client relationships were often more powerful than the ties of kinship and clan. In some instances, entire communities became clients, under the patronage of other, more powerful communities.

GREECE

BY CHRISTOPHER BLACKWELL

In the mythological history of ancient Greece, labor was accomplished by gods. Homer reports that the walls of Troy were built by the god Poseidon, and the Greeks assumed that the massive walls of Mycenae, whose blocks of stone measured 10 feet on a side, were constructed by the work of Cyclopes. In the historical period, the period for which we have evidence about real people doing real work, beginning (perhaps) with Hesiod’s epic poem *Works and Days*, from the seventh century B.C.E., we can see evidence that ancient attitudes toward labor had very little in common with “labor” as discussed by modern economists.

There is no evidence for anything like modern unions or guilds. We do not hear of labor strikes, and for the most

part labor was not considered in any way noble or admirable. The ideal life, as presented in literary sources, was one that did not involve manual work in any capacity—all such work being done by slaves. When work was necessary, it was reputable only in the context of agriculture on one's own land. So the poet Hesiod urges diligence and constant effort but on a privately held farm. His audience is assumed to be other landowners, however small and meager their holdings may have been. Other laborers appear in *Works and Days* but only as less-than-admirable tools that the independent farmer might hire, or buy, to support his own efforts.

There seems to have been among the ancient Greeks no distinction between a person and the person's labor. The consequence of this was a failure to distinguish in any meaningful way between wage labor and slavery. An employer was not buying merely the labor of a worker but in effect the worker himself, making the laborer nothing more than a temporary slave. Accordingly, there are passages in ancient literature where it seems that a wage laborer actually maintained a lower status than a slave. A slave was permanent property, after all, and enjoyed a place in the household; a slave's person was valuable and worth protection. A wage laborer had no fixed place in the community and, when the task for which he was hired came to completion, was no longer valuable.

The social and economic crises that afflicted many communities during the sixth century B.C.E. were reflections of this failure to distinguish between wage labor and slavery. Small farmers increasingly fell into debt to more wealthy landowners, having borrowed seed or money to buy seed in times of poor harvests. Since, in a largely premonetary economy, the small farmers had nothing of value with which to repay their creditors, they repaid them by mortgaging sections of their farms; the debtor would then, in a following year, continue to work that land, but the proceeds from its harvest belonged to the creditor. With even less produce for himself, the small farmer was likely to continue in this spiral of debt until the majority of his farm was worked for the profit of the creditor, making the debtor, in his own eyes and in the eyes of the community, a virtual slave, selling his own labor to another. The resolution to this state of affairs, in many Greek cities, was revolution and the institution of popular tyrannies and ultimately to enact democratic reforms.

There had to be, of course, members of the community who were not independent farmers, and even in the Homeric poetry of the Greek dark ages we find an acknowledgement of their worth. These were the "public workers," certain craftsmen, prophets, healers, builders, and singers of tales who were not attached to a particular household but whose labor, or at least the results of whose labor, benefited the farmers and their households.

Nonagricultural labor was always necessary, of course, as people needed manufactured goods, ores from mines, woven clothing, and luxury items. There were, therefore, various "industries" in any Greek community. Only rarely, however,

did they employ paid workers. Furniture pieces, ships, pottery items, weapons, perfumes, and the like were the products of "workshops," small local enterprises under the control of a master and staffed by slaves. The father of the orator Demosthenes, for example, died in the early fourth century B.C.E. and left as part of his estate two workshops, one manufacturing swords and knives and employing 32 slaves and the other a furniture shop employing 20 slaves. Such industry contributed useful implements to the local markets—swords and furniture—and generated wealth to the owner, Demosthenes' father, and presumably to the people who sold ivory, iron, and wood to the owner. But this kind of industry did not create wealth in the modern economic sense, since it did not employ anyone. The slaves earned no income, and so the financial benefit to the community of either of these workshops was much less than, for example, a bicycle shop in a small town, which might support its owner, but also provide incomes to several employees, who would in turn contribute to the economy in other ways.

During the fifth century B.C.E. the city of Athens undertook an enormous project of public building, funded by the tribute paid to Athens by its "allies," the cities and islands of the Aegean under Athenian domination. Inscriptions detailing the work on the temples of the Athenian Acropolis survive and show that, in this enormous community effort, the labor of slaves, resident aliens, and citizens was employed nearly equally. What is most remarkable is that laborers seem to have been paid the same, regardless of whether they were citizen, foreigner, or free.

The inscription noting wages paid for the workers who cut the flutes in the columns of the Erechtheum in 409 B.C.E. records these figures for workers cutting channels in one column: "Onesimus, a slave belonging to Nikostratos: 16 drachmas, 4 obols; Eudoxus from Alopeke [a citizen]: 16 drachmas, 4 obols; Kleon [perhaps a foreigner]: 16 drachmas, 4 obols; Simon [foreigner] who lives in Agryle: 16 drachmas, 4 obols; Antidotus, a slave of Glaukos: 16 drachmas, 4 obols; Eudikos [status unknown]: 16 drachmas, 4 obols." All told, of the architects, secretaries, guards, masons, sculptors, carpenters, and all the laborers who are recorded as having built this temple, 24 are known to have been citizens, 42 to have been resident aliens, 20 to have been slaves, with 21 whose status remains unknown.

Citizens, foreigners, and slaves alike were paid the same rate, and it seems that all these laborers were paid the same wage of one drachma per day, regardless of whether they were sculptors working on the statuary of the temple's frieze, sawyers making wooden scaffolding, architects, or guards. More than any other evidence, this serves to demonstrate that while "work" was necessary and known to have a certain value, "labor" as a concept—something that built wealth, that was itself a commodity with greater or lesser value according to the circumstances, the demand, the supply, and the skill involved—was largely absent from ancient Greek economic thinking.

ROME

BY KIRK H. BEETZ

Not much is known about employment and labor during the era of Rome's first kings (ca. 753–ca. 510 B.C.E.). By the reign of Tullus Hostilius (r. 673–642 B.C.E.) Rome seems to have developed an aristocracy, the patricians, and commoners, the plebeians. A key moment in the history of labor in Rome occurred during the reign of Tarquinius Priscus (r. 616–578 B.C.E.), who drained a swamp beside the Tiber River and built Rome's Forum on it. A rectangular open space, the Forum had a marketplace on one side, where farmers and craftspeople could sell their products. A basilica, or place of public assembly, was built at one end of the Forum. In the basilica laborers could find work.

During the Roman Republic (509–27 B.C.E.), Rome developed a large class of unemployed people, who gathered along one side of the Forum under a shelter the city provided for them. There they collected free food from the government and sometimes found work as unskilled labor. Throughout its existence the Roman Empire had a large number of unemployed people, probably because of slavery. Slavery affected all aspects of Roman society. Slaves served in households as nannies, cooks, and other servants. On farms they held every working position, and slaves were often in charge of large farming estates, doing all hiring and firing and directing all tasks for their owners. The effect of slaves on Roman society was primarily destructive. Among the patricians, they made for lazy owners who were unprepared for leadership or hardship. They took jobs that would otherwise have gone to free citizens who needed the employment. Further, slavery took away the incentive for Romans to be innovative. For example, when the steam turbine, called an *aeolipyle*, was invented in the first century of the Common Era, it languished because it was seen as a mere labor-saving device, and it was easier just to have slaves do the labor instead. Given how the steam turbine revolutionized European culture in the 1800s C.E., the *aeolipyle* could have given the Roman Empire an enormous technological lead over its rivals in the ancient world.

Slaves had no civil rights in Rome. Their owners could kill them, torture them, and abuse them without penalties. Slaves could earn money, but that money belonged to their owners. However, it was customary to allow slaves to save their own money and to allow them to use that money as their own, even to purchase their own businesses. Until the end of the 300s C.E. Rome's wars brought large numbers of slaves into the empire, so replacing a slave was usually easy. Thus, freeing slaves was common. According to custom, however, the former owner of a slave was still responsible for the freed slave's welfare and was expected to be accountable for the freed slave's debts.

In every form of employment slaves competed with free people. Sometimes they were more respected than wage earners, who were usually treated with contempt. Roman cities and towns were divided into areas of rich and poor, with trades-

people and crafts workers having their own sections. Those who owned their own businesses lived in well-kept areas. Wage earners lived in squalid areas of narrow streets with one-room homes and small apartments. When a Roman city was built on the site of a conquered village or town, the wage earners lived in the old barbarian part of the city. They were regarded as filthy and smelly, unfit for mingling in society. As such, they formed a permanent underclass that existed throughout the empire at all times. Wage earners sometimes rebelled against their maltreatment, and their riots were feared by other Romans.

There was a hierarchy among Rome's laborers. At the bottom were town criers and undertakers, who were forbidden by law to hold public office. At its top were construction workers and musicians. In the middle were mechanics, artists, bakers, weavers, among others. Barbers were feared because their iron razors were difficult to control and could cut. Clothes washers were avoided because the chemicals they used not only made them permanently smell awful but gave them skin diseases. Physicians fell into two categories, one being wage earners, who had to go visit patients, and the other consultants, to whom patients had to come. Greeks were generally regarded as crazy and immoral, but Greek doctors were well respected.

Marble relief of Jason the physician and patient, Roman, second century C.E.; Greek doctors were especially respected in Roman society, and all doctors were exempt from paying taxes. (© The Trustees of the British Museum)

All doctors were excluded from having to pay taxes. Roman laws dealt more harshly with laborers than with other Romans. Where a patrician might be fined for stealing, a laborer could expect to be whipped and sentenced to years of hard labor.

Wage earners tried to compensate for their low status in society by establishing their own institutions, called *collegia*. *Collegia* were formed by people with related skills, such as fishmongers, butchers, perfumers, auctioneers, interior decorators, and candy makers. The *collegia* gathered dues and spent the money to buy a meeting hall as well as food and drink. The *collegia* served primarily to provide dinners at which the members could gather and enjoy one another's company. The elected leaders of the *collegia* were held in high esteem by members.

Women could participate in many forms of employment. Male commoners were expected to serve 20 years in Rome's military, which in time of war left many jobs to be done by women. Even women from the wage-earning class tended to be educated, and they worked as secretaries, teachers, and doctors. They also worked as hairdressers, seamstresses, and midwives. When desperate, as they often were, they worked as prostitutes.

During the Roman Republic and the early years of imperial rule, wage earners were often paid with coins, but their employers were expected to feed them too. Milk, cabbages, and vegetables were given to laborers. Sometimes they were paid in kind, meaning that for their services they were paid with other services, perhaps the cleaning of a coat exchanged for repairing masonry. During the second century B.C.E. Rome developed a cash economy: Almost all buying and selling was done with money. Inflation ate away at the value of money, and in 301 C.E. the emperor Diocletian tried to stem inflation by fixing prices and wages by law. The best-paid workers were clothes washers and teachers, who were paid by the item of clothing or by the student. Carpenters and stonemasons could earn fifty *denarii* (roughly 50 American dollars) per day. Farm laborers earned half that amount. Scribes were paid per 100 lines.

Coins lost their value during the final three centuries of the Roman Empire, becoming smaller and having less and less real silver in them. During his reign, Constantine (r. 307–337 C.E.) regularized Rome's money and brought back the use of large silver coins. After his reign, money became increasingly hard to find, and laborers took payment in the form of goods for their services. Taxes on them became so high that many throughout the empire had to pay the government with their children, who became government-owned slaves. By the time Germanic kings put an end to the Western Roman Empire, wage earners were little more than slaves themselves, and they were mostly glad to be rid of the empire.

THE AMERICAS

BY MICHAEL ALLEN HOLMES AND TOM STREISSGUTH

Historians have a limited understanding of the systems of employment and labor that existed in ancient America. Re-

cords are scant and in many places were kept on perishable material, such as wood or bark. The Maya used hieroglyphic or ideographic texts painted on ceramic vases or inscribed on stone, but these writings deal with political or religious rather than practical matters. Still, certain conclusions regarding the manner in which people worked for and with each other have been gleaned from archaeological research.

As the ancient Native Americans settled the deserts, plains, and woodlands of North America, the division of labor followed the demands of available local resources. On the Great Plains, for example, hunters worked together to cull massive herds of bison. In the hunt for game, the bow and arrow replaced spears and stone points around 400–500 C.E. Archaeologists have discovered many buffalo jumps, where hunters ran bison herds over cliffs and then gathered the carcasses at the base. One such buffalo jump, in Alberta, Canada, was used for more than 7,000 years.

The development of agriculture demanded a more settled and sedentary life. The tasks of raising village homes and longhouses were taken up in a cooperative manner by large clan groups. Among many tribes it was the task of women to plant and harvest maize and other edible plants, while the men's duty was to hunt. In eastern North America fishing and the gathering of edible coastal shellfish became important occupations. Wherever competition for territory and available resources gave rise to armed conflict, Native American tribes developed a class of warriors, whose occupations were tracking, raiding, and using weapons, such as clubs, spears, and bows.

In the Olmec society of Mexico, systems of hired labor developed between roughly 1000 B.C.E. and 300 B.C.E. Apart from agricultural production, labor was performed largely at the direction of the priestly class, allowing for the construction of temples as well as the carving and transportation of massive stone heads. One of the most fruitful Olmec settlements has been La Venta, an island in modern eastern Mexico. Giant heads weighing as much as 40 tons were carved from basalt found at least 80 miles away. Workers dragged the heads along land to the nearest river and then floated them aboard massive rafts. The painstaking work of transporting, carving, and raising the heads demanded the use of skilled artisans and large gangs of common laborers.

The Maya built their largest, most complex structures fairly early in their overall development as a society, in about 600 B.C.E. Mayan city-states never attained widespread centralization and unification. Nevertheless, dominant cities arose where platforms and temples stood 100 feet high; the Danta complex of El Mirador, in the central Petén lowlands, was over 200 feet tall. Between 300 and 50 B.C.E. the Maya built a system of canals and reservoirs around Edzná, on the western Yucatán, which served some 1.75 square miles of farmland.

Archaeologists have concluded that the Maya developed important work specializations, including architects, stonemasons, plasterers, and sculptors, with priests and even astronomers contributing oversight to building efforts. Historians generally assume that laborers were not employed

for wages but were obligated—and perhaps perfectly willing—to provide their services as tribute to the religious and royal figures at the heads of their communities. While the most substantial coordinated labor efforts were performed at the behest of the nobility, individuals were undoubtedly occasionally employed on incidental bases. Members of the middle class could have employed peasants for such tasks as carrying goods, paying them with cacao beans. Labor would also have been bartered among peasants. Women might have exchanged hours of labor in such tasks as weaving, while men would have assisted each other in building homes.

The city of Teotihuacán, in central Mexico, an urban settlement serving much of the surrounding region, features some of the most impressive feats of peasant labor found in ancient America. Construction of the Pyramid of the Sun began around 100 C.E. and lasted at least a century. The pyramid stood some 250 feet high, with a base of more than 700 square feet. Nearby is the Pyramid of the Moon, standing almost 140 feet tall. Laborers moved more than 1 million cubic meters of brick and rubble to fill the interior of the Pyramid of the Sun. Artisans and sculptors decorated both pyramid complexes with fresco paintings and monumental sculpture. The rulers of Teotihuacán levied thousands of workers from the surrounding countryside to raise these monuments.

The Chavín of the Peruvian Andes were one of the earliest advanced societies of South America. By the ninth century B.C.E. they had developed a settled agriculture as well as industries producing textiles, pottery, and metalworking in gold, silver, and copper. They gathered and traded stone, wood, fish, shell, and pottery. In the arid lands near the Pacific coast, fishing was an important occupation. In the highlands the Chavín developed large villages and ceremonial centers. Highly skilled masons and sculptors were employed in the raising of ceremonial pyramids and other religious structures. The mining of obsidian, a hard and useful volcanic rock, also became an important occupation.

The Moche followed the Chavín culture and flourished at the beginning of the Common Era. They worked as farmers in the Andean valleys. They were highly skilled pottery artisans who pioneered the use of molds to mass-produce vases, jugs, and drinking vessels. Large labor gangs and masons raised two adobe temples, known as the Pyramids of the Sun and Moon, near the coast. The Moche are also known for their irrigation systems, which were built to canalize sparse groundwater and rainfall for agriculture. A long period of heavy rain and flooding in the sixth century, however, permanently disrupted Moche civilization.

► exploration

INTRODUCTION

In prehistory exploration and the migration of peoples were essentially one and the same. People lacked the means of exploring their world, and life was a daily struggle for survival, so exploration, as the term is understood in the 21st century, was a low priority. Most of the world was unpeopled, however, and much of the history of the world in ancient times was the history of migrations as people spread out and settled new lands, often to follow food supplies. As the glaciers from the north receded, people expanded into what is now Europe to find an abundance of game and fertile lands.

Perhaps one of the best examples is the Americas, whose human population was zero until some hardy Siberian hunters crossed the land bridge connecting Siberia and Alaska in search of game. In time, members of their community followed and began to make their way south through North America, into Mexico and Central America, and finally to the southern tip of South America. The people who undertook these arduous migrations were explorers, but unlike the great explorers of the 14th and 15th centuries, they did not return to their homelands bearing new knowledge about the world. Only later, when the great civilizations of Mesoamerica flourished, did people make an effort to explore outward. But even then their primary goal was to secure and expand their borders rather than to seek new knowledge of contact with new civilizations.

In Asia, too, exploration had ulterior motives. For some, exploration took place mainly with a view to expanding re-

ligious awareness. Primarily, though, the Chinese were interested in exploring trade routes. They explored southward and westward, eventually reaching central Asia. The earliest of these explorers returned with such things as seeds for new plants, and in time trade for Chinese silk developed between the two regions. Considerable exploration was done by the adventurous souls who set out in boats to migrate from island to island in the Pacific.

Perhaps the earliest true explorers were the ancient Greeks and Romans, probably because of their location in a sea that allowed travel by ship. The Greeks, in particular, exhibited a curiosity about lands beyond their boundaries, and numerous accounts exist of travels to such far-flung locations as the west coast of Africa, Britain, and the eastern Atlantic. In the other direction the Greeks explored such regions as India and Turkey. One prominent name in the history of geography and exploration was that of Ptolemy, a second-century Greek who compiled the first maps that located places by latitude and longitude. Ptolemy's maps, however, showed that the Greeks had not yet circumnavigated Africa, for he showed southern Africa as connected with China.

In and around the Mediterranean Sea most of the early exploration was done by the Greeks. After the Roman Empire absorbed the Greeks, little remained to be done, at least in that part of the world. What exploration the Romans did as they relentlessly expanded their empire west, north, and east was motivated by a desire for military conquest and to establish trade routes. Exploration more for its own sake took place primarily in Africa. After the Romans conquered the Carthaginians in the second century B.C.E., a number of Romans undertook exploration of the west coast of Africa and of sub-Saharan Africa.

AFRICA

BY MICHAEL J. O'NEAL

Archaeological evidence, which always remains open to new findings and new explanations for old findings, shows that the first humanlike species developed in Africa perhaps 5 million years ago. In 1974 in the Hadar region of Ethiopia, archaeologists unearthed "Lucy," the earliest-known ancestor of humans, whose fossilized skeleton is about 3.18 million years old. Through a process of continual evolution the species *Homo sapiens sapiens*—modern humans—developed in Africa some 150,000 to 200,000 years ago, though quite similar ancestor species had existed for some 400,000 years before that.

Modern geneticists—that is, scientists who study genetics, the branch of biology that explores the origins, variations, and heredity of organisms—are keenly interested in the emergence and spread of humans. Using DNA evidence, they have tentatively identified the genetic group of the first humans who emerged in southeastern Africa at the very dawn of the species. From there humans evolved into two further major groups. One was the San, or Khoisan, of

southern Africa, commonly called the Bushmen. The other group was that made up of the small-statured people sometimes referred to as the pygmies of central Africa. Roughly 60,000 years ago some of these humans migrated into the Arabian Peninsula and then into Asia. Meanwhile, the related species known today as Neanderthals (*Homo neanderthalensis*) had occupied parts of Europe, but in time *Homo sapiens* spread there as well and outcompeted the Neanderthals, who disappeared.

The earliest humans in Africa formed nomadic tribes. As these hunter-gatherers searched for food and other resources, they became the first explorers of the African continent. In the process they located resources they could use not only to ensure their own survival but also for trade. They built cities and transportation networks and thus created some of the world's oldest civilizations. But while historians know much about the end results of their explorations, they know little of the process of exploring. The absence of any kind of written records is the chief obstacle. Much of the history of the movements of African peoples is preserved orally by griots, or storytellers, who retain and pass along their knowledge of the ancestry of African peoples, including those who left their tribes in search of new horizons.

Thus, the world's first explorers were Africans, though none of their names survive in history textbooks. Modern people have to use their imaginations to envision the earliest explorations of their world by humans in Africa. Some of this exploration was no doubt motivated by simple human curiosity, the need to know what lay over the horizon, on the other side of a mountain range or river. Other exploration was doubtless driven by necessity as homelands became depleted of resources, natural disasters forced people to find new homes, or one group drove out another, so that explorers had to be sent out to discover a new place to live. Whatever the motivations, *Homo sapiens* in time spread out from its origins in southwest Africa to settle every inhabitable continent of the world.

Although history does not record the names of these early explorers, it does record those of some later ones, particularly from the Carthaginian Empire. The Carthaginians were named for their capital city, Carthage, on the Mediterranean north coast of Africa in what is today Libya. The Carthaginians were actually Phoenicians, a people originally from the region around modern-day Lebanon who became one of the most active seafaring and trading nations of the ancient world. Eventually the Romans conquered Carthage in the Punic Wars, so called because *Puni* was the Roman name for Carthaginians. The final defeat came in 146 B.C.E., but long before then the Carthaginians had explored a great deal of Africa and Europe.

The most important of Carthage's explorers was Hanno, often called Hanno the Navigator to distinguish him from a later political figure, Hanno the Great. The dates of Hanno's life are uncertain, but he is believed to have lived sometime between 633 and 530 B.C.E. At some point in this time frame

Carthage's rulers sent Hanno on a voyage of exploration. He commanded a fleet of 60 ships, each propelled by 50 rowers, and explored the west coast of Africa as far south as the Gulf of Guinea and modern-day Sierra Leone. Aboard his ships he also carried numerous colonists, who established cities along the west coast of Morocco.

Hanno documented his journey in a tablet that was housed in a temple in Carthage. Later the Greeks translated the tablet under the title *The Voyage of Hanno, commander of the Carthaginians, round the parts of Libya beyond the Pillars of Heracles, which he deposited in the temple of Cronus*. ("Pillars of Heracles" refers to the promontories on either side of the Strait of Gibraltar, the opening from the Mediterranean to the Atlantic.) Some historians question the accuracy of the translation—for example, they doubt that Hanno actually took along as many as 30,000 colonists—though others believe that it is reasonably accurate. In it Hanno noted details of his journey. Perhaps one of the most interesting was his encounter with what he called "hairy women," which some historians believe may have been gorillas. He also encountered the hippopotamus, or "water horse" (*hippo* being the Greek for "horse" and *potamus* for "water" or "river").

Another Carthaginian explorer was Himilco (the Greek version of his Phoenician name, Chimilkât). Virtually nothing is known about Himilco's background or personal life, but around the middle of the fifth century B.C.E. he became the first navigator from the Mediterranean region to explore the northwestern coast of Europe. The text that records his adventure does not survive, but the Roman naturalist Pliny the Elder mentions it in his *Natural History*, and so does the later Roman poet Avienus. Himilco apparently made contact with people Avienus calls the Oestrumnides, who perhaps lived in Brittany. He probably made the voyage for trade purposes, specifically to acquire tin that could be used in the making of bronze. According to legend, Himilco's account described a harrowing journey, complete with sea monsters. Historians believe that he fabricated details such as this to deter Carthage's rivals, the Greeks, from exploring the region themselves. His voyage, though, provides yet another example of the Carthaginian genius for exploration.

EGYPT

BY AMR KAMEL

Throughout their long history, the Egyptians were confident that Egypt was the heart of the world, where "god (Amun) established the land of Egypt first," before all other lands. To its inhabitants, Egypt was always the only place where it was worthwhile to live; all foreign territories lay somewhere on an uncertain and not very attractive edge of the world. Foreign lands were depicted as a three-peaked desert mountain ridge with a strip of green at its foot. The latter represented their ideal country—the Nile Valley. The same symbolism expressed the idea of order (the green strip of Egypt) and chaos (the desert ridge).

Thus, the Egyptians saw no reason to explore the bleak wilderness beyond their borders either out of curiosity or for science. Moreover, their literature frequently asserts that the dangers that one might face abroad, particularly lions and Near Easterners ("Asiatics"), greatly outweighed any justification to venture that far. A text from the Twelfth Dynasty (1991–1783 B.C.E.) describes traveling to Asia as a sufficient reason for an emissary to will his belongings to his children before leaving.

This attitude dominated the Egyptian mentality throughout the empire's history. It is apparent in official religious and royal texts, even with respect to countries with which Egypt enjoyed good economic or political relations. Thus, not much information is contained in Egyptian literature about exploration in the modern sense. However, the Egyptians did sometimes write descriptions and make drawings with abundant topographical details of the places they visited or discovered abroad. Texts give a careful description of several ethnic groups they encountered in Nubia or the Near East, including the social mores of these peoples, which typically the Egyptians thought strange.

These descriptions came in the form of travel accounts, which dealt mainly with trade, warfare, and diplomatic activities, composed by teams of skilled scribes or painters, who traditionally accompanied Egyptian expeditions to foreign lands in the Near East and in Nubia, especially during the New Kingdom (1550–1070 B.C.E.). The earliest-known example preserved in art comes from the Fifth Dynasty (2465–2323 B.C.E.) mortuary temple of Sahure at Abusir. The temple's decorations include a scene depicting what was likely the safe return home of an Egyptian trading expedition with exotic goods sent under royal patronage to visit far-off Byblos on the eastern Mediterranean coast. The oldest written account of an encounter was carved on the external walls of a late Old Kingdom (2575–2134 B.C.E.) tomb-chapel in Aswân. The tomb's owners held the title "head of translators," reflecting their understanding of local dialects in the areas they visited when they conducted several official voyages to explore, or literally "open," the southern territories of Nubia.

Another important account was that of Harkhuf, a Sixth Dynasty (2323–2150 B.C.E.) governor of Elephantine (Aswân) who was responsible for Egyptian interests in Nubia. Harkhuf, who traveled four times to Nubia, mentioned in his inscription the first royal assignment, which was to "open a way to this foreign country" and "bring back from there all sorts of beautiful and rare gifts." His inscriptions refer to three additional trips, literally to "fulfill a horizontal mission" to an unnamed area, that he took alone. Few topographical details of these territories were recorded. Nevertheless, Harkhuf reported a clash between the ruler of Yam and some Libyans, and his role in stopping it.

The first full description of a territory outside of Egypt appears in the story of Sinuhe, from the Twelfth Dynasty. The story describes Palestine, where the author had spent much of his life after his flight from Egypt immediately after the assassination of Amenemhet I (r. 1991–1962 B.C.E.). He describes

it as “as a good land, called Yaa,” with “more wine than water.” Along with describing the area’s bounty, he wrote that the area’s ruler made him chief of a tribe. Sinuhe spent many years with the ruler of Upper Retjenu and adopted the appearance, dress, and way of life of a local ruler. However, all failed to bring him happiness. Eventually, at the end of this tale, Sinuhe realizes that death is approaching, and he returns to Egypt at the king’s explicit request. He is forgiven and essentially reborn as a true Egyptian after being purified, almost ritually, of all the marks of foreignness acquired during his years in Palestine.

From the New Kingdom the most splendid narration about foreign lands described a voyage to the land of Punt. It is considered to be an ethnographic record, even though the land of Punt was first noted in the Old Kingdom. The voyage was documented in reliefs on the walls of Queen Hatshepsut’s (r. 1473–1458 B.C.E.) mortuary complex at Deir el-Bahri in pictures with a few captions explaining the place and the characters. The Egyptian artist carefully portrayed the Puntites, with red skin and facial features similar to Egyptians, long or bobbed hair, goatees, and kilts. These same reliefs show the Puntites as a settled people, with houses on stilts. The meticulously recorded flora and fauna suggest that the land was located in Eritrea or coastal Sudan, though scholars continue to debate this.

From the same period the Egyptian scribes who accompanied Thutmose III (1479–1425 B.C.E.) during his military campaigns into West Asia depicted them in the two chambers to the rear of his festival temple at Karnak. Egyptologists refer to these chambers as the “Botanical Garden” because of their depiction of 275 different types of plants, which are shown complete with their root systems. Adorning these walls appear to be genuine botanical specimens, thus making the chambers the world’s oldest herbal garden. Also illustrated are at least 52 animals, including 38 birds, a few of which are unique to Egypt, including the darter, the diver, and the great spotted cuckoo. Also prominently represented in the Botanical Garden are several head of cattle of the two-tailed and three-horned variety. Such oddities may be simple flights of creativity or, perhaps, farmyard oddities.

The Greek historian Herodotus mentioned an expedition sent by the pharaoh Necho II (r. ca. 610–595 B.C.E.), with the aim of sailing around Africa. This maritime expedition was apparently conducted by Phoenician sailors, presumably using their ships and not Egyptian ones. Although the circumnavigation of Africa was an important event, it remains obscure whether or not this voyage was completed; some scholars believe the expedition probably had more to do with the king’s naval policy rather than with a quest for knowledge.

THE MIDDLE EAST

BY KIRK H. BEETZ

As is often the case for ancient exploration, archaeologists and historians know that exploration took place, but the names of

the explorers are rarely known, and the details of what they did and when are hazy. For the ancient Near East, exploring commenced the moment human beings left Africa and began spreading throughout the world. They may have been looking for food, fleeing a drought, or just wanting to see what was beyond the horizon.

Probably searching for food, nomads seem to have passed through Mesopotamia constantly before people settled down into farming communities. From about 3500 B.C.E., when Sumerian city-states flourished, to about 625 B.C.E., when the Neo-Babylonian dynasty arose, Mesopotamians worshipped their cities as holy places, and they loved their cities. This practice may have tended to pull people toward their homes and to discourage exploration, yet some did explore. Their reasons for exploration were spiritual, commercial, political, and military. They also explored to achieve personal glory and to satisfy the common human desire to discover what is over the next hill.

One of the folk beliefs that persisted in the Near East was that a land where people lived forever lay to the far east. One of the world’s first great literary works, the Epic of Gilgamesh, tells of a true historical figure, Gilgamesh, who ruled the city of Uruk in about 2700 B.C.E. It tells about how Gilgamesh left his home to seek answers to fundamental aspects of human existence, especially why human beings are mortal. The story tells of his making a physical journey across strange lands to find the answers, and it probably reflects the idea of making spiritual pilgrimages that would have involved exploration. Perhaps contact with the Harappan civilization (2600–1500 B.C.E.) in the Indus River valley was first made by pilgrims seeking the land of immortality.

On the other hand, explorers may first have sought out the Harappans because of Harappan trade goods that were finding their way into the Near East through intermediaries, especially Arabian traders. People seeking out direct contact with such cultures as the Harappans to the east may have been motivated by a desire to skip the middlemen and thereby import goods less expensively. Indeed, the potential for finding new trading partners would have combined adventure with profit. Those who ventured into strange lands would have brought back with them tales of unusual peoples. It may have been such tales that inspired Sargon I (r. ca. 2334–2279 B.C.E.), founder of the Akkadian Empire, to conquer lands along trade routes. One could argue that he was just trying to monopolize trade, but he took an excursion into Anatolia during which he looted but did not absorb new territory into his empire, and the purpose of the excursion was probably primarily to explore—to find out whether there was anything worth conquering. Much later in history, from 336 to 326 B.C.E., Alexander the Great conquered his way across the Near East partly so that he could see the edge of the world, which supposedly lay to the east, beyond India. Like Sargon I’s venture into Anatolia, Alexander’s conquest was a form of military exploration.

Another form of exploration occurred when people wanted to escape bad economic times or to find work. En-

tire tribes of people migrated from the north, the east, and the south into Mesopotamia in the hope of finding a place to settle where they could prosper as the Mesopotamian city-states did. Skilled artisans could leave their homes and follow the trade routes, hoping to find a place where their handiwork would be rewarded. For example, Jewish metalworkers, beginning in the 500s B.C.E., searched the Near East and perhaps beyond to find work. Jewish metalworkers were especially valued and found new homes from Egypt to as far east as Iran. Their search for employment had begun in 586 B.C.E., when the Babylonian Empire had deported the people of Judah to Mesopotamia. After Persia's Cyrus the Great (r. 558–529 B.C.E.) conquered Babylon in 539 B.C.E., he told the Jews that they could return to Judah, but many remained in their new homes in distant lands, where they prospered.

Governments of the ancient Near East were often torn between a desire to keep their populations focused on their homes and on their duties to the government and a desire to know what opportunities lay beyond their territories. There was a dangerous world, with wars for seizing loot, conquering territory, and achieving glory resulting in destroyed cities and enslaved peoples. By the time of Sargon I, exploring unknown lands was becoming a necessity for survival. Governments would send explorers to travel into unfamiliar territories to learn about customs, trade, and other governments. Nomadic peoples often explored in order to find places to settle within the territory of a nation, as the Kassites did in the late 1700s B.C.E., when they moved into Babylon's lands.

The most impressive feat of government-sponsored exploration may have occurred in about 600 B.C.E. Over the centuries Egyptian governments had sent expeditions into the Sinai and south into sub-Saharan Africa to seek sources of geological deposits of metal, especially gold, and to discover sources for trade goods valued in Egypt. In about 600 B.C.E. the Egyptian pharaoh Necho II (r. 610–595 B.C.E.) commissioned the Phoenicians to send an expedition to discover how big Africa actually was. The explorers sailed south through the Red Sea, past Punt on the east coast of Africa, and then disappeared. Three years later they sailed east through the Strait of Gibraltar, having circumnavigated Africa.

The Phoenicians were great explorers. In the 2000s B.C.E. people in the northern Levant began trading with the rest of the Near East and Egypt. From 1100 to 800 B.C.E. the Phoenicians of the northern Levant established trading posts first on Cyprus, then on Crete, and then in southern Greece and the northern Aegean, yet most Phoenician trade was by land. In the 1100s B.C.E. the Phoenicians sailed westward, trying to find new opportunities for trade. They even sailed out of the Mediterranean to Cornwall in Britain and south along the west coast of Africa, where they established trading colonies. On the south coast of the Iberian Peninsula, now Portugal and Spain, they found sources of tin and silver. On the northern coast of Africa, Phoenician explorers found a good harbor, and between 814 and 714 B.C.E. they founded the city of Carthage there.

FABULOUS VOYAGES OF THE PHOENICIANS

The ancient Phoenicians sailed to Cornwall in Britain, to the Azores, to the Canary Islands, and even around the western hump of Africa into the Gulf of Guinea, where they found crocodiles and gorillas. In the 900s B.C.E. they sailed three times a year to the mysterious Ophir for King Solomon of Israel, bringing home exotic treasures, notably peacocks, suggesting that Ophir may have been in India. Yet one voyage stands out in ancient records: the one that circumnavigated Africa in about 600 B.C.E.

The Phoenicians were very experienced in voyages of discovery by the time Necho II of Egypt commissioned them to discover the full extent of Africa. They built ships of wood, usually cut from their extensive cedar forests. Some were large 100-foot-long cargo ships with a length-to-width ratio of 2.5 to 1. Others were sleek and swift. Both types of ships could sail the oceans, usually staying close to coastlines. It was probably in a sleek, swift ship that the Phoenicians sailed south in the Red Sea to start their great voyage.

The Phoenician explorers brought seeds with them, probably knowing from past experience that the seeds might be needed. When autumn came, they went ashore and planted crops. After harvesting the crops, they continued onward. They planted and harvested each year of their voyage. The Greek historian Herodotus recorded that the voyagers said that when they sailed westward around the southern end of Africa, the sun was to their right, meaning to the north. Living north of the equator, as the people of the Mediterranean did, meant that the sun crossed the sky to the south; from south of the equator, the sun would appear to cross to the north. The way for the Phoenician explorers to have noticed this phenomenon was to have sailed, as they claimed, south past the equator and then westward around the southern tip of the continent, when the sun would be to the north, on their right. It took them three years to circumnavigate Africa and enter the Mediterranean from the west and sail to Egypt.

Another group of impressive seagoing explorers was the Arabs. They lived mostly on the Arabian Peninsula. They became the great middlemen of southern Asia and explored along the coast of Africa, establishing trade relations with eastern Africa. They also ventured eastward, reaching southern India and Ceylon (now Sri Lanka) in the 500s B.C.E. When the Roman Empire wanted to explore southern Asia

and find new trading opportunities, the Arabs, as well as the Egyptians, were the people they chose for their crews.

ASIA AND THE PACIFIC

BY MICHAEL ALLEN HOLMES

Much of the exploration that took place in Asia and the Pacific in ancient times was motivated by desires for military conquest, enhanced trade, and religious enlightenment. On the Indian Subcontinent the early influx of Aryans, who arrived in waves from the north sometime between 1500 and 1300 B.C.E. (in what historians alternately describe as “invasions” and “migrations”), accounted for the importation of much of the foundations of future Indian culture, such as the language of Sanskrit. The Aryans themselves in time fully integrated with the darker resident populations of the valleys of the Indus and Ganges rivers. Much later, Buddhist missionaries proved responsible for much of the Indian peoples’ exploration of outlying lands. Siddhārtha Gautama (563–483 B.C.E.), the Buddha himself, essentially wandered throughout, rather than explored, portions of the Indian Subcontinent, especially into the northeastern region now known as Bihar. That region was named after the forest in which the Buddha reached enlightenment, as its hillsides grew dotted with the ascetic stone dwellings of the many monks who were inspired by and followed the Buddha’s teachings.

Later, in 250 B.C.E., the Mauryan emperor Asoka, who made sweeping efforts to spread the Buddhist affection for love and peace throughout India, held the Third Great Council of Buddhism in Pataliputra (now known as Patna), in the northeast. Afterward devout Buddhists began traveling well beyond the Indian Subcontinent, first to what are now Myanmar and Sri Lanka and later throughout Southeast Asia. By the first century C.E. Buddhism had spread along the central Asian silk trade route into China; similarly, Buddhist notions, if not the nominal faith and philosophy themselves, traveled northwest through Gandhara toward the Middle East, possibly inspiring the mythology surrounding the life of Jesus Christ. Overall, Indian rulers’ and peoples’ relative disinterest in exploration can largely be explained by the widely established ideal of a life of simplicity.

In China among the first frontiers breached in the name of exploratory interests were those in the north and northwest. In 139 B.C.E. the Han emperor Wu Ti (r. 141–87 B.C.E.) appointed a courtier named Chang Ch’ien both to subdue the nomadic peoples to the north and to secure the trade route into central Asia. In particular, Chang Ch’ien sought to ally the northwestern Yueh-chih tribe with the Han Empire against the feared Hsiung-nu of the north. However, in traversing the northwestern deserts and grasslands in attempting to make contact with the Yueh-chih, Chang Ch’ien was captured by the Hsiung-nu. Adapting to the circumstances, he lived with the Hsiung-nu for 10 years, marrying and even raising a family, before finally escaping and resuming his mission.

Stucco head of a monk, said to be from Hadda, Gandhara, fourth to fifth centuries C.E.; Buddhist missionaries were responsible for much of the exploration of outlying lands performed by Indian peoples in ancient times. (© The Trustees of the British Museum)

Chang Ch’ien thence traveled farther than any Chinese emissary had before, reaching Fergana, then Bactria, located in modern Afghanistan and Uzbekistan, where he discovered the Yueh-chih living peacefully. After finally traveling as far as Sogdiana, also in modern Uzbekistan, Chang Ch’ien returned home to report on what he had seen, bringing back various theretofore unknown seeds and plants. The Han then essentially took control of the trade routes and extended their empire as far as Chang Ch’ien had traveled, securing a means of exporting their widely coveted silk, among other goods. Chang Ch’ien is as renowned in Eastern history as are such explorers as Marco Polo and Ferdinand Magellan in Western history.

Much of ancient Chinese exploration was, in fact, carried out during the reign of the Han Dynasty, from 202 B.C.E. to 220 C.E., when territorial expansion was a priority. To the northeast, military colonies, termed *t’un-t’ien*, were set up in Manchuria and Korea. Often, where Han exploration led to encounters with hostile peoples, the dynasty at once made peace and increased commerce by presenting gifts; silk, in particular, proved an invaluable commodity. Mongoloid peoples first crossed the Korea Strait to the islands of Japan in the second and first centuries B.C.E., when they found such tribal peoples as the Ainu, who may have been primitive

Caucasians who had arrived there centuries earlier by way of Siberia. Here, as with the Aryans exploring as far as and moving into India, the Mongoloid peoples' integration with the local populace accounted for substantial cultural developments. Mongoloid horsemen from northeastern Asia made exploratory and invasive forays throughout Asia and as far as the Roman Empire after the dissolution of the Han Dynasty; some of these warriors made their way to Japan, further re-orienting society there.

Occasional Chinese ventures into Japan provided much of the evidence of the extent to which prehistoric civilization had developed there. One traveler noted in 238 C.E. that the small states that had come into existence on the Japanese islands were ruled by sorceresses, with much of the internal political structures arranged in matriarchal fashion. Another Chinese explorer noted the Japanese people's naturalistic habits, as they reportedly subsisted largely on raw vegetables and forwent footwear. Thus, exploration in this direction served primarily to increase knowledge of regional cultural differences.

Southern exploration, led largely by Ma Yuan (14 B.C.E.–49 C.E.), "Tamer of the Waves," went only as far as the dense forests and barbaric peoples there would allow; the demons and ghosts said to inhabit those regions especially inhibited would-be conquerors. Although the South China Sea was reached, making possible travel by ship to the Gulf of Siam, the Java Sea, and the Bay of Bengal, the coastal waters were especially treacherous, and the Chinese ventured along these maritime routes far less frequently than did foreign vessels. Nevertheless, the ports established there likewise allowed for increased trade, with Persian and Sinhalese merchant ships depositing gems, drugs, and hardwoods and departing with porcelain, musk, and slaves. Those Chinese who did set out returned with coconuts and ambergris from Nicobar and with saffron, sandalwood, and ivory from India. Thus, in many ways, Han exploration led more to the enrichment of the empire than to its actual territorial expansion; as the dynasty grew satisfied with its economic situation and as further excursions, over unfriendly seas and land alike, threatened more substantial costs, outward exploration came to a halt.

With regard to the islands of Southeast Asia and the Pacific, exploration by Chinese peoples beginning as early as 3000 B.C.E. led to the region's initial inhabitation. After traveling by sea to the northern reaches of the Philippines, peoples migrated southwest to Borneo and Sulawesi around 2500 B.C.E. and then farther southwest to Sumatra and east to Irian Jaya around 2000 B.C.E. Sometime around 1500 B.C.E. more capable seafarers ventured out to central Pacific islands from the Philippines and other eastern points on Indonesia and Papua New Guinea.

EUROPE

BY KIRK H. BEETZ

For thousands of years European tribes and nations were exploring new lands to find places to live. People continued to do

this even after the fall of the Western Roman Empire in 476 C.E. One way such explorations happened was recorded by Greek historians from the oral history of the Celts. According to the Greek written history, in the late 300s B.C.E. a Celtic tribe lived along the southern Danube River. Times were very hard for them, and crops were failing. Their children were dying, probably from malnutrition as well as disease. Their leaders failed to do anything worthwhile to improve the lives of the people; even the warriors, the elite of the society, looked for leadership instead of providing it. A woman named Onomaris declared that she would accept the thankless task of leadership.

First, she decided that the tribe had to move to better land, dividing the tribe's food, animals, tools, and weapons among the families according to how much each family would need for a long journey. Onomaris and her people did not know where they were going, but this would have seemed normal to the Celts who heard and retold the story, because the peoples of Europe often left their homes and moved as a group to find new lands. In the case of Onomaris and her people, they encountered rivers and swamps, and they sometimes had to fight hostile people. Eventually, they encountered an unclaimed place where they could farm the land, and they settled there, finding peace and good times. Exactly where they went is unclear; migrations from Onomaris's region tended to head eastward at that time, but north and south were also possibilities. Any tribe that moved as Onomaris's did would have to be prepared to fight people in their way and to carry what they needed.

Another reason for exploration was commerce. Among the earliest explorers in Europe who are known to modern historians were the Mycenaeans, who prospered in the Aegean region during the 1000s B.C.E. until their civilization collapsed in about 1200 B.C.E. In search of minerals, they explored the Balkans, central Europe, and northern Europe, finding metal ores and amber, which they traded with decorative goods such as glass beads they had brought from Egypt. Their presence as traders and their trading posts in Europe probably made Europeans curious about the origin of the Mycenaeans' wealth.

Among those who wanted to know were probably the Nordic peoples of southern Scandinavia. These people spoke a Germanic language and were loosely organized into tribal groups. They left a great deal of rock art, both carvings and paintings, of their boats, which resemble the later Viking ships with long bodies and oarsmen in rows on each side of the vessel. The prows do not seem to have the carved dragon heads typical of the Vikings longships, but they rise in the same graceful curve as Viking prows. Following the collapse of the Mycenaeans, little of their written literature was preserved, but some of the culture's artwork survived. A mural on the island of Thíra, in the Cyclades islands in the southern Aegean, hints at what Scandinavian explorers may have achieved. Painted in the 1500s B.C.E., it depicts the island's port, with tall houses, docks, and boats propelled by sails and oars. Among these boats is one that looks like a Nordic boat.

The Scandinavians were restless people, exploring along the coasts of the Baltic Sea and the North Sea. It is probable that they sailed south along the coast of continental Europe or out to Britain as well. Their motives were probably similar to those of the Vikings centuries later: They looked for new places to live and prosper, they looked for rich lands to loot, and they wanted the glory of discovering new lands. Sailing all the way to the Mediterranean would have taken great daring, but if they did as the Phoenicians usually did and stayed close to the coastline, they would have eventually discovered places to land and trade as well as the source of Mycenaean commerce. They may have also reached the Aegean by an overland route. There are only hints of what the ancient Scandinavians achieved because they were an illiterate people; however, they may have traveled as the Vikings did during medieval times, who would row or sail along a river until it became too shallow, then haul their longboats overland to another river and continue their journey.

Aggression was another motive for exploration. The Germanic and Celtic peoples of Europe were warrior cultures, and warriors were the elite social class. For the Celts, war was a matter of earning honor. The taking of booty was often a secondary consideration. On the other hand, war was sometimes viewed as a necessity, as one tribe needed to move from bad lands and dangerous circumstances to good lands and safety. Sometimes they seemed to explore alone or in small groups into territories where there might be a military weakness on which they could capitalize.

The Greek-Syrian explorer Posidonius (ca. 135–ca. 51 B.C.E.) lived among the Celts and noted that he was treated fairly well as an outsider. He had no merchandise to trade, which made him less interesting to his hosts than he might have been, but he was made a guest at meals given by chiefs and served as a curiosity for other visitors. He was not expected to behave like the Celts. Other explorers did not necessarily fare so well. By Posidonius's era, Germanic people were regarded with suspicion by Celts because the Germanic peoples often made war on the Celts. On the other hand, Celtic explorers from other tribes could find themselves guests and would be expected to give accounts of the lands they had visited. Such Celtic explorers were frequently restless young men sent abroad by their elders before they could make trouble for the rulers of their tribes. Singly or in small groups, these young men might kill, loot, or steal, or they might find a chief who wanted them to join his or her retainers. Among the Germanic peoples, this process was common as well, with chiefs taking in newcomers who pledged themselves to their service. This practice would later be part of the premise for the epic *Beowulf*.

While at times welcomed, a Celtic explorer could expect to be looked upon with suspicion, especially if it was plain that he was not a trader. When caught, spies would often be challenged to combat, with their severed heads being added to the collections of those who killed them. Often young explorers were very unwelcome because the local tribal leaders

already had too many hot-blooded young warriors to worry about, and the young explorers would be chased away. Still, for these voyagers, their journeys offered adventure, new and exciting experiences, and the chance to win honor in the service of the chiefs they met.

GREECE

BY CHRISTOPHER BLACKWELL

The earliest Greek explorers were the anonymous men and women who sailed off the coast of the European mainland and settled the islands of the Aegean Sea, eventually building the Bronze Age civilizations that archaeologists have found on Crete and neighboring islands. From there, early explorers made contact with the vastly more ancient civilization of Egypt as well as the empires of Asia Minor.

The earliest literary evidence for exploration is the Homeric *Odyssey*, a work of fiction and fantasy but one that reflects a resurgence of travel by sea at the end of the Greek dark ages around 800 B.C.E. Odysseus, on his 10-year journey home from the Trojan War, finds his way to Sicily, the Aeoliae Insulae (modern-day Lipari Islands), and other more obviously mythological locations. Through incidental details in this poem, it is possible to see past the fiction to a historical reality that involved adventurous Greeks going abroad to new places for trade and war. When Odysseus meets people on his journeys they invariably ask him, "Are you here for trade, or are you a pirate?" as if these were the two most likely professions of a stranger met on the beach.

During the eighth and seventh centuries B.C.E. trade between Greek cities and the rest of the world expanded greatly. Greek pottery is found throughout the Mediterranean and as far north in Europe as Sweden, although who brought it there is unknown. What is known of ancient Greek exploration has to be sifted from fragmentary accounts of voyages, some perhaps historical and some almost certainly fictional, that appear in works of authors who may have lived centuries after the events they describe. But accounts of journeys were common enough to be a named genre, *periplous*, meaning "voyage of discovery." The earliest is a narrative known to the Greeks of a voyage by Hanno, a Greek-speaking Carthaginian navigator from North Africa (in modern Tunisia). Around 480 B.C.E., when the Greek world was involved in its great war with Persia, Hanno journeyed past the Straits of Gibraltar (which the ancients called the "Pillars of Hercules") and into the Atlantic. This journey took him down the western coast of what is now Morocco. He records founding settlements of Carthaginians at Essaouira (formerly Mogador) and Agadir, and traveling south past Lixus. He also mentions seeing volcanoes and describes gorillas.

Another "voyage of discovery," known to the Greeks of the fifth century B.C.E. was that of Scylax, who was satrap, or governor, of the Caryanda, part of the Persian Empire of Darius the Great (r. 522–486 B.C.E.). Scylax is said to have sailed down the Indus River from near the Karakoram Range

of modern Pakistan to its mouth, and to have come to the area of the Suez.

In the second half of the fourth century B.C.E., Alexander the Great's invasion and conquest of Persia ended in a march of discovery from the area of modern Syria and Turkey, through what is now Iraq and Iran, bringing him to Bactria, Sogdiana, Samarqand, and ultimately to the Indus River and the ends of the Punjab in India. At this point his Macedonian army, who had walked thousands of miles and fought many battles, refused to go further, and Alexander took them on a forced march back west, which entailed a grim passage of the Gedrosia Desert.

At the end of the fourth century B.C.E. the Greek explorer and navigator Pytheas of Massilia (modern-day Marseille) wrote *About the Ocean*, which recounts his journey west and north, from Gades (present-day Cádiz) in southern Spain, up the Spanish coast, past the mouth of the Loire river (near modern-day Nantes), and to the Cassiterides (the "Tin Isles," the modern British Isles), and particularly to Belerium (modern Cornwall), an important center for trading tin. Copper and tin made bronze, and of the two elemental metals tin was much rarer in the Mediterranean world. Pytheas is believed to have circumnavigated Britain and recorded other lands that scholars have tentatively identified as Norway, the Vistula River (in modern-day Poland), and an island in the North Sea that may have been Helgoland, which Pytheas reported as being rich in amber.

Euhemerus of Messene, also from the late fourth century B.C.E., was a famous author of the literature of exploration. Euhemerus served under the Macedonian Cassander, who ruled in European Greece after the death of Alexander the Great in 323 B.C.E. Euhemerus's account of a voyage to islands of the Indian Ocean, including perhaps Sri Lanka, was popular and widely quoted by later authors, such as first century B.C.E. historian Diodorus Siculus. Although the writings of Euhemerus are based on real knowledge of Indian islands that may reflect the work of more authentic explorers, they are regarded as entirely fictional.

Because Alexander's conquests left Macedonians in charge of pieces of the former Persian Empire, which stretched from the Aegean to India, knowledge of the eastern parts of the world became much more readily available to the Greeks. Alexander had left Sibyrtius as governor of Gedrosia, in the east of his conquered territory, and Sibyrtius sent one Megasthenes as an ambassador to India. Megasthenes met with Candragupta (r. ca. 321–ca. 297 B.C.E.), founder of the Maurya Empire in northern India, and returned to write of his travels in a work entitled *Indika*.

Even under the Romans, many of the fundamental works of geography and books about exploration that provided geographical data were written in Greek by Greeks. For example, the Greek historian Polybius, who served with the Roman general Scipio during the Second Punic War in the second century B.C.E., accompanied Scipio on an exploratory voyage into the Atlantic Ocean. Also during the second century

B.C.E. the historian and geographer Agatharchides of Cnidus wrote of his voyage around the Red Sea, with descriptions of Arabia and Ethiopia. The historians Diodorus Siculus and Aelianus as well as the geographer Strabo, all of whom lived in Rome and wrote in Greek, relied heavily on Agatharchides' work for their own.

Ptolemy (also known as Claudius Ptolemaeus), considered one of the greatest ancient geographers, lived during the second century C.E. His treatises cover mathematics and astronomy, but he is most famous for his massive *Geography*, the first work to use latitude and longitude to identify the locations of places. For his description of lands to the east, Ptolemy relied heavily on Marinus of Tyre, about whom little is known except that he wrote during the first century C.E. and that he provided a cultural and geographical description of the "Seres," the ancient Greek term for the Chinese. Ptolemy also mentions a certain businessman from Damascus named Maes or Titianus, who claimed to know overland routes for travel to China, thus perhaps anticipating Marco Polo by over a thousand years. Ironically, the most significant error in Ptolemy's *Geography* can tell us much about ancient exploration. His maps show a large landmass connecting southern Africa to China, depicting the India Ocean as an enclosed sea. In a work as thoroughly researched as his, Ptolemy's error is convincing proof that no ancient Greek or Roman by the second century C.E. had circumnavigated Africa.

ROME

BY DUANE W. ROLLER

The Romans had no sense of exploration for its own merits; the Latin word *exploratio* refers to a military reconnaissance. But since the Roman world expanded over vast territories and since there were trade and commercial contacts throughout much of the Eastern Hemisphere, almost by accident the Romans were able to explore large regions, though inevitability as a by-product of political or mercantile interests.

In their early years the Romans made no addition to geographical knowledge. Their expansion from the fourth into the first century B.C.E. throughout Italy, into the western Mediterranean region, and eventually into the Greek world did not reach any areas previously unknown to Mediterranean cultures. Roman exploration actually began with their destruction of Carthage in 146 B.C.E. At this time the Romans acquired the cultural heritage of their defeated enemy and learned about a wide range of Carthaginian exploration into areas previously unknown to the Romans: down the west coast of Africa (and perhaps around the continent), into sub-Saharan Africa, and along the Atlantic coasts as far as the British islands.

Roman curiosity led Scipio Aemilianus (ca. 185–129 B.C.E.), the conqueror of Carthage, to commission his adviser, the historian Polybius (ca. 200–118 B.C.E.), to investigate. Polybius made a number of trips, going down the West African coast as far as the tropics and across France to its north-

The Dream of Scipio, by Raphael; Scipio was the Roman conqueror of Carthage, the destruction of which initiated Roman exploration. (© The Trustees of the British Museum)

west corner. He also inquired of the western Greek states such as Massilia (modern-day Marseille) what there might be of interest beyond the limits of Roman knowledge. Although both Carthaginians and Greeks tried to divert the Romans from involvement in the west—the results of their own explorations were considered state secrets—the Romans did learn about the Atlantic coast, and it became part of their cultural understanding.

In northwestern Europe, Greeks had explored the British Isles, the Baltic region, and parts of the Arctic and Scandinavia. Romans added little to this, though the North Sea coast, bypassed by the Greeks, was examined with great difficulty in the Julio-Claudian Dynasty (27–68 C.E.): Repeated maritime disasters led to a feeling that the Atlantic coasts were of no interest. Nevertheless, this completed ancient Roman knowledge of the coast from the West African tropics to the interior Baltic area. The amber trade from the Baltic acquainted the Romans with several routes across

northern Europe, especially the connections between the northern affluents of the Danube River, such as the Morava River, and the systems of the Oder and Vistula rivers, explored by a Roman merchant in the 50s C.E. Romans remained only vaguely aware of the farther side of the Baltic and Scandinavia.

Interior Africa had first been penetrated from the Mediterranean in early Greek times, and the routes up the Nile River or across the Sahara had been known since at least the fifth century B.C.E. The east coast was understood as far as Zanzibar. In the first century C.E. the Romans contributed significantly to the exploration of central Africa. The question of the source of the Nile was part of this interest, having been a topic of curiosity since at least the sixth century B.C.E. and not solved until modern times. Greeks had long tangled with the issue, but attempts to follow the Nile upstream had gone barely beyond the lower cataracts. Juba II, the Romanized king of Mauretania from 29 to 25 B.C.E., believed that the

river began in northwest Africa and published his proof, tracing its course across northern Africa, while admitting that it ran underground for some distance. Bizarre as this theory seems, it was still accepted in the 19th century.

Around 60 C.E. Roman officers moved up the Nile for a planned invasion of Ethiopia by the emperor Nero (r. 54–68 C.E.), reaching the marshes in present-day southern Sudan and hearing reports of the lakes beyond. A traveler named Diogenes, perhaps a generation later, moved inland from the vicinity of Zanzibar and saw or heard about the high mountains of central Africa, providing the name Mountains of the Moon, and he was also aware of the lakes around the source of the Nile. But the actual source itself remained elusive until the 19th century, and there was no further exploration of Africa in classical antiquity. Roman trade items and coins reached the southern parts, but the Romans seemed unaware of the interior south of a line from Zanzibar to Cameroon.

To the east the journey of Alexander the Great (356–323 B.C.E.) had brought India, and the routes to it, into Mediterranean knowledge, though details such as the size and shape of the Arabian Peninsula continued to be refined in the Roman period. In the first century C.E. Sri Lanka, known since the fourth century B.C.E., was examined in detail, and a Roman trading post was established at Arikamedu on the east coast of India around 50 C.E. In the following century the Bay of Bengal was explored by a certain Alexander, who may have gone as far as the Cambodian coast; by late in the century a Roman trading post may have existed at Oc-êo in the Mekong Delta.

China had been known since Greek times as the origin of silk; the name of the region first appears in Greek accounts (as “Thina”) of around 50 C.E. There is no evidence that Mediterranean peoples actually reached China until around 100 C.E. The one definitive record of Roman contact with China is in 166 C.E., when an embassy from the emperor Marcus Aurelius Antoninus (r. 161–180 C.E.) reached China and was recorded in Chinese records as a mission from An-Tun. From that time there were sporadic contacts and frequent trade in both directions.

Through trade routes the Romans were aware of parts of central Asia east of the Caspian Sea, though little was added to the knowledge existing since the late fourth century B.C.E. Routes north from the Black Sea to the Baltic region had also long been known, but otherwise Siberia lay completely outside ancient knowledge. Japan and southeastern Asia were similarly unknown to the Mediterranean world. Existence of the Western Hemisphere had long been presumed, largely on the basis of geographical symmetry, and much fantasy literature was written about the existence of a western continent. This was an inspiration to the European explorers of the Renaissance, but there is no evidence of European contact with the New World until Viking times, although the mid-Atlantic islands such as the Azores and Madeiras had been known since their Carthaginian discovery.

THE AMERICAS

BY J. J. GEORGE

At a site in Midland, Texas, the skull of a woman lacking facial bones was found protruding from sand in a windblown depression. Snail shells found in a layer of earth below her yielded a carbon 14 date of about 11,000 B.C.E. Artifacts found with her resembled Folsom-style objects and were dated to about 8000 B.C.E. Folsom, along with Clovis, are two of the earliest American cultural patterns. Scientists have suggested that the woman probably died there between 9000 and 10,000 B.C.E. In central Mexico at a place called Tepexpán the skeleton of a man was found in late Pleistocene sediment and dated 9000–8000 B.C.E., but the excavation was poorly reported. Chemical tests nonetheless confirmed the date. In the 1930s the archaeologist Junius Bird excavated a few skeletons from a South American site called Palli Aike in Patagonia. Bird discovered sloth and horse bones in an overlying deposit and a fishtail point deposit in an underlying lava deposit. Carbon 14 dates for these items ranged between 9000 B.C.E. and 8700 B.C.E. Are these the remains of some of America’s early explorers?

Ultimately, the idea of exploration in the ancient Americas presents a peculiar conundrum. On the one hand, the period’s defining quality is exploration, when one considers exploration’s relation to migration. As new peoples arrived in the Americas and diffused south, eventually reaching the southern tip of South America, their very existence was a form of exploration. On the other hand, the idea of exploration in a more familiar form, such as the maritime expeditions of Captain James Cook, Ferdinand Magellan, and Christopher Columbus or the overland exploration of the western United States by Meriwether Lewis and William Clark, in the name of colonization or science or Manifest Destiny, was virtually unknown until much later.

Exploration is a defining aspect of American migration and settlement and has its beginnings at Beringia, the name assigned by geologists for the continuous landmass that once connected Siberia and Alaska and offered a broad highway to the Americas not only to early humans but also to the animals they hunted. The traditional theory says the first North Americans were big game hunters on foot, following large animals such as the extinct mammoth. During the last glacial episode (10,500–11,000 years ago), when much of the earth’s water was locked up in frozen glaciers and water levels worldwide were much lower, the landmass was as much as 1,000 miles wide. The present geographic proximity of Alaska and Siberia is itself suggestive of an easily overcome barrier; only 56 miles of water separates the two landmasses. In the winter the strait often freezes and it is possible to walk across the ice. It is generally agreed that the diffusion of the earliest peoples crossed into the Americas via this passage.

Once in Alaska, however, the early explorers would have encountered a nearly impenetrable barrier to southward progress—the same glacial advances that lowered sea levels and revealed Beringia also covered Canada and northern

America in two massive ice sheets. The western ice sheet is called the American cordillera, and the eastern is called the Laurentia. At certain times these two sheets met, and at other times a narrow corridor opened, stretching to Alberta, Canada, and there opening to the northern plains. There is much disagreement still about whether it would have been possible to traverse what certainly would have been an inhospitable environment between massive glaciers.

While an inland route of exploration would have served a cold-adapted population best, it would not have been the only option available. When the land bridge was submerged, prehistoric peoples could have walked across the ice pack in winter or paddled across in small boats in summer. The Norwegian explorer and archaeologist Thor Heyerdahl, among others, has shown the extraordinary exploratory possibilities of seafaring among prehistoric peoples. He established the feasibility of contact via an ocean crossing between South America and the South Pacific. Archaeological evidence in Australia, Melanesia, and Japan indicate that boats were in use as far back as 25,000 to 40,000 years ago. However, any signs of an exploratory route along the Pleistocene coastal shelf is now submerged; consequently, there is no direct archaeological evidence to support a Pacific coastal migration route. It is also possible that populations crossed the 56 miles of the Bering Strait via boat when it was submerged and then continued south along the coast, a theory now growing in popularity.

Regardless of the route, highly mobile populations arrived and diffused as far as Patagonia in what appears to be an extremely abrupt period of time. This area of investigation is still contested; few agree on when and where the earliest explorers and settlers arrived and under what conditions. These hunter-gatherer societies slowly filled in the continents, eventually establishing sedentary or semisedentary patterns based on resource utilization. By approximately 4000 B.C.E. increased density and intensification of resource exploitation, characterized by pastoralism and agriculture, defined the period. Few areas remained without human populations. However, why some areas developed agriculture and domestication and some remained hunter-gatherer is still debated.

In South America, for example, during the Late Holocene (5,000 years ago to the present) the area from contemporary Venezuela and Colombia to central Chile and from the coast to the Andean cordillera was defined by agriculture and pastoralism, producing more than 80 percent of all food. In Amazonia, the area including most of contemporary Brazil and the drainage of the Amazon, Orinoco, and Paraná river systems, between 20 percent and 80 percent of food was produced. And in the southern portion, dominated by Patagonia, a hunter-gatherer system was maintained.

Similarly, between 4,000 and 6,000 years ago, back at the point after the original entrance into North America, the Inuit explored the top of the globe, pushing east as far as Greenland. Subsequent cultural efflorescences and declines, and population expansions and contractions, from the standpoint of exploration, meant that people were continually on the move, populating new territory and sometimes repopulating previously occupied land. Given the great amount of time that passed, these populations might have had no idea if they were the first to explore an area.

Increasingly sedentary civilizations led to development of ceremonial centers and ultimately to cultures with greater density and more complex social, political, and economic structures. As civilizations advanced, exploration took on a different form, based in part on trade and exchange. Likewise, as states grew and empires arose, exploration developed into a form related to war and conquest in the interest of securing and expanding borders, spreading state-supported religious ideals, and procuring objects or materials of significant value.

► family

INTRODUCTION

Throughout most of the ancient world the family was the basic unit of social organization. “Family” included not just the nuclear family of mother, father, and children but typically a much more extended family of aunts, uncles, cousins, and, if they survived to an old age, grandparents. The responsibility for raising children was often shared by members of the extended family. Typically, too, a family considered itself part of a much more extended clan of people who were linked by blood or marriage. In places like ancient Europe it was not uncommon for clans to be at odds with one another and engage in extended feuds. In some cultures, such as that of the Chinese, ancestor worship was practiced as a form of religion and as a way for people to remain linked to the wisdom of those who had gone before them.

Marriage in the ancient world was primarily a social, political, and economic institution. Rarely did modern concepts of romantic love play any role in the formation of a marriage and family, and marriage was usually regarded as a contractual arrangement rather than an expression of love. In the ancient world, for example, it was common for grooms to pay a bride-price to compensate a family for the loss of a daughter; alternatively, it was common for the bride’s family to pay a dowry to the husband as a way of compensating him for, in effect, taking the girl off of the family’s hands and promising to support her.

Marriages were often arranged as a way of linking the resources of two families, and it was not uncommon for husbands to be considerably older than their brides; the older

husband had resources that enabled him to support his wife and family, and the younger bride had years of fertility to help ensure the birth of children and the survival of the family name. Further, marriages were arranged according to social class, with the bride’s parents, in particular, doing everything possible to ensure that the husband-to-be was of the right class. This was particularly true in ancient India, where people were unable to marry members of a different caste. Before the advent of Christianity in some parts of the world, though, polygyny, or the practice of a man’s having two or more wives, was common. Divorce, too, was relatively common in the ancient world.

Most ancient cultures were male dominated. In ancient Rome, for example, the concept of *paterfamilias*, whereby the father was the source of authority in the family, was common. In most other cultures women were regarded as inferior or subject to their husbands. Their primary role was the production of children, specifically a healthy male heir; in some cultures, babies who were not healthy were left to die. If the woman and child survived childbirth, the woman’s role was to raise the children and maintain the home, performing such domestic chores as cooking and cleaning. Most ancient cultures were “patrilocal,” meaning that at marriage the woman left her family and moved in with her husband and his family.

AFRICA

BY SAHEED ADERINTO

The family in Africa is as old as the history of human existence on the continent. The agricultural revolution that took place

on the continent some 5,000 years ago led to the development of a sedentary lifestyle, domestication of animals and crops, and the formation of organized societies, which took the form of villages and larger human settlements. The typical African family in ancient times was both a social/cultural and production unit. It was a social unit because all individuals belonged to a family, which served as a vehicle for socialization and cultural assimilation. The family therefore integrated people into the culture of the entire community. As a production unit, all members of a family were collectively involved in tilling the land and producing agricultural products. Farm produce was consumed collectively, while excesses were sold in exchange for other goods the family lacked.

As in most ancient cultures, marriage was needed for families to be established. Marriage was a compulsory rite of passage. All individuals were expected to get married and form their own families. Conditions that prevented people from marrying were rare. Marriage was a union not just of a woman and man but of two families, clans, and sometimes villages and empires. Naturally, new families were established from preexisting ones, and the link between the old and the new was important for generational continuity. Thus, the Karanko of Sierra Leone had a proverb: *Soron i la ko yolke*, meaning "One's birth is like a chain." Only through family formation could humans guarantee generational continuity because the African race would have been wiped out of existence without marriage, procreation, and family organization.

The most prevalent type of family in ancient Africa was the extended family. An extended family consists of numerous families that descend from a single ancestor. Most extended families, often made up of several generations, lived in compounds, with different huts belonging to individual families. New family compounds were established when members of an extended family migrated to another part of the town or an entirely new settlement. The history of several communities in Africa is therefore replete with references to migration. Also, new communities, which later developed into large human settlements, were sometimes founded by migratory families. Among the Yoruba of southwestern Nigeria, some families were exclusively responsible for producing the king because the oral history of the community indicates that their forefathers were responsible for establishing the community and laying the foundation of its culture and tradition.

The family played a significant role in determining the social, economic, and political status or standing of an individual within the larger community. In both theory and practice, an individual's behavior represented the attitude and general character of the family. The reason for this is simple: The family was a vehicle for socialization. All members conformed to certain modes or patterns of behavior that had been laid down by the family's founders or ancestors. Human socialization began with the family, which molded its members in important ways. A Yoruba saying, *Ile la tin ko eso r'*

ode ("Charity begins at home"), indicated that the household molded and determined the public attitude and disposition of an individual. The oral history of African peoples is replete with references to families that are boastful, polite, humane, aggressive, or antisocial.

While the family served as the primary and basic unit of socialization, the well-being of the entire community was measured by the stability of its numerous families. Families marked by tension and crises risked neglect. Contracting a marriage was more difficult, and a person's social and economic standing in the larger community was threatened. Community-oriented opportunities, such as becoming chief, were limited.

All families were traditionally headed by the oldest male, because most African societies are patrilineal. Also, ancient African societies were predominantly gerontocratic, meaning that the oldest men and women were expected to guide and lead the community because of their wealth of wisdom, which comes with age. Again, among the Yoruba the oldest man who looked after the day-to-day activities of the extended family was called the *Olori ebi*, or "the head of the family." It was also the role of the head of the family to reduce friction among family members. Most families held regular meetings to discuss the family's affairs. The head of the family was the custodian of the family's heritage. He organized the family's affairs in accordance with the rules and regulations laid down by the ancestors. All these rules and regulations were parts of larger unwritten traditions and customs transmitted orally from one generation to another.

Most families had cults of gods and goddesses they worshiped daily, weekly, or yearly. The origins of some of these cults are obscure, but what is clear is that they were associated with the history of the family's ancestors or founders. Interfamily relations served as the vehicle for the dispersal of ancestral worship. The worship of some gods and goddesses spread from one community to another through family migration. Sometimes, other families borrowed or adopted gods that belonged to another family, or entire communities worshiped of the deities of the ruling family.

The family was also a unit of production and distribution. One of the major purposes of family formation was the need for helping hands on farms. Polygyny, or the practice of taking more than one wife, guaranteed large households when manpower was needed for agricultural production. The size of families was significant in determining an individual's status. Chieftaincies were sometimes conferred on people who could prove that they had a large household.

Not all families derived means of survival and livelihood from agriculture. Some were artisans such as wood carvers and blacksmiths. Some were entertainers, while others were diviners and healers. The skills required in these professions were transmitted from one generation to another. The endogamous nature of African families, where marriage took place within the tribe or clan, ensured that skills were passed from one generation to another within the family and was a

significant factor in the survival and resilience of most ancient crafts.

Aristocratic families had slaves as members. In most cases, these slaves were bought and integrated into the family for the purpose of agricultural production. Theoretically, slave owners had the power to kill or sacrifice them to the gods. A female slave could be made a wife of her master, making the slave and her offspring free.

EGYPT

BY KELLY-ANNE DIAMOND REED

Ancient Egyptian society was structured around the family unit. The purpose of marriage was procreation and maintaining the family. Egyptian wisdom literature, or texts that contain instructions or philosophical dialogue, regularly speaks of a man prospering, establishing a house, finding a wife, and having children as ideal. In the Pharaonic Period marriage is sparsely documented, with no mention of any formal ceremony that recognized marriage. It is clear, though, that the idea of a household permeated society and that the woman entered into the household of the man. From this point on, the man and woman lived together. Very few texts testify to the idea of “giving a wife” in marriage, so a man may have found a wife in a variety of ways.

Among royalty diplomatic marriages took place. This arrangement either created an alliance between two separate kingdoms or indicated submission on the part of the ruler who provided the daughter. Likewise, father-daughter and brother-sister marriages were common within the royal family as a way of preserving the bloodline and maintaining political power.

Evidence is more common for divorce than it is for marriage. Marriage contracts, which concentrated on the property rights of each partner but did not, despite their name, comment on the ceremony of marriage, specified grounds for divorce. These grounds included the wife’s infidelity or infertility, the man’s dislike of the wife, or his desire to marry another woman. It is known that around 500 B.C.E. a wife could initiate a divorce, possibly on the grounds of her husband’s infidelity. It is not known whether the Egyptians knew the difference between impotence and infertility in men. Regardless, women were always blamed for the inability to conceive a child. Both men and women were able to remarry after a divorce.

Men belonging to the elite class, including royalty, could take more than one wife if they could afford to do so and if the wives could contribute to the household. Because most women could, by working either in the fields or with textiles, it may have been more profitable to have more than one wife.

In essence, one could create a free workforce. Little evidence points to polygynous relationships among middle- and lower-class populations. However, little information exists about the lower classes in general, so men from all classes may have had the option of having more than one wife at a time. No evidence shows that women could have more than one husband at the same time.

Related to the topic of divorce is adultery. Many ancient Egyptian sources suggest that men had access to women other than their wives. Some tomb scenes show children who are not biologically related to the wife; that they appear in the tomb scenes demonstrates that they were not seen in a negative light. The idea of illegitimacy did not seem to exist, though it was taboo to have intercourse with another man's wife. Literary works suggest that the punishment for doing so was death, primarily because then the paternity of a child could be in doubt. In turn, it was not socially acceptable for a wife to have intercourse with other men. The paternity of a child was important, because a family's assets would eventually be passed on to the children. This was also the case with the inheritance of the mother, but the maternity of a child was never an issue.

Once a man and woman resided together (or were married), they began to have children as soon as possible. A Twelfth Dynasty gynecological papyrus indicates that the ancient Egyptians knew how to conceive a baby but probably not the biological details. This same document reveals how the Egyptians found out if a woman was pregnant, how they tried to prevent miscarriages, their methods of birth control, and how they predicted the sex of an unborn child. Small anthropomorphic jars—that is, jars whose shapes have human characteristics—have been found that are thought to have contained the oil pregnant women rubbed on their skin to prevent stretch marks or to relieve the itching of the belly as it expanded through pregnancy.

Surviving literature provides many suggestions about where birth took place—in a room of the house, on the roof, in the courtyard, in the garden, or in a confinement pavilion made of plant material. Pottery shards from Deir el-Medina and paintings from Amarna show illustrations of this pavilion-like structure, which may have also been used for the mother's confinement after birth. The mother was to remain in seclusion for 14 days, according to one document.

At Deir el-Medina are other structures often called birthing beds. These beds often feature feminine iconography, including depictions of the deities Bes and Taweret, who were associated with pregnancy and childbirth. Historians differ in their interpretations of the beds' intended purpose. Some believe that mothers gave birth in them. Others have noted that the placement of the structure in the first room of the house would not suit this function. Likewise, these were permanent structures, but they would have been used only once a year at most, suggesting a different function. Another possibility is that this was where the mother was secluded after birth.

Childbirth was a precarious event. The infant mortality rate was high, and thus many magical spells were employed to help ensure the safe arrival of the newborn. Over 150 apotropaic wands—that is, wands having the power to ward off evil or bad luck—have been found that bear protective phrases regarding children. There is also evidence for adoption in ancient Egypt. The legal details are unknown, but the adopted child would have had access to the adoptive parents' inheritance and, in turn, would have been responsible for their burial and funerary cults.

THE MIDDLE EAST

BY KAREN RADNER

Tens of thousands of clay tablets recording legal contracts and letters give historians considerable insight into the lives of well-to-do urban families in ancient Mesopotamia, and the information matches that to be gained from the far-less-plentiful source material available for the other regions of the Middle East, including Persia. The spacious town houses of big cities such as Babylon, Sippar, and Assur did not house just nuclear family units (father, mother, and children) but also extended families that encompassed at least three generations. Family names, however, are found only from the late second millennium onward and only in the Babylonian cities. These family names were either professions such as "Baker," "Smith," or "Potter" or else the names of famous ancestors, such as the prominent scholar Sinleqiunninni, the compiler of the Epic of Gilgamesh, or the antediluvian sage Enmeduranki.

At the core of the household was the married couple, who lived in the husband's ancestral home. Normally the husband was considerably older than his bride, as men often married only after coming into their inheritance, that is, after their father's death. Women, in contrast, usually married as soon as they reached sexual maturity. Marriages were often not arranged by bridegrooms themselves but by their fathers. The new couple then lived at the groom's parental home, under his father's authority. The bride officially had no say in her marriage arrangement; the groom or his father reached an agreement with her father or, if he was deceased, the male relative under whose care she lived, usually a brother.

Marriage was expensive. The bride's family had to provide a dowry, which the groom's family was obliged to match with gifts. The occasion was celebrated with a lavish feast. As part of the wedding ritual the bride formally left her own family's home and entered the groom's house, severing links with her birth family and becoming a member of her husband's family. This included worshipping her husband's household gods and providing memorial service to his ancestors. The sharp divide between the husband's family and the wife's family was reflected also by the separate terms for maternal relatives, clearly distinguishing them from the paternal ones.

Divorce was possible, with the wife (and her dowry) returning to her birth family, but children stayed in the husband's care. The most common reason for divorce, though,

Scarab stamp seal and impressions, in lapis lazuli, depicting Ishtar, the Babylonian goddess of love, fertility, marriage, and childbirth. (Courtesy of the Oriental Institute of the University of Chicago)

was the couple's failure to have children, specifically a male heir to continue the family line. In most such cases, however, the couple did not seek a divorce. Divorce was costly because of the need to return the bride's dowry and often to provide additional compensation. It was also an inconvenience because it disrupted the amicable connection between the groom's and the bride's families. Thus, couples often found other ways to produce an heir. One alternative was for the husband to take a second wife, a decision that required the consent of his first wife. Another was to find a surrogate mother, to be chosen by the wife, who was considered the mother of the child. The most common and easiest option was to adopt.

In the Akkadian language, the word for family literally means "nest," illustrating the ancient Near Eastern concept of marriage and family life: Above all, the family centered on creating and bringing up offspring, since children were the focal point of the family and guaranteed its survival into the future. The mortality rate of babies and young children was very high, and children were considered gifts from the gods, their conception and well-being the subject of many prayers.

A typical family setup consisted of the head of the household, his wife, the husband's widowed mother, the husband's younger unmarried brothers and sisters, the couple's children, and a number of slaves, mostly women and some of them with children, usually fathered by the husband. These children, too, were slaves but could be made legitimate by adoption, often providing a solution to the lack of an heir when the wife could not conceive or carry a pregnancy to term or bore only girls. Otherwise legitimizing the children born by a slave to her master was unusual, though possible.

All members of the extended family were dependent on the head of the household, and this dependency implied that he was entitled to sell or pledge not only the slaves but also any other member of his family whenever he wished to do

so. This right, however, was exercised only in extreme situations, typically bankruptcy. Slaves born into a household usually spent their entire lives there, and selling one of them often implied that the family was in dire straits. The manner of treatment of members of his extended family was at the discretion of the head of household. Certain slaves were not treated much differently from legitimate relatives, and some masters arranged marriages for male slaves, who were very likely their natural sons.

Polygyny, having two or more wives, was practiced in the ancient Near East. While the kings of Mesopotamia and Persia commonly had more than one wife as a way to guarantee the succession to the crown, evidence suggests that the practice of polygyny was limited, certainly because of the expense involved. Meanwhile, cohabitation with slave women who were not considered legitimate wives was common and probably standard practice for the average head of household of an urban family.

Many women died during a pregnancy or in childbirth, and widowers were normally quick to marry again. Widows, on the other hand, typically stayed single if there was a male heir. If that boy was too young to succeed his father immediately, his mother could act as his legal guardian. According to surviving testaments, the wife's position in these circumstances was elevated to that of "father and mother." A widow without children, however—most likely a young, only recently married woman—could also return to her birth family's house or else remain in her husband's home under the authority of his brother(s).

Historians know far less about conditions in the countryside. Many families living on rural estates as farmers were slaves. They belonged either to wealthy households in the cities or to institutions such as temples and palaces. The available information comes largely from institutional archives, and from these rosters of personnel historians learn little more than the basic family setup, which corresponds to that of the urban elites but without slaves: a couple with their children living with the husband's widowed mother and his unmarried siblings.

ASIA AND THE PACIFIC

BY MICHAEL ALLEN HOLMES

Family life in ancient Asia has been difficult to reconstruct based on archaeological records, for customs governing relationships can rarely be determined by the inspection of artifacts and objects. Written records, meanwhile, generally address the activities of royalty or of gods and goddesses, likewise revealing little of life among common people. As a result, much of what is known about ancient familial attitudes comes from knowledge about the spread and rise of religious philosophies.

Confucius (551–479 B.C.E.), whose Chinese name is K'ung Futzu, meaning "Master Kong," exerted extraordinary influence over the cultures of the East. In his philosophy Confu-

cius focused on devising a system of ethics that all morally upstanding persons were to live by. While much of Confucianism specifies social rituals to be performed during certain times or on certain occasions (for example, the period of mourning to be observed after the death of a parent), the philosophy is rooted in broader principles, with attitudes such as righteousness and empathy highly valued. While Confucianism developed into various schools, particularly after Confucius's death, by the third century B.C.E., filial piety, or the child's respect for parents, was largely seen as the foremost of all virtues. During the Han Dynasty, from 202 B.C.E. to 220 C.E., Confucian beliefs were incorporated into the state religion because rulers looking to maintain widespread cultural unification found Confucianism's dictates regarding social behavior perhaps particularly appealing.

Related to the Confucian ideal of filial piety was the domestic worship of ancestors. Even before the time of Confucius, the Chinese people believed that the spirits of the deceased lingered in the afterlife and determined the fates of their descendants. For this reason, the Chinese people made—and in modern times still make—offerings of food, drink, and other items to their ancestors, often at shrines set up in their homes. In ancient times royalty and the wealthy were particularly generous toward their ancestor spirits, presenting their gifts in elaborate bronze vessels. A king might ask his forebears to bestow good fortune not just on himself but on his subjects as well, such as through the provision of a good harvest or luck in battle.

In association with ancestor worship, fathers taught their children to respect ancestors fully and eternally; no man or woman would want to be ignored as a spirit. Thus, the young universally complied in serving their parents, and even the rich performed menial tasks for their parents, such as patching articles of clothing, rather than delegate those tasks to servants. Overall, the practice of ancestor worship and Confucian teachings about the primacy of family largely determined the extent to which unconditional and oft-demonstrated love has dominated the home lives of the Chinese.

A final prominent characteristic of Chinese domestic life in ancient times was the subservience of women. While little evidence exists about precisely how peasants arranged family matters, the lives of courtly men and women were often recorded in works of art and writing, such as *Admonitions of the Instructress to the Court Ladies*, dating from the fourth century C.E. Women were obligated to be dutiful, yielding, reverential, and humble; a precept of the time read, "A husband is Heaven, and Heaven cannot be shirked." Further, women were often denied education and exposure to the outside world, limiting their intellectual development and ensuring their future treatment as inferior. Although the historical origins of the practice are uncertain, Chinese women historically were literally given to men in arranged marriages and sent off to live with the husband's family.

In India the family had similarly sacred importance, as established by the love-based doctrines of Buddhism and as

solidified by the popularization of Hinduism through the reign of the Guptas (240–550 C.E.). Many of the values and traditions of Hinduism, such as dharma, karma, and the transmigration of souls, were in fact first presented and advocated by Buddhists. Regardless, the Hindu caste system, which assigned people to a hierarchy of social categories, served to cement existing familial practices, for the caste system itself was maintained through indoctrination carried out within individual families.

While founded in love and respect, the institution of the Indian family, as in many other cultures, was a patriarchal one from as early as 1000 B.C.E. Within an extended family, the words spoken by the eldest males were essentially law, and these patriarchs were treated almost as gods. As in China, through arranged marriages a woman was brought to live with the extended family of her new husband. Within a family, brothers and cousins alike—both referred to with the same word, *bhai*—supported each other in all respects, sometimes even sharing a wife. Such fraternal unity was reinforced throughout Indian history by the moral teachings found in ancient texts like the Sanskrit epics Mahabharata and Ramayana.

In accord with the patriarchal tradition, women in ancient India were largely relegated to secondary roles. The code known as the Laws of Manu, which was developed probably between 200 B.C.E. and 200 C.E., legalized the notion that women were inferior to men, with fathers, husbands, and sons successively offering "protection." If a Hindu husband was himself wholly immoral, even to the extent of committing adultery, his wife was nevertheless expected literally to worship him. In fact, a woman was expected to obey her husband even if he commanded her to perform acts that would be degrading or self-destructive. Whether supervised, guarded, or confined outright, women were essentially the possessions of the men in their family. Further cultural expectations dealt specifically with reproduction and the bearing of children: Child rearing (along with constant attention to the husband) was specifically termed the obligation of women, and if no children were produced, the husband was within his rights to find another wife.

Women did retain a greater degree of power in certain isolated societies in ancient Asia. In South India, in fact, families have long been arranged matrilineally, presumably as far back as ancient times. Although even less is known about family structures in ancient Japan, because historical records developed much later, Chinese travelers wrote that in southwestern Japan in 238 C.E., society was arranged in matriarchal fashion. States were then under the rule of sorceresses; women, in fact, maintained rulership in Japan periodically until the eighth century C.E.

EUROPE

BY AMY HACKNEY BLACKWELL

Archaeological evidence provides relatively little information on the specific details of family structure in prehistoric

Europe. Archaeologists believe that during the Paleolithic and Mesolithic, society was organized into bands of perhaps several dozen individuals connected by loose kinship bonds. Subsequently, with the spread of agriculture beginning in about 7000 B.C.E., societies were organized into households, presumably occupied by members of a single family that included several generations, though we do not know the precise composition of each residential group. Such households were the fundamental social units throughout later prehistoric times.

Textual sources, despite their imperfections, confirm that ancient Europeans lived in extended family groups. Several generations of relatives would live in households together, along with their servants, if they were members of the social elite. The most important social unit was the clan, which formed part of a larger tribe. European peoples tried to keep wealth within their clans by marrying relatives to one another. When a German or a Celtic man married, he paid the bride's family a bride-price, a fee in the form of animals or goods that compensated them for the loss of their daughter. This bride-price often consisted of a herd of cattle, but among the Germans it could include a pair of yoked oxen, a saddled warhorse, a shield, a lance, and a sword. A German bride would present her husband with weapons as well. These gifts were meant to symbolize that the couple were partners in war and in work.

The Roman historian Tacitus described his impressions about Germanic family life in his *Germania*. He wrote that young men and women did not engage in romantic escapades before marriage and that both sexes married relatively late, after they had reached their full growth. He praised the chastity of Germanic women, claiming that all women entered marriage as virgins and remained committed solely to one husband for life. According to Tacitus, adultery was rare; if a wife committed adultery, her husband would cut off her hair, strip her naked, and drive her through the village with a whip. Modern historians, however, believe that many ancient Europeans did not especially value sexual fidelity or modesty. Ancient couples did live together without being married, and men often kept concubines. Polygamy was common among ancient European groups.

Celtic people recognized several legally defined forms of marriage. All types of marriage were designed to ensure that resulting children would be cared for; the permanence of the union was not the primary consideration. Some couples declared their intention to marry through handfasting, or engagement; if they had sex before the end of the engagement, they were automatically considered married. Some couples entered into temporary marriages that would dissolve at a prearranged time. A couple could agree to a union in which the man was allowed to visit the woman at her home with the consent of her family, but this union was not a true marriage. In another kind of union the man visited the woman at home without the knowledge of her family.

There were several types of formal marriage, distinguished by which partner brought property into the union.

Women could own property and keep it after marriage; a woman who owned property in her own right had more power than one with no property. Marriages involving property were usually arranged between partners of similar social

IRISH MYTHICAL COUPLES

Irish myths contain numerous depictions of married couples and lovers. The women in these stories come across as tough and outspoken, and they are as sexually aggressive as men. Ireland's great prose epic the *Táin bó Cúailnge*, or *Cattle Raid of Cooley*, is mainly about a domestic dispute. A married couple, the husband Ailil and the wife Medb (Maeve), get into an argument over which one of them owns the most property; the dispute escalates into a nationwide war over a bull. Medb considers herself her husband's equal in war and wealth, bargaining with neighboring kings for military aid against her husband and even promising them her own "friendly thighs" as payment. She rides to battle and strikes fear in the hearts of all her enemies.

Another mythical wife, Derdriu, is promised in marriage to the old king Conchobar, but when she meets the handsome young hero Noisiu, she runs off with him. When Conchobar kills Noisiu, Derdriu sings a heartbreaking song of lament in which she praises her lover's beauty, courage, and generosity. She never smiles again. Conchobar, piqued at her lack of interest in him, decides to share her with a neighboring king. Rather than submit, she leaps out of a chariot and smashes her head to bits on a stone.

When the Irish hero Cuchulainn meets the girl Emer, the first thing he does is peer down her dress and remark, "I see a sweet country. I could rest my weapon there." She is not at all offended but refuses to submit to his advances until he performs a series of tasks she sets him—killing a hundred men at every ford on a river, striking down three groups of nine men with a single stroke, and going without sleep for half the year. Until he does these deeds, she will not have him.

In Irish mythology, Irish heroines are tough even when they are pregnant. In one story, the goddess Macha takes human form and marries a man. He is so proud of her legs that he forces her to run a race against the king's chariot when she is nine months pregnant. She ties with the chariot but goes into labor at the finish line. As she gives birth, she curses the audience, announcing that the descendants of the men who heard her scream would suffer the pain of labor at their most desperate moments.

class. Celtic husbands had to pay a bride-price to the family of the bride. The bride kept a portion of this bride-price, which was considered her property while she was married. If the marriage ended through the husband's fault, the woman kept her portion of the bride-price. If the wife were to blame for the end of the marriage, the husband took the property back. Celtic women were allowed to reject prospective husbands and were not forced to marry men they did not want.

As Christianity spread through Europe in the 300s and 400s, Europeans adopted some Christian marital practices. They stopped allowing marriages between close relatives, such as cousins, and discouraged unmarried couples from living together. Divorce was common among ancient Europeans and carried no social stigma. A woman was allowed to divorce her husband if he failed to support her, lied to her, struck her, became impotent, or slept with another woman. A man could divorce his wife for being unfaithful, stealing, shaming him, performing an abortion on herself, or smothering her infant.

Ancient people had no effective means of contraception, so women typically bore many children during their lives. Most women gave birth assisted by female family members or midwives; the ancient Germans and Celts did not have effective doctors. Ancient Europeans did not understand the mechanisms of birth and had few useful treatments to offer mothers. They could instruct women on breathing techniques, and they spent much of their energy reassuring and encouraging the mother. They could not, however, perform surgery, such as cesarean sections, without killing the woman. Many women and infants died in childbirth. If a newborn's mother died, the father quickly had to find a lactating woman to act as a foster mother or a wet nurse to feed the baby.

Ancient Europeans did not make a significant distinction between legitimate and illegitimate children. Fathers acknowledged the children of concubines, though they might not grant these children the same status as their children by official wives. Some ancient Europeans practiced infanticide, abandoning or killing newborn infants they did not want to raise. During peacetime Celts and Germans lived in small settlements containing several houses and surrounded by farmed fields, yielding enough food to feed the immediate clan members. The women and older family members handled most of the home needs, tending the fields and cattle.

Children grew up among many relatives who all lived close to one another. Each German household was headed by a man who had power over the other members; he decided who would live where, who would marry whom, and which infants to raise. Children were not heavily supervised; Tacitus described Germanic children as "naked and filthy." The entire clan was responsible for raising all the clan's children. The relationship between uncles and nephews was especially strong; men took particular care of the sons of their sisters. Children often went to live as foster children in the homes of relatives, especially their uncles.

Warfare was a family affair. Young men learned the art of war from their fathers and uncles. The men within a clan held ranks based on their skill at fighting and on their leadership ability. Family members stood by one another in battle and were bound to avenge the deaths of kinsmen. Chiefs would choose young male relatives to march next to them everywhere, both during battles and in more peaceable activities. Relatives defended one another in fights; young men who allowed their older male relatives or chiefs to die were dishonored. Wives and children were expected to cheer for their men as they marched to battle and to treat their men's wounds. Family honor was extremely important. European peoples readily entered into feuds with other clans over insults or murders, but they also readily ended them after a suitable payment of cattle.

GREECE

BY CHRISTOPHER BLACKWELL

No word in the ancient Greek language corresponds closely to the English word *family*. The Greek *genos* (the root of such English words as *genealogy* and *genetics*) refers to a tribe, or widely extended family. The fundamental unit of Greek domestic life was the *oikos*, or "household," consisting of all the people who lived together. Some were bound by kinship, but others, such as slaves, were bound by social, legal, or economic ties.

The legal and traditional head of the *oikos* was the senior man. He was the *kurios*, the legal lord of the household, with power over and responsibility for all its members. The senior woman of the household, usually the wife of the *kurios* but sometimes his mother or sister, tended to have day-to-day responsibility for the food supply and cooking, making and mending clothing, arranging for domestic chores, caring for infants, educating the younger male children and all the female children, and training and disciplining the slaves.

Households tended to be patrilocal, meaning that when a man and woman married, the woman moved into the man's household. Consequently, while the household often contained many members related by blood (aunts, uncles, grandparents), they were more often related to the man of the house than to the woman. Marriage involved the transfer of a woman from one *kurios* to another, usually from her father to her new husband. In most Greek communities laws governed this process, because the institution of marriage affected inheritance and the citizen status of children. Thus it was a concern of the whole community. For example, in Athens during the fifth century B.C.E. the law forbade marriage between an Athenian citizen man and the daughter of a noncitizen. (Women did not formally enjoy citizenship, even under the democratic constitution of Athens.)

Marriage often involved the exchange of gifts, sometime in two directions. A potential husband offered bride gifts to his potential father-in-law, which served to establish the suitor as economically and socially suitable. The future fa-

ther-in-law, in turn, promised a dowry, a certain amount of property that accompanied his daughter into marriage. The dowry was, after the marriage, available to the new husband for his use but nevertheless belonged in a certain sense to the wife. If the husband divorced her, or she divorced him, the dowry was to be repaid to her father.

Weddings were religious ceremonies, in most Greek communities involving a triad of goddesses. Artemis was invoked, as the goddess overseeing a young woman's transition from girlhood to womanhood. So, too, were Hera, the goddess overseeing the institution of marriage, and Aphrodite, responsible for the sexual and erotic aspects of marriage. Weddings usually took place at the house of the bride's father, ending with a public procession to the husband's house; the procession was often accompanied by a crowd of celebrants shouting bawdy jokes. At the husband's house was a ceremony of *katachusma*, a "uniting" of the bride with the new household. This ceremony was also used when new slaves were brought into a house, which may shed some light on assumptions about marriage. The age of marriage differed in different communities, but the general practice was for young women to marry between the ages of 16 and 23 and men to marry in their 20s or 30s. Marriages between much older men and much younger women were relatively common.

Childbirth was generally left in the hands of women, either relatives of the mother-to-be or midwives. Male doctors seem to have been involved only rarely, though the ancient medical writers, all of whom were male, left some treatises on childbirth. Soranus, writing in the first century C.E., describes childbirth as taking place on a birthing chair or on a hard bed (the latter when the woman was too weak to sit). Given the limits of ancient medical knowledge, his treatise is responsible and humane, emphasizing the importance of breathing, of having the midwife reassure the mother, and of taking care not to embarrass the mother. Estimates vary as to how many women died in childbirth, ranging from a high of 25 of every 1,000 women to a low of five of 20,000. The figure surely varied according to the prosperity of the family, if only because more prosperous women would likely be better fed and therefore stronger.

After a baby was born, the midwife laid it on the ground to assess its health and vitality. If it was deemed worth rearing, it would be given to the mother or a wet nurse for feeding. Later, sometimes days later, the father displayed the baby to the members of the household, thus acknowledging it as legitimately his. If a baby was not deemed worth rearing, or if the husband refused to accept it, it might be exposed, that is, left outside to die or be taken away. There is no good evidence regarding how frequently infants were exposed. The practice figures frequently in literature, which may reflect how common it was but also may reflect merely a cultural anxiety about the practice.

Mothers generally breast-fed their children themselves, for this was considered the duty of a responsible woman of the house and most wholesome for the child and the mother's

Fragment of an archaic Greek stela, with the heads of a mother and child. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

relationship with it. Soranus recommended the hiring of a wet nurse when the mother could not produce enough milk or was too sick or exhausted to nurse her baby herself. The status of a wet nurse could vary, but evidence suggests that wet nurses could be valued members of the family. An Athenian woman of the fourth century B.C.E. named Hippostrata had this inscription carved on the tomb of her wet nurse: "I loved you while you were alive, nurse, I love you still now even beneath the earth, and I shall honor you as long as I live."

Divorce was possible, at the initiation of either a husband or wife. The community of Gortyn, a small city in Crete whose laws survive on an inscription from the 450s B.C.E., required that in cases of divorce a wife retained all property she brought into the marriage, as well as half of any profits or proceeds that came from that property, with provisions for judgment in the case of disputes. Existing children remained in the father's household in cases of divorce. Children born to a woman after she was divorced were to be brought to the father; if he accepted them, they would be reared in his household, but if he rejected them, the mother was free to rear them or expose them herself.

After the death of either spouse, the survivor was free to remarry. In the case of a widowed woman, she brought her own property into her new marriage, but any property she had held in common with her former husband belonged to

her children from the first marriage. Through inscriptions on tombs ancient Greeks would sometimes try to speak to a dead spouse or praise them to passing strangers. One such inscription, from Athens in the fourth century B.C.E., contains a dialogue between husband and wife: "Farewell, tomb of Melite; a good woman lies here. You loved your husband Onesimus, and he loved you back. You were the best of wives, and he mourns your death. You were a good wife." And the wife's reply: "And farewell to you, my dearest man; love my children."

ROME

BY AMY HACKNEY BLACKWELL

The family was the most important unit in Roman social organization. Every Roman belonged to a family, and a person's ancestry was considered of great importance. Families were tracked along male lines; children took their fathers' names. Romans knew the details of their mothers' families as well. Kinship of any sort was considered a strong bond, and family members were expected to help their relatives when possible.

The head of a family was the *paterfamilias*. This was usually the father or grandfather of the family, who held a power called *patria potestas* over all his descendants, male and female. The *paterfamilias* technically had the power of life or death over his children; this power to kill children was rarely exercised during the republic and the empire, except in the case of newborn infants. The *paterfamilias* had to give consent for his children to marry; anything his children earned technically belonged to him. A young man could leave the *patria potestas* only if his *paterfamilias* freed him, either by dying or by deliberately releasing him. A young boy could become a *paterfamilias* through the death of his father, or a young man could remain under the authority of his *paterfamilias* even after he had become a husband and a father himself.

Girls were always under the authority of a male. A girl's father or *paterfamilias* had control over her actions until she married, but at that point her husband gained authority over her. If her husband died, her son or uncle or another male relative would become *paterfamilias* and keep control of the family. Roman women did, however, retain some rights. Depending on the details of her marriage contract and domestic situation, a Roman woman could retain some control over her own dowry and could transact business on her own. Some women ran prosperous businesses with their husbands' consents.

Marriages were often made for political or economic reasons; romantic considerations were often irrelevant. A *paterfamilias* would decide whom a woman would marry and would handle all arrangements of her property for her. Young men also had to follow the desires of a *paterfamilias* in choosing a bride. Roman women typically married for the first time around the age of 18. Men married later, in their late 20s or early 30s, after they had spent some time in military service and had established a career. June was the most popu-

lar month for weddings. A bride dressed in a white tunic and wore a flame-colored scarf and shoes. The wedding took place in the bride's father's house. After the ceremony and the feast, the bridal party walked in procession to the groom's house, where the groom carried the bride over the threshold.

There were several different types of marriage. *Confarreatio* was the oldest style of marriage; it could be contracted only between two patricians (members of the Roman nobility), and it put the bride entirely under her husband's control, or *manus*. It was very difficult to dissolve through divorce. By the time of the Roman Republic (509–27 B.C.E.) other forms of marriage contracts that were easier to end and that gave women more independence had become much more common, except among priests, who were required to marry *confarreatio*. A bride was expected to bring a dowry to the marriage; this property usually remained hers if she divorced.

Divorce was easy, unless the couple was married *confarreatio*. Either partner could end the marriage simply by informing his or her spouse that the marriage was over. Augustus (r. 27 B.C.E.–14 C.E.) introduced the practice of using written documents to prove that a wife had committed adultery, but for the most part no formal procedure was necessary to end a marriage. Children usually stayed with their father after their parents divorced. Roman men were often absent from the home for extended periods while they went off to wars or conducted business overseas. They expected their wives to maintain the home while they were gone.

Romans wanted children to carry on their names and care for them in their old age. Though they preferred biological children, they did not hesitate to adopt children from relatives or friends if they could not produce their own. People sometimes adopted children for political reasons as well; adults could even have themselves adopted if they needed a particular name or social class for some political purpose.

Most women gave birth assisted by female family members or midwives, though occasionally male doctors helped with difficult labors. Many women died during or after childbirth from bleeding, exhaustion, or infection. Many infants also died during the birth process. If a baby survived birth, the father or *paterfamilias* could decide whether to keep the child. If he decided not to keep it, the child would be left outside to die. Historians do not know what percentage of Roman babies were abandoned, but it is known that people were much more likely to expose girls, illegitimate children, deformed infants, and the children of slaves than they were to expose boys, legitimate children, or children of well-to-do families. If the parents kept the child, they celebrated its birth on its eighth day of life in a purification ceremony called the *lustratio*.

Mothers might breast-feed their own infants, or they might hire wet nurses to nurse the babies for them. Many people believed that women should not have sexual intercourse while they were nursing babies because it would harm their milk, so some wives hired wet nurses so that they could

resume relations with their husbands. Women also knew that breast-feeding could delay the next pregnancy; some chose to breast-feed their own babies for this reason. Wet nurses might live with the family, or they might come to the house for regular feedings. Babies were nursed for two years or so, with solids gradually introduced during this period.

About one-fourth of Roman babies died of various illnesses before the age of one, but young children were not the only people at risk of sudden death. Romans of all ages were prone to dying of various illnesses for which there were no treatments as well as of accidents and injuries from war. Roman families were not surprised when their members died young. Despite this fact, there is ample evidence that Romans found the deaths of their loved ones just as tragic as modern people do. They spent a great deal of money on elaborate funerals, hiring actors to portray dead family members in a procession through the city streets.

Both boys and girls of wealthy people spent their early childhood in the home nursery in the care of women. They usually slept in the nursery until they were about 12 years old and could be given rooms of their own. Poorer children slept in much closer quarters, all inhabitants of a dwelling sharing a room. Many wealthy mothers employed slaves as caretakers for their young children. Corporal punishment was a common means of enforcing discipline.

THE AMERICAS

BY ANGELA HERREN

While we know little about family life in ancient North and South America, archaeological evidence gives us some indication of how communities developed. Studies of residential groupings suggest that families of the ancient Americas began to shift from nomadic to sedentary lifestyles with the development of agricultural practices. Many families lived in small villages or hamlets, and some larger populations with elaborate communal civic and religious spaces developed.

In the four corners region of the American Southwest, the area where Colorado, Utah, Arizona, and New Mexico meet, a lifestyle of hunting and gathering prevailed for the first millennium B.C.E. The ancestors of the Hohokam, Mogollon, and Anasazi peoples fished the streams and rivers and hunted elk, deer, antelope, rabbits, and other local animals. Seasonal gathering of nuts, berries, cacti, and other flora rounded out the early diet. In the first centuries C.E. the cultivation of maize and squash began to supplement the indigenous diet, and “pit house” villages sprang up around these agricultural areas. For example, the Mimbres people, a branch of the Mogollon culture of southwestern New Mexico, began establishing pit-house villages of 10 to 15 households around 200 C.E. Over the next thousand years more permanent architectural forms developed, and many of these early settlements expanded into communities of 200 to 300 people as local populations grew and additional families adopted a more sedentary lifestyle.

In ancient South America most families lived in small hamlets and villages, but larger residential settlements grew up around some of the more elaborate ritual centers. Like later Andean cultures, early societies probably maintained a moiety structure, divided into two separate, unequal but complementary parts. Families engaged in activities appropriate to their position in a stratified society.

At Chavín de Huántar, a highland site that flourished between 900 and 200 B.C.E., Andean families survived by hunting deer, herding llamas, and growing important staple crops like maize and potatoes. In addition to subsistence activities, many families contributed labor and artistic skills that led to the construction and decoration of the site’s Old Temple (900–500 B.C.E.) and New Temple (500–200 B.C.E.). As society turned increasingly to Chavín’s deities to maintain their subsistence economy, most families probably engaged in communal ritual activity to some extent.

The necropolises, or cemeteries, of Paracas culture (ca. 700 B.C.E.–200 C.E.), discovered along the south coast of Peru, provide information about the stratification of Andean society. Twentieth-century excavations along the sandy desert coastline revealed hundreds of mummy bundles buried in shallow shaft tombs. Paracas communities placed the body of a deceased family member in a fetal position within a basket and wrapped it in layer upon layer of textiles. The quality of the textiles, the size of the mummy bundles, and the goods and offerings wrapped in the bundles indicate a strong social hierarchy. Groupings of individuals in burial may indicate familial or social relationships.

As they had at Chavín de Huántar, early Andeans built residential structures near important ceremonial buildings at the site of Moche (ca. 1–600 C.E.) on the north coast of Peru. Between two large mud-brick pyramids known as the Huaca del Sol and Huaca de la Luna, archaeologists unearthed a series of housing compounds. Plazas and streets connected the patios and rooms where Moche families lived and worked. Moche ceramics depict the basic forms of housing. Using construction techniques still employed today, the Moche built adobe structures as well as simple houses of matting supported by poles. Using a naturalistic representational style, the Moche created tens of thousands of ceramic vessels that document many aspects of Moche life. Images of women weaving, male and female copulation, and childbirth may represent some aspects of daily family life.

The highland site of Tiahuanaco (ca. 300 B.C.E.–1100 C.E.) contains one of the largest residential groupings of the ancient Americas. Archaeologists estimate populations as high as 30,000 to 60,000. Most families lived outside the moat that surrounded Tiahuanaco’s ceremonial core. Only the highest political and religious practitioners occupied the city center. Excavations indicate that during the period of around 400–1100 C.E., residential neighborhoods, like the ceremonial core, were oriented to the cardinal directions. Archaeologists theorize that Tiahuanaco society consisted of three classes: a

governing group of lineages composed of warrior elites who held political and religious offices; a middle class of artisans, who worked as retainers of the ruling lineages; and a commoner class of farmers, herders, and fishers, who sustained the economic system.

Early Mesoamericans practiced settled agriculture as early as around 2000 B.C.E. and developed more complex societies in the first millennium B.C.E. During the first 500 years C.E. small settlements grew, interacted with one another, and gave rise to bustling urban cities like Teotihuacán. Beginning about 1500 B.C.E. the Olmec began establishing major centers at the Gulf Coast sites of San Lorenzo, La Venta, Laguna de los Cerros, and Tres Zapotes, a region often referred to as the Olmec “heartland.” Archaeological studies indicate that families typically lived in small wattle-and-daub houses with thatched palm roofs, similar to those built near these sites today. They clustered their houses around a central patio, where the community performed various tasks and grew maize nearby. At the larger sites, like San Lorenzo, excavations have revealed more elaborate housing complexes inhabited by the ruler, his family, and attendants. Like the palaces of the elite, these residences occupied a prime location very close to the ritual center. Olmec culture was far-reaching, and families also lived in rural villages in central Mexico and surrounding regions.

Early inhabitants of the Pacific coastal region, the ancestors of the Maya, established some of the first settled communities in the Maya area between 2000 to 1000 B.C.E. Over the next millennium societies in this region developed political and social complexity, with the emergence of Maya civilization between ca. 400 B.C.E. and 100 C.E. Many families practiced swidden, or slash-and-burn, agriculture and settled at early sites like Izapa, Kaminaljuyú, Takalik Abaj, El Baúl, Uaxactún, Tikal, El Mirador, and Cerros.

Our knowledge of West Mexico during the ancient period comes primarily from objects recovered from shaft tombs. A variety of ceramic vessels, figurines, and objects found in the modern Mexican states of Colima, Jalisco, and Nayarit, as well as near the Mezcala River, provide valuable information about West Mexican architecture, spiritual beliefs, and society. In Nayarit many tombs contained pairs of male and female ceramic figures that may have accompanied married couples in the tomb. The painted slip on the figures details the elaborate accoutrement of the matching costumes, and the pairs often hold musical instruments.

Early inhabitants of Teotihuacán, a central Mexican site that flourished ca. 150–600 C.E., laid out their city on a grid plan with residential compounds of various sizes flanking the elaborate pyramid structures of the ceremonial core. Walls surrounded each residential compound with a single entry offering access to the many dwellings within. Each grouping included three shrines and a platform for ritual activities. Consistency in materials and structure suggests state-sponsored building. The most elaborate apartment complexes contained painted fresco murals depicting warfare, deities, and sacrifice. Populations have been estimated as high as 125,000.

VIII. MARRIAGE

***Contract for Marriage, Reign of Shamshu-ilu-na,
ca. 2200 B.C.E.***

RIMUM, son of Shamkhatum, has taken as a wife and spouse Bashtum, the daughter of Belizunu, the priestess

(?) of Shamash, daughter of Uzibitum. Her bridal present shall be _____ shekels of money. When she receives it she shall be free. If Bashtum to Rimum, her husband shall say, “You are not my husband,” they shall strangle her and cast her into the river. If Rimum to Bashtum, his wife, shall say, “You are not my wife,” he shall pay ten

shekels of money as her alimony. They swore by Shamash, Marduk, their king Shamshu-ilu-na, and Sippar.

Contract for Marriage, Thirteenth year of Nebuchadnezzar II, 591 B.C.E.

Dagil-ili, son of Zambubu, spoke to Khamma, daughter of Nergal-iddin, son of Babutu, saying: "Give me Latubashinni your daughter; let her be my wife." Khamma heard, and gave him Latubashinni, her daughter, as a wife; and Dagil-ili, of his own free will, gave Ana-eli-Bel-amur, a slave, which he had bought for half a mana of money, and half a mana therewith to Khamma instead of Latubashinni, her daughter. On the day that Dagil-ili another wife shall take, Dagil-ili shall give one mana of money unto Latubashinni, and she shall return to her place—her former one. [Done] at the dwelling of Shum-iddin, son of Ishi-etir, son of Sin-damaqu.

IX. DIVORCE

Contract for Divorce, Third year of Nabonidus, 552 B.C.E.

NA'ID-MARDUK, son of Shamash-balatsu-iqbi, will give, of his own free-will, to Ramua, his wife, and Arad-Bunini, his son, per day four *qa* of food, three *qa* of drink; per year fifteen *manas* of goods, one *pi* sesame, one *pi* salt, which is at the storehouse. Na'id-Marduk will not increase it. In case she flees to Nergal [i.e., she dies], the flight shall not annul it. [Done] at the office of Mushezib-Marduk, priest of Sippar.

The Middle East

~ *Herodotus: Excerpt from The History of the Persian Wars, ca. 430 B.C.E.* ~

I.196: Of their customs, whereof I shall now proceed to give an account, the following (which I understand belongs to them in common with the Illyrian tribe of the Eneti) is the wisest in my judgment. Once a year in each village the maidens of age to marry were collected all together into one place, while the men stood round them in a circle. Then a herald called up the damsels one by one and offered them for sale. He began with the most beautiful. When she was sold for no small sum of money, he offered for sale the one who came next to her in beauty. All of them were sold to be wives. The richest of the Babylonians who wished to wed bid against each other for the loveliest maidens, while the humbler wife-seekers, who were indifferent about beauty, took the more homely damsels with marriage-portions.

For the custom was that when the herald had gone through the whole number of the beautiful damsels, he should then call up the ugliest—a cripple, if there chanced to be one—and offer her to the men, asking who would agree to take her with the smallest marriage-portion. And the man who offered to

take the smallest sum had her assigned to him. The marriage-portions were furnished by the money paid for the beautiful damsels, and thus the fairer maidens portioned out the uglier. No one was allowed to give his daughter in marriage to the man of his choice, nor might any one carry away the damsel whom he had purchased without finding bail really and truly to make her his wife; if, however, it turned out that they did not agree, the money might be paid back. All who liked might come even from distant villages and bid for the women. This was the best of all their customs, but it has now fallen into disuse. They have lately hit upon a very different plan to save their maidens from violence and prevent their being torn from them and carried to distant cities, which is to bring up their daughters to be courtesans. This is now done by all the poorer of the common people, who since the conquest have been maltreated by their lords and have had ruin brought upon their families.

Asia and the Pacific

~ Kautilya: Excerpt from the Arthashastra,
ca. 250 B.C.E. ~

BOOK III, CHAPTER 2, CONCERNING MARRIAGE AND WOMEN

Marriage is the basis of all disputes. The giving in marriage of a virgin well adorned is called "Brahma-marriage." The joint performance of sacred duties by a man and a woman is known as "prajapatya-marriage." The giving in marriage of a virgin for a couple of cows is called "Arsha-marriage." The giving in marriage of a virgin to an officiating priest in a sacrifice is called "Daiva-marriage." The voluntary union of a virgin with her lover is called "Gandharva-marriage." Giving a virgin after receiving plenty of wealth is termed "Asura-marriage." The abduction of a virgin is called "Rakshasa-marriage." The abduction of a virgin while she is still asleep and intoxicated is called "Paisacha-marriage." Of these, the first four are ancestral customs of old and are valid on their being approved of by the father. The rest are to be sanctioned by both the father and the mother; for it is they that receive the money paid by the bridegroom for their daughter. In case of the absence by death of either the father or the mother, the survivor will receive the money-payment. If both of them are dead, the virgin herself shall receive it. Any kind of marriage is approvable, provided it pleases all those that are concerned in it.

Means of subsistence or jewelry constitutes what is called the property of a woman. Means of subsistence above two thousand shall be endowed in her name. There is no limit to jewelry. It is no guilt for the wife to make use of this property in maintaining her son, her daughter-in-law, or herself, whenever her absent husband has made no provision for her maintenance. In calamities, disease and famine, in warding off dangers and in charitable acts, the husband, too, may make use of this property. . . . On the death of her husband a woman, desirous to lead a pious life, shall at once receive not only her endowment and jewelry but also the balance of the marriage-price due her. If after obtaining these two things she remarries another, she shall be caused to pay them back together with interest on their value. . . . If a widow marries any man other than of her father-in-law's selection, she shall forfeit whatever had been given to her by her father-in-law and her deceased husband. . . . No woman shall succeed in her attempt to establish her title to the property of her deceased husband after she remarries. If she lives a pious life, she may enjoy it. No woman with a son or sons shall after remarriage be at liberty to make free

use of her property; for that property of hers, her sons shall receive. . . .

If a woman either brings forth no live children, or has no male issue, or is barren, her husband shall wait for eight years before marrying another. If she bears only a dead child, he has to wait for ten years. If she brings forth only females, he has to wait for twelve years. Then, if he is desirous to have sons, he may marry another. .

. If a husband either is of bad character, or is long gone abroad, or has become a traitor to his king, or is likely to endanger the life of his wife, or has fallen from his caste, or has lost virility, he may be abandoned by his wife.

BOOK III, CHAPTER 3, THE DUTY OF A WIFE

Women, when twelve years old, attain their majority, and men when sixteen years old. If, after attaining their majority, they prove disobedient to lawful authority, women shall be fined fifteen *panas*, and men twice the amount. A woman who has a right to claim maintenance for an unlimited period of time shall be given as much food and clothing as is necessary for her, or more than is necessary in proportion to the income of her maintainer. . . . Women of refractive natures shall not be taught manners by using such expressions as "You, half-naked!; you, fully-naked; you, cripple; you, fatherless; you, motherless." Nor shall she be given more than three beats, either with a bamboo bark or with a rope or with the palm of the hand, on her hips. Violation of the above rules shall be liable to half the punishment levied for defamation and criminal hurt. The same kind of punishments shall be meted out to a woman who, moved with jealousy or hatred, shows cruelty to her husband. . . .

A woman who hates her husband, who has passed the period of seven turns of her menses, and who loves another, shall immediately return to her husband both the endowment and jewelry she has received from him, and allow him to lie down with another woman. A man, hating his wife, shall allow her to take shelter in the house of a beggar woman, or of her lawful guardians or of her kinsmen. . . . A woman, hating her husband, cannot divorce her husband against his will. Nor can a man divorce his wife against her will. But from mutual enmity divorce may be obtained.

Europe

~ Tacitus: Excerpt from Germania ~

Marriage Laws. Their marriage code, however, is strict, and indeed no part of their manners is more praiseworthy. Almost alone among barbarians they are content with one wife, except a very few among them, and these not from sensuality but because their noble birth procures for them many offers of alliance. The wife does not bring a dowry to the husband, but the husband to the wife. The parents and relatives are present and pass judgment on the marriage-gifts, gifts not meant to suit a woman's taste, nor such as a bride would deck herself with, but oxen, a caparisoned steed, a shield, a lance, and a sword. With these presents the wife is espoused, and she herself in her turn brings her husband a gift of arms. This they count their strongest bond of union, these their sacred mysteries, these their gods of marriage. Lest the woman should think herself to stand apart from aspirations after noble deeds and from the perils of war, she is reminded by the ceremony which inaugurates marriage that she is her husband's partner in toil and danger, destined to suffer and to dare with him alike both in peace and war. The yoked oxen, the harnessed steed, the gift of arms proclaim this fact. She must live and die with the feeling that she is receiving what she must hand down to her children neither tarnished nor depreciated, what future daughters-in-law may receive and may be so passed on to her grandchildren.

Thus with their virtue protected they live uncorrupted by the allurements of public shows or the stimulant of feasting. Clandestine correspondence is equally unknown to men and women. Very rare for so numerous a population is adultery, the punishment for which is prompt, and in the husband's power. Having cut off the hair of the adulteress and stripped her naked, he expels her from the house in the presence of her kinsfolk and then flogs her through the whole village. The loss of chastity meets with no indulgence; neither beauty, youth, nor wealth will procure the culprit a husband. No one in Germany laughs at vice, nor do they call it the fashion to corrupt and to be corrupted. Still better is the condition of those states in which only maidens are given in marriage and where the hopes and expectations of a bride are then finally terminated. They receive one husband, as having one body and one life, that they may have no thoughts beyond, no further-reaching desires, that they may love not so much the husband as the married state. To limit the number of children or to destroy any of their subsequent offspring is accounted infamous, and good habits are here more effectual than good laws elsewhere.

► festivals

INTRODUCTION

Ancient peoples were highly dependent on their natural environment. Rather than conquering it, they usually learned to find ways to make peace with it and try to understand their place within the natural world. Many of the festivals ancient peoples took part in served the purpose of reflecting their cosmology, or understanding of the origins and structure of the world.

Throughout the ancient world, festivals of various sorts were held in conjunction with natural events. In colder northern climates, for example, the course of people's lives was dic-

tated by the cycle of the seasons, and even in warmer climates, cycles of flooding and dry seasons dictated many activities. Thus, many festivals were held to celebrate such events as the solstice in spring and fall and the equinox in summer and winter. Because many early calendars were structured according to the moon and its phases, many festivals were held in conjunction with a new moon. Major life events, such as the initiation of children into the adult community, were also a cause for celebration and festivals. Some early harvest festivals in the fall evolved into Halloween, and the roots of many modern-day Christmastime celebrations extend back to ancient winter festivals. The beginning of May, when warmer weather signaled the opportunity to start planting, was also a common time for festivals.

Many ancient festivals had religious motivations. Just as people were dependent on the cycles of nature, so, too, they believed that their fates depended on the will of the gods. It is no surprise, then, that many ancient festivals were organized and run by priests and religious leaders to give honor to a particular god or group of gods or to celebrate events in the community's shared mythological history. Some festivals, for example, were motivated by the desire for fertility as a way of ensuring the continuity of the community, so people set aside time to pay homage to a fertility goddess. In some cultures, such as that of ancient Mesopotamia, the purpose was to demonstrate the divine right to rule of kings by structuring the festival to show the role of kings as intermediaries with the gods. Throughout much of the world these gods and goddesses were local; that is, a particular deity might have been worshiped only in a local community rather than throughout the larger region.

Festivals served other purposes as well. Much as they do in the 21st century, they gave workers time off from labor, and they brought people together to help them forge a sense of community. By allowing behavior that would otherwise be frowned on (such as drunkenness), they served as a social safety valve, giving people a chance to "blow off steam." Just as in modern life festivals are often held in connection with sports and the arts, so, too, were festivals held in connection with sporting events in ancient Rome, and Greece was the source of the Olympic Games. Theater was also a time for festivities, with theatrical festivals held in ancient Greece and the Americas.

AFRICA

BY ROBERT SHANAFELT

In the ancient world festivals were generally special occasions for celebration and public commemoration of particular deities or religious ideals based on the calendar and the season of the year. Ancient Egypt had numerous festivals; less is known about ancient festivals in other African traditions, though the celebration of Jewish and Christian festivals in Africa goes back to antiquity. In all cases, it can be difficult to tell the precise origins of religious festivals because they involve sacred

myths and oral traditions where other sources of objective evidence may be lacking.

In many instances, historians have to extrapolate backward from modern African festivals to their ancient roots. A good example is Kwanzaa, a modern African celebration that takes place during the Christmas season in the West. Kwanzaa is thought by some to be a replacement for the Christian traditions of Christmas, but this belief is incorrect. Kwanzaa is, in fact, a harvest festival, as reflected in the Swahili origin of the name, *matunda ya kwanza*, meaning "first fruits of the harvest." Thus, Kwanzaa is a seasonal celebration that has been practiced by Africans for thousands of years.

Ethiopia's Timkat festival, which has deep roots in tradition, is one festival about which much is known. Although it is a celebration of the Christian holiday of Epiphany (January 6), at which time the three kings brought presents to the newborn Jesus, it is also connected to the belief that the Ethiopian Orthodox Church is the guardian of Judaism's Ark of the Covenant, the chest that holds the Ten Commandments. The belief is that the ark is hidden at the site of the Church of Our Lady Mary of Zion, built over the ruins of a temple constructed by the ancient Axumite kingdom. While a great deal of uncertainty surrounds the fate of the ark, many people believe that it was stolen from the temple in Jerusalem by Menelik, the son of Axum's most famous historical figure, the Queen of Sheba, and deposited at the remote Christian outpost. During this festival thousands of white-clad worshippers parade through the streets carrying crosses as well as replicas of the holy object.

History, tradition, and sacred myth also come together in the annual Olójó festival held in the Nigerian city of Ilé-Ife. Although historians date the origin of the city to later times, in Yoruba traditional accounts the world actually began at Ilé-Ife, and the city continues to be at its center. As it is practiced in contemporary times, the Olójó festival is a festival of renewal, in which the king renews the power of the god of war and the goddess of wealth and fertility. The ceremony is highlighted by a ritual procession led by the Ooni, or king, of Ilé-Ife and his entourage. The two end points of the procession are the shrines to the divinities, where offerings are made to ensure the political and economic well-being of the people.

A number of contemporary black African peoples claim Jewish descent. They practice Jewish customs, including Jewish rituals such as circumcision, which are traditionally celebrated during community festivals. Until recently, these claims were often not taken literally and certainly not thought to represent genetic realities that go back to antiquity. However, genetic evidence is starting to validate at least some of these claims. For example, a certain lineage of the Lemba of South Africa has been shown to descend from the Cohen ancestral line, the Kohanim, a line of descent traditionally ascribed to Jewish priests. In Ethiopia a group called Beta Israel also trace their roots to Judaism. They lived with their traditions for hundreds of years, but thousands immigrated to Israel in the 1980s. The Jewish feast days and festi-

Ethiopian Orthodox priests at festival of Timkat, celebrated since ancient times. (© Board of Regents of the University of Wisconsin System)

vals they respect include New Year, Yom Kippur, Sucot, and Passover. They also had a special day to celebrate the Torah, which involved bowing and making offerings on hilltops near their homes.

In southern Africa there is cultural continuity between scenes depicted on ancient rock paintings and the religious traditions of the people known as the Khoisan, or Bushmen. Although it is hard to say if their ceremonies fit the category of a festival, rock paintings dating back thousand of years shows their ancestors engaged in what appear to be ritual dances and hunts. Some paintings show scenes reminiscent of contemporary rituals. One interpretation is that the rock paintings were commemorations of trance states experienced by shamans during particularly important ritual occasions.

EGYPT

BY MARIAM F. AYAD

Festivals, or periodically occurring religious celebrations, were an integral part of life in ancient Egypt. The Egyptian word for festival was *heb*. Text and iconographic (pictorial) evidence provides us with details concerning the nature, timing, and duration of such celebrations. While a few were civic

in nature, most Egyptian festivals were associated with the cult of a specific deity. In ancient Egypt each temple was dedicated to the cult of a specific god, or group of gods, such as the temple of Amun at Karnak, the temple of Hathor at Dendera, and the temple of Horus at Idfu.

Temple representations indicate that boat processions were an integral component of celebrating some of the major Egyptian festivals. Enclosed within a shrine, the cult statue of the deity would be carried out of the temple by priests. Because lay people had limited access to the inner halls and sanctuary of the temple, cult festivals became occasions for oracles. Supplicants would place their yes-or-no questions to the god. Forward motion of the shrine indicated a positive outcome. The evidence suggests that nonroyal officials took part in religious festivals both as priests and as festival leaders.

In an Egyptian temple, texts inscribed on the walls and doorways of the temple describe religious services performed for the benefit of its divine occupant. Such texts include not only hymns, prayers, and liturgies but also detailed lists of festivals or feasts associated with the temple. Often referred to as festival calendars, these lists provide organized and detailed accounts of the cultic and liturgical activities per-

formed in the temple. Such calendars were probably copied from liturgical papyrus rolls kept in the temple archives. Dating to the Old Kingdom, the earliest known festival calendar is inscribed on the walls of the Fifth Dynasty sun temple of King Niuserre (ca. 2450 B.C.E.). Private tombs of the Old Kingdom also included brief feast lists.

Temple calendars indicate that the Egyptians celebrated annual festivals. Whether a festival lasted for one day or for several days, each had a fixed date within the Egyptian civic calendar, occurring on the same day, or over the same period, every year. Festival calendars also include brief accounts of the major religious events celebrated within the confines of a particular temple.

Wep Renpet (New Year's Day) was celebrated on the first day of the civic calendar (first day of the first month of the year, or first month of Akhet, day 1). This festival marked the New Year and celebrated the notions of rejuvenation and rebirth.

The festival of Wagy was originally a lunar festival that was celebrated on the 18th day of the first month of the civic calendar (first month of Akhet, day 18). This festival was funerary in nature, but evidence for it comes from both major cult centers and private tombs. From the Fourth Dynasty (2575–2465 B.C.E.) onward, this festival is included in feast lists inscribed in private tombs. Because the civic and lunar dates for this festival did not always coincide, the Egyptians eventually celebrated this festival on two separate occasions: once on its firmly set date within the civic calendar and at another time according to its actual lunar date.

The Opet festival, which was first celebrated in the reign of Hatshepsut of the Eighteenth Dynasty (ca. 1470 B.C.E.), lasted up to 27 days during the Twentieth Dynasty (ca. 1196–1070 B.C.E.). This New Kingdom festival took place in the second month of the civic calendar. The Opet festival included a procession during which the pharaoh-elect traveled to the temple of Amun at Luxor, where he would receive emblems of kingship from his divine father. During the course of this festival the pharaoh was identified with Horus, the divine ruler of the living, and was officially crowned as king of Egypt. Because of its importance in asserting the power and divinity of the Egyptian king, this festival held special significance in royal ideology and was closely supervised by state officials.

The festival of the god Sokar, or Choiak, was celebrated during the fourth month of the civic year. This ancient festival was dedicated to the cult of Osiris, the divine ruler of the afterworld. This festival, which was included in Old Kingdom private feast lists, linked Osiris both to the city of Memphis and to the god Sokar. Originally celebrated over a period of six days, this festival lasted for almost an entire month during the Late Period (712–332 B.C.E.). Since the Egyptian civic calendar comprised three seasons of four months each, the feast of Sokar served as a celebratory conclusion to the first season of the year (Akhet, or Inundation). By day 26 of the Sokar feast, Osiris was considered officially dead, and a period of four days marked by intense sadness and mourning followed.

Nehebkau was a festival celebrated on the first day of the fifth month. Similar to a New Year's Day festival and occurring just five days after the festival of Sokar, this feast became another occasion to celebrate rebirth. In the interim five-day period, the king, who was identified with Osiris in his death, was reborn as the living Horus. Because the concepts commemorated during this festival were very similar to those celebrated on the first day of the civic year, this festival shared many rituals with the Wep Renpet festival, the original New Year Day's celebration.

The festival of Min, the god of fertility, was celebrated at the beginning of the harvest season (Shemu); the festival of Min occurred in the ninth civic month. The date of this predominately agricultural festival was set according to the lunar calendar. During the course of this archaic festival, the king would harvest the first sheaf of grain and would ritually act as the provider and sustainer of his people.

The Beautiful Feast of the Valley was enacted during the 10th month of the year. Dating to the Middle Kingdom (ca. 2040–1640 B.C.E.), this Theban festival became very important during the New Kingdom. A major part of celebrating this festival involved a boat procession during which the statues of the divine Theban triad Amun, Mut, and Khonsu were ferried across the Nile to the temple of Hatshepsut at Deir el-Bahri on the western bank of the Nile. Because the city of the dead was also located on the western bank, this festival became an occasion to visit the tombs of deceased family members.

Because festival calendars are primarily preserved on temple and tomb walls, it should come as no surprise that the extant evidence is biased toward official religious celebrations, providing us with very little information on nonreligious civic festivals. One very important noncultic festival was a royal jubilee celebration, known as the Heb-Sed festival. Celebrated throughout the Dynastic Period, the Heb-Sed festival is first mentioned on ivory tags dating to the reign of King Den of the First Dynasty (ca. 2900 B.C.E.) and may have originated in a predynastic tradition. During the course of this celebration the king performed a series of physically strenuous rituals, possibly to prove his virility. While in theory the Heb-Sed was celebrated every 30 years, the evidence suggests that Egyptian rulers may have held it more frequently. Representations of the Heb-Sed festival are found in the sun temple of Niuserre, in the tomb of Kheruef at Thebes, in the temple of Amenhotep III at Soleb in Nubia, in the temple of Akhenaten in East Karnak, in the Twenty-second Dynasty (945–712 B.C.E.) temple of Osorkon II at Bubastic, and from the Twenty-sixth Dynasty (664–525 B.C.E.).

THE MIDDLE EAST

BY KAREN RADNER

In the ancient Near East there was no working week culminating in a fixed Sabbath or Sunday to provide time for rest and relaxation as well as worship. Instead, the course of daily

life was interrupted by various festivals that were part of the cultic calendar, the schedule of interaction between a community and its deity. The importance of religious festivals to structure time is made most obvious by the fact that many month names are actually the names of festivals, for example, the Sumerian month name *Ezem-mah-Nanna*, "Great Festival of the Moon God," or the Akkadian month name *Kinunum*, "Brazier Festival" (celebrated at the advent of winter).

Festivals were those occasions when the gods met with the public, not just with the specialized personnel who served them on a daily basis. At the core of every festival lies an encounter with the divine, and those who together met with the deity gained a strong sense of group identity from the event.

In the third millennium B.C.E., in the period of early city-states, every city had its own distinctive calendar. This calendar reflected the individual schedule of each city's local deity, starting every year anew with the celebration of the new year, when the god bestowed his blessing on his people. Although the beginning of the year was often celebrated in early spring, the various city-states did not celebrate at the exact same time. In the northern Mesopotamian city of *Ekalatum*, for example, the New Year festival took place in autumn. Only with political unification came the merging and synchronization of these local calendars. Typically, the cultic calendar of the royal dynasty's city of origin was imposed on the entire country, while the most prominent festivals of regional centers were integrated into this calendar. As late as in the seventh century B.C.E. we have evidence that the Assyrian king not only participated in the New Year festival at the imperial god *Assur's* temple at the city of the same name, the cultic capital of Assyria, but also celebrated the New Year festival at *Kalchu*, in the temple of the god *Nabû*, and at *Arbil*, in the temple of the goddess *Ishtar*.

The king's prominent role in all important festivals is the legacy of the personal union between political leader and high priest in the early city-states. It was the obligation of vassals personally to attend the main festivals of their overlords or at least to send a high-ranking deputy. The same was expected of allies, and from the diplomatic correspondence found at *Amarna* we know that *Kadashman-Enlil I*, the king of *Babylon*, felt slighted that *Amenophis III* of *Egypt* had not invited him to join him in celebrating his "great festival," in all likelihood the *Sed* festival, a sort of royal jubilee.

While those festivals that took place in a yearly cycle were closely connected to and reflected by the calendar, there are other festivals that were celebrated less often, for example, in a seven-year cycle, such as the *Zukru* festival to commemorate the dead of the Syrian city of *Emar*, or at entirely irregular intervals, such as the funeral of a king or the installation of a new high priestess after the demise of her predecessor. Some of these festivals could take several or even dozens of days, as we know from surviving texts that describe the programs for the events. It is not surprising to find that it is often the irregular festivals that are documented in this way: Their schedule was laid down in writing so that future generations would

be guaranteed to hold the celebration in the correct way; an exact liturgy, down to the songs to be sung and the prayers to be recited, needed to be followed, as any mistake would have upset the meeting with the divine, with possibly fatal consequences for the community. As members of the elite, including rulers and priestly personnel, could reasonably hope to live to old age, many decades could pass before a royal funeral or an investiture ceremony was necessary. Hence, the installation of the high priestess of the storm god's temple at *Emar* is one of the best-known Near Eastern festivals. The event, as it was celebrated in the second half of the second millennium B.C.E., took nine days and involved the participation of the residents of the entire city, who selected one of their daughters to be given to the god as his human consort.

While the number of those who could enter the temple and meet with the god or goddess in his or her shrine was always restricted, the general public had the chance to come into contact with the divine when, as was an important part of many festivals, the deity left the temple on a procession through the city or even the country. The deity did so in the form of a statue and traveled by chariot or on a boat. So important was the moment when the god left the shrine that a series of omens was recorded that forecast the future from the way the statue looked or "acted" at that particular time. The divine statue on its vehicle provided the focal point, but the procession consisted of many participants: Priests, musicians, and singers formed the human entourage, together with attendants, who steered and protected the divine means of transport. The god often found himself in the company of other deities who partook in his festival. While the procession in itself was an important element of the festival, the outing would often lead to a particular destination, such as a garden residence, a game park, or another temple, where the deity was to undertake elaborate activities, such as hunting expeditions or wedding ceremonies; we probably should imagine this practice as a form of ritual drama, possibly similar to early Greek theater.

With the processions being the most public part of the festivals, the communion of selected individuals, as the representatives of their entire community, with the god in the privacy of the temple was at the heart of every celebration. The meeting was accompanied by sacrifices, consisting of food, drink, and incense; the community, or at least parts of it, benefited from these sacrifices because these provisions were in turn distributed in the form of public feasts. As the sacrifices included luxury food, such as wine, meat, and fruit, festivals were also occasions when the general populace had a chance to enjoy these otherwise rare treats.

Hence, ancient Near Eastern festivals served a variety of purposes. For the community, festivals strengthened the group's identity and provided public entertainment, holidays from work, and the opportunity to encounter the divine; for the leaders of the community, festivals served to legitimize and highlight their role as the intermediaries between the divine and the people.

ASIA AND THE PACIFIC

BY MICHAEL ALLEN HOLMES

Throughout Asia many ancient festivals had origins in the natural world. As early agriculture rooted peoples in homelands, communities flourished not just because of individual efforts but also because of the intensified labor of extended family, friends, and neighbors. Meanwhile, humans became more dependent on the cooperation of nature—and more endangered by its caprices, as droughts, floods, and brutal winters could all lead to great loss of life. Festivals allowed communities both to recognize the powers of nature and to cement the social ties that allowed them to persevere through difficult times.

In ancient China most festivals featured some form of dancing. During the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) kings would dance to avoid incurring the wrath of the demons believed to cause droughts. During the ensuing Zhou Dynasty, lasting until 256 B.C.E., kings welcomed barbarians into their courts for the performance of dances. The men waved around the tails of yaks and also rods with pheasant feathers attached to the ends, likewise driving away destructive spirits. Among the masses in the Sichuan region during the Han Dynasty (ca. 202 B.C.E.–220 C.E.) general feasts and revelry grew so popular and disruptive that the government had to restrict such activity to designated festival times.

Popular Chinese festivals revolved around the changing of the seasons. The end of winter and beginning of spring were celebrated with particular vigor, amplifying widespread feelings of joy and renewal. Festivals at this time of year featured offerings to earthly spirits as well as human-oriented rites related to mating and fertility. The Chinese New Year, also known as the Spring Festival, generally occurred on the day of the second new moon after the winter solstice, thus falling during this celebratory time. While various changes to the time of the New Year were made by various rulers, the New Year was oriented as it currently stands by Emperor Wu in 104 B.C.E.

Another seasonal celebration still held is the Mid-Autumn Festival, which has several other names, including the Mooncake Festival. Falling in the middle of the eighth lunar month of the Chinese calendar (usually aligning with late September and the autumnal equinox), when the moon is especially bright, this festival is a celebration of the year's harvest. The general worship of the moon in China has been traced back through the second millennium B.C.E. During the Zhou Dynasty moon worship centered on the Mid-Autumn Festival.

An ancient Chinese festival unrelated to nature is the Duan Wu Festival, also known as the Dragon Boat Festival, commemorating the death of Qu Yuan (ca. 340–278 B.C.E.). Qu Yuan was said to be a patriotic minister from the state of Chu who was exiled by his deceived king. After long wandering and writing poetry near his hometown, he waded into a river and committed suicide when he learned that his state had been overrun by the state of Qin. Local people searched

for his body in boats while scattering rice as an offering to his spirit until his spirit told his friends that a river dragon was eating the rice and that they should wrap it in silk. The honoring of Qu Yuan's death and the search for his body evolved into a tradition of dragon boat racing, held on the fifth day of the fifth lunar month.

In India many festivals over time focused on events of a mythical or religious nature, similar to Christian festivals in the Western world. Since the major Sanskrit epics are among the earliest surviving writings from the Indian subcontinent, the precise origins of festivals cannot necessarily be attributed to specific aspects of the annual cycle. Also, in certain parts of India seasonal changes were not nearly as prominent as they were throughout more northerly Asian regions.

The most prominent ancient Indian festivals, which in modern times are celebrated as Hindu festivals, serve as commemorations of mythical and sacred events. The majority of these events are narrated in the ancient Sanskrit epics *Ramayana* and *Mahabharata*, the former dating from roughly the third century B.C.E., the latter from a less certain date in ancient times. Both of these texts are considered not only great mythological epics but also compilations of much ancient philosophy and wisdom. Given the ancient origins of these epics, the festivals associated with events described in them have presumably been celebrated since ancient times. Some Indian festivals evolved from the more ancient recognition of the seasonal cycles.

Holi, also called the Festival of Color, occurs on the full-moon day falling in late February or early March and features carefree springtime revelry. The name is derived from a mythical event in which Holika was burned to death when her father, the king of the demons, tried to set fire to her brother, a devotee of Lord Vishnu. To commemorate the flirtatious playfulness of Lord Krishna, whose mother used color to darken the face of his fair-skinned consort Radha, Indians celebrate Holi by throwing colored powder and water at each other. The festival is understood to have originated in the agricultural celebration of the arrival of spring and its variegated colors.

Diwali, also known as the Festival of Lights and usually falling in October or November, is generally regarded as a celebration of the victory of good over evil. Specifically, in the *Ramayana*, Lord Rama returned victorious from a war with Ravana, a demon king, on this day. Upon his return, people lit lamps to reveal paths in the darkness. Also, in accordance with the *Mahabharata*, Diwali commemorates certain events associated with the goddess Shakti and Lord Krishna's wife. Diwali celebrations generally involve lighting lamps and lanterns and sharing time with family and friends. In much of India, Diwali marks the opening of the New Year. The festival of Dussehra, also called Dasara and occurring roughly a month earlier, is closely related to Diwali, as it marks the day on which Rama actually killed Ravana. Other significant Indian festivals mark the birthdays of Lords Ganesha, Krishna, Rama, and Hanuman.

EUROPE

BY AMY HACKNEY BLACKWELL

The people of Europe celebrated festivals that marked the seasons dividing the year. There were eight main points of celebration. The summer and winter solstices (the longest and shortest days of the year, respectively) and the spring and autumn equinoxes (the days in the spring and fall when night and day are the same length) marked the year's turning points and were occasions for feasts and parties. The other four were festivals that did not fall on solstices or equinoxes and thus were usually scheduled for the full moon between these events. The Celtic calendar used both solar and lunar cycles, so dates for such festivals varied from year to year. Ancient Europeans divided the year into two halves, the dark winter half and the bright summer half. The festivals known as Samhain and Beltane in Ireland (but celebrated under other names throughout ancient Europe) marked the dividing lines between these two halves of the year.

The Celtic year began at the end of autumn and the beginning of winter, around October 31, when Celts celebrated the final harvest. This festival was known as Samhain in Ireland. On this date the spirits of the dead were said to walk the earth to visit their old homes. Gods were also believed to roam about the dwellings of the living, intent on doing harm. People lit large bonfires to honor the dead and protect themselves from evil spirits wandering the land. Young men lit torches and ran around the boundaries of their farms to protect their families and property from evil spirits. Families put out the fires in their homes and used flames from the communal bonfires to rekindle their hearths; they tried to keep these same fires lit for the entire year. Because the line between the living and the dead was blurred at this time, Druids believed that Samhain was the best possible time to predict the future.

Tribes gathered at this festival to hold political discussions, horse races, and markets, and to exchange spouses. Animal sacrifices were common, as people killed and ate animals fattened during the summer. In some areas of Gaul (modern-day France) and Germany people dressed in animal costumes and paraded about. In Roman Gaul this harvest festival blended with the Roman festival Feralia. People celebrated Feralia by leaving food on the graves of their ancestors and decorating their homes with apples. This autumn festival gradually transformed into the modern festival Halloween.

Ancient Germanic and Norse peoples celebrated a winter solstice festival called Jól, or Yule. Historians believe this name may have come from the Anglo-Saxon word for "yellow," possibly derived from sun shining off the snow or perhaps from the festival's purpose of bringing back the sun from the depths of the cold, dark northern winter. The festival occurred on or around December 21, the shortest day of the year. The significance of the winter solstice has considerable antiquity, as seen in the construction of the megalithic tomb at Newgrange around 3000 B.C.E., where the sunrise

on December 21 shines directly down the entrance passage into the burial chamber. People celebrated with feasts, especially with roast pig, which may have been a sacrifice to the god Freyr. They decorated their homes with branches of holly and mistletoe and burned special oak logs in the fires; they kept these traditions after converting to Christianity in the medieval period. The ancient Germans also honored sacred trees at this time by sacrificing and killing male animals and slaves and hanging them from the tree branches. This practice may have influenced the custom of decorating trees for Christmas.

Imbolc was the ancient festival marking the end of winter. It was traditionally celebrated on the full moon halfway between the winter solstice and the spring equinox, which fell around February 1. This was the date on which people began to milk their ewes (female sheep), which gave birth around this time. Days began to grow visibly longer at this time, and people marked the coming of spring by lighting large numbers of candles and lamps. The Mound of the Hostages in Tara, Ireland, appears to have been constructed to identify the date of Imbolc; it is aligned to catch the rising sun that morning. Irish people continued to observe Imbolc after converting to Christianity, transforming the festival into Saint Bridget's Day.

The first day of spring fell on the spring equinox, around March 21. Celtic people traditionally sowed their crops on this date. Ancient Germans believed that their fertility goddess Ostara mated with the sun god on the spring equinox; her son Jól, or Yule, was born on the winter solstice. Ancient Europeans celebrated the return of spring around May 1, on the full moon between the spring equinox and the summer solstice. In Ireland this festival was called Beltane. At this point people celebrated the return of life to the soil and the beginning of the planting season. People lit enormous bonfires out of sacred wood and drove their animals past them to protect them through the summer. They decorated their houses with branches of hawthorn, the tree of hope and protection. This festival was particularly popular with young lovers, who gathered flowers, danced around maypoles, and spent the night in the forest cavorting with one another. Leaping over fires was believed to bring luck to all who did it, from pregnant women hoping for smooth deliveries to travelers embarking on journeys. This tradition was preserved in Germany as the May Day festival.

The summer solstice, or midsummer, fell around June 21. This was the longest day of the year, with a very short night; in the far north the sky hardly darkened at all on midsummer. Stonehenge in England is aligned precisely to catch the light of the rising sun on Midsummer's Day. This was an occasion for giant bonfires, dancing, games, and outdoor feasts. In some areas people walked their domestic animals around the bonfires to bless them.

The harvest festival, called Lughnasa in Ireland, fell on the full moon between the summer solstice and autumn equinox, usually around August 1. It was named after the

Celtic god Lugh, the god of the sun and agricultural fertility. The harvest season began at this time and lasted until the end of October. In some areas the beginning of the harvest was marked by gathering wild berries; if the berries were plentiful, crops would be too. Young people participated in games of athletic skill; horse racing naked was a popular sport in Ireland.

The autumn equinox fell around September 21 and marked the beginning of autumn. Numerous ancient stone structures were designed to catch the light of the rising sun on this date. The Druids celebrated the equinox by burning a large wicker figure that represented the plant spirit; some scholars believe that this custom was the origin of Julius Caesar's belief that Druids practiced human sacrifice.

GREECE

BY CHRISTOPHER BLACKWELL

Every ancient Greek community celebrated a number of festivals, *heortai*, throughout the year. These were simultaneously religious and social events. Festivals honored various gods but also provided occasions for members of a community or members of various communities to come together in celebration. There were other religious events during the year, recurring rituals of various kinds, and public sacrifices. Festivals stand out, however, because they were decidedly enjoyable occasions, never somber or grim, as certain other rituals might be.

Some of the oldest festivals had to do with the cycles of the agricultural year and were associated with divinities of the earth and the environment. The Mysteries celebrated at Eleusis, near Athens, honored Demeter and marked the end of winter. Citizens of Athens celebrated plowing with the Proerosia, planting with the Thesmophoria, and harvesting with the Anthesteria. Other festivals marked periods of transition in human life, particularly transitions during childhood and from childhood to adulthood. Athenian boys were initiated into the community at the festival of the Apaturia. This took place in the autumn at each of the small subcommunities of Attica. The three days of this festival included the Dorpia, a dinner feast ringed in the festival; a sacrifice to Zeus and Athena (the patron goddess of Athens); and the Koureōtis, the final admission of the young men into the community. Boys would participate in this festival at least three times during their childhood: first when they were small children; again when they entered the "*ephebate*," a period of military instruction for adolescents; and finally when they married.

Athenian girls were initiated into the community at the festival of the Brauronia, named after its location at a sanctuary in the town of Brauron near Athens, also called the Arkteia, or "bear festival." Celebrated in honor of the goddess Artemis, this festival involved Athenian girls between five and 10 years old who dressed as bears and gathered to perform dances. Scholars disagree on the meaning of this ritual, but many think it was an occasion to celebrate the "wildness"

of young girls, who would eventually be "tamed" by marriage and take their position as women of the community.

Some festivals were purely local, specific to a small village or town. Others emphasized the relationship among towns, united into the larger political entity of the city-state, or polis. Athens, which was a political unity of the city of Athens with the many towns of the territory of Attica, celebrated this coming together, or *synoikism*, during the festival of the Synoikia and celebrated its unity and greatness at the Panathenaea, or All-Athens festival. The latter festival, in honor of the goddess Athena, began with a procession, or *pompē*, through the city; the procession involved all members of the community, including children, unmarried young men and women, soldiers, and resident aliens. During this festival the married women of Athens would present a new cloak, or *peplos*, to the statue of Athena in the Parthenon, having woven the garment collectively during the year.

The most famous of festivals among the ancient Greeks were the "agonistic" festivals, featuring competitions. These competitions fell into two categories: Gymnastic festivals had athletic competition, and musical festivals, having to do with the Muses, had competitions in poetry or drama. The most famous gymnastic festival was that in honor of Zeus, held at Olympia in the Peloponnese every four years beginning in 776 B.C.E. This festival, open to participants throughout the Greek world, featured competitions in foot racing (including a race in which runners wore bronze armor), chariot racing, boxing and wrestling, and weight lifting. So important was this Olympic festival that warring states regularly called a truce to enable participants to travel to Olympia safely. Other festivals of athletic competition were the Nemean Games, held in honor of Heracles; the Pythian Games, held in Delphi in honor of Apollo; and the Panathenaic Games, held in Athens.

Of the musical festivals, the most famous were the dramatic festivals at Athens, the occasion for the production and performance of tragedies and comedies. There were two main dramatic festivals celebrated by the Athenians, the Dionysia and the Lenaea. The Dionysia was celebrated in the spring, timed to coincide with the opening of the sailing season on the Aegean Sea, after the unpredictable storms of winter had passed. This festival was the occasion for Athens to show itself off to the rest of the Greek world, and it was open to all Greeks. During the period of Athens's naval empire, in the fifth century, their "allies," subject states, sent representatives bearing annual tribute, which was presented to the city of Athens in a public ceremony during the festival.

The focus of the Dionysia was the Theater of Dionysus, which was at once a theater and a temple. The democratic government of Athens arranged for public funding of plays, both tragedies and comedies. Each play was acted by two or three professional actors and a trained and choreographed chorus of citizens. Plays competed for prizes, with a panel of judges awarding prizes for best play, best actor, and so forth. A comic playwright would compete with a single play, but

tragedians submitted four plays, a trilogy of tragedies, and a so-called satyr play. The Dionysia ran for five or six days.

The Lenaea took place in midwinter and was a smaller and more intimate festival for Athenians alone. There is evidence that slaves could attend performances at the Lenaea and even act in the plays. It is not clear whether women were allowed to attend plays at either of the major dramatic festivals. At both of these festivals and at other festivals throughout the Greek world, there were competitions in other kinds of poetry and music, especially choral singing and dancing, reciting Homeric epic, and performing on the double flute and the kithara.

Festivals generally served to reinforce community, through a shared enjoyment of art, through eating and drinking, and by means of other activities. Some festivals emphasized drinking, with drunkenness serving as a release. Others invited people to invert normal social roles, allowing slaves to order their masters around or men to dress in women's clothing. Some emphasized the shared history, real or mythological, of a community, such as the Oschophoria and the Depnophoria at Athens, which involved reenactments of events in the mythology of Theseus, the legendary king of Athens.

After the fourth century B.C.E., during the Hellenistic Period, new festivals arose in parts of the Greek world, in honor of (and sponsored by) the dynastic monarchs who then held power over large territories; one such festival was the Ptolemaia, in honor of the Macedonian Ptolemies, the dynasty that ruled Egypt after the third century B.C.E.

ROME

BY AMY HACKNEY BLACKWELL

The ancient Romans celebrated numerous festivals, or *feriae*. These festivals served both as occasions to honor gods and as days off from work, since most businesses closed for the occasion. Rome's many priests and legal officials fixed the dates for festivals on the calendar. Some festivals had set dates, but others moved around from year to year. Many Roman festivals had their origins in older cultures and religions. Many of them also form the basis for modern seasonal and religious festivals.

Some festivals occurred on specific dates, but others were set monthly according to the phases of the moon and other signs. Every month had significant days. The first of the month, called the Kalends, was considered sacred to the goddess Juno. It was meant to coincide with the new moon. The fifth or seventh day of the month was called the Nones, and on this day the priest would announce that month's festivals. The Ides, sacred to Jupiter, occurred in the middle of the month and ideally coincided with the full moon. Priests set festivals to occur during the second half of the month because it was easier to track the moon's phases then.

The Bona Dea, or Good Goddess, was a goddess worshipped only by women, who considered her responsible for their fertility and the safe development and birth of their

children as well as the fertility of the earth. She was often depicted wreathed with vines next to a jar of wine and a holy snake. Every year the wife of the consul or of the pontifex maximus (chief priest) and the vestal virgins (priestesses of the hearth goddess, Vesta) held a party to celebrate her feast day. The wealthiest women in Rome attended this party, where they drank wine that they called "milk"; an ancient and largely disregarded law forbade women to drink wine, so calling the wine "milk" was a way to acknowledge this law while disobeying it. In 161 B.C.E. Publius Clodius Pulcher, a man, dressed as a woman in order to sneak into the Bona Dea party. The Roman women panicked when they discovered this, fearing that all childbirth that year would be cursed.

The Magna Mater was the Great Mother goddess, also called Cybele. People believed that she made plants and animals grow and celebrated her festival in the spring. One festival in her honor involved cutting down a pine tree and placing it in her temple.

Hand of Sabazius, Roman (second or third century C.E.), found at Tournai, Belgium; such hands were associated with the cult of the god Sabazius and were carried in religious processions. (© The Trustees of the British Museum)

The Bacchanalia were festivals to honor the god Bacchus, called Dionysius in Greek. The Bacchanalia began around 200 B.C.E. as secret women-only festivals, but men quickly joined in. Because Bacchus was the god of wine, the festival included a great deal of wine drinking and could also involve wild sex and other unrestrained behavior.

The *ludi Romani*, or Roman games, were the games held every year to celebrate the festival of Jupiter Optimus Maximus on September 13. By the time of the Roman Republic (509–27 B.C.E.) the games went on for 10 days and included chariot races, boxing, wrestling, and many plays. Most of the events occurred in Rome's Circus Maximus, a giant arena.

The Lupercalia, held on February 15, honored the god Faunus and seems to have been named after a wolf god. Young men sacrificed a dog or goat at the Lupercal, a temple on the Palatine Hill, and skinned it. They then stripped naked, wrapped themselves in pieces of the fresh skin, and ran through the streets of the neighborhood hitting onlookers with strips of the skin. This treatment was said to enhance fertility, so women who wanted children made sure they were in the path of the runners.

Quirinalia happened two days after the Lupercalia, on February 17. This festival honored the Sabine god Quirinus, the patron god of Rome's Quirinal Hill and one of the gods associated with the founding of the city by Romulus. Quirinus was believed to watch over the government and citizenry of Rome, and the citizens were sometimes referred to collectively as *quirites*.

The Saturnalia, a feast honoring the god Saturn, or Saturnus, every December 17, was a major public festival. Modern scholars are not sure what exactly Saturn represented to the Roman people. Some suggest that he was responsible for the sowing of wheat and that the festival celebrated the successful completion of the autumn sowing. Romans celebrated the Saturnalia by performing a sacrifice at the temple of Saturn and then spending several days feasting. During the republic the Saturnalia lasted seven days. The emperor Augustus reduced it to three days, but most people continued to celebrate it for the full week. In addition to eating and drinking, people visited friends and relatives and gave one another gifts. The most notable aspect of the Saturnalia was the inversion of the social order. Slaves were given the day off, and their masters waited on them at meals for a change.

Several festivals celebrated the military and warfare. Festivals for the god Mars in March included sacrifices and horse races. Another festival in honor of Mars occurred on October 15. At this festival the army selected its best warhorses and ran them in pairs in chariot races on the Campus Martius, Rome's drilling ground. The right-hand horse of the winning team was killed with a spear on an altar dedicated to Mars. The priests then cut off its head, genitals, and tail. The genitals and tail were rushed to the Forum, where the horse's blood was dripped onto the altar of the Regia, one of the oldest buildings in the Forum. Meanwhile, at the altar at the Campus Martius, the priests conducted various ceremonies over

the horse's head, including covering it with cakes. When they were done, they tossed the head to the crowd of onlookers. These onlookers came from two separate neighborhoods, the Subura and the Via Sacra, and they fought to take possession of the head for their own neighborhoods. Whichever team won took the head home and nailed it in a prominent place.

Romans celebrated numerous other major and minor festivals throughout the year. The Agonalia, celebrated in January and in other months, honored the god Janus. The Matronalia on March 1 honored Juno and was a day for families to give gifts to their wives and mothers. March 19 was the Quinquatria, a festival sacred to Minerva. The goddess Venus had a feast day on April 1. Mercury had his on May 15. In addition to formal festivals, many days were considered bad luck and people avoided conducting important business on them.

THE AMERICAS

BY PENNY MORRILL

Archaeological records provide knowledge and understanding of the earliest high cultures in the Americas. Large-scale ceremonial centers, such as La Venta, the Olmec site in Veracruz (ca. 900–ca. 400 B.C.E.); Chavín de Huántar, the Chavín site on the northwestern coast of Peru (ca. 900–ca. 200 B.C.E.); and those constructed by the Adena (ca. 1000 B.C.E.–ca. 200 C.E.) and Hopewell (ca. 200 B.C.E.–ca. 400 C.E.) groups in the Ohio River Valley, were settings for festival activities. These centers consisted of pyramids, platforms, altars, and open plazas, indicating societies that were hieratic, led by chieftains or shaman-lords. The festivals followed the agricultural cycle, a characterization that would have been true for early ceremonial sites throughout the Americas. Thus, religion, politics, and economics would have revolved around the ceremonial complex.

Many of the peoples of the Americas believed in a multileveled universe with an axis mundi (center of the world). For the Olmec this center was represented as a tree, a mountain-pyramid, or a dragon. For the Chavín in Peru the sacred center was marked by the sculpted Lanzón figure, a statue of the central god. The Hopewell culture adopted the circle and the cross of four directions in their architecture and artwork. Across the Americas the shaman was able to move through multiple cosmic realms by transforming himself through bloodletting or the use of hallucinogens or accompanied by an animal alter-ego. Masks worn by the shaman-leaders had symbolic features that provided new identities. In Mesoamerica a shaman could call up ancestral spirits, assume the identity of an animal, or act out myth, and the audience would have understood his masquerade as transformation.

Ritual, festival, trade, and the ball game brought dispersed people from the surrounding villages and farmlands to the centers. The farmers of the Americas looked to their shaman-leaders for critical advice on plant husbandry—when and how to plant, what seeds to store, and methods of hybrid-

ization. The ceremonial center's architecture tracked and revealed astronomical phenomena: the movements of the sun, moon, planets (especially Venus), and stars and the timing of the solar equinox, solstices, and eclipses. A metaphor for the cosmos, the carefully configured architectural setting allowed the shaman seemingly to manipulate astronomical events for the betterment of the subject peoples, especially concerning agriculture. The festival audience would have gathered to await the occurrence of the phenomenon, brought about by the costumed shaman from his platform stage or atop a pyramid. Examples of such sites include Building J at Monte Albán in Oaxaca, Mexico (after 150 B.C.E.); Structure 5 at Cerros, a Mayan site in Belize (after 100 B.C.E.); and the Nasca lines in Peru (after 100 C.E.), the latter probably considered visible only to a transcendent birdlike shaman.

Much of the artwork that has been unearthed at these sites and others indicates theater on a grand scale, appropriate to the architecture. Around the perimeter of the Sunken Court at Chavín de Huántar humans and jaguars are depicted in procession. Carvings in the Olmec heartland and at other Mesoamerican sites represent costumed shaman-leaders acting out ritual in theatrical settings. On a platform throne at La Venta a leader wearing a bird headdress is shown seated in the open jaws of the earth beneath a sky dragon and holding a rope to which are attached captives. On the upper surface is a carved jaguar pelt, a symbol of power. On this throne before his subject audience, the shaman was able to combine transcendence with military prowess to enhance and centralize his power.

In the present-day Mexican state of Morelos, a cave doorway, the opening into the underworld in the form of a monster mask at Chalcatzingo (ca. 500–ca. 300 B.C.E.), is a dramatic stage set. At La Venta and Chalcatzingo sculpted figures wear large, ornate headdresses that must have been impressive whether closely inspected or viewed from a distance. In a cave painting at Oxtotitlan, in the Mexican state of Guerrero, a shaman is seated on a throne and wears an elaborate bird costume. He raises his arms and attached wings, giving the appearance of flight. Sculptures of transformation figures depicting humans becoming jaguars or birds indicate ritual festivals that must have brought together large numbers of participants into the plazas of Chavín de Huántar, La Venta, and Monte Albán.

Stela 5 from the Late Formative (ca. 400 B.C.E.–ca. 150 C.E.) Mayan site of Izapa in the state of Chiapas, Mexico, seems to record one of these presentations acted out before an audience. Below sky symbols, a supernatural tree appears in the center of the carved scene, rising up from a platform that is elaborated with earth and water symbols. A large figure to the right creates an opening in the tree from which humans emerge. On the other side of the tree are an elderly man and woman engaged in divination, perhaps the ancestral couple.

These ceremonies inspired the production of costumes made of feathers and other fine materials, jewels, masks, and ritual objects carved of jade and other prized stones. The

Pottery dog, from Colima, West Mexico, 300 B.C.E. to 300 C.E.; dogs were believed to assist the dead in their journey to the Underworld, and the hairless type depicted here was eaten at feasts. (© The Trustees of the British Museum)

jewelry and costumes of sumptuous materials denoted high status and, at the same time, meant substantial cost for the people served by the shaman-leaders. Materials for these accessories came from distant locales. Thus, as a result of this grand ceremonial activity, production and trade moved beyond agriculture to include precious ritualistic objects for the elite.

The Olmec played a game with a rubber ball on a court at San Lorenzo in Veracruz (ca. 1500–ca. 1200 B.C.E.). From this early precedent, ball courts continued to be placed within ceremonial centers in Mesoamerica. The game was considered a metaphor for cosmic events and thus part of religious festival activity. Audiences gathered to watch for an outcome that could bring life or death to the players.

In Mesoamerica the origin of the 260-day ritual almanac and the solar festival calendar of 365 days can be traced to the activity of the shamans at the ceremonial centers. The shaman-priests joined together the two calendars to create the 52-year Calendar Round, which was both divinatory (foretelling the future or uncovering secret knowledge) and a transcription of the cycle of festivals that followed the seasonal movement of the sun and other celestial bodies. On carved stone stelae at La Mojarra in Veracruz (after 150 C.E.) and El Baúl in the Mayan region of Guatemala (Stela 1 dating to 37 C.E.), the combination of hieroglyphs with dramatically costumed shaman-lords reveals the power that came with control over the passage of time.

► food and diet

INTRODUCTION

The earliest humans were “hunter-gatherers,” meaning that their food supply came from hunting animals and gathering plant foods that grew naturally without their help. Clearly, a community’s diet depended on the nature of the foodstuffs found in that part of the world. Hunters searched for large game animals, small animals (including rodents and, among some people, even bats), birds (including their eggs), seafood, and fish. Plant food included leafy vegetables and greens, nuts, roots, grains, honey, berries, and other fruits. Food supplies were affected by the season of the year, and early hunter-gatherer societies moved about in search of food as conditions in the environment changed. Famine and starvation were their principal enemies, and these enemies were never very far away. In an era of short life expectancies, the concept of a “balanced diet” would have been meaningless. Hunter-gatherers ate what they could find when they could find it, and they hoped that tomorrow they could find more.

The development of agriculture introduced some measure of security into the life of ancient peoples, and this added security enabled them to form more complex and sophisticated civilizations. Now they had at least some control over

the availability of food, and with a little luck they could store food for the future and avoid starvation. One major result was a dramatic increase in the world’s population. Food surpluses allowed ancient peoples to support classes of craftsmen, builders, civil servants, warriors, priests, artists, and poets, enriching the life of the community.

Still, ancient peoples were constrained by their environment, and the nature of the crops they could grow or the animals they could raise depended on such matters as temperature, rainfall, soil conditions, elevation, and the like. Ancient agriculturalists were acutely aware of changing seasons and weather conditions, and they took what steps they could to accommodate their farming practices to local conditions. The ancient Egyptians, for example, lived along the Nile River valley, a fertile region surrounded by harsh deserts. Each year the Nile flooded; when its waters receded, they left behind a layer of rich silt, where they Egyptians planted crops. The Egyptians became adept at water management, building a massive system of canals and dikes to store and distribute water for irrigation during the dry season.

Nearly every culture in the world developed a single staple crop that formed the bulk of its diet. In ancient Greece and Rome, for example, wheat was the main staple crop, so bread was an important part of the diet, supplemented by fruits and vegetables, oils (such as olive oil), legumes (that is, beans such as lentils), and fish. In Asia low-lying wetlands were ideal for rice cultivation, so rice became the staple crop, while in parts of the Americas, corn and beans were the main crops. Animal husbandry enabled some agriculturalists to maintain herds of cattle, sheep, goats, oxen, or pigs as well as birds, such as chickens, ducks, and geese. These animals supplied not only meat but also eggs, milk, and products derived from milk, such as cheese and butter. Most cultures, too, found a way to preserve beverages such as beer and wine; they could depend on these types of fermented beverages to remain wholesome and drinkable over time.

AFRICA

BY MICHAEL J. O’NEAL

The history of food and diet begins with the consumption patterns of ancient Africans, the first humans who faced the need to find sustenance in the natural world around them. As in any geographical region, the types of foods early Africans consumed tended to vary by climate and terrain. Thus, for example, coastal East Africans relied more heavily on fish and seafood than did people who inhabited the interior of the continent. Crops that flourished in the highlands of Ethiopia might not have done as well in lowland areas and vice versa. Foods that were available in lush, forested regions of the continent were not as widely available in the hot, dry savannahs of central Africa. Furthermore, climate changes over the millennia altered food and dietary habits. At one time much of the Sahara was lush and green, but in about 6000 B.C.E. the

region became arid, forcing people to move and find new sources of food. Thus, over long stretches of time, the dietary habits of the ancient Africans changed.

In spite of all these variables, a number of generalizations can be made about the food and diet of ancient Africans. Until the advent of agriculture, the earliest Africans survived by hunting, gathering, and fishing. Anthropologists theorize that the earliest humans became bipedal—that is, walked upright on two legs—because natural selection favored those who could travel long distances in the search primarily for tubers, or rounded roots, such as the potato, that grew underground. While tubers were an important source of food to the very earliest Africans, Africa has few native tubers, about half a dozen species, and those that did grow were small. Other, imported varieties of tubers would later become important agricultural crops.

Meat made up a major portion of the diet of early hunter-gatherers; among many Bantu-speaking peoples, the words for “food” and “meat” are still the same as they were in ancient times. In the equatorial forests of East Africa, for example, bands of small-statured African groups (sometimes termed Pygmies) survived by using spears, snares, nets, and arrows to capture and kill a range of game, from birds and rabbits to such large animals as hippopotamuses, giraffes, antelope, buffalo, gazelles, and elephants. Women, meanwhile, gathered mushrooms, nuts, berries, fruits, some varieties of cactus, and leafy vegetables. Nutritionists believe that the diet of ancient Africans was in many respects superior to that of modern peoples. Because hunter-gatherers consumed at least 80 different types of plants and possibly many more, they had a great deal of variety in their diet and suffered no vitamin or mineral deficiencies—though starvation was an ever-present threat. Eggs were gathered as well, but in some parts of the continent eggs were a taboo item, thought to weaken men and cause women to miscarry or become sterile. In some parts of Africa eggs are still taboo.

Fineware cup decorated with frogs and lotus flowers painted in black, from Faras, Sudan, dating to the first or second century C.E. (© The Trustees of the British Museum)

In some portions of Africa termites and caterpillars were roasted and eaten, often with honey, as snacks. Most commonly, the meat from game animals was preserved by smoking and drying. When it was cooked, it was either roasted over an open fire or cooked in stews with vegetables; many of these stews were also used as sauces for meat. A common sweetener was honey, and a common beverage was made by brewing kola nuts, herbs, and berries into a drink; kola nuts contain caffeine, and the ancient Africans learned that they could energize people, especially men before a battle. Along the coasts and rivers people caught and ate fish, which they fried, boiled, pickled, or sometimes ate raw. Fish included mackerel, flounder, carp, pike, cod, and others; seafood included crab, snails, oysters, lobster, prawns, shrimp, and crayfish.

The diet of ancient Africans changed as they came to place less emphasis on hunting and gathering and more on agriculture and livestock herding. Livestock herding, which provided not only meat but also milk, cheese, butter, and yogurt, was practiced primarily by people who lived in more arid regions of the continent; in damper regions diseases spread by such pests as the tsetse fly made livestock herding more precarious. Livestock included camels, cattle, donkeys, goats, and sheep. Interestingly, modern peoples of Africa, in common with Europeans, have the world’s lowest incidence of lactose intolerance, or the inability to digest the sugar in milk. It is believed that this tolerance for milk is a dietary adaptation that dates back thousands of years to ancient Africa. Historians believe that the first domesticated cattle appeared sometime between 3000 and 2000 B.C.E. The hardy Tunis sheep from North Africa had been tended for some 2,000 years when the U.S. president George Washington had some imported to help replenish his own sheep herd. While pigs could be found in North Africa, they were not domesticated. Many African tribes domesticated species of dogs as sources of food.

Crop cultivation added considerable range to the ancient African diet. The earliest African agriculturists lived in the highlands of Ethiopia, though Bantu-speaking people from East Africa and the Nilotes from northwest Africa were also among the earliest farmers. Some of the crops that formed an important part of the African diet included sorghum, millet, beans, okra, and cowpeas. In some parts of the continent pumpkins, cassava, and sweet potatoes were cultivated.

The African diet expanded again with the development of trade with other regions of the world, particularly Asia. Chief among imported foods were rice, yams, plantain, taro, and bananas. Tubers continued to be an important part of the diet. One variety of potato, for example, could weigh up to 9 pounds and was an important source of water in the diet for travelers and isolated herders. These foods, in combination with indigenous crops, enabled the African population to expand significantly. In particular, they contributed to the spread of Bantu-speaking people throughout large portions of central and southern Africa. Wheat, too, was added to the African diet, and such crops as wheat, millet, sorghum, and

yams became especially important because they were not overly sensitive to intemperate weather conditions. The influence of wheat was felt particularly in North Africa, which came under the influence of the Roman Empire. The Romans introduced couscous and many bread products still common in North Africa today. Throughout the rest of Africa, grain products were used primarily to make such dishes as porridges, gruels, and pancake-like foods.

Anthropologists and archaeologists have been able to reconstruct the diet of ancient Africans, at least in part, by using modern scientific tools. They operate under the proverb that people “are what they eat.” Foods that ancient people consumed leave identifiable chemical signatures in bones, teeth, and hair. By using sophisticated scientific instruments, scientists can examine, for example, carbon isotopes that remain in the skeletons of ancient people, including those of Africa. From this evidence, they can deduce what ancient peoples ate.

EGYPT

BY CHRISTINE END

Knowledge about the diet of the ancient Egyptians comes from two-dimensional depictions, three-dimensional models, and archaeological evidence such as food and animal remains. Farming was an important part of this agrarian nation, not just because it allowed individuals to feed their families. A person’s crop production determined his wealth and dictated the amount of his annual tax. The Egyptians also compensated workers, paid their taxes, and bartered for other goods with food products.

In comparison with other ancient civilizations, the Egyptians ate a well-balanced diet. Forensic evidence from the examination of mummies suggests that Egyptians rarely suffered from malnutrition. The reason for Egypt’s well-nourished population was the Nile River, which supplied its people with a prolific food source. The fertile soil deposited after the inundation (the annual flooding of the Nile) nourished Egypt’s crops, and the river itself provided a lush habitat for many species of animals and birds.

It is common to find two-dimensional representations of food offerings as well as of hunting and food preparation on ancient Egyptian tomb walls. The Egyptians believed these images could magically materialize and perpetually be available for the deceased in the afterlife. Three-dimensional models of food and food production also offered eternal sustenance for the deceased in the tomb. Additionally, a variety of preserved foodstuffs recovered from tombs give Egyptologists information about the preferred diet of the ancient Egyptians.

The particulars of meals and the dining schedules of the ancient Egyptians are unknown. Pictorial evidence and the remains of food suggest that the Egyptians prepared their diet in a variety of ways, including stewing, frying, boiling, roasting, grilling, drying, and salting. More written and vi-

sual data survives about food-related celebrations and festivals than about customary daily meals. Elaborate banquets during which people indulged in abundant food, drink, music, and entertainment marked these events.

The two main food staples of ancient Egyptians from all social classes were bread and beer. Within the customary funerary-offering formula (texts written on funeral objects), these two items always figure prominently. Bread loaves were typically triangular or ovoid, but many shapes and sizes existed, including a variety of odd-shaped loaves specially formed for religious reasons. Stone-ground emmer or barley wheat was the principal grain used in breads. Stone grinding produced grit-laden bread that ground down people’s teeth over their lifetime. Wealthy Egyptians often enjoyed sweetbreads, biscuits, and cakes, while commoners may have tasted these luxuries only on special occasions.

Egyptian beer was a thick, nutritious mixture of varying alcohol content consumed by adults and children alike. As with bread, barley and emmer were the main components in Egyptian beer. Because it was such a staple in the diet, beer brewing in the home was commonplace. Sometimes the Egyptians enjoyed flavored beers by adding fruits, honey, or spices.

Ancient Egyptians ate a variety of locally grown fruits and vegetables. Onions were the most popular vegetable, as evidenced in many offering table depictions. Other vegetables favored by the Egyptians were beets, garlic, cucumbers, celery, turnips, leeks, and lettuces. The Nile River was an additional source of other edible plants, including water-borne sedges, lotus, and tiger nut.

Fruits included dates, grapes, dom palm, pomegranates, berries, and figs. Fruit was eaten fresh but also used in cooking or preserved for future use by drying. Elite Egyptians enjoyed red and white wine produced from grapes. Ancient Egyptian wine amphorae were carefully marked with the type of wine, production year, and sometimes an indication of the quality of the wine they contained. Figs, dates, palm leaves, and possibly pomegranates were alternative ingredients used to make wine. Fruits were additionally included in recipes for sweetness, as was the carob pod, though not as frequently as honey. Although it was a luxury, honey was the primary sweetener. Bees were also kept as a source of beeswax used to create models for the casting of metal and as a waxy polish. Legumes such as beans, peas, and lentils rounded out the Egyptian diet. They supplied an easily cultivated protein source that was less expensive than meat. Of these three, lentils were the most common.

Local and imported spices seasoned the ancient Egyptian diet. Thyme, coriander, marjoram, fenugreek, dill, parsley, and cumin were all regionally grown spices. Salt improved flavor but also was used as a preserving agent for meat, fish, and fowl. Luxurious imported spices used in cooking may have included pepper and cinnamon.

The ancient Greek traveler Herodotus erroneously reported that the Egyptians did not eat fish, possibly because

of a myth involving a fish eating the phallus of the god Osiris after his evil brother Seth mutilated him. Although fish do not frequently appear depicted on offering tables, many species of fish are seen in representations on tomb walls as well as in fishing scenes, indicating that the Egyptians did indeed enjoy fish as part of their diet.

Many species of birds, both domesticated and wild, were consumed by the ancient Egyptians, including most often duck and goose but also ostrich, pigeon, quail, partridge, and dove. Containers in the shape of prepared (strangled and plucked) birds from funerary contexts survive; these receptacles contain cooked or preserved fowl for the deceased to enjoy in the afterlife. Bird eggs included those from many species, even ostrich.

The ancient Egyptians both hunted mammals in the wild and bred them in captivity. With the exception of the upper classes, most individuals consumed meat only on special occasions and during religious festivals. The rich could afford meat from cows, bulls, and oxen, while the less affluent may have eaten solely sheep and goat meat. Tomb scenes depict captive animals being force-fed to produce more meat per animal. Despite rare representations and Herodotus's claim that swine were taboo to the Egyptians, archaeological evidence suggests that Egyptians domesticated pigs and consumed pork. Smaller and perhaps more abundant animal food sources may have included mice, hedgehogs, and hares. No part of a food animal was wasted; animal products and by-products included milk (from goats and cows), cheeses, fats, medicines, and oils used for fragrance and cooking.

THE MIDDLE EAST

BY KAREN RADNER

Evidence about the ancient Near Eastern diet comes from two sources. One is the analysis of the remains of foodstuffs and human skeletons discovered in archaeological excavations. The other is information found in ancient texts and, to a lesser extent, images. These materials add up to a surprisingly detailed picture, and the ancient Mesopotamian menu is one of the best known of antiquity. The basic diet of an ordinary person consisted mostly of plant products, with only about 10 percent derived from animals, usually domesticated ones. The members of the elite, because they had access to luxury foods, could have a substantially higher proportion of animal products, including milk and milk products and eggs in their diet.

The emergence of ancient Near Eastern civilization is closely connected to the development of agriculture. It is therefore not surprising to find that cereals constituted the most important part of the diet, with barley being predominant and wheat occupying a distant second place. Barley was either ground into flour to make bread or porridge or used to brew beer, which was drunk habitually by people of all ages. Although regular beer had a low alcohol content, it nevertheless had enough to kill germs in the water during fer-

mentation. Beer was therefore the solution to the dangers of drinking contaminated water. Stronger beer, often flavored with sweet or spicy ingredients, was reserved for recreational drinking and served during festivals and in taverns. Typically beer was drunk through straws from large vessels resting on pot stands.

The palm tree was present throughout southern Mesopotamia, and its fruit, the date, played an important role in the Near Eastern diet and economy, in antiquity as today. Unprocessed dates could be stored and transported easily and, once dried, kept for a considerable time, making them ideal provisions for the road. Date syrup was widely used as a sweetener; because the climate of southern Mesopotamia was not favorable for bees, the use of honey was largely restricted to the north. Vegetable oil constituted an important element of the diet, with pronounced regional differences: Whereas olive oil was common in Anatolia and along the Mediterranean coast, where the olive tree found ideal conditions, sesame oil was used in the rest of the Near East.

From the first millennium B.C.E. Babylonian texts record the movements of the stars (hence their modern designation as "astronomical dairies"), important events, and the fluctuation of prices for key products. It is a testament to the importance of barley, dates, and sesame to find these foodstuffs among them, together with two popular spices, cardamom and mustard. Many other spices were used as well, often imported from faraway countries; together with locally grown herbs, they were used to flavor food. Salt came primarily from desert salt beds and the sea, but rock salt of a much higher quality was also imported from salt mines in the area of modern-day Iran and beyond. Salt was used as a flavoring and to preserve meat. It was a far less costly alternative to refrigeration, the method used in palaces, which imported ice at great expense from the mountain regions to stock icehouses. In the early second millennium B.C.E. icehouses enabled King Zimrilim of Mari to treat his guests to refreshing fruit sorbet.

The basic diet also included various vegetables. Most important were garlic and onions, which could be stored easily, and fruit such as figs, apples, pomegranates, and peaches, which were grown in dedicated fruit groves. Vineyards were widespread in regions with enough natural rainfall, such as along the foothills of the mountain ranges surrounding Mesopotamia and in the coastal regions of the Mediterranean Sea, but they could not be established in southern Mesopotamia. Consumption of grapes and grape products such as raisins and especially wine was always the privilege of the ruling elite; because of its exclusivity, wine, in common with all luxury foodstuffs, was also an appropriate item to sacrifice to the gods. The high prestige of wine drinking was reflected in the highly elaborate vessels, often made from precious metals, used to serve it, mix it with water, pour it, and drink it. In Assyria wine was more widely available to a wider section of society: A letter from the correspondence of King Sargon II of Assyria (r. 721–705 B.C.E.) documents the

exploits of some soldiers who had enjoyed too much wine, and in the seventh century B.C.E. numerous inhabitants of the city of Assur invested in wine imports, undoubtedly destined for private consumption.

Wine was best served alongside meat, the two essential components of a festive banquet fit for kings and gods. Most common was the meat of domesticated animals. Beef, mutton, and poultry (from ducks and geese, for the chicken arrived in Mesopotamia from India only in the first millennium B.C.E.) were prepared in a variety of styles, including grilled, roasted, steamed, cooked in water, or cooked inside a pie or as part of a soup. Pork was less common, although no taboo prevented its consumption.

Recipes for various meat dishes survive in a group of texts from the city of Larsa, dating to the early second millennium B.C.E. These oldest-known recipes are extremely elaborate and give considerable insight into the haute cuisine of Babylonia, a truly international cuisine that incorporated recipes that reflected Assyrian and Elamite cooking styles. While not all ingredients, especially the many spices and herbs, can be identified with certainty, the sheer amount of effort invested in the preparation of these dishes illustrates an appreciation for rich culinary delights. As such, they counterbalance descriptions of the bland basic diet of ordinary people, who ate meat only on rare occasions, usually during festivals. Fish, however, was far more common on the menu. Fish was widely available in the rivers and, according to Greek historian Herodotus, the exclusive diet of the inhabitants of the swamps in the extreme south of Mesopotamia, who are said to have eaten cakes made from ground-up fish instead of bread.

The Near Eastern diet also included items that seem alien, such as locusts, which were either grilled on spits or ground up and processed into cakes. However, other foodstuffs that seem very ordinary were highly unusual in the ancient Near East. Eggs, for example, were almost exclusively reserved for the plates of kings and gods. When the Assyrian king Ashurnasirpal II (883–859 B.C.E.) stated in an inscription that he served, among a wealth of gastronomic highlights, 10,000 eggs at the inauguration feast of his new palace in Kalchu, many of his guests would have eaten these treats for the first time in their lives.

ASIA AND THE PACIFIC

BY CONSTANCE A. COOK

The production of food in ancient Asia and the Pacific went through the same uneven transition from hunting and gathering to farming seen in the rest of the world. Some regions were resistant to this change, while in others cultivation techniques seemed to spread rapidly. Archaeology reveals some correlation between the production and use of pottery and the rise of agricultural and sedentary communities. These communities tended also to develop ranked social patterns and reveal more material evidence for food storage and the use of food and beverages in ritual contexts.

The earliest hunter-gatherer communities occupied southern China (south of the Yangtze River) and upland Southeast Asia (modern-day Burma, Thailand, Laos, and Vietnam), possibly after having migrated from the west over one million years ago. They hunted wild pigs, deer, gaur, rhinoceros, stegodon (a type of elephant), bovids (antelope, oxen, sheep, and goats), monkeys, muntjacs (a type of deer), tapir, hyena, pandas, squirrels, rodents, bats, birds, fish, mollusks, shellfish, and other fauna. They gathered wild grains, fruits, nuts, yams, taro, legumes and other flora.

The food sources available naturally varied according to environment. Mainland Asians had access to large animals and cereals, whereas those on some of the islands of Southeast Asia and the Pacific did not. Along seacoasts and rivers, those who lived in the mangrove swamps in southern Thailand foraged for marine and river estuarine fauna. In highland areas or plains there is evidence that some early peoples began small-scale cultivation of tubers. Foraging in rainforests and forest horticulture were likely sources of food in Southeast Asia and island Southeast Asia. Wild rice was also available throughout much of south China and mainland Southeast Asia.

The transition to farming and a more sedentary lifestyle may have begun 14,000 years ago during the Paleolithic Era, although the large-scale adoption of agriculture and animal husbandry is linked to the Neolithic Revolution and occurred in different regions at different times—and some places, such as Australia, island Southeast Asia, and north and northwestern Asia not at all or not until the historical period. Because of changes in the climate, with northern areas becoming noticeably warmer, a variety of farming styles and dietary habits developed. Rice was cultivated in wetland paddies beginning in the middle Yangtze River basin possibly as early as 12,000 years ago. From there it spread southward and eventually northward.

Early peoples also cultivated yams, adzuki beans, melons, fruits, and vegetables in addition to hunting. The 8,000-year-old site of Jiahu in Henan Province in the Huai River valley shows that the people cultivated first japonica and then indica rice as well as other plants. They also had access to buffalo, alligator, fish, and other animals. In the 7,000-year-old site of Hemudu (Yuyao, Zhejiang, near the Pacific coast), where intensive rice farming occurred, archeologists have found evidence of domesticated pigs, water buffaloes, and dogs. They hunted deer, muntjac, rhinoceros, elephant, tiger, bear, and birds. As coastal dwellers, they speared fish, whales, and sharks. They also ate acorns, water chestnuts, wild jujubes (a Chinese date), water lily, gourds, and beans.

The variable climate in the north encouraged people around the Yangtze River and its tributaries to cultivate millet in dryland fields in the Yellow River basin, especially in Hebei and Henan. They cultivated foxtail and broomcorn millets and eventually soybeans, sorghum, wheat, barley, vegetables, melons, fruit, and hemp. By 6000 B.C.E. dryland farming communities were well established and extended as

far west as Gansu, as far east as Shandong, and as far north as Inner Mongolia. Hunting and gathering, particularly for meat such as deer, continued to be important, though domesticated animals, such as pigs, chickens, and dogs, were also common. Horses did not become common after the third millennium B.C.E. and, then, like buffalo, were used for transportation as well as food.

By 7000 B.C.E. the spread of sedentary living, pottery making, plant cultivation, and animal husbandry had clearly spread from the river valleys of China north to the lower and middle Amur River basin in the Russian Far East, and eventually through Korea to Japan in about 1000 B.C.E. They had also spread southward through southern China into Southeast Asia and island Southeast Asia, perhaps through Taiwan around 5000 B.C.E. and the Philippines and Indonesia by 3000 B.C.E. Eventually, these practices reached the Lapita cultures of western Polynesia (1500 B.C.E.) and Polynesia to the southeast and the Ban Kao Neolithic peoples to the southwest in Thailand. By 2000 B.C.E. they had moved westward into the Late Harappan and related Indus Valley farming cultures in south Asia. Each society had its own cultural characteristics and dietary habits. This is clearly evident not only in the localized food groups, limited by the local environment, growing conditions, and habit, but also in the pottery assemblages, which reveal diversity in food preparation and serving.

The greatest evidence for elaborate food preparation and service is found in late Neolithic tombs in China. Food was processed using mortars, pestles, and rollers and then steamed, simmered, boiled, and roasted in a variety of high-footed vessels that stood over fire pits or placed on clay stoves. Food and beverages were stored in a variety of large and small jars. They could be served with ladles or poured. The elite in some areas ate off high-stemmed platters and drank out of delicately manufactured high-stemmed cups. Less prestigious ware, such as short cups with or without handles, were also used. By 2400 B.C.E. early peoples were making alcoholic beverages of rice and fruit. By this time food preparation and service, particularly in feasting environments—probably having to do with mortuary ritual and rituals involving change in the social hierarchy—had become quiet complex, as indicated by the increasingly elaborate decorations and manufacturing methods of the pottery and the range of service vessel types. By the end of the second millennium B.C.E. elite peoples controlled the large-scale production and use of ritual implements used during banquets that increasingly used bronze and jade as well as other materials.

Outside the Indus Valley and northern China this level of civilization or social complexity is not evident in the Asia-Pacific area until much later. In northern Thailand the site of Ban Chiang (2100–900 B.C.E., contemporary with the Shang and Zhou historical periods in China) reveals a sophisticated use of technology, including the production of metal vessels. The ancient Thai ate rice, taro, yams, and mangrove embryos, along with hunted animals and fish. They sweetened their foods with bananas, palm sugars, and honey. Likewise, to the

northeast, the increasingly sophisticated Korean culture of the Mumun Period (1500–300 B.C.E.) produced cooking and service vessels for a diet consisting mostly of fish and millet or wheat (with soy and adzuki beans, beefsteak plants, and other vegetables), but it was not until around the eighth century B.C.E. that high-status remains with metal vessels are found. In Japan metal artifacts are not evident until the fourth century B.C.E., when the Yayoi rice farmers came over from the mainland and replaced the Jōmon culture. A combination of hunting and gathering and some cultivation of trees and roots continued in the islands. In Lapita cultural complexes in the Pacific islands at this time, archeologists have found cooking ovens, storage pits for foods, vegetable scrapers, and evidence for the use of domesticated pigs, dogs, and chickens.

EUROPE

BY JACQUI WOOD

Our understanding of prehistoric food and drink in Europe comes from a variety of sources. From the Stone Age (10,000 years ago) to the Bronze Age (3,500 years ago) information is found in archaeological data gleaned from pollen analysis. Such analysis relies on soil samples taken from excavated areas of an archaeological dig and studied to discover the sorts of plants that were growing in the local environment at the time of occupation of particular sites. Sometimes, too, the charred remains of ceramic pots leave more direct evidence of what people ate. Charring preserves the remains so that archaeologists can determine the ingredients of the last meal cooked in the pot.

Cooking fires in dwellings also can give us information as to specific types of cooking techniques used by the occupants, such as the remains of clay baking. Clay baking was a method employed to cook meat and fish slowly. The meat or fish was wrapped in grass and then smeared with silty river clay and placed at the edge of an open fire to gently cook in its clay casing. When the meat or fish was ready to eat, its casing would crack as the steam from the cooked food tried to escape. The discarded remains of this baking process are found at numerous prehistoric sites. At a site called Trethellan in Cornwall, England, dating to 3,500 years ago, a fire pit was full of these clay fragments. At this site bird bone impressions were found in the clay fragments, indicating the type of meat that had been cooked in it. Much earlier, approximately 10,000 years ago, the hunter-gatherer diet consisted of lots of meat and fish, supplemented by nuts and berries collected in the autumn. This diet was nutritious and quite adequate for thousands of years, because high-protein diets such as this would satisfy hunger for longer than a cereal-based or vegetable-based diet.

The seasonal aspect of food was very important too. Eggs, for instance, would have been taken from any bird and eaten only in the springtime. In the New Stone Age or Neolithic Period, 6,000 years ago, communities started to settle along the coastlines, owing to the abundance of wild food available

in that environment. Seaweeds and shellfish were collected, and it is still true today that the tastiest wild vegetables can be found only on the shorelines of northern Europe.

From this time there is also archaeological evidence from the residues in ceramics that milk products were consumed. This evidence is confirmed by the high proportion of calf bones excavated from Neolithic camps around Europe, implying both the consumption of veal and the need for a large supply of milk. Butter making would have been an important by-product of milk consumption. Surplus butter was often placed in wooden barrels and submerged into peat bogs to keep it cool until it was needed. Archaeologists have discovered large quantities of this butter, termed *bog butter*; these discoveries range from a few pounds to as much as a hundredweight of butter at one site in Ireland.

In the later Iron Age (2,800 years ago) we have the comments of various classical historians about the food of the barbarians they encountered. It has been well documented in such texts that the barbarians of Europe loved wine and beer, and this was true for the peoples who preceded them as well. The fermenting of liquids to produce alcohol was one of the

earliest culinary activities after humans started to settle in one place and grow grains. Simple beer was consumed as a regular drink, because, among its many virtues as a beverage, it contained vitamins that were often lacking in a cereal-based diet.

The discovery of malt may have been the result of storing grain in underground storage pits; the dampness at the base of the pits would have caused the remaining grain to sprout in the spring. Attempts to preserve these tasty sprouts possibly led to the creation of malt, the base ingredient of our beers today. Once dried, the grain sprouts turn into sweet-smelling malt owing to the concentration of sugars in the dried sprouted grain. Malted grain ground into flour and added to hot water makes a pleasant drink. A pot of this malt drink left near a fire for a day or two would have produced a simple beer. Archaeological evidence of such malt processing was excavated in a burned-down Iron Age house in Denmark at a settlement called Osterbolle, in Jutland. Archaeologists discovered two clay pots containing sprouted barley. One was set away from the fire, presumably to ferment, and the other was next to the fire to possibly begin the drying process.

A variety of herbal teas was also consumed, not just for medical purposes but also as a refreshing drink. Herbs and flowers were put into a ceramic pot with water, and small red-hot stones the size of hen's eggs were dropped into it. Once the water was boiling, the herbs would release their flavors. The stone was then taken out and the drink set aside to cool before consuming.

The most important type of cooking equipment from the earliest times was hot stones used to heat water. Possibly one of the first skills a prehistoric child would learn was the difference between igneous stones, formed as molten rock cools and hardens, and sedimentary stones, formed by deposits of sediment in a seabed. Having been subjected to extreme heat, igneous rock can withstand the heat of a fire. Sedimentary rock, on the other hand, absorbs liquid readily; if such stones are put into a fire to heat, the water inside can expand and cause the stone to explode, possibly injuring those around the fire. Volcanic stones, however, can be heated to red hot and dropped into water pits many times before they begin to crack and become unusable.

Huge crescent-shaped mounds of these fire-cracked stones are found around Europe. In Ireland these sites are called *Fulachta Fliadh*, meaning "cooking places" in Gaelic. In the middle of these mounds of stones is usually found a rectangular wood-lined pit dug into the water table. In *The History of Ireland* (1908) Geoffrey Keating describes the method. Early hunters would wrap meat in moorland grasses and drop it into water pits with hot stones to cook. Cooking experiments have shown that when red-hot stones are added to water, it begins to boil within minutes. Odd stones then would be added over the course of hours to keep the water simmering until the meat was cooked. The grass was wrapped around the meat to prevent ash and grit from the stones from getting into the cooking meat.

"Empress" pepper pot, from the Hoxne hoard in Suffolk, Roman Britain; it was buried in the fifth century C.E., when Britain was passing out of the control of Rome. (© The Trustees of the British Museum)

Meat was also cooked in an earth oven. A pit was dug and lined with stone, and a fire was then lit in the pit; at the same time, another fire was started next to it to heat more stones. When the pit stones were red hot, the embers were removed, and a large piece of meat would be put directly on top of the stones; then the stones from the second fire were placed on top. This earth oven could be left for the rest of the day to slowly cook the meat for the evening meal.

The spread of the Roman Empire by 133 B.C.E. brought with it a wondrous array of exotic foods and spices to the peoples of northern Europe. Root crops began to be cultivated; in earlier days most wild root vegetables were very small and bitter to the taste. New fruits and nuts, such as figs, dates, apricots, almonds, and walnuts, were introduced, and large, sweet apples and pears began to be grown in the Roman colonies. The most prized new spice was black pepper (*Piper nigrum*), which enhanced the flavor of any foods. The introduction of these delicacies and Roman wine could have been a deciding factor in the Romanization of the peoples of Europe.

GREECE

BY CHRISTOPHER BLACKWELL

The diet of the ancient Greeks was in most ways similar to that of Mediterranean peoples today, nutritious and healthy but relatively limited in its staple components. The main source of calories was bread or porridge made from grains. Einkorn (*triticum monococcum*), emmer wheat (*triticum dicoccum*), durum wheat (*triticum durum*), bread wheat (*triticum aestivum*), and spelt (*triticum spelta*) were the most common varieties. The advantage of bread wheat and emmer wheat was that the husks of the grain could be removed by threshing (striking and tossing the wheat over a hard floor), while the other varieties required more difficult processes of toasting and grinding to extract the edible grain. The other varieties, on the other hand, were the grain of choice in many communities because they tended to produce more abundant crops.

In the earliest times grain was ground into flour using simple stone grinders, or querns, but by historical time more sophisticated and productive rotary grinders, sometimes driven by oxen or donkeys, ground wheat more efficiently. Bread was leavened with yeast and could be coarse or fine, with the finer “white” bread being a luxury only the wealthy could afford. Bread was such a central part of the diet that the same Greek word *sitos* means “grain,” “bread,” or “food” almost interchangeably. The Greek writer Athenaeus, whose quirky book *Deipnosophistae* (Learned Men at a Dinner Party) contains much evidence for ancient Greek cookery, describes a great variety of breads and cakes, some leavened and some flat, flavored with various herbs or sweetened with honey.

The main source of fat, and an additional valuable source of calories, was oil, mainly the oil of the domesticated olive. Ripe olives were shaken from trees onto nets, collected, and

pressed in mills to extract the oil. Olives were only rarely eaten. Olive oil made the bread-based diet more palatable, was easily stored and transported, and had a great number of other uses—as soap, as a lubricant for machinery, as a fuel for lamps, and as a medicinal salve. Cultivation of olive trees for oil increased steadily throughout antiquity, reaching a peak in the middle of the first millennium of the Common Era, with a devastating effect on the environment because olive trees do little to prevent topsoil erosion.

The main source of protein in the ancient Greek diet was the legume, particularly lentils, chickpeas, and field peas. These were sometimes ground into flour and incorporated into bread or boiled into soup seasoned with onions, garlic, or vinegar. For protein the ancient Greeks did eat meat and fish, but relatively rarely. The Mediterranean is too salty and too clear to support the variety of fish found in the Atlantic, and fishing was a dangerous activity yielding unpredictable results.

But the ancient Greeks liked fish, and fish provided a welcome change of taste from the regular diet of bread, olive oil, and beans. Because of its relative scarcity and the difficulties of transporting it fresh, fish was most often pickled and used as a relish to enhance the taste of bread. The ancient Greek word for “relish” is *opson* or *opsarion*, and the modern Greek word for “fish,” *psari*, is derived from this word. Salted fish was popular, too, because it was easy to transport and store. It is likely that the salts and trace minerals in salted fish were as important nutritionally as the protein in the fish.

Meat was rare and expensive, and the fact that the heroes in the Homeric epics seem to eat little else suggests that a meat-rich diet was the stuff of fantasy and that meat was a food fit for the children of gods. Greeks raised pigs, sheep, goats, and a few cows, but the rocky terrain did not lend itself to animal husbandry on a large scale. Hunting also provided meat from birds, hares, or deer, but only in small amounts. For many ancient Greeks in cities, meat appeared in their diet only during public festivals, when animals killed as sacrifices to the gods were barbecued and served as a part of a public feast.

While goats and sheep provided milk, milk was used mainly for making cheeses, either salty cheeses like modern feta or sweeter ones like modern ricotta. Ancient Greeks did not drink much milk and did not use butter. In Homer’s *Odyssey*, the “lawless, outrageous” Cyclops enjoys a diet that consists mostly of milk, when he is not eating human beings, which may indicate a common view that milk was barbaric.

Onions, garlic, radishes, and cabbages were the main vegetables, along with leeks, cucumbers, artichokes, and celery. The tomato was unknown before the discovery of the Americas, as was the potato. Wild herbs such as asafetida, basil, and mint served as seasonings.

Rainwater was plentiful during the winter and could be collected in barrels, pots, or underground cisterns, but wells and natural springs were more reliable during the dry summer months. Because of uncertain water supplies and their

Terra-cotta utensil with six receptacles, thought to be an egg dish or cup holder. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

potential health hazards, the most common drink was wine, generally diluted and drunk at every meal, from morning to night, even by children. While beer was known to the Greeks because it was a common drink among their neighbors in Europe to the north and in Egypt to the south, it was considered an uncouth drink.

The science of making wine, oenology, and the science of growing grapes for wine, viticulture, were highly developed among the Greeks, who understood the complex relationship between variety of grape, climate, and condition of soil in determining the quality of a wine. Certain areas were noted for their wines. Chios, with its Chian wine, was probably the most famous, but the islands of Cos, Thasos, and Lesbos were also well known for their vintages. Coan wine, from Cos, was made by incorporating seawater into the fermenting grapes early in production, which was said to make an especially smooth drink.

Drinking undiluted wine was rare, the mark of a barbarian. The Spartan king Cleomenes was said to have learned from the Persians to drink wine “straight,” and consequently he went mad. Nevertheless, at symposia, the drinking-and-discussion parties popular among aristocrats, huge amounts of wine could be consumed, resulting in drunkenness, the effects of which are often comically depicted on painted vases, particularly vases intended for use at a symposium.

ROME

BY AMY HACKNEY BLACKWELL

The ancient Roman diet was simple at its core but could rise to great heights of invention and extravagance. The staple ingredients of Roman cooking were olive oil, wine, and wheat. In many cases these components formed the entire meal, perhaps with the addition of a few fresh vegetables. Wealthy Ro-

mans, however, enjoyed dining in company and encouraged the creation of expensive and original dishes.

Numerous works by Romans on food and drink survive today. Cato the Censor (234–149 B.C.E.) wrote a great deal about food in his treatise on farm management, *De agri cultura*. He describes the best way to produce and sell oil, wine, grain, and livestock and records many recipes for preserving food made on the farm. The most elaborate source on the subject of Roman cuisine is *Apicius on Cookery*, a compilation of recipes said to have been written by the gourmet Caelius Apicius and probably completed around the fourth century C.E.

Wheat formed the foundation of most meals. In the earliest days of Rome wheat was most commonly cooked into porridge, but by the time of the Roman Republic (509–27 B.C.E.) baked bread was more common. Getting this bread to Roman tables was no small feat. During the republic most of Rome’s wheat was grown in Sicily and Sardinia. To prevent famines and the peasant revolts that could accompany them, the Roman government created a system to provide wheat to all citizens. This system began under Gaius Gracchus, who in 123 B.C.E. passed a *lex frumentaria*, or grain law, that provided grain to each citizen at a subsidized price. Clodius Pulcher made grain free to all citizens in 58 B.C.E. By the time of the emperor Trajan (r. 98–117 C.E.), Rome was importing much of its wheat from Egypt and Africa and still distributing it free to citizens. Administering this enterprise required a large bureaucracy of officials to keep track of distributions.

Romans supplemented their bread with olive oil and wine. The olive grew readily in Italy and the Mediterranean, and olive oil was ubiquitous. Olive oil is packed with calories and nutrients and was the main source of fat in the ancient Roman diet. Romans also ate cured olives. Wine and water were the main Roman beverages. People typically mixed their wine with water. Women were not supposed to drink wine; one of Rome’s most ancient laws made it illegal for women to drink wine, and although the law was not enforced, it was still considered improper for women to drink too much. Greek wine was popular, but Italy produced its fair share of vintages as well. Romans sometimes mixed honey and spices into wine. They did not drink beer, mead, or milk because they considered these the drinks of barbarians such as Germans. They likewise did not make distilled drinks.

Vegetables and fruits filled out most meals. The most common vegetables included onions, garlic, radishes, celery, asparagus, carrots, beets, and zucchini. Poor people gathered wild greens and boiled them. Typical fruits included figs, grapes, dates, apples, pears, mulberries, peaches, apricots, and cherries. Walnuts and almonds were popular nuts. Tomatoes and potatoes did not grow in Europe at that time; the traditional Italian tomato sauce did not arise until after the discovery of the Americas.

Many Romans were completely vegetarian, both from necessity and from inclination. Most Romans got their pro-

tein from beans and lentils eaten with bread. Fish from the Mediterranean was commonly eaten, but meat was not popular. Italy's terrain was not good for growing large livestock such as cattle, and beef was another item considered more appropriate for barbarians. People did eat chickens and their eggs, and they ate some pork and veal, but these foods were not a substantial part of the average diet. Cheese made from goat's or sheep's milk was common; some cooks mixed it with garlic.

Roman cooks loved to add sauces to food and sometimes added 10 or more spices and flavorings to a dish. The most common seasoning was *garum*, a sauce made by covering fish with salt and leaving it to ferment for several months. Other flavorings included honey, vinegar, dry or sweet wine, oregano, cumin, coriander, fennel, lovage, rue, and silphium or asafetida, the resin of a plant related to fennel. A dish of peas could be topped with a sauce of honey, vinegar, olive oil, white wine, *garum*, lovage, ginger, pepper, and egg yolk blended together.

Although the typical meal was simple, a Roman feast was not. Many Romans subscribed to the teaching of the Greek philosopher Epicurus (341–270 B.C.E.), who maintained that pleasure of the body achieved by satisfying physical desires was the best way to achieve a happy life. These people called themselves epicures and preferred to consume the finest of foods and wines. Epicures and other wealthy nobles seeking to impress their guests sought out the most exotic foods. Caelius Apicius describes delicacies such as flamingoes, peacocks, sea urchins, sows' wombs, camels' hoofs, and dormice. He provides a recipe for a chicken salad that involved layering pieces of bread, chicken, sweetbreads, cheese, pine nuts, cucumbers, and onions, dressed with a sauce made of celery seed, pennyroyal, mint, ginger, cilantro, raisins, honey, vinegar, oil, and wine. Gourmets in Rome itself raved about licker fish, a freshwater bass that lived in the Tiber River and fed on the outflow from the city's sewer pipes.

Breakfast was very simple and could consist merely of bread and salt. The midday meal, *prandium*, was more complicated and could include meat or eggs. The main meal of the day was *cena*, eaten in the late afternoon. Among the wealthy the *cena* could include several courses, beginning with an appetizer and honeyed wine, followed by several main dishes, and concluded with sweets and fruit. This meal was eaten in the dining room, or *triclinium*, so called because it contained three couches on which men reclined to dine. During the republic women generally sat in chairs, but it became more common for them to recline as time went on.

Roman kitchens were equipped with brick hearths that included grills and ovens. Cooks used pots and pans made of clay or metal. A pestle and mortar were essential for pureeing foods. Not all households did their own cooking. In the countryside wives did much of the cooking for their families, but wealthy families maintained elaborate kitchens and expensive slaves who did the cooking. Within Rome many poor

people lived in tenement buildings and did little or no cooking because of limited facilities and the risk of fire. They purchased most of their food from the numerous street vendors who sold bread, wine, cakes, kebabs, and other snacks.

THE AMERICAS

BY MICHAEL J. O'NEAL

Archaeologists can often determine what ancient peoples ate by examining their skeletal remains, which provide clues about nutrients that were present—or absent—in their diets. They also find clues in tombs, where containers with food items were placed, as well as from traces of foods found in pots and other containers.

Like ancient peoples throughout the world, prehistoric Americans subsisted on a diet that nature provided for them until they learned to cultivate some or most of their own food. Prehistoric hunter-gatherers, depending on what was available in their area, ate wild game, fish, nuts, root vegetables, wild fruits, berries, and even insects, along with such foodstuffs as honey and occasionally eggs. Interestingly, in modern life many doctors and nutritionists recommend what is sometimes called the “Paleolithic diet,” arguing that in many respects it was superior to the diets of modern people because it was low in fat and starches and high in vitamins and minerals.

Local sources of nutrition varied greatly from place to place. People who lived along the seacoasts relied on fish and seafood, and in the northernmost regions of North America, the Inuit people consumed the meat of animals such as seals and whales, along with fish. Woodlands tribes in the eastern half of the modern-day United States found in the forests they inhabited an abundance of deer and smaller game animals, game birds, and waterfowl and fish in rivers and lakes, supplemented with seasonal fruits, vegetables, and nuts. In contrast, those who lived in desert regions such as portions of Central America and the southwestern United States relied more on small game animals and such vegetable foods as the nopal cactus, which can be eaten cooked or raw (and which modern science has shown reduces cholesterol levels). They also consumed other types of cactus, as well as plants known as agaves, such as the maguey. This variety was the source of pulque, an alcoholic beverage made from the plant's fermented juices and drunk primarily on ceremonial religious occasions; pulque is still made and consumed in many rural areas of central Mexico.

With the emergence of agriculture Native American peoples found that they were able to increase dramatically the amount of food available to them. North Americans, for example, grew various types of beans, which they combined with dog meat, corn, and bear fat to make succotash. They also ate tubers, or root vegetables, which they cooked until they were the consistency of a thick soup. In the moister temperate regions of North America rice became an important staple crop. Also valued as food were organ meats, buffalo

tongue, blood soup (made by mixing corn flour with animal blood), and bear meat; these items were often consumed as part of religious ceremonies. Another important food item among North American Indians was pemmican, made with preserved meat and berries. The meat came from deer, elk, rabbits, and, especially among the Plains Indians, buffalo. For beverages, maple sugar-sweetened teas that might be made from various savory twigs, roots, or leaves, such as the roots of the sassafras tree, a member of the laurel family. California Indians produced an early form of lemonade by adding citrus berries to water.

Mesoamerican Indians developed a greater variety of cultivated foodstuffs, in large part because the sparse deserts of parts of the region did not support as much wild game or as many naturally occurring plant foods, at least in the abundance needed for populations to grow. One of the most significant developments in Mesoamerican history was the cultivation of maize, or corn, a crop that was domesticated from a native plant. By about 1400 B.C.E. maize had become the most important staple food crop in Mesoamerica, used to make bread dough and porridges. Corn was especially valuable because, once dried, it can be stored indefinitely without spoiling. In addition to maize the Mesoamericans cultivated and consumed numerous grains, including millet, and beans. Uncooked beans contain natural toxins that make them resistant to pests and microorganisms and have enzyme blockers that prevent them from sprouting when dry. Thus beans, like corn, can be stored for very long periods.

Other important food crops in ancient Mesoamerica included amaranth, a coarse herb rich in proteins, amino acids, and various vitamins and minerals and still a popular food in modern Mexico. Vanilla was cultivated and widely used as a flavoring. So, too, were chili peppers, members of the nightshade family of plants that also includes potatoes, eggplant, and tomatoes. Historians believe that avocados were grown and eaten in Mesoamerica as far back as 10,000 years ago.

The ancient Mesoamericans left another food legacy for which many modern people remain grateful: chocolate. The chocolate came from seeds contained in the fruit of the cacao tree, which grew extensively in the more tropical regions of Central America and Mexico. Historians believe that cacao was first cultivated and used by the Olmec in about 1000 B.C.E. The fruit's seeds were extracted, dried, and roasted and then ground on a flat stone. The resulting powder was then usually mixed with water to make a cocoalike beverage. Because the concoction was bitter, it was commonly flavored with herbs, nuts, seeds, vanilla, honey, and even chili peppers. It was drunk primarily by the upper classes. More widely consumed was *cacao chicha*, a fermented beverage somewhat similar to beer and including the pulp that surrounds the seeds. Cacao beans (as the fruits are often called) were so highly regarded that they were sometimes used as a form of money.

It is believed that the South Americans were the first to develop squash, prized as much for its edible seeds as for its flesh. Another important food item was the potato, first cultivated in the Andes Mountains some seven thousand years ago, when people discovered that it was a highly durable crop that could grow at high elevations and in poor soil. While potatoes are eaten throughout most of the modern world, they were exclusively a South American crop until the 16th century. Yet another important food was the peanut, which is actually not a nut but a member of the bean family. Archaeologists have discovered pots in the shape of peanuts and decorated with pictures of peanuts in South America dating to roughly 1500 B.C.E. Finally, an important food crop in ancient South America was quinoa, often described as a pseudograin, for while it was handled and used like a grain, it actually consists of the seeds of a plant from the goosefoot family. This was another food plant that Andes farmers discovered to be hardy at high elevations. Quinoa is high in fiber and various nutrients, and because it is gluten free, it is easy to digest. Further, in its uncooked state, it is extremely bitter, helping offer protection from birds and other animals.

► foreigners and barbarians

INTRODUCTION

In the ancient world travel for most people was difficult. In early hunter-gatherer societies people moved about in search of food supplies, and the world's relatively tiny population spread out over millennia, generally avoiding contact with one another. But as early societies turned to agriculture for their food, they lived in settled communities, and it is likely that the average person never traveled more than a day or two's distance from his or her place of birth. People tended to live in societies that were organized by family, clan, and tribal relationships, so they had little contact with people from outside their communities.

Accordingly, early peoples tended to regard "others" with suspicion. People from other communities were potential enemies, bent on conquest or thievery. Furthermore, people from other cultures were likely to have strange customs, habits, languages, modes of dress, and gods. Their very strangeness made them objects of suspicion and hostility. Almost always, they were "barbarians." Among Native Americans in North America, for example, legends and myths record contact with magical strangers who were held in fear. These myths probably originated in brief contact with other tribes.

This suspicion and hostility were not universal, however. In ancient Rome, for example, people from the outside were more or less welcome when Rome was just a small city, not an empire. The ancient Egyptians, too, absorbed foreigners who were willing to adopt Egyptian ways. In the ancient Near East people became accustomed to foreigners because this part of the world was a kind of crossroads, where people from different nations and with different religious beliefs had routine contact with one another. As time went on and nations such as these gained power and empire, they came to view foreigners with suspicion. Meanwhile, countries such as China remained closed to outsiders, who were seen as crude and barbaric. One major form of cultural contact was warfare, but during war people from other cultures were seen as potential slaves. Similarly, the development of empires, such as the Roman Empire, brought cultures into contact, but the nature of the contact was that of master and subject.

The development of trade relationships to some degree broke down these barriers between people. Ancient China, for example, developed trade relationships with people living to the west, and archaeological evidence shows that the ancient Europeans had trade contacts with one another. In Africa some similarities in the continent's many languages, primarily in the form of loan words, suggest that African tribes had trade contact with one another. And, of course, the ancient Romans maintained trade relationships throughout the Mediterranean region. The presence of traders and merchants helped introduce one culture to the customs and manners of another culture, though relationships in general continued to be conducted at arm's length, with little contact

between the merchants and ordinary citizens. Religion, too, was a factor in cultural contact. In such nations as India the devoutly religious were eager to spread their beliefs, leading to contact with foreigners.

AFRICA

BY JUSTIN CORFIELD

Traders and merchants traveled throughout Africa in ancient times. Little evidence suggests that they faced any real opposition except during wars, though they were always at risk of being attacked by bandits, pirates, or brigands. It might be thought that language differences were a major obstacle, but this does not seem to have been as much of a problem as it might have been. According to the Greek historian Herodotus, some Carthaginian traders devised a system of bartering by which they would arrive at a place, spread their merchandise on the shore, and then retire to their ships, where they used smoke signals to attract attention. The locals then examined the goods and left gold. If the Carthaginians thought it was enough, they left; if not, they waited until enough was offered. As a point of honor, the locals did not take the goods nor did the Carthaginians take the gold until both sides were satisfied.

Initial contact with foreigners from outside Africa was by boat. Indeed, the Carthaginians themselves were descended from Phoenician sea traders. When she arrived on the coast of modern-day Tunisia, Queen Dido, the legendary founder of Carthage, managed to purchase land from the local ruler, Iargas. According to legend, he told Dido that she could have as much land as she could contain within a piece of leather. She then cut leather into strips and with it marked out a promontory. The city of Carthage later emerged near the site. Additionally, a large number of other cosmopolitan ports developed along the north coast of Africa. Differences in fashion seem to have been more remarkable than race in these centers. Wealth was displayed in jewelry and dress, and the Carthaginians rarely wore belts, making Roman and Greek traders all the more noticeable in the city of Carthage and other parts of Africa they controlled.

The attitude toward the Romans in North Africa changed considerably after the Punic Wars. They had been seen as enemies and invaders, but after the destruction of Carthage in 146 B.C.E. they became colonial masters. Gradually they came to be accepted throughout the ports of North Africa. Septimus Severus, born in Lepcis Magna, was emperor from 193 to 211 C.E., the only African-born emperor to rule the Roman Empire. In 212 C.E. the Edict of Caracalla, known as the *Constitutio Antoniniana*, or the Edict of Antoninus, was issued by the Roman emperor Caracalla (Marcus Aurelius Antoninus, r. 211–217 C.E.). According to this edict, all freeborn men in the Roman Empire became Roman citizens, thus creating a degree of equality throughout Roman North Africa.

Herodotus wrote extensive descriptions of many of the peoples of northern Africa and parts of modern-day Sudan

and Ethiopia, and in these descriptions he clearly shows that travelers were able to visit these areas with few problems. Indeed, some of his descriptions are similar to those of 19th-century European anthropologists, who similarly traveled in these regions with freedom.

The trade routes from North Africa that cut through the Sahara had been traveled by merchants throughout ancient times. A number of these routes connected modern-day Morocco with the source of the Niger River, and others connected the port cities of modern-day Algeria, Tunisia, and Libya with sub-Saharan Africa. Much of this can be seen in ancient drawings of chariots, which may have been used for trade or perhaps for sport or even war. Although there are no records of hostility or friendship between the people of the Sahara and foreigners, the fact that merchants continued to venture across the desert indicates a certain mutual interest in trade.

Maritime expeditions were organized both through the Straits of Gibraltar around the west coast of Africa and from the Red Sea down the east coast to Zanzibar. Certainly the Carthaginians ventured to West Africa. Some accounts of travelers survive, usually secondhand. Some goods from the west coast of Africa did make their way into the Mediterranean and vice versa, and it seems likely that many merchants would have attempted to make contact with the source of the items wanted, mainly gold and ivory.

Pursuing this and other theories, in 1969–1970 Thor Heyerdahl, in his two *Ra* expeditions, was able to fit out a boat similar to those used by the Egyptians, made by boat builders from modern-day Chad, and sail across the Atlantic Ocean on his second attempt. With a similarly constructed boat, *Tigris*, Heyerdahl showed in 1979 it was possible for Sumerians to have sailed to Africa. Arabs certainly traded with East Africa, and the Alexandrian Greek handbook *The Periplus of the Erythraean Sea* describes people living along the Somali coast and Juba as being “men of the tallest stature.” Some historians see this portrayal as suggesting that, in the absence of any description of them as blacks, they were not. That such voyages could have taken place on an ongoing basis, and possibly did, does not indicate the reactions of Africans to the arrival of foreigners. However, the existence of maritime trade routes suggests that there was extensive harmonious contact. The presence of early silk in the northeast corner of Madagascar shows that there was trade with Southeast Asia.

Archaeological work in central and southern Africa has not shown much contact throughout the African continent in ancient times, though it would seem likely that it did exist. With no written records, attitudes to foreigners are hard to extrapolate. Archaeologists have drawn conflicting conclusions about the nature of central and southern African civilizations based on pottery fragments, but linguistic analysis provides evidence of a level of contact, interaction, and use of loan words between different groups of people. For example, many words are common to 300 Bantu languages spoken from Duala in modern-day Cameroon to the East African

coast and as far south as the Xhosa in modern-day South Africa. These language similarities indicate that different groups interacted; the words for “palm tree” and “fig tree,” for example, are the same even in areas where these trees are not found. When combined with analysis of iron tools and some pottery designs, it is easy to see that contact over wide areas took place.

EGYPT

BY MARIE PASSANANTE

The Greek historian Herodotus, who visited Egypt in the fifth century B.C.E., was able to observe Egyptian attitudes toward foreigners at a time when the population of foreigners in Egypt was at its peak. According to Herodotus, Egyptians considered anyone who could not speak the Egyptian language a barbarian. The Egyptians defined themselves by their land and culture, not by physical characteristics. In effect, a foreigner could become Egyptian by adapting Egyptian customs, a process that was not discouraged. However, the Egyptians also viewed their neighbors in a more practical light; foreigners could be enemies. Egyptian kings affirmed their right to rule by their victories over their enemies and described themselves in the language of conquerors. For instance, the king was the one “who repels the Nine Bows” or “who protects Egypt and who curbs the foreign lands.”

The Nine Bows represented the peoples conquered by Egypt, either through submission or defeat in war. These peoples were represented by bows alone or as individual prisoners labeled with their nationalities. The bow itself was a generic symbol representing the men of a tribe. As the geography of the ancient world changed, so did the names on the list; however, the number of peoples remained nine. The nations named included Nubians, Libyans, and Asiatics. Because these nations typically were named as enemies of Egypt, it is easy to believe that the Nine Bows represented the enemies of Egypt. However, Upper Egypt and Lower Egypt were also listed among the Nine Bows. In addition, the Nine Bows often were depicted alongside the *rekhyt* bird, which represents the Egyptian people. The Nine Bows defined all the peoples of the ancient world—Egyptian and non-Egyptian alike—as being equally subject to Egypt. The earliest depiction of the Nine Bows is on the ceremonial mace head of King Scorpion (Early Dynastic Period, ca. 2920–2575 B.C.E.) found at Hierakonpolis in Upper Egypt. A statue of King Djoser (r. 2630–2611 B.C.E.) portrays the bows underneath the feet of the king; the trampling of the Nine Bows by the king was a vivid representation of the king's power over the peoples of the world and was used throughout Egyptian history.

Similar to the Nine Bows are the lists recorded in the execration texts. Execration texts were written on pottery or statuettes of prisoners and list foreign kings and peoples, including the countries of Nubia—Irtjet, Wawat, Yam, Medja, and Satju—and cities throughout Palestine. The peoples listed may or may not have been current enemies; for exam-

ple, the texts include both Nubia, where Egyptian military forces were constantly on alert, and Byblos, with which Egypt maintained a mainly peaceful trading relationship. Unlike the Nine Bows, the execration texts list only non-Egyptian peoples. The implication in the texts is that any non-Egyptian—any foreigner—was a potential enemy of Egypt.

Although foreigners typically were viewed as potential enemies of the Egyptian state, warriors from Nubia and Libya were recruited as mercenaries for the Egyptian army. When the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) official Weni led the Egyptian army against Asiatics in the north and the nomadic tribes in the east, he commanded an army made up of Egyptians and Nubians from Wawat, Irtjet, Kaau, Yam, and Medja from the eastern desert. Recruits from Nubia and Medja also joined the armies of the Herakleopolitan and Theban dynasties in the First Intermediate Period (2134–2040 B.C.E.). These Nubian mercenaries fought for the Egyptians against Asiatics, but they also fought in battles meant to secure the southern border against their fellow Nubians. Middle Kingdom Egypt (2040–1640 B.C.E.) saw mercenaries recruited from the oases in the western desert. In the 19th and 20th Dynasties (1307–1070 B.C.E.) major wars with the Libyans resulted in large numbers of Libyan prisoners, who were relocated to settlements in the eastern delta. These Libyans, former enemies of Egypt, consequently were relied upon to protect Egypt's eastern border. In the Late Period the kings of the Saite Dynasty (664–525 B.C.E.) were said to have relied heavily on Greek and Carian mercenaries. The nature of foreign mercenaries and the fact that they often fought against their own people show an ambiguity on the part of the Egyptians; both the enemy of Egypt and the army protecting Egypt were of the same people.

The attitude of the Egyptians toward the Nubians in the south was increasingly one of domination and fear. In the Old Kingdom, King Merenre (2255–2246 B.C.E.) visited the southern frontier and met with the chiefs of Wawat, Irtjet, and the Medja. The Egyptian texts interpreted this as an act of homage on the part of the Nubians, but it was probably a mission geared toward promoting goodwill along the southern border. This goodwill policy was far from the normal course of action. There are records of military campaigns against Nubia from the Early Dynastic Period on. In the Middle Kingdom, Egyptian kings built two series of large fortresses along the Nile in Nubia. The largest fort had a garrison of approximately 300 soldiers and their families. In all, several thousand soldiers and supporting staff were stationed in the 13 forts. This is an immense force, given that the indigenous population of Lower Nubia has been estimated at only 10,000. The pharaohs of the New Kingdom (1550–1070 B.C.E.) built even more forts and established a branch of the Egyptian government to rule in Nubia. To assimilate the Nubians into Egyptian society, the children of the Kushite chiefs were sent to the Egyptian court to learn the language, customs, religion, and so forth of the Egyptian people. The indigenous population was subject to the viceroy of Kush, who acted on the king's behalf.

The Egyptians took less drastic measures when dealing with the lands of Palestine during the period of Egyptian domination in the New Kingdom. While warfare in this area was not unknown, the nations of Palestine were less likely to be a major threat; the Egyptians, while still cautious, did not fear them as they did Nubia. Fortified Egyptian settlements in Palestine were rare. Indigenous populations became vassal states, but in some cases were able to rule themselves as opposed to being ruled by Egyptian governors.

THE MIDDLE EAST

BY JUSTIN CORFIELD

Many of the large empires that covered the ancient Near East were multiethnic, consisting of large numbers of different and often linguistically diverse peoples. The Assyrian, Babylonian, and Persian Empires embraced much wider areas than those of the city-states of Sumer and often subjugated alien peoples through force. The Assyrians, in particular, gained a reputation for the persecution of their enemies. Their great king Ashurbanipal (r. 668–627 B.C.E.) sacked Tyre, and his subsequent suppression of the people of Elam resulted in the deportation of many leading Elamites to Samaria in Palestine. The holding of the Hebrews in exile in Babylonia from 587 to 538 B.C.E. is another well-known case, documented in the Bible.

Achaemenid Persia was a massive, multilingual empire extending over the entire Near East. The Persians used Aramaic as the written language of administration and communication between the capital and outlying areas, Elamite as the principal language of administration at the capital Persepolis, and Old Persian when erecting public monuments with royal inscriptions (which, however, were usually written in Babylonian and Elamite as well). The Persians freed the Hebrews from their Babylonian exile and began to reverse some of the deportations perpetrated by the Assyrians. As the Persian Empire grew in importance, it attracted many Greek merchants and soldiers. By the time of the invasion of Alexander the Great, large Greek communities existed throughout much of the Persian Empire, and substantial units of Greek soldiers fought in the Persian army. At Gaugamela in 331 B.C.E. these soldiers were placed around the Immortals who guarded Darius III (r. 336–330 B.C.E.), showing his trust for them on the battlefield. These Greeks were to be heavily persecuted when Alexander the Great and his successors came to power.

Alexander the Great and the "Successor States" that emerged from the Diadochi Wars after his death were also multiethnic. Although there was always a Greek-Macedonian governing class, most of the administrators were locally born. For many of the farmers in small villages and settlements throughout the Near East, the change in rule from the Persians to the Seleucids probably had little real impact. Many of the cities in the Near East most likely became increasingly multiethnic and multilingual. Although occasional racial scapegoating must have occurred, and stereotyping abounds

Detail of an Ethiopian tribute bearer, from a relief in stairway of the palace at Persepolis, Persia (modern-day Iran). (Courtesy of the Oriental Institute of the University of Chicago)

in many surviving images, ethnicity does not seem to have been a major cause for trouble except when an uprising took place. This was certainly the case in the First Jewish Revolt (66–70 C.E.), after which the Romans persecuted the Jews. This theme appeared again in the revolt led by the Jewish leader Bar Kokhba (d. 135 C.E.), after which Jews were forbidden to enter Jerusalem.

Before these two revolts the attitudes to foreigners in the Holy Land were mixed. During the period of the Old Testament the fierce battles between tribes were commonplace and ferocious, but by the time of the Roman occupation of Palestine the situation had relaxed considerably. Trade had ameliorated the previously hostile tribes in the Holy Land and presumably elsewhere in the Near East as well. Many foreigners were no doubt accepted by locals. Others were viewed with suspicion.

The proximity of areas inhabited by Jews and non-Jews meant that there were large numbers of *telones* (customs officials or, more commonly, tax collectors) around the river Galilee. There were certainly Gentiles in Tiberias, an overwhelmingly Jewish city, and Jews lived in largely Gentile

cities, such as Scythopolis. Although the Jews did exclude Gentiles from their temples and had several other restrictions, relations were generally fairly harmonious. Herod the Great (r. 37–4 B.C.E.), king of Judea, helped by administering the Gentile areas in more of a Greco-Roman manner than he did the Jewish parts of his lands. The Romans respected the Jewish observance of the Sabbath and exempted Jews from conscription in Roman armies. However, there were occasional tensions, as when Pontius Pilate hung images of the Roman emperor in Jerusalem and minted coins that were seen by the Jews as bearing pagan images.

Evidence from the letters of Saint Paul clearly shows a far more harmonious Near East, whereby travelers from some parts of the region, or from outside it, were made welcome in many towns and cities. In Ephesians (2:19), Paul states, “Now therefore ye are no more strangers and foreigners.” This is also borne out by the ease of travel by Romans, who were able to journey throughout the Roman Empire without any problems. In addition, a number of them established trading operations outside the empire. The emperor Valens (r. 364–378 C.E.) managed to forge a peace treaty with the Goths, allowing Roman traders to have access to parts of modern-day Romania controlled by the Goths.

ASIA AND THE PACIFIC

BY DAVID KELLY

Historically, records have not been kept of the attitudes held by individuals who were not of social prominence, as history has been written about the wealthy and powerful and not about average citizens. Still, there are some characteristics that can be noted with respect to the ways in which the ancient societies of Asia and the Pacific region viewed outsiders.

The largest and most stable culture in the region, China, has traditionally been a closed society, living in willing isolation from the rest of the world, a tradition that is only beginning to come apart in the 21st century. By far the most common connection that ancient Chinese and others in the region had with strangers from foreign lands came through trade. From the second millennium B.C.E. China was connected by trade with the Near East kingdom of Mesopotamia, centered in what is now Iran. By the first century C.E. there developed an overland trade route from the Roman Empire to China, dubbed the “Silk Road” because silk was China’s most coveted export; the secret of its production was carefully hidden from foreigners until five centuries later. Although this path ran through many important cities as it wound from Damascus in the west to China’s far eastern shore for nearly a thousand years, most Chinese citizens still kept their distance from the traders who traveled from Europe. Evidence suggests that westerners trading in China dealt with a limited number of merchants, while most ordinary citizens had no interaction with them. This narrow engagement of the East with foreigners was true of other countries in the area, such as Vietnam and Cambodia, which

did their trading almost exclusively with China and not with foreigners.

When trade routes by sea were established between India and Asia in the second century B.C.E., there was possibly even less interaction with foreigners. For example, there was the trading polity of Funan, a kingdom at the tip of the Mekong Delta around the third century C.E. that reached as far as Malaysia and Burma. Artifacts from China, India, and Rome have been found in the remains of the Funan Empire, but foreigners were geographically limited by mountains close to the shore that inhibited travel. Unlike lands that were openly available to traders, the lands of Asia and the Pacific were not physically open to exploration. Although traders did not travel freely from India, Indian culture did have strong influences on Funan that spread across Asia. By 400 C.E. Indian writing systems, Sanskrit vocabulary, and Hindu beliefs had been adapted across China.

One social aspect that did promote positive interaction with foreigners was the spread of religion. Religious conversion generally followed routes of trade. Java and Sumatra show signs of the presence of Hinduism as early as the second century B.C.E., and from there its influence grew throughout Asia and the Pacific. Followers of Mahayana Buddhism, which also had its roots in India, made a concerted effort around 100 C.E. to spread its teachings eastward and quickly overtook the Asian continent, moving in a relatively short time through Southeast Asia to Korea, China, and Japan.

There has been speculation that the spread of Hinduism and Buddhism from India into Southeast Asia might have been related in part at least to the fact that native rulers might have welcomed missionaries from India, making them participants in their courts in order to strengthen their hold. The Hindu concept of kingship is captured in the word *devaraja*, which comes from Sanskrit and translates as “god who is a king.” Rulers who welcomed the arrival of Hinduism to their lands were inviting their subjects to see them as incarnations of the Hindu gods.

In general, the countries that had means of self-sufficiency, including China, Thailand, Cambodia, Vietnam, and Korea, were naturally more insular and less open to interaction with people from other countries, while island nations, of which there are dozens scattered throughout the South Pacific, tended to be more familiar with the idea of trading with outsiders over the course of hundreds of years and were therefore more comfortable with the idea of associating with westerners when they began arriving.

Although they were more open to trading with foreigners, many cultures of the Pacific Islands retained a spiritual distance from outsiders, including those who lived in villages that were in close geographical proximity to their own. Headhunting was a common practice in many cultures throughout Southeast Asia by the second century C.E., and it was to remain an important practice for centuries to come. The practice entailed planned, unprovoked, surprise attacks against others. Victims were decapitated as they were killed, and

their heads were taken by the aggressors back to their villages, where the skulls were cleaned and often painted with ceremonial designs.

There are several theories about the beliefs that compelled headhunting. Most interpretations reject the simple idea that such ritualized violence could have been motivated purely for the sake of intimidating one’s neighbors for military and political gain. There was almost universally a religious motivation behind it. In many cultures beheading a stranger and keeping the head was considered a way of making them a part of one’s own ancestral lineage. There were also cultures that refused to see strangers as humans and viewed them instead as demons in human form. Taking the head from such a non-human entity and bringing it to one’s village, the headhunter could humanize the spirit that dwelled within it. In this case, the heads were often given names and spoken to in a friendly fashion. Headhunting was practiced for different reasons in different societies, and its meaning is not entirely clear; still, it is apparent that the practice was widespread and that rather than being motivated by violence, it often reflected the tribe’s complex view of outsiders.

EUROPE

BY PETER S. WELLS

Human communities have always come into contact with other communities. From earliest historical times (those from which we have written texts as sources of information) literary evidence informs us about how members of one group thought about other peoples—peoples they considered to be “foreigners” or “barbarians.” By the latter part of the Early Stone Age, from about 40,000 years ago, archaeological evidence shows that people were acquiring materials not available to them locally, such as high-quality flint for making tools and shells from the seashores, which they used as ornaments. To procure these items, they needed either to trade with other groups who lived near the resources or to travel to those resources, which would have brought them into contact with other groups. From these earliest prehistoric times we do not have direct evidence about what people thought about others with whom they came into contact, but ideas about “others” must have developed through these contacts. In later periods, such as the Neolithic, the Bronze Age, and the Iron Age (taken together and representing all of Europe, 7000 B.C.E.–500 C.E.), archaeological evidence for interaction between communities is increasingly abundant. People were coming into contact with others through trade, migration, war, and other kinds of travel, such as trips to visit relatives and religious pilgrimages.

In the archaeological evidence we can recognize the development of distinctive types of personal ornaments and styles of dress that probably served to mark the identities of different communities. From the distributions of such objects in different regions, we can discern “borderlands” where groups came into contact. We can gain some insight into atti-

tudes toward foreigners and reactions to them through analysis of the patterns of display of signs of identity, such as dress pins, belt ornaments, neck rings, decoration on weapons, and other material signs.

Although we have no written sources from temperate Europe to inform us about attitudes toward the Greek world of the Mediterranean (because the Iron Age peoples of Europe did not have a system of writing), we can learn something about their attitudes from their trade for Greek objects. During the sixth and fifth centuries B.C.E. many of the larger communities north of the Alps, such as those at Mont Lassois in eastern France and at the Heuneburg in southwestern Germany, acquired Greek luxury objects, including fine painted pottery, bronze wine-serving vessels, and ornaments of coral and ivory. Such items are found in the wealthiest burials at the largest communities of the period (550–450 B.C.E.). The grave of one rich woman at Vix near Mont Lassois, with two ornate ceramic wine cups and an enormous bronze krater for mixing wine with water, all made in Greek workshops, is a good example. The presence of such objects in the graves of the elite of Early Iron Age society indicates that Greek luxury goods and the society that produced them were held in high regard by the local rulers in temperate Europe. There is even evidence to suggest that elites in Iron Age Europe adopted the wine-drinking ritual practiced in Greece as a means of expressing their status and power within their societies.

As with the attitudes toward the Greek world in the Early Iron Age, in the Late Iron Age luxury objects made in the Roman world were highly valued by the elites of society. Roman ceramic amphorae, used to bring in Mediterranean wine, as well as bronze vessels for serving it, together with fine pottery, coins, and other objects, were highly prized by wealthy and powerful individuals in Late Iron Age society. These items are found in the richest graves, frequently in association with other objects of special value and prestige. Examples of such burials are those at Welwyn Garden City in the United Kingdom and at Goeblingen-Nospelt in Luxembourg. During and after the Roman conquests many people who lived in lands north of the newly won imperial territories showed their admiration for things Roman. In graves in northern Germany, Denmark, and elsewhere beyond the frontier, Roman bronze vessels and other signs of connection with Rome were proudly displayed in the funeral ceremonies and then placed next to the deceased individuals in their graves.

GREECE

BY JOHN THORBURN

According to the Greek ideal, people from other towns or countries were to be treated in a kindly manner. In the earliest Greek literature, especially Homer's *Iliad* and *Odyssey*—probably first written down in the eighth century B.C.E.—the proper treatment of strangers and outsiders is of great significance. The most common Homeric word for an outsider is *xenos*, which usually means “foreigner,” “stranger,” “guest,”

or “guest-friend.” Another Greek word, *xenia*, primarily denotes either the hospitality shown to an outsider or good relations between two towns or cities.

The Homeric epics, core texts of Greek education, provided many examples of how strangers or outsiders should be treated. In the sixth book of the *Iliad* the Greek Diomedes encounters the Trojan Glaucus on the battlefield, where they discover that their fathers had a host-guest relationship. For this reason Diomedes and Glaucus decide not to fight and even exchange gifts of hospitality with each other. In Homer's *Odyssey*, Odysseus, returning to his country after 20 years abroad, is disguised as a beggar from another land. Before Odysseus goes to his home, he encounters one of his swineherds, who despite his own lowly social and financial status offers this unknown beggar shelter, food, drink, and even clothing. In contrast to the swineherd's hospitality is the behavior of the lawless Cyclops. Although Odysseus warns the Cyclops that Zeus himself, king of the gods, protects strangers, the monster declares that he and his race are more powerful than Zeus. The Cyclops further violates the customs of hospitality by imprisoning Odysseus and several of his men and even eating six of Odysseus's companions. Odysseus eventually escapes the Cyclops's cave after blinding the monster, thus punishing him for violating the customs of hospitality.

As the Homeric epics show, those upholding the customs of hospitality could expect fair treatment, whereas those behaving in an uncivilized or barbaric manner would be punished. The English word *barbarian* comes from a Greek word, *barbaros*, which may have originated from the way the language of non-Greeks sounded to Greek speakers (“ba-ba-ba”). So, in a strict sense, the Greeks regarded non-Greek speakers as barbarians. Because the expansion of the Persian Empire in the sixth and fifth centuries B.C.E. brought increased contact with and warfare against the Greeks, they regarded the Persians in particular as *barbaroi*. Nevertheless, some Greeks, even after fighting the Persians early in the fifth century B.C.E., later associated with the Persians and other so-called barbarians either for their own benefit or the benefit of their cities.

Although non-Greek speakers were labeled barbarians, some Greeks regarded their fellow Greeks as outsiders. During the eighth and seventh centuries B.C.E. the Spartans conquered and enslaved many of their neighbors. Some of the defeated towns, called *perioikoi* (“those living round about”) could keep their own governments but had to serve in the Spartan military and could not vote in the Spartan citizen assembly. Sparta's slaves, called helots, had to give their masters half of what their land produced. Because the helots outnumbered the Spartans and thus might try to overthrow them, the Spartans terrorized them with an annual practice, called the *krypteia*, in which selected Spartans assassinated suspicious helots. Sometimes, however, helots could be freed from their slavery, especially for outstanding military service when the ranks of the Spartan citizens needed supplementing.

Although the treatment of the helots is an extreme example, being an outsider in a Greek town could have disadvantages. People who were neither slaves nor citizens of the towns in which they lived were called *metics*. The laws governing *metics* differed in each town, but *metics* often had to perform some type of military service or pay additional fees to live in a town or both. In Athens *metics* could not own land. The disadvantages of being a *metic* in Athens may not have been too oppressive, however, because many outsiders resided there, such as the famous philosophers Aristotle and Theophrastus.

It was not just that Athenian *metics* faced certain restrictions; in 451 B.C.E. the Athenian statesman Pericles persuaded his fellow citizens to approve a law limiting citizenship only to those born to Athenian parents. Before Pericles' law took effect, a person with an Athenian father but a non-Athenian mother could be a citizen. Ironically, later in his life Pericles was a victim of his own law when he fathered a son by a non-Athenian woman. An exception was made for this son, however, and the law was soon repealed.

When Pericles was Athens's leading citizen, he also persuaded the Athenians to embark upon an ambitious building program. The most famous product of this program was the Parthenon, built between 447 and 432 B.C.E. Given Pericles' law on citizenship, some of the sculpture on this temple is noteworthy. The temple's southern metopes (decorated panels) show a battle between two mythical tribes, the Lapiths and the centaurs (the western end of Zeus's temple at Olympia also depicts this subject); its northern metopes have scenes from the Trojan War; the eastern and western metopes portray, respectively, the Olympian gods battling a group of giants and the Greeks battling the Amazons, a tribe of warlike women. Thus, each sculptural group portrays Greeks battling against non-Greeks (Trojans, Amazons) or beings (centaurs, giants) that threaten their civilization. According to mythology, the Greeks or their gods had triumphed over these "foreign" enemies in each case.

The Athenian ideal of triumphing over barbarians or uncivilized peoples suffered a severe blow after Pericles' death in 429 B.C.E. By 404 B.C.E. the Spartans had defeated the Athenians in the Peloponnesian War. Ironically, Greek culture experienced its widest diffusion by a people that most Greeks would have considered barbarians, even though they spoke a dialect of Greek. By 323 B.C.E. the Macedonian Philip II and his successor, his son Alexander, had conquered the whole of Greece. Alexander went on to triumph over the Persians and tribes as far away as India, and he spread Greek culture by encouraging his soldiers to intermarry with these foreigners.

After Alexander's death and the gradual breakup of his empire, both Macedonians and Greeks eventually came under the control of the Romans in the second century B.C.E. Although they were non-Greek speakers, the Romans became captivated by the culture of their captives and incorporated many Greek elements into their own society. In the first century C.E., however, Christianity began spreading through both

Greek and Roman cultures, and the apostle Paul, writing in Greek, would declare to the Colossians that in the Christian way of life distinctions no longer existed between Greeks and Jews, slaves or free persons, or Scythians and barbarians.

ROME

BY KIRK H. BEETZ

During the era of Rome's first kings (ca. 753–ca. 510 B.C.E.) Romans apparently held fairly relaxed attitudes toward outsiders. Foreigners were absorbed into the city and could even achieve important positions in government. For instance, the legendary king Ancus Marcius (r. 642–617 B.C.E.) was a Sabine (a people of the Apennine Mountains) by ancestry. Perhaps this accommodating attitude reflected Rome's small size—at that time it was still a small town—as well as its not yet having achieved a view of itself as different from the other towns in its part of Italy. These circumstances changed in 510 B.C.E. when Tarquinius Superbus (r. 534–510 B.C.E.), a king who had been exiled from Rome, returned with an Etruscan army to reclaim his throne. There was no question that Tarquinius Superbus's army represented outsiders trying to impose their will on Rome.

During the early years of the Roman Republic (ca. 509–27 B.C.E.) almost everyone was a foreigner to the Romans, and nearly every foreigner was a potential enemy. Italy was populated by several cultures, with Celts in the north, Greeks in the south, and at least eight other distinct cultures, the Latin culture of the Romans being the smallest in population. Yet through conquest and diplomacy Rome managed to gain control of central Italy by 290 B.C.E. Those under its rule who were not Roman citizens were the "Italian allies." Romans regarded them with disdain, but by about 200 B.C.E. the Italian allies wished to be recognized as Roman citizens themselves.

By then the Roman government included the office of tribune, a person elected by the plebeians (lower-class Roman citizens) to represent them in government affairs. One tribune, Gaius Gracchus, was a hero to the plebeians for advocating their rights until, in 121 B.C.E., he proposed extending Roman citizenship to the Italian allies. It was a serious misjudgment of public opinion. The plebeians did not want to share the benefits of Roman citizenship with outsiders, and Gaius committed suicide just before an angry mob could kill him. In 91 B.C.E. the tribune Marius Livius Drusus was murdered because he advocated giving citizenship to everyone in Italy, all of which Rome by then controlled. His enemies insisted that other Italians were barbarians and utterly inferior to Romans. His death touched off the Social War of 91–89 B.C.E., during which the Italian allies tried to set up their own independent state. They lost the war but won Roman citizenship.

In 146 B.C.E. Rome had conquered Macedonia and most of Greece. To the Romans the Greeks were puzzling. For instance, Greeks were comfortable with homosexuality, which Romans regarded as degenerate behavior. Yet the Romans had

an inferiority complex toward the Greeks, whose language, literature, and knowledge of science they considered superior to their own. Any Roman who could afford one wanted a Greek and not a Roman physician. Romans therefore made exceptions to their laws when it came to the Greeks. This policy toward the Greeks may have influenced how Rome shaped its laws for other foreigners.

To the Romans any foreigner was a barbarian, and as the Roman Empire expanded, it absorbed numerous foreign cultures, all of which had their own supposedly barbaric laws and customs. It seemed unreasonable to the Romans to apply laws to the barbarians that the barbarians would not understand. For instance, foreigners from cultures in which everyone communally co-owned the farmland would probably have trouble understanding a law against planting crops on someone else's property. The Romans were practical, and Roman magistrates based their interpretations of laws on general principles about how people should treat one another; they saw the need to make humane—rather than merely legal—decisions when a barbarian ignorant of Roman ways violated a Roman law.

Still, there were certain behaviors Romans did not tolerate from barbarians. One was rebellion. Another was disrespect to Roman gods. Romans were willing to allow worship of foreign gods, but they also expected everyone to follow the rules regarding Roman gods. When emperors became god-kings, shrines were established for them in Roman cities, and everyone was expected to pay proper respect. In regions such as North Africa this worked out well. The North Africans were content to turn whole temples over to the worship of Roman emperors because they saw themselves as being protected by those emperors.

Palestine was different. It took the Romans hundreds of years to figure out why Jews and Christians refused to offer simple, inexpensive sacrifices to the Roman emperors. After numerous very bloody revolts by Jews, Titus (r. 79–81 C.E.) the son of the emperor Vespasian (r. 69–79 C.E.), destroyed Jerusalem in 70 C.E. A sign that the Romans still failed to understand Jewish religious beliefs was the founding of the city Aelia Capitolina on the site of the ruined Jerusalem in 130 C.E., something the emperor Hadrian (r. 117–38 C.E.) expected the local people to greet with happiness. The Jews instead revolted because of the violation of their sacred city, and the rebellion lasted three years (132–35 C.E.) before the Romans put it down.

Hadrian had good reason to think Aelia Capitolina would be successful. Almost everywhere Rome built a city, people welcomed it, and it filled quickly with local people as well as Romans. This the Romans took as evidence that their way of life was better than everyone else's. Romans were sure that being Roman was the best thing any human could ever be. Romanization—the process of changing the behavior of barbarians into behavior that matched or at least closely resembled that of Romans themselves—usually succeeded, and Romans were surprised when it did not.

When Marcus Aurelius Antoninus (r. 211–17 C.E.), nicknamed Caracalla for a style of coat he supposedly designed, became emperor, the Roman Empire extended throughout North Africa, east into Mesopotamia, west through Spain, and north to the Rhine River and even into Britain. Many people in these areas came to speak like Romans, behave like Romans, and think of themselves as Romans, but Roman citizens still considered them foreigners. Then, in 212 C.E., Caracalla changed their status by declaring every free man living in the Roman Empire a Roman citizen. This sweeping decree did not, however, end Roman snobbery. Italian Romans continued to regard the accents of North Africans and northern Celts as somewhat primitive. They viewed the Parthians to the east as self-indulgent and decadent, morally inferior to “real” Romans. And they considered the Germanic peoples of northern Europe and Ukraine crude, dirty, and excessively violent. That Germanic tribes eventually overran the Western Roman Empire did not stop Romans from thinking of them as uncivilized.

THE AMERICAS

BY PENELOPE OJEDA DE HUALA

The ancient remains of the indigenous people of the Americas offer few clues about their attitudes toward strangers and foreigners. However, archaeological evidence points to a high level of interaction among the diverse groups that populated the New World, including a widespread trade network. Long-distance trade was only one component of the relationships among foreign and local communities. Along with commodities the varied societies of the New World exchanged ideas, customs, and beliefs—and sometimes forced them upon one another. These ancient cultural clashes are difficult to decipher, though scholars and scientists have gleaned valuable knowledge concerning them.

From very early times the indigenous groups of the Americas depended on local trade for survival. The diverse and sometimes harsh weather and geography of the American continents not only allowed for but indeed almost demanded interregional reciprocity. Neighboring groups often depended on one another, and over the course of time especially through migration and intermarriage, larger social and economic networks developed.

NORTH AMERICA

In the Middle Woodland Period (ca. 300 B.C.E. to 500 C.E.), Hopewell culture came to encompass a unique cultural sphere of influence. Centered in southern Ohio, the Hopewell built on the burial practices of their predecessors, the Adena culture, expanding and disseminating a mortuary ceremonialism throughout the woodland areas of the northeast and as far away as Illinois. This Hopewell interaction sphere (system of exchange) included wide-ranging interregional interactions and exchanges, where foreign and local traditions and art forms flowed freely from place to place. Mound building

became especially prolific throughout this period, as did the use of copper and mica ornaments.

Hohokam culture emerged from the desert regions of the Southwest in southern Arizona around 200 B.C.E. Archaeologists trace their origin to northern Mexico. This foreign connection continued throughout Hohokam development and is evidenced in the use of ceremonial ball court, irrigation, and copper bells. Evidence also suggests a thriving trade existed between Hohokam and its neighbors, including the Mogollon (ca. 200–1400 C.E.) of southeastern Arizona and southwestern New Mexico.

MESOAMERICA

In prehistoric Mesoamerica (the present-day regions of Mexico, Guatemala, Belize, El Salvador, and Honduras) attitudes toward foreigners and strangers appear in various artworks produced in the Pre-Classic Period (1500 B.C.E.–300 C.E.). Depictions of foreign captives became common beginning with the Olmec (ca. 1200–ca. 400 B.C.E.) who prospered in the Gulf coast region of Mexico. Images of defeated foreigners symbolized power and hegemony for the various civilizations that flourished in Pre-Classic Mesoamerica.

Olmec art centers on the promotion of rulership. At the archaeological site of La Venta, an early example, Altar 4 (ca. 900 B.C.E.) depicts a ruler coming out of a carved niche. In his hand he holds a rope that wraps around the base and leads to two bound captives, one on either side. This monument probably served as a throne and was a symbol of both the Olmec state (ruler) and its religion (the Olmec creation myth featured a primordial cave). However, the presence of bound captives directly tied to the seat of power also reflects the importance of warfare in Olmec power symbolism.

Similarly, in Monte Alban, capital of the Zapotec civilization (500 B.C.E.–1000 C.E.), in the Valley of Oaxaca (south-central Mexico) the so-called Temple of the Danzantes (Temple of the Dancers) contains 150 stone slabs depicting captives carved in low relief. These figures, all individually posed and all men, are incised with such an elegant line that they were at first believed to be dancers; however, they are shown with closed eyes and scroll markings indicating that they are dead and possibly mutilated. In Mesoamerica war was often waged not only for extension of territory and tribute but also for acquiring precious objects for rituals, including foreign sacrificial victims.

SOUTH AMERICA

The South American continent is a world of extremes—desert coast gives way to the majestic Andes, which give way to the mighty Amazon. This striking environment shaped the daily life and cultural development of ancient Andean cultures, creating a deeply transcendent aesthetic tradition defined by its sacred architecture, textiles, and stonework.

The archaeological site of Cerro Sechín (ca. 1000 B.C.E.) in the northern highlands of present-day Peru combines the spiritual aspects typical of Andean art with a sinister twist. A

mazelike temple complex surrounded by more than 300 10-foot-tall slabs features numerous images of bodies and severed body parts. The site has been interpreted as a memorial to a horrific massacre, and there are also indications that it may refer to a shamanic initiation ritual. However, among the dismembered bodies are men with battle clubs, which suggests ritual warfare. Whatever the case may be, the gruesome nature of this depiction points to the possibility of unfriendly relations with neighboring groups. Here, as in Mesoamerica, foreigners were often depicted in scenes of war or sacrifice and seem to have been embedded in the trappings of political propaganda.

Another example, a Nazca (Peru, ca. 400 B.C.E.) ceramic in the shape of a stepped fret—an abstract form resembling a mountain and a symbol of prestige—exhibits a complicated narrative scene of a cosmic battle between bird-headed shamans and writhing opponents. Representing a victory over an enemy (whether real or supernatural), this work is testimony to the political nature of the Nazca culture and provides insight into the complicated interactions among the people of that time and place.

► gender structures and roles

INTRODUCTION

Much of what historians know, or think they know, about gender relationships in prehistory comes primarily from burial practices and artwork. Surviving tombs provide insight, for example, into the status of women and men, and artwork depicts men and women engaged in various activities that were likely an outgrowth of assumptions about gender in that culture. During later periods written documents survive that shed light on gender issues, at least in some parts of the world.

The concept of gender and gender roles was felt in a number of areas of ancient life, including power and rulership, religion, family structure, and occupation, and these roles were typically taught to both boys and girls early in life through initiation rituals and segregation of the sexes. With regard to power, it comes as no surprise that most ancient world cultures were dominated by men, with women playing more passive, domestic roles. This was not universally true at all times and all places, however. From time to time—in ancient Greece and Egypt, for example—a powerful woman emerged who assumed the reins of power. In doing so, though, she probably had to take on many stereotypical masculine traits, such as ruthlessness.

In religion men tended to serve as priests, shamans, and religious gurus, but again, this was not universally true. In the ancient Americas, for example, archaeological evidence suggests that women often served as shamans and priests. It was also common in many cultures for its pantheon of deities

to include goddesses as well as gods. The ancient Greeks and Romans are prominent in this regard, but examples of goddess figures can be found in ancient cultures the world over. These goddess figures were thought to have ruled over various spheres of life, and this idea would have affected concepts of proper gender roles and expectations.

With regard to family structure, the status and role of women was probably determined in large part by the economic conditions of the culture. In hunter-gatherer societies it was long assumed that men did both the hunting and gathering while women tended to the home. Some scholars dispute this assumption, arguing that women took an active role in gathering food and may very well have hunted small game. As cultures turned to agriculture and became more sedentary and complex, gender specialization became the norm, with men involved in public affairs and women performing primarily domestic tasks.

Women may have taken primary responsibility for domestic tasks, but in many cultures they also held occupations, primarily crafts. In the ancient Americas, for example, women were primarily responsible for such activities as textile production and weaving. Because a great deal of craftwork took place in homes, it is reasonable to conclude that women took part as potters, wood carvers, and the like. Men generally were of higher status in patriarchal cultures and had authority over their wives and family, but some cultures, particularly in Africa, were more matriarchal, with the wife and mother ruling in the home. It was not uncommon in many cultures for men and women to spend most of their time apart, with women living in separate “women’s quarters” and men taking part in separate activities. It should be

noted as well that in some ancient cultures, homosexuality was more widely accepted than it is in modern life.

AFRICA

BY MICHAEL J. O'NEAL

The chief difficulty historians have with reconstructing gender roles in ancient Africa is the absence of written records. Gender is not an object, something with a tangible existence; gender is a social construct, meaning that gender roles are established by the assumptions people make about the relationship between men and women in society. Some written records touching on African gender relationships survive from the ancient Roman writers, but they tend to be unreliable, for they embody the cultural assumptions of the Romans, which may not correspond to those of the Africans they observed. Some information has been transmitted orally through the centuries, but it is difficult to determine the extent to which that information remains accurate 2,000 or more years later. Finally, a certain amount of information can be gleaned from the archaeological record. For example, tombs and artwork, and even such objects as tools and seeds, can provide insight into the relative status of men and women, but this record is spotty, so historians have to try to fill in the details.

During prehistoric times, when the primary social activity of bands of hunter-gatherers was the acquisition of food, labor was divided along gender lines. Men tended to be the hunters, particularly when they were after big game; women's hunting activities tended to be restricted to small game and birds. Otherwise, women were the primary gatherers, finding and storing nuts, grains, tubers, leafy vegetables, fruits, berries, and eggs, though men learned to gather as well when they were children at their mother's sides. In coastal regions men were the primary fishermen, but both men and women took part in the search for shallow-water seafood. Women likely chose as mates men who were adept at acquiring and sharing food.

Women were in general the primary caregivers for children and nursed them during infancy, though men, too, played an important role, particularly as children grew older. Women could not become bound to several children, for their role in gathering food was essential. Thus, women tended to space their children, typically four or five years apart, so that they could devote their attention to one at a time. Ancient African women developed slings they could use to strap infants to themselves, leaving their hands free for gathering and preparing food.

It might be assumed that ancient African women were less valued than men, especially given that most African societies were patriarchal, meaning that men were dominant, and patrilineal, meaning that descent was traced through the father's rather than the mother's bloodlines. This assumption, however, is not entirely true, for in many ancient African societies women were highly honored and, in fact, wielded a considerable amount of power. In doing so, they gained sup-

port from a worldview that placed a great deal of emphasis on collective obligations and responsibilities. Important values included group solidarity and harmony, with the group in turn integrated with nature, ancestors, and the gods. To maintain this harmony and to ensure the continued existence of the group, the interests of everyone had to be respected. Thus, women, far from being excluded, played a vital role in the affairs of many African tribes. Further, traditional gender roles did not always correspond with biological sex.

For example, kinship was important in African tribal society. Kinship networks, rather than a central government, provided a link between a person and the larger community, and kinfolk were responsible for socializing children into the community's values and folkways. But even though most African societies were patrilineal, the mother's kin were important in the lives of children. Thus, among the Sotho-Venda of South Africa, the brother of a child's mother was called the "male mother" and enjoyed a close relationship with his nephews and nieces. Similarly, the father's sister was the focus of great respect and referred to as the "female father." In family councils the father's sister was given the status of priestess and was an important link between the family and its ancestors. Ruling over the household of the tribal chief was his sister, who had great influence in tribal matters; the chief always deferred to her judgment in ruling on the tribe's affairs. In some ancient African societies, when it was necessary to name a new chief, the deceased chief's brother and sister jointly determined who the successor would be.

Among the Swazi tribe in southeastern Africa, the Queen Mother, or the chief's mother, similarly played a major role in the affairs of the community. She was referred to as the She-Elephant, and she was a joint ruler with her son. Her views were given equal weight with those of her son in such matters as legal disputes, land allocation, and community ritual. Conflict between the chief and his mother was a matter of great concern to the people because it threatened the stability of the community.

The Lovedu tribe of the Limpopo Province of South Africa provides a unique example of gender roles and relations. The Lovedu were a patrilineal society that determined descent through the male line; however, at the same time it was a matriarchal society in which women wielded the power. The governmental and religious head of the society was the Rain Queen. Among the Lovedu—and other ancient African cultures—marriages between women were common. A woman who took a wife paid to her family a bride-price to acquire her, just as men did, and then she had a male relative impregnate her. The children called the woman whose relative conceived them "father." Moreover, a daughter of every local chieftain married the queen, creating a system in which the society was integrated by the bride-price the queen paid to the chieftains. Within each district was a "mother," who could be either female or male and who served as a representative and intermediary between the chiefs and the queen.

Women also served an important function in the religious affairs of ancient African communities. Many of these communities practiced ancestor worship. This meant that dead ancestors continued to play a role in the affairs of the community. They attained mythic significance, and the link between the living and dead fostered social harmony and the transmittal of values from one generation to the next. Although men often functioned as the shamans who mediated between the living and the dead, in many tribes women fulfilled this function. And while some tribes emphasized worship of male ancestors, many accorded equal worship to both male and female ancestors, particularly a deceased mother or grandmother.

A common practice that dates back at least 4,000 years is female circumcision, or the surgical removal of the young woman's clitoris. This practiced was followed not only in ancient Egypt but also among numerous other communities, including the Nubians, the Ethiopians, and people in communities along the Sahel, or the region just to the south of the Sahara Desert. The practice had a number of purposes. One was to "mark" the girl, making her less than perfect so that the gods did not reclaim her; ear piercing had a similar function. Another was to bind the woman to the patrilineal clan into which she married by ensuring her virginity and marital faithfulness, for her circumcision was inspected by the groom's female relatives. A circumcised woman was thought to be more docile and obedient, ready to assume her place in the family. Yet another purpose was to affirm the belief that circumcision, of both men and women, purified people for the next generation.

EGYPT

BY EMILY JANE O'DELL

Any discussion of gender must first admit that categories of gender and gender expression are largely constructed by the society and culture from which they spring. Gender is usually defined in relation to biological sexual differences; however, there are many different types of intersexuality. While the numbers of genders in a society can vary across cultures, ancient Egypt recognized female and male gender, and these genders were correlated with biological sexual differences between men and women. However, before the law, men and women were equal. Both men and women could inherit and dispose of property as free agents, testify in court, initiate divorce, and participate in business contracts.

Royal women enjoyed a great deal of prestige, privilege, and power. Theoretically, the throne in ancient Egypt passed through the women of the royal family. Some of the pharaohs married members of their own family to claim a throne, and many other pharaohs married princesses in order to ally with the royal family. While a royal woman could have only one husband, a king could have multiple wives and concubines. In the Old Kingdom (2575–2134 B.C.E.) royal wives, mothers, and daughters held administrative positions as well as reli-

gious positions, such as priestesses of Thoth or Hathor. The kingship, however, was not restricted to men. While the large majority of pharaohs were men, there were also a handful of female kings, such as Sebeknefru (r. ca. 1787–1783 B.C.E.) and Hatshepsut (r. ca. 1473–1458 B.C.E.). When ruling the country, these women were seen as "kings," not queens. Many queens, however, ruled as regents for their husbands or children.

Male kings built majestic and large burial places for their prominent queens, such as the tomb of Nefertari (wife of Ramses II) in the Valley of the Queens. Many queens, such as Queen Ahhotep (of the Seventeenth Dynasty) and Queen Ahmose-Nefertari (of the Eighteenth Dynasty), were venerated long after their deaths. While women were denied many of the key positions in the state's bureaucracy, they did attempt to assert their authority through other means. For example, several conspiracies against the king were instigated by queens, and harem conspiracies arose during the reigns of Pepi I (r. ca. 2289–2255 B.C.E.), Amenemhet I (r. ca. 1991–1962 B.C.E.), and Ramses III (r. ca. 1194–1163 B.C.E.).

While men and women were equal in terms of legal rights, men held more positions in the clergy and state bureaucracy. Men and women received equal wages for their jobs. While men dominated the bureaucracy, women held many different jobs, such as selling products and food in the marketplace, harvesting crops, gathering and winnowing wheat and flax, grinding grain and baking, weaving, brewing beer, making perfume, and participating in the compulsory temporary state labor service. Women could also serve as supervisors over these activities. Men were field laborers as well but could also be butchers or jewelers; some men made furniture, leather products, and sculpture. In many lines of work, a woman could also inherit her father's position. However, men dominated government positions because these jobs required literacy.

While there were most likely elite, literate women as well, they would have been the exception. While women in the Old Kingdom did hold administrative positions, they seem to have worked for high-ranking women, not the general state bureaucracy. During the Old Kingdom in ancient Egypt, musicians and dancers were primarily women, but after the end of the Old Kingdom men performed as musicians and dancers at private parties, festivals, and religious ceremonies. During the reign of Ramses III, women participated in the first work strike in history in support of their civil servant husbands. Women were also in charge of managing the household and the family. After the Middle Kingdom (2040–1640 B.C.E.) they had the title "mistress of the house." They were responsible for raising the children, and the royal family also employed royal wet nurses and tutors for the royal children.

In ancient Egyptian mythology there were both male gods and female goddesses. Some gods and goddesses had qualities that were peculiar to their gender, such as child-bearing, but others had qualities that were uncharacteristic of their gender. For example, the goddess Neith was a goddess of war, yet women in ancient Egypt did not participate in war-

related activities. Some of the goddesses were the embodiment of powerful elements of the state and universe, such as the throne, justice, and the heavens. While most priests were men, women were priestesses in the cults of Hathor, Thoth, Nut, and Neith. The cult of Hathor was restricted to women priestesses. Royal women held such titles as “great royal wife,” “God’s wife,” and “divine adoratrice.” In fact, during the New Kingdom (1550–1070 B.C.E.), the great royal wife lived separately from her husband, though the couple would still meet frequently.

Women could also be scribes, prophets, and funerary priests, jobs typically belonging to men. Musician priestesses used music to praise the gods and goddesses and to provide accompaniment to the religious rituals and recitations. Women could also be professional mourners. A woman could obtain titles through her husband if he were a priest; such titles might include “songstress of Amon” or “chief concubine of Amon Re.” While the eldest male child was expected to oversee the funerary plans, women in the family or a priest could do so if necessary. Most common women participated in temple cults, even if they did not hold a religious title.

Marriage in ancient Egypt was surprisingly equitable, especially when compared with other parts of the ancient world. There was intimate and playful love poetry in ancient Egypt, and the poetry suggests that sexual intimacy occurred before marriage and that virginity was not a prerequisite to marriage. Some tomb reliefs portray naked young women at banquets and festivals, and other erotic papyri suggest that sex was not taboo. However, homosexuality was discouraged, and adultery was seen as a terrible crime. While royal men took more than one wife, common men and women were supposed to have monogamous unions.

Ancient Egyptian couples with formal marriages had marriage contracts. Men and women also practiced common-law marriage by way of cohabitation. In these marriage contracts a woman came to a marriage with some property, while the man was supposed to supply the house. A married woman could own her own property—she did not forfeit her property or her wages to her husband. She could have her own income and could sell, lease, or loan her property, land, and money without the permission of her husband or a male relative. Both men and women could sue, adopt children, or initiate a divorce. A woman could receive spousal support. If a woman’s husband died, she received one-third of his estate while the children received two-thirds of the estate. A man could also “adopt” his wife to make her the sole heir of his property.

In Egyptian art and statuary, men and women are usually depicted in the ideal physique for their gender. Men are shown with reddish skin, probably as a result of their working outdoors. They are portrayed as muscular and youthful. However, older men are sometimes shown as portly to emphasize their wealth and position. Women, however, are portrayed with yellow skin and are mostly shown as young and thin, wearing tight-fitting clothes that emphasize their

taut abdomens and slender hips and that accentuate the pubic area, perhaps to reflect their childbearing potential. Statues portraying common people, however, are much less idealized and represent all types, even humpbacks and dwarfs. Men and women are sometimes depicted as the same size, but men are often shown as taller and closer to the center of the scene to emphasize their dominance.

THE MIDDLE EAST

BY KAREN RADNER

From the mid-third millennium B.C.E. to the Hellenistic Period (323–31 B.C.E.) the predominant writing materials in Mesopotamia were extremely durable clay tablets inscribed in the cuneiform script. Hundreds of thousands of such texts have been unearthed in the ancient cities of modern Iraq, Syria, and Turkey, making Mesopotamia the best-documented area for gender and structure roles of the ancient Near East. Information gained from the Bible indicates a broadly similar pattern of gender structures and roles for Israel and Judah in the first millennium B.C.E., as suggested by the more limited documentation available for other parts of the Middle East, namely Anatolia, Iran, and the Levant.

While many languages of the ancient Near East distinguish grammatically between masculine and feminine, for example, the Semitic languages Akkadian, Old Hebrew, Old Aramaic, and Phoenician and the Indo-European languages Hittite and Old Persian, some do not, most prominently the Sumerian language, which was widely spoken in Babylonia during the third millennium B.C.E. and remained the dominant language of learning until the last centuries of the first millennium B.C.E. Sumerian is found in two distinct forms that use separate vocabularies and differ profoundly in pronunciation: One form was spoken by men and called the “native tongue,” and the other was spoken by women and called the “high-pitched tongue.” Long after Sumerian ceased to be used as a colloquial language, lamentations—songs of mourning and despair—addressed to the gods in the course of temple worship were exclusively performed in the high-pitched tongue, albeit by men, who thereby assumed the traditional female gender role of mourning and keening. This example demonstrates the difference between gender and sex, gender being a socially defined category and, hence, far more flexible than the physical characteristics of a person’s sex.

Written scripts also offer some insight into gender roles and stereotypes. In the cuneiform script used to record Sumerian, Akkadian, Hurrian, and Hittite, the sign with the meaning “man, male” depicts an erect penis, while the sign with the meaning “woman, female” shows the pubic triangle. The gender stereotypes of warrior and spinstress are endorsed by another system of categories—magic. The items representing men and women in magic rituals recorded in texts from Mesopotamia and also second-millennium Anatolia are weapons and spindles and other tools for textile production, respectively. This makes it very plain that the place

of a woman was considered the domestic sphere, where she gave birth and raised children; cooked, baked, and brewed; made textiles by spinning, weaving, and sewing; laundered and cleaned; and kept the household running. While women were certainly not restricted to the house and were free to go about in the city, as best illustrated by several biblical narratives in which women fetch water at the well or at the river, a woman traveling beyond the city limits was always an exception and considered in need of a male protector, as described in the relevant rules and regulations found in the Middle Assyrian Law Code (ca. 1100 B.C.E.).

In general, ancient Near Eastern gender roles are defined by a set of mutually exclusive classifications: sex (male versus female), gender (masculine versus feminine), sexuality (penetration versus receptivity), and hierarchy (domination versus subordination). Male sexuality was equaled with penetration and domination, and to be penetrated corresponded with female sexuality. Being the receiving partner in a homosexual union between men or ceding the dominant role in a sexual encounter to a woman was seen as unmanly, as is clear from a Babylonian collection of omens—or rather, as in these specific cases, moral guidelines that at least in part date back to the early second millennium B.C.E. and continued to be popular throughout the first millennium B.C.E.—“If a man has sexual relations with a male house slave, hardship will seize him”; “If a woman mounts a man, that woman will take his vigor.”

With the man socially expected to be the dominant, active sexual partner, unions between older men and younger women were very common, while the reverse situation was possible but not considered ideal. This is again made clear in the already mentioned Babylonian omen collection: “If a man has sexual relations with an old woman he will quarrel daily.” This attitude bears especially on the options available to widows. Married women who were fortunate to survive the birth of their children had a good chance of outliving their husbands and were theoretically able to enter a second marriage, yet ancient Near East law codes and legal documents from all periods show a clear interest in encouraging wealthy widows to remain unmarried in order to protect the family’s financial assets against outsiders. The same concern lies at the root of the practice to marry one’s brother’s widow, as related in the Bible.

While sexuality is not exclusive to humanity, it is exactly its controlled practice—adhering to the allowed and disallowed customs defined by society—that was seen to set humankind apart from animals and to work as an instrument of civilization. This attitude is best illustrated by the Epic of Gilgamesh, popular in the entire ancient Near East from the second millennium B.C.E. onward: When the savage animal-like Enkidu consorts with a prostitute, he becomes “human” and is rejected by his previous companions, the wild beasts; he leaves the steppe for an urban and civilized life.

Mutually exclusive extremes are at the core of ancient Near Eastern gender roles, and yet one of the most important

Sumerian deities transcends these polarities: Inanna, or to use her Akkadian name, Ishtar, incorporates within herself the opposites of male and female. She is androgynous and ambiguous, as is her heavenly representation, the planet Venus, which the Sumerians referred to as the masculine evening star and the feminine morning star. Inanna/Ishtar was, therefore, closely associated with all those who fell outside the binary system of male and female, including eunuchs. Far from being social outcasts, as might be expected in a culture that valued family and children over all, eunuchs had an important role in the state organization of the Neo-Assyrian Empire (ninth century B.C.E.–seventh century B.C.E.). Having been made sterile at an early age and forsaken the chance to sire children, their loyalty belonged exclusively to the royal family, and they were often chosen to act as the king’s local representative as provincial governors. In contemporary art eunuchs are shown as beardless yet are otherwise dressed like men, and their legal rights were not different from men. But Inanna/Ishtar played a key role in the lives of all people, men and women alike, as the carnivalesque festivals organized in her honor offered the participants an opportunity to digress from the rigorous gender roles, thereby stabilizing what may otherwise have been a regulated and stifling society.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Throughout ancient Asia women were generally regarded as subservient to men, and their lives were controlled by their male relatives. Despite these circumstances, women received some honor and respect for performing their roles well, especially as they grew older and their sons married. Sexuality was considered an important part of life throughout the region, with males and females both playing a key part in relations.

In the Chinese Daoist philosophy of the first millennium B.C.E. the sexes were characterized as yin and yang. Yin, the feminine principle, was said to be soft, yielding, dark, and passive and was symbolized by water. Yang, the male principle, was considered rigid, active, and bright and was represented by fire or wind. Women were believed to possess large amounts of yin, while men were filled with yang. Chinese people thought that it was important for men and women to exchange energy types by engaging in extended sexual play with multiple female orgasms. It was believed to be especially unhealthy for men to exhaust their yang essence by ejaculating too quickly, before they absorbed the necessary yin from women. During the later Zhou Dynasty (770–256 B.C.E.) men were encouraged to visit prostitutes for the purpose of increasing their yin.

During the period between about 220 B.C.E. and 25 C.E. Confucianism became the prevailing philosophy in China. In Confucian doctrine women were considered inferior to men and were expected to be subservient to them. The Confucian writings say very little about women, which most

scholars take as evidence of the insignificance of women to most men. Confucians believed that in order to maintain social harmony husbands must be superior to wives, and brothers must be superior to sisters. Thoughts on sexuality changed. Confucianism taught that sex was somewhat sinful and should be confined to the bedroom; husbands and wives were not to touch each other outside the marriage bed. Sexual acts between spouses were restricted to procreation and meant for the maintenance of family stability. Men were allowed to have concubines, but Confucianism regulated the practice with numerous rules, such as those concerning how frequently men should have sex with concubines and whether concubines could remain in the bed after the sex act was completed.

During the Eastern Han Dynasty (25–220 C.E.), Daoism once more became the prevailing philosophy, and sex was again encouraged. Scholars published sex manuals that described breathing techniques that could prolong male performance and increase female response, in an effort to transfer yin and yang energy between the man and the woman. Sex between men and women was thought to be a way to improve health and achieve a longer life. During this time the color red became associated with women and white with men.

Although they were not considered the equals of men at any time in China, women could wield a large amount of power within the household. This power came with age and the birth of sons. Young girls were valued less than boys, and female infants were more at risk of being abandoned or killed at birth. Girls were considered an expense because they were destined to leave home when they married; their parents had to furnish them with a dowry and could not count on their daughters' care in old age. When a woman married, she went to live with her husband's family and often became a virtual servant to him and his relatives. She was expected to get up early and stay up late to carry out all her domestic work and to make her home and family her only priority, living quietly and performing her spiritual duties to the family's ancestors. A wife had to please her in-laws, especially her mother-in-law, and could be punished if she protested. She gradually gained more power as she produced children and grew older. When a woman's son married and she herself became a mother-in-law, she took control of the household and was allowed to dominate a daughter-in-law. A mother-in-law's word was law to her daughter-in-law; unquestioning obedience was required at all times.

Husbands had duties toward their wives as well. Although men were considered superior to women, people believed that if men did not act properly, they lost the power to control their wives. Men and women were supposed to live in harmony. Men were not to strike their wives, and women were not to scold their husbands.

In India women married young. Men were expected to support their wives and were also responsible for their wives' behavior. They were not, however, supposed to use

force to maintain discipline, aside from a small number of blows that did not inflict damage. India's caste system provided many rules for sexual behavior. Female virginity was highly prized, and violating it could bring serious punishment. A man who had sex with a virgin of the same caste as his was either heavily fined or had his hand cut off. Having sex with a virgin of a lower caste resulted in a smaller fine or the loss of the man's middle finger. If a woman had sex with a man outside marriage, she could be fined a small amount. If a man rescued a woman from some danger, such as war, fire, or flood, he was allowed to have sex with her unless she was of high caste and had children, in which case she or her family could pay him a ransom instead. The punishment for adultery depended on the castes of the partners. The higher the rank of the woman and the lower the rank of the man, the worse the punishment. A low-caste man who committed adultery with a Brahman (highest caste) woman would be burned alive, whereas a man of a higher caste would merely lose his property.

Although very little is known about gender roles in ancient Japan, there is some historical evidence that women and men were considered equals and that women served as powerful religious leaders. Ancient Australians also left little evidence about gender structures, but modern scholars believe they may have had a fair degree of equality between the sexes while also dividing work by sex.

Homosexuality existed throughout ancient Asia, with varying degrees of approval. In ancient China male masturbation and homosexuality were thought to be unhealthy because they built up an overabundance of yang energy, while the same practices were encouraged for women. In India the Vedas (the earliest sacred Hindu writings) and other ancient texts mention individuals who are neither male nor female and sometimes refer to hermaphrodites as a third gender. The Pali Canon, a set of early Buddhist scriptures in Thailand, mentions a sexual category called *pandaka*; this category is traditionally believed to include homosexual male monks. Modern Thai scholars have termed these homosexual men *kathoe*, the word used to refer to transvestites or transsexuals, on the assumption that these monks dressed and comported themselves as women or acted in some other manner that went against expected masculine behavior. Some historians are now not so sure that these *pandaka* monks were indeed transvestites in the modern sense and think that they might have acted according to the conventions of male behavior but engaged in homosexual acts with other men.

EUROPE

BY MICHAEL J. O'NEAL

The challenge historians face in studying gender structures and roles in the ancient world is the overall lack of written records. Gender has no tangible existence as a piece of pottery or a building does. Gender is a social construct, meaning that gender roles are assigned and played out in the context of so-

cial and marital relationships. Without written descriptions of these roles, historians have to rely on whatever archaeological record is available, then make inferences about what they find. This record includes tombs, remains of homes, and artwork, which can tell historians something about how men and women were regarded. Sometimes archaeologists rely on what they do *not* find to make these kinds of inferences.

Complicating the matter is that for generations, historians and archaeologists have tended to make generalizations about gender roles in ancient Europe that might be only partially true. The usual view is that men held all the power. They were the kings, priests, chieftains, warlords, shamans, craftsmen, and warriors, fulfilling functions largely outside the home. Women were thought to be peaceful; they were in charge of the domestic sphere, and their influence was limited almost entirely to this sphere. While this generalization has a great deal of truth to it, it does not tell the entire story. Some archaeological finds, along with new ways of thinking about those finds, suggest that women were not always restricted to the domestic sphere. In fact, many women held positions of power as priests, shamans, and warriors. Some took part in public activities such as trade. Others were skilled at craftwork, particularly spinning, weaving, dyeing, and textile production.

One type of written record that does exist and that has a bearing on gender relationships includes legends, myths, and tales. While these stories were not written down at the time the ancients lived, they survived because they were passed along orally throughout the generations. In many cases, these stories provide insight into the gender relationships of ancient peoples.

A good example is provided by Scandinavian mythology, much of which emerged during the Nordic Bronze Age, which extended from about 1800 to 600 B.C.E. This mythology was intimately connected with Scandinavian religious beliefs. At the center of Nordic mythology was a male sun god, depicted as traveling the heavens in a chariot. Later, this sun god evolved into a sun goddess, both in Scandinavia and among the Germanic tribes, though historians are not sure why. Also worshipped was a female mother goddess, Nerthus, who evolved into various female mother goddesses in Scandinavian and Germanic mythology. Most of the gods, such as Thor, are represented in surviving artwork as carrying swords and spears, suggesting that men were viewed as the warrior and governing class.

Female goddesses, in contrast, were associated with fertility and such events as the harvest. Nonetheless, Scandinavian mythology is rife with female giants and warrior maidens. The best example is the Valkyries. These were nine warrior maidens who served as attendants to Odin, the ruler of the gods. Their principal role was to accompany warriors to Valhalla, Odin's great hall; that is, they were to accompany slain soldiers into the afterlife. In battle they wore elaborate armor. Their leader was Brunhilda, who was the goddess not only of fertility and love but also of death and battle. Histo-

rians believe that the warrior goddess of Celtic mythology, Morrigan, was a parallel development, especially because both Morrigan and the Valkyries were able to prophesy the outcome of great battles.

Taken together, these and other mythological figures suggest that the ancient Scandinavians and the Germanic tribes of northern Europe took something of an equal view of men and women. While men were still principally responsible for war and governance, women played a prominent role as well and were not limited to the domestic sphere.

Tomb excavations also provide insight into gender relations and issues surrounding the power and influence of women. Among the ancient Celts, for example, historians know that women enjoyed a respectable amount of influence. They were able to own property and divorce their husbands, and they took part in a wide range of occupations, including those of merchant, warrior, and healer. In excavating Celtic tombs, archaeologists have discovered that many Celtic women enjoyed high social status. This can be determined by the nature of the goods that were buried with the women as well as by items of personal adornment that suggest high social status. In some instances horses and horse tack were buried with women, suggesting that these women may have played an important role in what is traditionally regarded as a male sphere. Along the same lines, archaeological sites of homes throughout ancient Europe have yielded tools used in craft production. In some cases men performed craftwork in the home, but in others it is believed that crafts production was the province of women working the home.

Archaeologists are occasionally able to make generalizations about gender relationships on the basis of what seems to be missing from the archaeological record. A good example is provided by the British Isles, where historians were long puzzled by their inability to find Bronze Age homes that contained artifacts typically considered domestic. These would include tools for food storage and preservation, cooking, and the like. Recently some archaeologists have argued that nothing is missing—that, in fact, these remains were never present. Their argument is that during the Bronze Age in Britain, no sharp distinction was made between the public and domestic spheres. Items used for domestic activity are found in many different types of sites. Their conclusion is that there was no domestic sphere presided over by women. They believe that men and women played equal or nearly equal roles in a public, community life.

Some historians have taken an interest in the nature and extent of homosexual relationships in ancient Europe. In general, it is believed that ancient Europeans were relatively tolerant of homosexuality, having absorbed this tolerance from the ancient Greeks. Among the ancient Celts, for example, poems and legends contain hints that homosexual relationships between soldiers were not uncommon. Many historians, too, point to the ambiguous sexuality of some of the region's mythological figures, suggesting that ancient Europeans were not offended by homosexuality.

GREECE

BY BRADLEY SKEEN

In the earliest period of Greek history, the Minoan civilization (ca. 2600–ca. 14,500 B.C.E.) on the island of Crete was a highly centralized culture of palaces, of which Knossos was the most important. Evidence from the material remains of this culture, including paintings on palace walls, offers grounds for speculation rather than clear evidence about gender structures and roles. Two factors are often cited to argue that the Minoan society had equality between the sexes or may even have been a matriarchy.

First, many paintings show women seemingly active in public life, especially the Minoan ritual and sport of acrobatically vaulting over the backs of dangerous bulls. But the mere presence of women does not tell us their role. There is no way to determine whether the participants (male and female) in bull jumping were aristocratic youths, trained slaves (like Roman gladiators), or even prisoners preparing

to be sacrificed. (This latter fate might be suggested by the myth of Theseus and the Minotaur, in which Theseus, an Athenian prince, is sent to Crete as tribute to be sacrificed to the half-human, half-bull Minotaur but instead kills the monster and frees his city from the tyrannical rule of King Minos of Crete.)

Second, most surviving cult statues suggest that the main figures worshipped in Minoan religion were goddesses. But this fact need not imply a high status for women in society, any more than the importance of Mary (Jesus' mother) in European religion in the Middle Ages was equated with a high status of women in that culture. Interestingly, Minoan art typically depicts men as having brown skin and women as having white skin. This might suggest that aristocratic women led comparatively sheltered and inactive lives, kept away from the outside world, whereas men became suntanned from the outdoor tasks of business, war, and agriculture.

The Mycenaean civilization (ca. 1600–ca. 1100 B.C.E.) rose from the invasion of Greece and the Aegean islands by

Terra-cotta statuettes: woman holding pancake and woman kneading dough (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

Greek-speaking peoples who absorbed Minoan culture. This civilization is the background of the Homeric poems the *Iliad* and the *Odyssey* and of many Greek myths. It was dominated by a warrior aristocracy that gained status through success in battle and the collection of plunder from the conquered. Women's lives were entirely under the control of their fathers, husbands, or even sons, and as the literary tradition shows, the men were fully aware that many women felt this condition to be unjust. Nevertheless, women could often assert themselves through their personal influence over powerful male relatives.

The Mycenaean culture ended in the face of new invasions. Greece entered a dark age in which society broke down into small villages and individual farmsteads. From this primitive social organization there emerged the Greek cities of the Classical Age (ca. 480–323 B.C.E.). The amazing rebirth of Greek civilization established an ideal against which many later cultures measured themselves, but gender roles developed unequally. Greek culture had been transformed by an influx of tribal peoples who organized gender roles around bands of male warrior-hunters that lived and worked together apart from female society. In Sparta, for instance, this early pattern was reflected in a militarized state. The entire population of male youths and adult men spent all their time training for war or fighting. They lived in barracks under military discipline and visited their own families and farms only infrequently, on formal leave. This regimentation led to the unparalleled military strength of Sparta and to a male ideal famous for its fortitude, duty, and indifference to circumstance.

Spartan women lived apart from men and acted as stewards over their husbands' property, wielding a unique degree of power and independence. Greeks were very hostile to anyone who violated accepted social roles. Because Sparta's women seemed to be out from under male control, they attracted the criticism of other Greeks as being lesbians, whether or not there was any basis for the claim.

In Athens, on the other hand, aristocratic women lived secluded lives inside the women's quarters of the family house, and even in this home setting men and women ate their meals separately. The legal rights and social status of Athenian women were very restricted, but ancient dramas suggest that women could exert tremendous influence within the family through sheer force of personality. Women from the lower classes had more exposure to the outside world because they had to work in the family business or farm.

Paradoxically, some women who abandoned idealized gender roles could rise to social prominence, acting in the same cultural environment as men. These were the *hetaerae* (literally "companions," but in classical Greece a word signifying a social role somewhere between that of a mistress and a prostitute). Aspasia (469–406 B.C.E.), mistress of Pericles, leader of Athens, gained wide popularity for her wit and intelligence. Muesarete (fl. ca. 330 B.C.E.)—ironically nicknamed

"Phryne" ("Toad") because of her beauty—was the mistress of the orator Hyperides and of the great sculptor Praxiteles and amassed one of the largest fortunes in Athens. However, both women had to defend themselves in court (successfully) against charges of impiety (the crime of violating religious law) occasioned by resentment over their prominence obtained apart from social expectations.

Despite the restrictions imposed on most Greek women, some reached great heights of personal achievement. Artemisia I, for instance, queen of the Greek city of Halicarnassus in modern Turkey, acted as a governor in the Persian Empire and as an admiral in the Persian force that invaded Greece in 480 B.C.E. Another exceptional woman, Sappho (ca. 630–570 B.C.E.), wrote lyric verse that sets her among the very greatest poets and can also be considered the first poet in the modern sense. Some of her poems seem to describe desire for a woman, but it is not clear whether this reflects her own feelings or those of a perhaps male character.

The male band of earlier times lived on in Athens in the typical male gathering, the symposium. Today this term usually signifies a relatively staid intellectual gathering. In ancient Greek it meant simply "drinking party." Held among male friends and relatives, the symposium was the height of fashionable life in Athens and embodied collective cultural fantasies of ideal manhood. Pederasty, one of the most striking features of the symposium, was the sexual courting of adolescent youths by adult men. (Erotic contact between adult men, however, was stigmatized in Greek society.) The men sought the sexual favors of the youths in return for education, contacts, and other forms of assistance in entering into society. This practice may have evolved from earlier initiation rites typical of tribal cultures.

The symposium properly began after dinner and involved a long night of drinking, during which the guests took turns entertaining the group by reciting poetry, composing speeches, and engaging in other elevated and not-so-elevated activities. The presence of prostitutes (of either sex) was not unusual, nor was drunkenness. In this setting the indulgence of pleasure was a more common social value than its restraint.

ROME

BY BRADLEY SKEEN

Roman social ideals were shaped during the city's early history as Romans came in contact with more sophisticated cultures. The early influence of Etruscan civilization ensured that within the household the two sexes would live in close contact, that couples would always dine together, and that women could move about more or less freely in public. Thus, there was more equality between the sexes in Roman society than in many other Mediterranean cultures. Nevertheless, gender roles in the Roman world were largely the creation of aristocratic men and are known to us through their writings.

We rarely hear women or other classes speak for themselves, though there is little reason to think that they did not embrace the social ideals of the male aristocracy.

In the early days of Rome gender roles were determined by the structure of the family. The father had absolute control (*patria potestas*) over the entire household, including his children, slaves, and other dependents; *patria potestas* gave the father even the power of life and death. This rule was less absolute with regard to the wife, who in some respects was an outsider in the family. Marriage was considered to be an alliance between two families more than an expression of romantic love. A wife was indeed under her husband's control, but she had earlier been under her father's control. Moreover, since her father would have provided her with a dowry (a substantial gift of property that was usually paid in cash in later times), she could, if the marriage became intolerable, retreat from it back to the control of her father, taking the dowry with her. (Later she could simply divorce.) In practice, however, such separations rarely occurred, and the husband generally had the use of his wife's dowry throughout her lifetime and inherited it as part of his own estate at the time of her death.

The greater mass of people had only a small farm or, especially in the Imperial Period, no property at all. For them, marriage was a more informal arrangement in which a man and a woman simply decided to live together. Many slaves (at least among those whose working conditions permitted) lived in situations amounting to marriages recognized by their masters. The social roles of lower classes were self-consciously modeled on those of aristocrats to the extent possible. The secluded lives of aristocratic women, however, could not be duplicated by poor women, who were often forced to work in family shops, as peddlers, or in other businesses.

Roman aristocratic men saw themselves as active and efficient, equally skilled in the arts of peace (civil governance) and war. They viewed business—preferably working in the law courts but perhaps managing a large agricultural or industrial concern—as a necessity that distracted them from their ideal of a retirement devoted to study and literature. The vital quality of good reputation, without which a man would be humiliated in his attempts to make his way in the world, depended not so much on his own behavior as on that of his female family members—that is, on his ability to control them.

The ideal way of life for a Roman matron consisted of domestic virtues: loyalty, obedience, affability, reasonableness, attendance to religion without superstition, sobriety of attire, modest appearance, and skill in wool working (which was praiseworthy because it was old-fashioned). Any woman who had had only a single husband throughout her life (*uni-vira*) was considered fortunate. But Roman social ideology also had a vision of a woman who had fallen away from virtue. She began by drinking, which led to her taking a lover,

with whom she would plot to murder her husband. This idea expressed male fears over the loss of control. Thus, men, especially men in the public eye as politicians, felt the need to watch their women carefully. In contrast, it was very common for a politician, such as Cicero (106–43 B.C.E.), to denounce a rival on the ground that his women were out of line, even insinuating that incest went on in his household. This accusation was made not because of factual evidence but because such activity was a direct violation of accepted gender roles and would automatically incite outrage in those who heard about it. Such political maneuvering makes it very difficult to understand whether the reports of the moral degradation of the emperors and their families have any basis in fact. Such accounts are common in writings by historical authors like Suetonius (ca. 70–130 C.E.), who claims, for example, that the emperor Caligula (r. 37–41 C.E.) slept with his sisters and that Nero (r. 54–68 C.E.) slept with his mother, Agrippina the Younger.

Although Roman women were never closeted away within the house as were women in Greece, Greek customs deeply affected Roman ideas about the interaction of gender with sexuality (especially after the second century B.C.E., when Rome conquered Greece and Greeks flooded into Italy as slaves, paradoxically more sophisticated than their masters). What the Romans borrowed from the Greeks was a very different set of social roles than we usually encounter in modern Western countries. Roman men were supposed to be active, and women were expected to be passive; other considerations were secondary.

A more ambiguous situation involved male puberty, a period of masculine life marked sharply in Roman times from around age 12, when a boy would have his first haircut (the shorn hair was dedicated at a temple in a religious ceremony) and dress in adult clothes for the first time, until the physical course of puberty was completed and the beard was growing fully. According to Roman tradition, a teenage male ought to act like a man in all respects. But the influence of Greek culture on Roman society was so great that a youth could engage in love affairs with older men, as did Julius Caesar (r. 46–44 B.C.E.), without damaging his reputation excessively. More generally, Roman men could legitimately have sexual relations with their wives, with youths, or with prostitutes or slaves of either gender, without any social judgment against them for transgressing gender roles. What mattered to the masculine image was not the physical gender of the partners but maintaining the active role. Thus, a man who became known for taking the passive role in homoerotic relations would be publicly shamed as a pervert, but so would a man who was suspected of sexual subservience to women, even to his own wife.

The image of aristocratic women demanded strict fidelity to husbands, but as society became more cosmopolitan, especially in the late republic and empire (first century B.C.E. to third century C.E.), legal reforms that resulted in a high rate

of divorce liberated many women from the authority of either father or husband, granting some degree of sexual freedom. Nevertheless, the essentially passive characteristic of women's sexual lives had to be maintained. Homoerotic contact between women seems to have been extremely rare compared with such contact between men (or at least it is seldom mentioned in surviving writings); nevertheless, it is clear that in a female homosexual relationship, one of the female partners assumed an active or aggressive role that was properly seen as masculine.

THE AMERICAS

BY ARDEN DECKER

The study of gender and sexuality is key to the understanding of any culture, particularly with regard to labor practices, social status, leadership, and religion. The role of gender and sexuality differs greatly from culture to culture and across time, making it nearly impossible to identify any standard model to which all cultures adhere. Much of what is currently known about gender and sexuality in ancient America is based on archaeological evidence, particularly from burial caches and artworks. Information and evidence gathered from archaeological sites and material culture have helped scholars to begin to make deductions about the function of gender in ancient communities and provide a more complete picture of daily life.

The Paleo-Indians (ca. 13,000–ca. 8000 B.C.E.) are the earliest-known human inhabitants of the Americas. They are believed to have been hunter-gatherers. It is difficult to define any labor function or position as being conclusively identified with one gender in particular. It is generally accepted that these early societies divided labor responsibilities by sex, but these roles could shift with changes, for example, in population growth, environment, and season. Many archaeologists and anthropologists have begun to reexamine the commonly held belief that men were the hunters and women dealt only with household labor.

Women's role of childbearing often affected the amount and type of work they could perform, and individual societies would certainly have accommodated this fact. However, it would be shortsighted to assume that the activities of women in the ancient Americas were limited to the household. We must be careful not to superimpose our present-day understanding of gender roles onto civilizations that existed hundreds or thousands of years ago. In ancient cultures both men and women retained their own unique status within their respective spheres and would not have competed with each other for power or status as is done in today's society. Recent research suggests that men were not solely responsible for subsistence among the earliest cultures; women also participated in providing food by hunting small animals and birds and gathering edible plants. Both women and men would have been trained to do specialized work, such as prepar-

Spout and bridge vessel in the shape of a woman, holding what is thought to be a spindle wrapped in cloth, from the Nasca culture (200 B.C.E. to 600 C.E.) of Peru; such figures were associated with various activities of daily life. (© The Trustees of the British Museum)

ing materials for clothing and making those materials into finished products. Hunter-gatherer societies throughout the ancient Americas were primarily egalitarian, and the sexes worked together and separately for the survival and improvement of the community.

With the rise of agriculture, societies grew more sedentary and more complex, and they left us more information regarding the nature of gender and labor. As a society changed, so did its needs, leading to new types of specialized labor and requiring a fluid definition of gender-based labor division. Similarly, food production and the development of economy led to far more complex systems of dividing labor that were no longer based simply on sex but also on age and social status. Both men and women engaged in difficult physical labor, but craft production grew ever more important to developing economies. For example, in Mesoamerica pottery was a specialization practiced by both sexes, but textiles and weaving became associated primarily with women.

Although few monumental artworks from ancient America feature images of women, many figurines depicting both males and females (as well as some sexually neutral figures) have been recovered throughout Mesoamerica and North and South America. The greatest range occurs at the site of Tla-

tilco, in western Mexico, dating to the first or second century B.C.E. These ceramic figurines display the desire among early Mesoamericans to differentiate and define gender and status through costume, hairstyle, ornament, and activity.

The study of costume and ornament has greatly increased our understanding of status in the ancient Americas. Naturally, much of this information comes from later ancient cultures that were organized in a relatively stratified manner. Burial caches found throughout Mesoamerica demonstrate that ornaments buried with women and men varied according to age, sex, and social status. There are also a few exceptions to the lack of monumental images of women from the ancient period, two notable examples being the stela (a carved commemorative pillar) of a female ruler from the Olmec site of La Venta (1200–400 B.C.E.) near the central coast of Mexico and the monument of a female ruler from the central Mexican site of Chalcatzingo (900–600 B.C.E.). Although rulership and ritual may have “officially” been the purviews primarily of men, these exceptions suggest that women sometimes held positions of power. A similar example of assigning gender and status may be seen with the ceramic production of the Moche culture (1–600 C.E.) of northern Peru. A cross-section of Moche ceramic vessels demonstrates a surprising range of means for depicting gender identity and roles, particularly with regard to women. Gender is assigned not only through hairstyle, clothing, and ornament but also through social roles, as the Moches depict women as rulers, as deities, and as mothers.

All ancient American societies possessed goddesses and gods within their pantheons, and both women and men participated in ritual and ceremony. Physical evidence suggests that both sexes acted as shamans, priests, and curers and that both engaged in ritual sacrifice. Shamans were particularly important in most American cultures, serving not only as leaders but also as intermediaries between the human and spiritual realms. Thus the existence of female shamans suggests that women held at least some religious and political power. The Chavín (ca. 900–ca. 200 B.C.E.) of northern Peru were the earliest American culture known to have had women as deities and important supernatural beings, but many subsequent cultures throughout the Americas also worshipped goddesses. One extraordinary example can be seen near present-day Mexico City at the site of Teotihuacán (1–650 C.E.), where the cult of the “Great Goddess” became so prevalent that many scholars believe she was the official patron goddess of the city.

The Middle East

~ Herodotus: Excerpt from *The History* of the Persian Wars, ca. 430 B.C.E. ~

I.199: The Babylonians have one most shameful custom. Every woman born in the country must once in her life go and sit down in the precinct of Venus [Ishtar] and there consort with a stranger. Many of the wealthier sort, who are too proud to mix with the others, drive in covered carriages to the precinct, followed by a goodly train of attendants, and there take their station. But the larger number seat themselves within the holy enclosure with wreaths of string about their heads—and here there is always a great crowd, some coming and others going; lines of cord mark out paths in all directions; the women and the strangers pass along them to make their choice. A woman who has once taken her seat is not allowed to return home till one of the strangers throws a silver coin into her lap, and takes her with him beyond the holy ground. When he throws the coin, he says these words: “The goddess

Mylitta prosper you.” (Venus is called Mylitta by the Assyrians.) The silver coin may be of any size; it cannot be refused, for that is forbidden by the law, since once thrown it is sacred. The woman goes with the first man who throws her money and rejects no one. When she has gone with him and so satisfied the goddess, she returns home, and from that time forth no gift however great will prevail with her. Such of the women as are tall and beautiful are soon released, but others who are ugly have to stay a long time before they can fulfill the law. Some have waited three or four years in the precinct. A custom very much like this is found also in certain parts of the island of Cyprus.

Asia and the Pacific

~ Ban Zhao: Excerpt from Lessons for
a Woman, ca. 80 C.E. ~

THE VIEWS OF A FEMALE CONFUCIAN

I, the unworthy writer, am unsophisticated, unenlightened, and by nature unintelligent, but I am fortunate both to have received not a little favor from my scholarly Father and to have had a cultured mother and instructresses upon whom to rely for a literary education as well as for training in good manners. More than forty years have passed since at the age of fourteen I took up the dustpan and the broom in the Cao family [*the family into which she married*]. During this time with trembling heart I feared constantly that I might disgrace my parents and that I might multiply difficulties for both the women and the men of my husband's family. Day and night I was distressed in heart, but I labored without confessing weariness. Now and hereafter, however, I know how to escape from such fears.

Being careless and by nature stupid, I taught and trained my children without system. . . . I do grieve that you, my daughters, just now at the age for marriage, have not at this time had gradual training and advice, that you still have not learned the proper customs for married women. I fear that by failure in good manners in other families you will humiliate both your ancestors and your clan. I am now seriously ill, life is uncertain. As I have thought of you all in so untrained a state, I have been uneasy many a time for you. At hours of leisure I have composed . . . these instructions. . . . In order that you may have something wherewith to benefit your persons, I wish every one of you, my daughters each to write out a copy for yourself. From this time on every one of you strive to practice these lessons. . . .

HUMILITY

On the third day after the birth of a girl the ancients observed three customs: first to place the baby below the bed, second to give her a potsherd . . . with which to play, and third to announce her birth to her ancestors by an offering. Now to lay the baby below the bed plainly indicated that she is lowly and weak and should regard it as her primary duty to humble herself before others. To give her potsherds with which to play indubitably signified that she should practice labor and consider it her primary duty to be industrious. To announce her birth before her ancestors clearly meant that she ought to esteem as her primary duty the continuation of the observance of worship in the home. . . .

Let a woman modestly yield to others; let her respect others; let her put others first, herself last. Should she do something good, let her not mention it; should she do something bad, let her not deny it. Let her bear disgrace; let her even endure when others speak or do evil to her. Always let her seem to tremble and to fear. When a woman follows such maxims as these then she may be said to humble herself before others.

Let a woman retire late to bed but rise early to duties; let her not dread tasks by day or by night. Let her not refuse to perform domestic duties whether easy or difficult. That which must be done, let her finish completely, tidily, and systematically. When a woman follows such rules as these, then she may be said to be industrious.

Let a woman be correct in manner and upright in character in order to serve her husband. Let her live in purity and quietness of spirit, and attend to her own affairs. Let her love not gossip and silly laughter. Let her cleanse and purify and arrange in order the wine and the food for the offerings to the ancestors. When a woman observes such principles as these, then she may be said to continue ancestral worship.

No woman who observes these three fundamentals of life has ever had a bad reputation or has fallen into disgrace. If a woman fails to observe them, how can her name be honored; how can she but bring disgrace upon herself? . . .

WOMANLY QUALIFICATIONS

A woman ought to have four qualifications: (1) womanly virtue, (2) womanly words, (3) womanly bearing, and (4) womanly work. Now what is called womanly virtue need not be brilliant ability, exceptionally different from others. Womanly words need be neither clever in debate nor keen in conversation. Womanly appearance requires neither a pretty nor a perfect face and form. Womanly work need not be work done more skillfully than that of others.

To guard carefully her chastity, to control circumspectly her behavior, in every motion to exhibit modesty, and to model each act on the best usage, this is womanly virtue.

To choose her words with care, to avoid vulgar language, to speak at appropriate times, and nor to weary others with much conversation may be called the characteristics of womanly words.

(continued)

(continues)

To wash and scrub filth away, to keep clothes and ornaments fresh and clean, to wash the head and bathe the body regularly, and to keep the person free from disgraceful filth may be called the characteristics of womanly bearing.

With whole-hearted devotion to sew and to weave, to love not gossip and silly laughter, in cleanliness and

order to prepare the wine and food for serving guests may be called the characteristics of womanly work.

These four qualifications characterize the greatest virtue of a woman. No woman can afford to be without them. In fact, they are very easy to possess if a woman only treasures them in her heart.

Greece

~ Semonides of Amorgos: “The Types of Women,” ca. 550 B.C.E. ~

God made the mind of woman in the beginning of different qualities; for *one he fashioned like a bristly hog*, in whose house everything tumbles about in disorder, bespattered with mud, and rolls upon the ground; she, dirty, with unwashed clothes, sits and grows fat on a dungheap. *The woman like mud* is ignorant of everything, both good and bad; her only accomplishment is eating: cold though the winters be, she is too stupid to draw near the fire. *The woman made like the sea* has two minds; when she laughs and is glad, the stranger seeing her at home will give her praise—there is nothing better than this on the earth, no, nor fairer; but another day she is unbearable, not to be looked at or approached, for she is raging mad. To friend and foe she is alike implacable and odious. Thus, as the sea is often calm and innocent, a great delight to sailors in summertime, and oftentimes again is frantic, tearing along with roaring billows, so is this woman in her temper.

The woman who resembles a mare is delicate and long-haired, unfit for drudgery or toil; she would not touch the mill, or lift the sieve, or clean the house out! She bathes twice or thrice a day and anoints herself with myrrh; then she wears her hair combed out long and wavy, dressed with flowers. It follows that this woman is a rare sight to one’s guests; but to her husband she is a

curse, unless he be a tyrant who prides himself on such expensive luxuries. *The ape-like wife* has Zeus given as the greatest evil to men. Her face is most hateful. Such a woman goes through the city a laughing-stock to all the men. Short of neck, with narrow hips, withered of limb, she moves about with difficulty. O! wretched man, who weds such a woman! She knows every cunning art, just like an ape, nor is ridicule a concern to her. To no one would she do a kindness, but every day she schemes to this end—how she may work someone the greatest injury.

The man who gets *the woman like a bee* is lucky; to her alone belongs no censure; one’s household goods thrive and increase under her management; loving, with a loving spouse, she grows old, the mother of a fair and famous race. She is preeminent among all women, and a heavenly grace attends her. She cares not to sit among the women when they indulge in lascivious chatter. Such wives are the best and wisest mates Zeus grants to men. *Zeus made this supreme evil—woman*: even though she seem to be a blessing, when a man has wedded one she becomes a plague.

► government organization

INTRODUCTION

The word *government* comes from the Greek word *kybernan*, meaning “to steer.” Throughout history human communities have exhibited a natural tendency to create a system that steers people through chaos and prevents what the ancient Romans called *bellum omnium contra omnes*, or “the war of all against all.”

The earliest human communities had no real system of government as the term is understood in modern life. Early hunter-gatherers lived and traveled in small bands, and to the extent that anyone ruled, it was primarily by force. In the daily struggle for simple survival, the person in a small community who emerged as the strongest would most likely assume a leadership role. Such a person would have been able to help the community acquire valuable resources such as food, and in the event of conflict with competing tribes, the strongest, most forceful member of the community could

provide valuable military leadership. This system of government continued to exist throughout the ancient world, and indeed forms of it exist in the 21st century. Sometimes called the “force theory” of government, it led to tribal leaders and warlords who seized control over a certain area and of the people who lived in that area. Such a system existed, for example, in the ancient Americas, where warlords held power in chiefdoms.

Force and strength, though, were not the only sources of power. In some cultures, such as that of ancient Japan, shamans and other religious leaders held power. Their subjects believed that shamans possessed magical influence with the gods, so they were the rightful rulers. Similarly, in some cultures, such as the Aborigines of Australia, no formal government existed, but tribal elders held power because the community believed that these elders possessed ancient wisdom.

A repeated theme in discussions of the ancient world is the profound impact of the development of agriculture. When ancient cultures turned to agriculture rather than strictly hunting and gathering, they became what historians called “sedentary.” This word does not mean that they were lazy or inactive. It means that people, instead of moving around in search of food, settled in more or less permanent communities, where they could tend fields and livestock and cultivate crops.

In time, those small villages and hamlets grew, and the most prosperous among them evolved into towns and small cities. Agriculture allowed people to store food surpluses; they no longer had to survive day to day. This food surplus enabled communities to support classes of people who were not directly involved in food production, including a military, civil servants, poets and artists, craftsmen, and civic leaders. Thus, it is fair to say that without the development of agriculture, government and government organization would not exist—or that they would exist in only the most primitive forms.

In time, communities had to find a way to ensure some form of stability in their government. The alternative was repeated civil war, as a ruler would die and others would compete for his position. The solution was heredity, with power passed down usually from father to son, though the ancient world provides noteworthy instances of women assuming power. Further, many cultures’ history, mythology, and religious values supported the belief that rulers ruled by divine right. That is, they were thought of as holding power that came from the hands of the gods, and the rulers themselves were often looked on as either gods themselves or as intermediaries between the gods and humans.

The result of this system of government was the emergence of dynastic families, some of which ruled for hundreds of years or longer. Good examples are the dynasties of ancient Egypt and China; in fact, historians identify periods of ancient Egyptian and Chinese history by the family dynasties that ruled. A ruling dynasty would come to an end for

a number of reasons, including lack of an heir to the throne or conquest by another nation. In some civilizations, power struggles emerged when no clear heir existed, and ruling dynasties would change when, for example, a king's brother or nephew seized power.

Kingship was the dominant form of government in the ancient world, but this does not mean that the ancient world did not provide the first stirrings of democracy. While modern historians make generalizations about large nations, at the time it was difficult to extend rule over a wide geographical area. The result was the emergence of city-states. These city-states often shared a common language and culture with other nearby city-states, but they tended to be self-governing. In ancient Mesopotamia, for example, early city-states often governed themselves, and this government had some of the characteristics of a democracy, with citizens taking part in decisions that affected the community. Ancient Greece, too, consisted of a number of city-states, such as Sparta, which were often in competition and conflict with other Greek city-states. These Greek city-states, too, offered some measure of citizen government. Sometimes, for protection and trade, a handful of city-states formed a league.

Another ancient form of government organization was the oligarchy. This term refers to government by a small group, usually prominent or powerful citizens who held some interest in common. While the civilizations of ancient Europe were monarchies, they had some of the characteristics of an oligarchy, for kings remained dependent on a class of powerful land-owning nobles who supported the king with taxes and military service—but who also sometimes opposed their king when their interests demanded it.

Government and government organization necessarily became more complex as the notion of empire became more common. Ancient Rome provides a classic example. Rome began humbly as a city-state in about the ninth century B.C.E. Over the next 12 centuries, it evolved into first a monarchy ruled by a king, then into an oligarchy, and finally into a massive empire. The power of the king, and later the emperor, was restricted by various advisory and legislative bodies. The Roman Senate, for example, was a body that served in an advisory capacity to the emperor, who found it difficult to rule without the Senate's support. Over time, a large class of officials was appointed to administer the affairs of the empire. In the outlying provinces another class of officials was appointed to administer the affairs of each province.

AFRICA

BY JUSTIN CORFIELD

Ancient Africa was largely made up of kingdoms controlled by hereditary rulers. Most followed the domestication of animals, which ended the nomadic existence of many tribes and resulted in the introduction of more structured governmental systems. Although the extent of some of these entities can be ascertained from archaeological evidence, information on

how most were run comes from oral sources, so there are obvious doubts about their accuracy. However, the Greek historian Herodotus, of the fifth century B.C.E., recorded a few descriptions of kingdoms in North Africa that predated the dominance of Carthage, which was, for several centuries, the major economic and military power in North Africa. Egyptian, Persian, Greek, and Roman sources also provide some information.

CARTHAGE

The city of Carthage, founded by Phoenicians from Tyre, was initially ruled by a governor appointed by the king of Tyre. This was the same as for other Phoenician settlements such as Hadrumetum (modern-day Sousse), Utica (Bordj bou Chateur), Hippo Regius (Hippone, near Annaba/Bône) and Hippo Diarrhytus (Bizerta). Similarly, the Greeks also established colonies such as Cyrene, ruled by the Theraeans since its foundation in 630 B.C.E. At Cyrene the Greek merchants seem to have established an intermediary center of trade, which may have been controlled by a business class, with the minting of their own coins to a similar standard of those produced in Athens, Corinth, and Samos.

It appears that by the seventh century B.C.E. Carthage was ruled by hereditary kings, including Mago, who may have reigned from 550 to 530 B.C.E.; his son Hastrubal, who also reigned for about 20 years; and Hamilcar, a grandson of Mago, who ruled from about 510 to 490 B.C.E. Hanno the Navigator was the ruler who extended the size of Carthage along the coast of North Africa; it already had bases on Sicily and Sardinia. The other kings recorded are Hannibal (d. 406 B.C.E.), Himilco (r. 406–396 B.C.E.), and Mago (r. 396–375 B.C.E.).

The role of the government in Carthage included taxation and the coining of money, with the revenue expended on the defense of the city of Carthage, its hinterland, and also the lands of its allies; maintaining law and order within the city of Carthage; gaining and sustaining access to reliable supplies of food; and public works projects. All of this required a relatively complicated government structure, and it seems that Carthage had a significant aristocratic and administrative class. Because important decisions were made in the city of Carthage itself, there seems to have developed a centralized form of government whereby edicts from Carthage were transmitted to the hinterland and to the Carthaginian bases in Sicily, Malta, and other locations.

By the sixth century B.C.E. Carthage had come to be dominated by a city-based aristocratic oligarchy (government controlled by a small group). Although Roman authors such as Livy (59 B.C.E.–17 C.E.) wrote extensively about the Punic Wars between Carthage and Rome, it is clear that he knew little about how Carthage was governed. As a result, many of the descriptions come from the Greek philosopher Aristotle (384–322 B.C.E.), and hence the comparisons are largely with Greek models. It is uncertain exactly when Carthage changed from a monarchy to a republic, though the date is tradition-

ally given as 309 B.C.E. However, before then it is not clear whether all the rulers came from one family or whether they were semi-elected or indeed wholly elected by the people of Carthage or their representatives. Much of the account of the period after Aristotle comes from *The Histories* by the Greek historian Polybius (ca. 205–ca. 123 B.C.E.), who often uses the term “king” carelessly in several other contexts.

Aristotle notes in the fourth century B.C.E. that the Carthaginians operated with an unwritten constitution that was similar to that in many Greek cities. Indeed, it is clear that an oligarchy exercised total power over political decisions except in the short democratic period that followed the War of the Mercenaries in about 240–238 B.C.E. Officially Carthage was ruled through a general assembly, but it was dominated by the Senate, with several hundred members who were all elected for life, and a “Committee of Five.” Members of the Senate seem to have been co-opted to form committees that advised two annually elected judges. Military generals were also elected to hold military commands when needed. For this reason even extremely powerful and successful generals like Hannibal owed their command to the Carthaginian Senate, as shown by their recall of him in 203 B.C.E.

Because Carthage relied for most of its history on mercenaries, their rebellion and subsequent blockade of the city of Carthage itself shattered the people’s confidence in the government of the empire. Hanno the Great, a general put in command, was able to deploy an army but, after an initial victory, was defeated at Utica. This led to the appointment of Hamilcar. Hamilcar was not only an important general but also a keen politician. One of Hamilcar’s daughters married Bomilcar, then the titular ruler (or “king”) of Carthage. This gave Hamilcar not just military but also political power. According to Polybius, Hamilcar is said to have offered the troops the opportunity of choosing their general—and they elected him. This started the system by which a military monarchy could have come into existence. With the death of Bomilcar, the system of titular “king” of Carthage ended.

The uneasy relationship between the Carthaginian Senate and these generals is shown by the “Court of the Four Hundred” that tried to manage the First Punic War (264–241 B.C.E.) and was involved in ordering that four generals be crucified for their failures. As the distrust between the politicians and the generals grew, Barca (d. 229 B.C.E.) and his son Hannibal (247–183 B.C.E.) both technically held power at the behest of the Senate of Carthage. For this reason Hamilcar established a separate power base in Spain to allow him to raise money and soldiers for what would eventually lead to the Second Punic War (218–202 B.C.E.).

Hannibal’s invasion of Italy may or may not have had the support of the Senate in Carthage, though when it was successful most would have rejoiced. Some, however, were clearly enemies of the Barcid family, and it showed in their attitude to him when he was unable to capture the city of Rome. The failure of the Carthaginian Senate to send reinforcements to Hannibal during his time in Italy and to recall Hannibal in

203 B.C.E. after Publius Cornelius Scipio (later “Africanus”) landed an expeditionary force in North Africa, are two clear examples of the power of the Senate over the military. Livy implies this in his descriptions of Carthaginian Senate, probably based on recollections by a Roman based on what might have been said in Carthage.

Overall, the Carthaginian system of government was not dissimilar to that later adopted by the Roman Republic, by which powerful families could control the city but were not powerful enough to establish hereditary rule. However, it does not appear that the Carthaginians ever allowed a popular vote for positions, leading many historians to see the Punic Wars to a war between Roman democracy and Carthaginian dictatorship.

During the Third Punic War (149–146 B.C.E.), the Carthaginian government seemed to have a much more important role in the running of the city than was the case during the Second Punic War. In 203 B.C.E., when Carthage itself was under attack, the responsibility for the stockpiling of food seemed to have been held by the individual families themselves. With the final siege of Carthage, however, it was the task of the government to hoard much of the food to prevent the people from starving. It is also possible that on the first occasion, in 203 B.C.E., the threat to the city was not seen as being as serious as that which led to the final siege of the city, leading to its sacking and the total overthrow of the Carthaginian government.

NORTH AFRICA

Two of the major states in North Africa, Mauretania and Numidia, occupied what are now modern-day Morocco and Algeria. Both were ruled by kings who were nominally independent but who relied on strong alliances first with Carthage and then Rome, both being eventually annexed by the Romans.

In Numidia a kingdom was originally formed by former nomads, who before they established permanent settlements, were a confederation of various tribes, with leaders often linked by political marriages; some of the more powerful ones vied for control of the whole entity. Syphax (d. ca. 201 B.C.E.), the chief of the Masaesydes tribe, wore a diadem like a Hellenistic monarch, probably modeling his style of government on that of Alexander the Great, with allegiances formed in battle. He used Phoenician rather than Berber as the language of government. His system proved unsuccessful and was replaced by the formation of a dynastic government after the emergence of Masinissa (ca. 240–148 B.C.E.). The Greek writer Strabo records that Masinissa made “nomads into farmers and welded them into a state.” He also turned local warlords into feudal chiefs who owed their large estates, wealth, and power to Masinissa himself, who dispensed them in return for loyalty. Masinissa also saw the role of the king in the Hellenistic mould.

The structure of government in Mauretania was probably similar, though there is clearer evidence of a hereditary aris-

tocratic government than was the case in Numidia. However, while Numidia was being united politically, in Mauretania there seemed to have been far more regional autonomy, with different cities issuing their own coins inscribed in Neo-Punic, or Carthaginian, which seems to indicate a greater independence exercised by regional governors.

SAHARAN AFRICA

Beyond the areas which became parts of the Roman Empire, the system of government in the rest of Africa is much harder to define, owing to the lack of written records. A major source that discusses the people who lived in what is now Saharan Africa remains Herodotus, who described a number of the tribes in detail. However, Herodotus is unreliable because he has been shown to be wrong on other matters, and his detail is more about their customs than how they ruled or were ruled.

Herodotus begins his discussion of North and Saharan Africa after describing Persian rule over Cyrenaica and Libya. The first place in his account is Adyrmachidae in modern-day eastern Libya. It was ruled by a king whom Herodotus said had a right to “any girl who catches his fancy.” The neighboring tribe, the Gilgamae, operated from a summer capital and a winter headquarters. Other tribes in the area included the Nasamones, the Psylli, the Garamantes, the Macae, the Gindanes, and the Machlydes. Herodotus gives no description of the government of any of them except for a reference to the Psylli’s calling of a council meeting to declare war on the south wind (and whose army is alleged to have disappeared in a sandstorm), obviously an apocryphal story, but showing that some tribes had collective decision-making procedures. For most of the other tribes Herodotus describes their use of war chariots but nothing about their method of government. The Egyptians and the Romans both tried to trade in the region but tended to like to deal with other governments rather than nomadic tribes.

In the Nilotic Sudan and Ethiopia, descriptions from the ancient Egyptians, a few Roman and Greek accounts, and some archaeological work have allowed historians to gain some idea of the style of rule in that area. Certainly the governments in these regions were heavily influenced by developments in Egypt, a finding augmented by surviving inscriptions. They were based on rule by kings, in a way similar but on a less lavish scale than the Egyptian monarchy.

In Kush the government centered on a king and his royal court, who lived apart from the rest of the population. There were no fixed rules on royal descent, so it was not uncommon for older brothers and people in the maternal line to ascend to the throne. This state of affairs shows that there was possibly a regency council or similar body that made the final decision on royal succession. There were certainly established roles for the Queen Mother, the Queen Sister, various other royal personages, and many other titled office bearers. One surviving image in the Indian style of a king of Kush riding an elephant indicates that the Royal

Court included at least one Indian sculptor. The role of the government in Kush was clearly to defend the population from attack by outsiders, which included the construction of defensive walls as well as the raising of armies in time of war. The government also maintained supplies of food, which could be drawn upon in times of shortage. It was certainly an effective system, and it kept the kingdom together for nearly a thousand years.

In ancient Ethiopia there have been strong links between the kingdoms there and those in Egypt, with some evidence that the two areas were ruled by the same kings in about 2500 B.C.E., with the capital located at Napata, north of modern-day Sudan. This suggests that the governing structures that came to be used in Ethiopia would have been largely modeled on those of ancient Egypt, with hereditary rulers seen as divine or semidivine, a ruling class, a middle class of scribes and merchants, and the remainder of the “free” population and the slaves.

The origins of the kingdom of Axum are believed either to have come from or to have been very closely linked with developments in South Arabia. The language of government in Axum was Ge’ez, which used a modified South Arabian alphabet. The deities in Axum were also similar to those in South Arabia. Axum certainly had a number of women rulers, one of them perhaps being the legendary “Queen of Sheba.” Although the names of some of the kings have survived, there is little known about the nature of government. Given the size of the kingdom, there would seem to have been a number of regional governors responsible for different parts of the kingdom. This would certainly have been necessary when Axum started to occupy the lands of the Himyarites in South Arabia. Indeed, King Ezānā of Axum (r. ca. 330–ca. 356 B.C.E.) used as a part of his title “king of Saba and Salhen, Himyar and Dhu-Raydan” and also “King of the Habshat,” later adopting the title *negusa nagast* (“king of kings”). These names tend to suggest that the merger of a number of kingdoms or a merger or confederation of smaller states had taken place. As the first king in Ethiopia to accept Christianity, Ezānā was also keen to have a diplomatic alliance with Byzantium, sending a government embassy there.

Traditionally, one would expect that hereditary kings ruled African tribes, but this is largely supposition, though one based on folklore and work by early anthropologists. That the tribes had rulers and that there was wealth inequality are obvious. Archaeological work at some sites has resulted in the unearthing of the remains of large houses and also smaller ones. Objects of art with a high level of workmanship and the use of precious (and rare) metals found at some sites suggest that these were prized items of the wealthy, with the poorer people probably having wooden objects that have not survived. This has led some scholars to suggest that there might have been a small elite group that controlled the iron-making process, using it to maintain their rule over their own and even other nearby tribes.

SUB-SAHARAN AFRICA

In some parts of sub-Saharan Africa tribes operated without any predetermined rulers, with decisions reached by village elders or groups after discussions. This seems clear from linguistic evidence of non-Bantu African languages that lack many hierarchical terms used to refer to hereditary rulers. With much of the non-Bantu society operating in small villages, the decisions would be made by consensus, and the role of the government was probably fairly limited and largely confined to issues of defense and storage of grain for times of drought or famine.

Certainly, the major role of the government has long been to provide their people with protection from attack. This function is often evident in the location of villages in ancient Africa. One ancient settlement in the Hoggar region, some 1,000 miles south of Algiers, was excavated in 1926 and again in 1933. Essentially, the layout of the town was such that as many houses as possible could be protected by fortified walls. As it was in a relatively uninhabited region, it can be assumed that large bands of marauders were major potential threats. Similarly in Tichit-Walata, in the Sudan, people tended to live fortified cliff-top villages, with little access to much arable land, clearly showing that protection from attack was extremely important. Both of these examples show the origins of “government” as being essentially a way of organizing people for their own protection.

The Bantu tribes of southern Africa appear to have operated through hereditary chiefs, a form of monarchical government that developed during the first millennium C.E. The system seems to have had chiefs of tribes who ruled with the support of “headmen” of villages, who were commoners. Many of these chiefs may have had large numbers of children, and they often assimilated with commoners so that their children lost their royal status. This process left a core royal family living in the tribal headquarters, with other relatives dispersed through the population but owing their absolute loyalty, through their ancestry, to the main chief. In some ways this is similar to how many absolute monarchies existed, and some dynasties in China used this “dispersal” of members of their imperial houses as a way of controlling the empire, ensuring that the government had a level of support throughout its territory. It also served as a system that could put some constraints on unscrupulous governors and vice-roys, as there were people in many villages who had direct access to rulers in periods of gubernatorial misrule.

Another aspect of the government structure of the Bantu tribes is that they often lived in large communities and that war was common between (and even probably within) tribes. This meant that there was a clear need for a hierarchical society. Most of the evidence for the Bantu tribes during this period comes from a relatively small amount of archaeological evidence, detailed linguistic studies of the differences between the tribes, and the nature of these tribes when the first Europeans arrived in southern Africa and recorded the de-

tails of their lifestyle. The developments of the early Iron Age in Africa, such as the manufacture of iron arrowheads, were as much for protection and offense as for hunting.

In the course of archaeological work the remains of large structures are often unearthed. These appear to have been storage centers for grain or other crops in anticipation of times of hardship, and the size of these stockpiles shows that the task of gathering the grain or other foodstuffs was clearly a government responsibility rather than private hoarding. In East Africa large numbers of sites of villages have been excavated by archaeologists, and they tend to have larger huts, presumably occupied by chiefs, and other buildings that would have served as stores of grain, indicating at the least a community store if not one maintained by the “government.”

None of the many surviving cave paintings in southern Africa, in present-day Zimbabwe and South Africa, show any kings, rulers, governors, or other type of governmental authority, as is common in some imagery from elsewhere in the ancient world. In West Africa the finding of large numbers of statues at Nok has shown that a highly developed culture flourished in modern-day Nigeria in the mid- to late first millennium B.C.E. It was based on iron production, which was developed from about 500 B.C.E. The many ornaments and stone carvings from Nok, however, add little to the debate about the type of government that existed in the area. The legends of the Bantu tribes also show the increasing move to a hierarchical government that more and more regulated people’s lives. While many scholars suggest that the Bantu people were illiterate, it is also possible that there was some system of carving onto wood or records kept in a way that has not survived.

EGYPT

BY MARIAM F. AYAD

KINGSHIP IN EGYPT

At the top of the ancient Egyptian political, religious, and administrative hierarchy was an absolute ruler: the king of Upper and Lower Egypt. The king was the chief executive officer of the state, the high priest, the chief justice, and the commander in chief of the troops. There is no Egyptian word for king. Most often the king was politely referred to as “his majesty.” From the time of the Nineteenth and Twentieth Dynasties (1307–1070 B.C.E.) onward the phrase *great house* (*per-aa*) referred to both the king and his residence. It is from the Greek version of this name that the title “pharaoh” comes. The king’s name, enclosed in the royal cartouche (an oval figure designed for the purpose), was introduced by one of two titles: “King of Upper and Lower Egypt” or “Son of Re,” referring to an Egyptian god.

As the living incarnation of Horus, the falcon god and “ruler of the living,” the king was divine. In theory, the king’s divinity enabled him to act as an intermediary between the gods and humankind, whose main duties were to appease

the gods and gain favor with their cults. The king was responsible for maintaining the cult of the gods, and he did so by endowing the temple with land and granting temple estates special tax privileges and exemptions. But the king was also responsible for providing sustenance to the gods. The Egyptians believed that their gods needed everything that humans needed: food, drink, and clothes. Scenes preserved on temple walls show the king pouring drinks and consecrating offerings to the gods, who, in return, embraced, purified, suckled, and crowned him. Because the king was one of the gods, he was represented on the same scale as the gods. Because he was the mediator between the divine and human realms, the king's most important task was the maintenance of *maat* (order, justice, and harmony), for which he was solely responsible.

Visually, the king's divinity was expressed through the special costume he wore and the special insignia he carried: his crowns, the *nemes* (or striped headcloth), the long straight-edged false beard attached to his chin, a three-part pleated kilt called the *shendyt*, his crook and flail (which symbolized his role as the shepherd of his people), and a forked staff called a *was* scepter. At the king's brow was a rearing cobra, known as *uraeus* (a word derived from the Egyptian term for "rising goddess"). Shown in "her moment," the rearing cobra is ready for action. At the slightest threat, she would protectively spit her venom against the king's enemies. Because the cobra also protects the son god, this feature further asserts the king's solar connections.

Several types of headgear were worn by Egyptian kings. One, the double crown of Upper and Lower Egypt, comprised the red crown of Lower Egypt and the white crown of Upper Egypt. This crown was held in place by its distinctive frontal coil. Although some deities may be represented by one or the other of its two component crowns, human subjects could not wear them. Another, the blue crown, known in earlier literature as a "war crown," was worn on political occasions and was an adaptation of a close-fitting cap.

In addition, the king's titles and epithets also emphasized his divinity. Upon ascending to the throne, the king acquired a formal titulary, that is, a series of set titles. A monumental inscription of Thutmose I (r. ca. 1504–1492 B.C.E.) addressed to an official by the name of Turi, an "overseer of the southern hill country" (that is, Nubia, a region just south of Egypt), and similar inscriptions indicate that the palace sought to propagate the king's titulary in remote areas under Egyptian control. The text, which dates to the first year of Thutmose I's reign specifies, for example, that the king was Horus, He of the Two Ladies, the Golden Horus, the King of Upper and Lower Egypt, and the son of Re.

The royal titulary, such as the one for Thutmose I, was composed of five "names" or epithets and declared the king's political program. Dating to the time prior to the Dynastic Period and the earliest names, "Horus" related the king directly to the falcon god Horus—as did another name: his Golden Horus/Golden falcon name. By the middle of the First Dy-

nasty (2920–2770 B.C.E.), two other names were in use. One, literally "he of the sedge and the bee," is more commonly translated as King of Upper and Lower Egypt. The other was "he of the two ladies," referring to the titular goddesses of Upper and Lower Egypt, Wadjet and Nekhbet, respectively. By the Fourth Dynasty (2575–2465 B.C.E.), a fifth name was added: "son of Re." Originally worshipped in Heliopolis, Re, a solar deity, was one of the earliest solar deities. In the Old Kingdom (ca. 2575–2134 B.C.E.), he became the supreme god of the Egyptian pantheon. In addition to emphasizing the king's close association with the supreme deity, this title also declared the king's solar religious affiliation.

The Son of Re name is viewed as the Egyptians' ingenious way of reconciling their realization of the king's humanity with the official dictum of his divinity. Despite all the trappings of divinity, the Egyptians were only too aware of the king's humanity and understood that his frailty and physical limitations often prevented him from acting as the immortal, omnipresent (that is, existing everywhere), omniscient (all-knowing) being that he was supposed to be. While the title relates the king to the supreme solar deity, it also implies that the king was somewhat removed from the true essence of divinity. It has been suggested that the Egyptian theologians never considered the king himself to be divine, but rather the institution of kingship. Thus a mortal became divine on ascending the throne only through the power inherent in the office of kingship itself. A deceased king was typically referred to as *netjer-nefer*, "the perfect god."

Having an accurate set of royal titles was crucial to provincial officials who oversaw multiple activities on behalf of the king, including the presentation of offerings in the temple and the construction of new monuments. Each new monument would be dated to the king's regnal year (that is, the year he ascended to the throne) and inscribed with his full titulary.

The king's divinity was also proclaimed through temple iconography, or images and symbolic representations. A series of scenes preserved on the walls of the temple of Amun at Luxor depict the divine conception and birth of King Amenhotep III (1391–1353 B.C.E.). In one scene Amun is led to the queen's chambers. Although Amun assumes the guise of her husband Thutmose IV, the god's sweet aroma betrays him, and the queen recognizes him as the supreme god and not her mortal husband. During this conjugal visit, the queen is impregnated. Attended by deities, the queen later gives birth to the future Amenhotep III. In the next scene the goddesses Mut and Hathor nurse the child while Amun looks on. Spun after the fact, the birth cycles were depicted on temple walls after the birth took place. Representations of birth cycles are portrayed in the mortuary temple of Hatshepsut at Deir el-Bahri (ca. 1450 B.C.E.) and in several Ptolemaic and Roman temples. Birth cycles were represented after a king assumed the throne and served the political purpose of further legitimating his (or her) rule. A Middle Kingdom (2040–1640 B.C.E.) literary text relates the birth of three Fifth Dynasty

(2465–2323 B.C.E.) kings. The kings are brothers born to a priest in the cult of Re at Heliopolis and his wife, Ruddjedet. The birth is assisted by the sister goddess pair Isis and Nephtys and by the god Khnum.

The Egyptians realized that the transition of power involved a certain measure of risk that could potentially lead to turmoil. To avoid potential power struggles, a ruling king might decide to share his power with his son, the crown prince. Vested with all the trappings and power of kingship, the son would rule alongside his father as his coregent. The evidence suggests that often the older king retained more authority and prestige, while the younger ruler was sent out on more physically strenuous activities, such as leading a military expedition or traveling around the country. Typically monuments built during the joint reigns of a father and his son would bear double dates, giving the regnal year and titles of the younger king alongside those of his father. Although the more common representation of a ruling king next to his predecessor, his deceased father, was initially taken by Egyptologists to signify a period of joint reign, it is now less certain that this was the case. The new king may have chosen to be represented next to his father to legitimize his claim to the throne.

EGYPTIAN GOVERNMENT ORGANIZATION AND BUREAUCRACY

One of the earliest and most bureaucratic administrative systems known, the Egyptian government system was highly structured and hierarchical. At the head of this complex system was an official by the title of *thaty* or *chaty*, commonly translated as “vizier” or “prime minister.” For all practical purposes, the vizier was second only to the king and often served as the king’s deputy. The vizier may initially have been a member of the king’s immediate family, even a king’s son. Several viziers of the Old Kingdom bore the title of *sa-nesou*, or “king’s son.” However, this title does not necessarily reflect a blood relation to the king. Officials occasionally added on such titles to indicate a certain level of achievement or their rank at court.

In later periods of Egyptian history, the title of vizier was given to individuals who were clearly not members of the royal family. Normally, the vizier was a royal appointee. However, in times of weakened royal authority, the title could become hereditary, and a certain level of nepotism existed. For example, the Thirteenth Dynasty (ca. 1783–after 1640 B.C.E.) autobiographical inscription of the vizier Ankhu suggests that not only Ankhu but also other members of his family served as viziers under several kings.

As early as the Third Dynasty (ca. 2649–2575 B.C.E.), the vizier supervised all government departments. Perhaps because the power of the vizier rivaled the king’s, by the beginning of the New Kingdom (1550–1070 B.C.E.) the office was shared by two people. Residing in Memphis was the vizier of Lower Egypt. The vizier of Upper Egypt had his seat in several different cities.

The installation and duties of the vizier are detailed in the 18th Dynasty (1550–1307 B.C.E.) Theban Tomb of Rekhmire. Rekhmire served as vizier under Thutmose III (ca. 1479–1425 B.C.E.). One of the best-preserved texts detailing the duties of the vizier, this text commences with a formal speech given by the king, in which the office of the vizier is described as “the support of the whole land.” The king then goes on to comment on the nature of the office, asserting that “it is not sweet; it is bitter as bile.” Part of a much older tradition, such statements were probably formulaic.

This text describes Rekhmire as responsible for several different departments, including the royal treasury, the bureau for land assessment and property exchange, and the court system. For tax purposes the vizier had the additional responsibility of conducting a census of cattle, produce, and land every two years. Moreover, the text refers to Rekhmire as serving as “the ears and eyes of the sovereign.” Another epithet, which refers to Rekhmire as the “heart of [his] Lord,” may refer to his advisory role. In ancient Egyptian the heart was the seat of thought and intellect.

In addition to providing a detailed account of the government departments supervised by the vizier, the lengthy text begins with a description of the physical layout of the office of the vizier. It describes his stool, his mat, the garb that he wore, his staff, and the placement of his assistants and scribes. The text also provides an idea of the decorum observed in the vizier’s chambers. It concludes with a summation of the vizier’s duties: to dispatch envoys, district councilors, and mayors and governors; to appoint officeholders such as overseers; to hear their reports and read their records; to appoint the master of the army and review the state of fortresses; to mark boundaries for districts, garden plots, and estates; and to hear legal disputes, among numerous other duties.

The vizier was thus responsible for every aspect of civil government. One of the most prominent features of the Egyptian administrative system was the royal archives. Every transaction was recorded: wills, title deeds, census lists, conscription lists, orders, memos, tax lists, letters, journals, inventories, regulations, and trial transcripts. The office of the vizier was the main repository of the archives. The vizier was *the* tax assessor of the country. As such, he was responsible for the annual budget. In ancient Egypt the main source of income was agricultural produce. In view of the generally arid climate of Egypt, the vizier needed to monitor the levels of the Nile closely. A particularly low Nile would lead to drought and was therefore disastrous, so special preparations were in order.

One of the main objectives of the treasury was to finance royal building projects. Taxes were collected in the form of grain and stored in the royal granary. The produce collected would be used to pay officials and craftsmen and may have been used to supplement the incomes of local temples and funerary cult complexes. Payment to individuals and estates was made in kind. Individual craftsmen and artisans received bread and beer as wages. Additional tax demands were regu-

larly made whenever the need arose. Local mayors (*haty*) were responsible for the collection of these additional taxes.

Along with the treasury, other key areas of administration included the department of agriculture, the department of works, the judiciary, and the army. The title of “*imy-ra*,” or “overseer,” was used by every senior or middle-ranking official in every level of the administration. Reporting directly to the vizier were the all-important overseer of the treasury (*imy-ra per hedj*, literally “overseer of the ‘the house of silver’”) and the overseer of the royal construction works (*imy-ra kawet nesut*). During the Fourth Dynasty, the golden age of pyramid building, several viziers also held the title of overseer of the royal construction works.

A Nineteenth Dynasty inscription found in Nuri (in Nubia, a region to the south of Egypt) instructs various government officials to observe tax exemptions granted his funerary temple at Abydos. The text, which dates to the reign of Seti I (ca. 1306–1290 B.C.E.) outlines the major officials of the realm: “the vizier, magistrates, courtiers, councils of hearers, the viceroy of Kush, the commandants, the superintendents of gold, mayors of town and controllers of camps/tribes of Upper and Lower Egypt, the charioteers, the stable-chiefs, the standard bearers, every agent belonging to the king’s estate, all persons sent on mission to Kush.”

PROVINCIAL ADMINISTRATION

Administratively, Egypt was divided into 42 discrete administrative units, or provinces, known as “*nomes*” (derived from the Greek *nomos*, meaning “district,” which is a direct translation of the Egyptian term *spat*). To the ancient Egyptians, Egypt was known as “the Two Lands” in reference to Upper Egypt (the valley) and Lower Egypt (the delta). There were 22 Upper Egyptian nomes, with the first nome at Aswān being also the southernmost. The nomes were numbered sequentially northward. Memphis, the “Balance of the Two Lands,” constituted the first Lower Egyptian nome, with the 19 other nomes of Lower Egypt lying in the delta. Despite various changes, this division of Egyptian into discrete provinces survived into the Roman period.

By the Sixth Dynasty (ca. 2323–2150 B.C.E.) the Upper Egyptian nomes were grouped together into three larger administrative units. The “northern region” comprised the 16th Oryx nome to Memphis. The “middle nomes” extended from the modern city of Akhmīm to the Hare nome (that is, nomes 9 to 15). The “southern region” included the first through the eighth Upper Egyptian nomes. Abydos and Aswān seem to have maintained their administrative separateness. Little is known about Lower Egyptian nomes in the Old Kingdom. An overseer of these administrative districts (known in Egyptian as *waret*) interacted directly with the local governors.

Each province had its own governor (or “nomarch,” literally “governor of a nome”). Each nomarch was an absolute ruler in his province, running it as a miniature version of the state, with its own treasury and militia. Nomarchs were rewarded with titles and land parcels (estates) and occasionally

the right to build a tomb in the royal necropolis, the greatest of all honors. The demise of central government at the end of the Old Kingdom is sometimes attributed the increased power of the local rulers, who challenged the central authority at Memphis.

Although originally a nomarch was appointed by the king (or his deputy), during the First Intermediate Period (ca. 2134–2040 B.C.E.) the office of nomarch became hereditary. Some nomarchs sought to expand their territory through the use of military force or strategic political alliances and intermarriage. Sesostri III installed several governmental reforms that curtailed the power of the nomarchs. At the local level, authority was given to capable administrators rather than to important regional families. In ancient Egypt government administration and high office were open to capable individuals from all classes. Ideally, it was a person’s aptitude and hard work that brought him success, and it was that principle that propelled Egyptian society.

THE MIDDLE EAST

BY JAMES A. CORRICK

Ten thousand years ago the ancient Near East was home to small farming communities and nomadic tribes. No doubt, a variety of ways of governing these groups existed. A number of them were surely led by chiefs, with some being elected and some inheriting their position, while other bands were probably headed by priests or councils of elders. Their authority was limited to each these leader’s or council’s small group, numbering only a few dozen individuals on average and no more than a few hundred at the most. Over time local rule was extended to include more and more people, as first city-states, such as Uruk (beginning in the fourth century B.C.E.), Ur, and Babylon, and then larger domains, such as the Assyrian and Persian empires, rose in Mesopotamia and the rest of the ancient Near East. The cities alone had populations in the tens of thousands: Large ones like Uruk exceeded 50,000 inhabitants, and Babylon had a population of 100,000. In addition, each city controlled many thousands more in the villages surrounding it. In later periods the Assyrians and the Persians ruled over hundreds of thousands of people.

KINGSHIP IN MESOPOTAMIA

Leadership of these states generally came to rest in the hands of a single autocratic ruler, most often a king—and occasionally a queen—who was aided by a cadre of advisers and bureaucrats. The first of these monarchs appeared in the Sumerian cities of Mesopotamia, probably sometime in the late fourth millennium B.C.E. Kings may not have originally ruled the city-states of the Sumerians. Rather, the early cities may have had a form of democratic rule exercised through an assembly. This assembly appears to have been made up of two divisions, a council of elders and a congress of all free residents, both men and women. Policy was determined through debate that eventually led to consensus; in this give-and-take

the opinions of the elders carried more weight than did that of the ordinary citizen.

To carry out policy, the assembly appointed a leader known as an *en*. Originally, the *en* could be either a man or a woman. In addition to secular duties, the *en* also had religious obligations, conducting religious ceremonies and supervising temple activities as well as the working of temple lands. The power of the *en* grew with time, as did changes in the office. Women became ineligible to be the *en*; indeed, they had no place in city politics, even being banned from membership in the assembly. As the authority of the *en* grew, so did that of the assembly erode until the latter became little more than an advisory body to the *en*.

In some city-states the *en* became a king, while in others the *en* relinquished his secular duties—finding the administration of temple and city too burdensome—and turned them over to an *ensi*, or governor. The *en* thus became the high priest of the main temple. The *ensi*, meanwhile, concentrated on creating and enforcing laws, regulating commerce, maintaining city streets and buildings, collecting city taxes, and seeing to the defense of the city. Over time the powers inherent in the office may have made some of the *ensi* kings.

The kings of some city-states arrived at the throne via a third route. During the early Sumerian period a *lugal*, or “big man,” was often appointed when a city-state faced a crisis, generally the threat of attack by a neighboring state. At the end of the emergency the *lugal* was supposed to step down. However, if the crisis continued for a long time or if the *lugal* was ambitious, he might retain permanent power, thus becoming a king.

KINGS AND DIVINITY IN MESOPOTAMIA

To Mesopotamians the land and everything and everyone on it belonged to the gods and goddesses. Indeed, each city had supposedly been built by a particular god or goddess, who was the city’s patron deity. Thus, Uruk’s patron was Inanna, later known as Ishtar, who, among her other duties, was the goddess of love, while that of Nippur was Entil, god of the wind. Since each city was the property of its patron deity, Mesopotamians came to see the king as a divinely appointed administrator. Yet despite their godly connection, most Mesopotamian kings did not actually claim to be divine. The third millennium Akkadian king Naram-Sin (r. 2254–2218 B.C.E.) and Shulgi (r. 2094–2047 B.C.E.), king of Ur, were among the few that did make such a claim, as shown by the addition of the superscript *dingir*, meaning “god,” to their names.

More common was the practice of emphasizing a king’s divine ties. Thus the king was spoken of as being surrounded by an aura and of being the metaphorical son of the patron deity of his city. His connection to the divine was also represented in carved reliefs by making him appear taller than other people or, as was done in a relief of Hammurabi of Babylon (r. 1792–1750 B.C.E.), by having him stand in front of the patron deity, whose light bathed the monarch. The king was also spoken of as a reflection of the divine patron and as the king of all four quarters of the earth and the heavens.

SUCCESSION IN MESOPOTAMIA

The king had three symbols of his authority vested in him by the city’s patron deity: the crown, the scepter, and the throne. The crown represented the king’s divine connection, the scepter stood for justice, and the throne signified his dominance over the living. A new king sat upon the throne and was given the scepter to hold and the crown to wear in a ceremony designed to underscore his power. At the time of this ceremony the king might also speak of his legitimate right to be the city’s ruler. He based his claim on the fact that his ancestors had been kings before him. Still, even though a kingship was hereditary, it did not necessarily pass to a ruler’s eldest son. Instead, a younger son or even a brother might be the royal heir. Cousins and nephews generally were not in the line of succession, but some sometimes did illegally seize the throne, becoming usurpers.

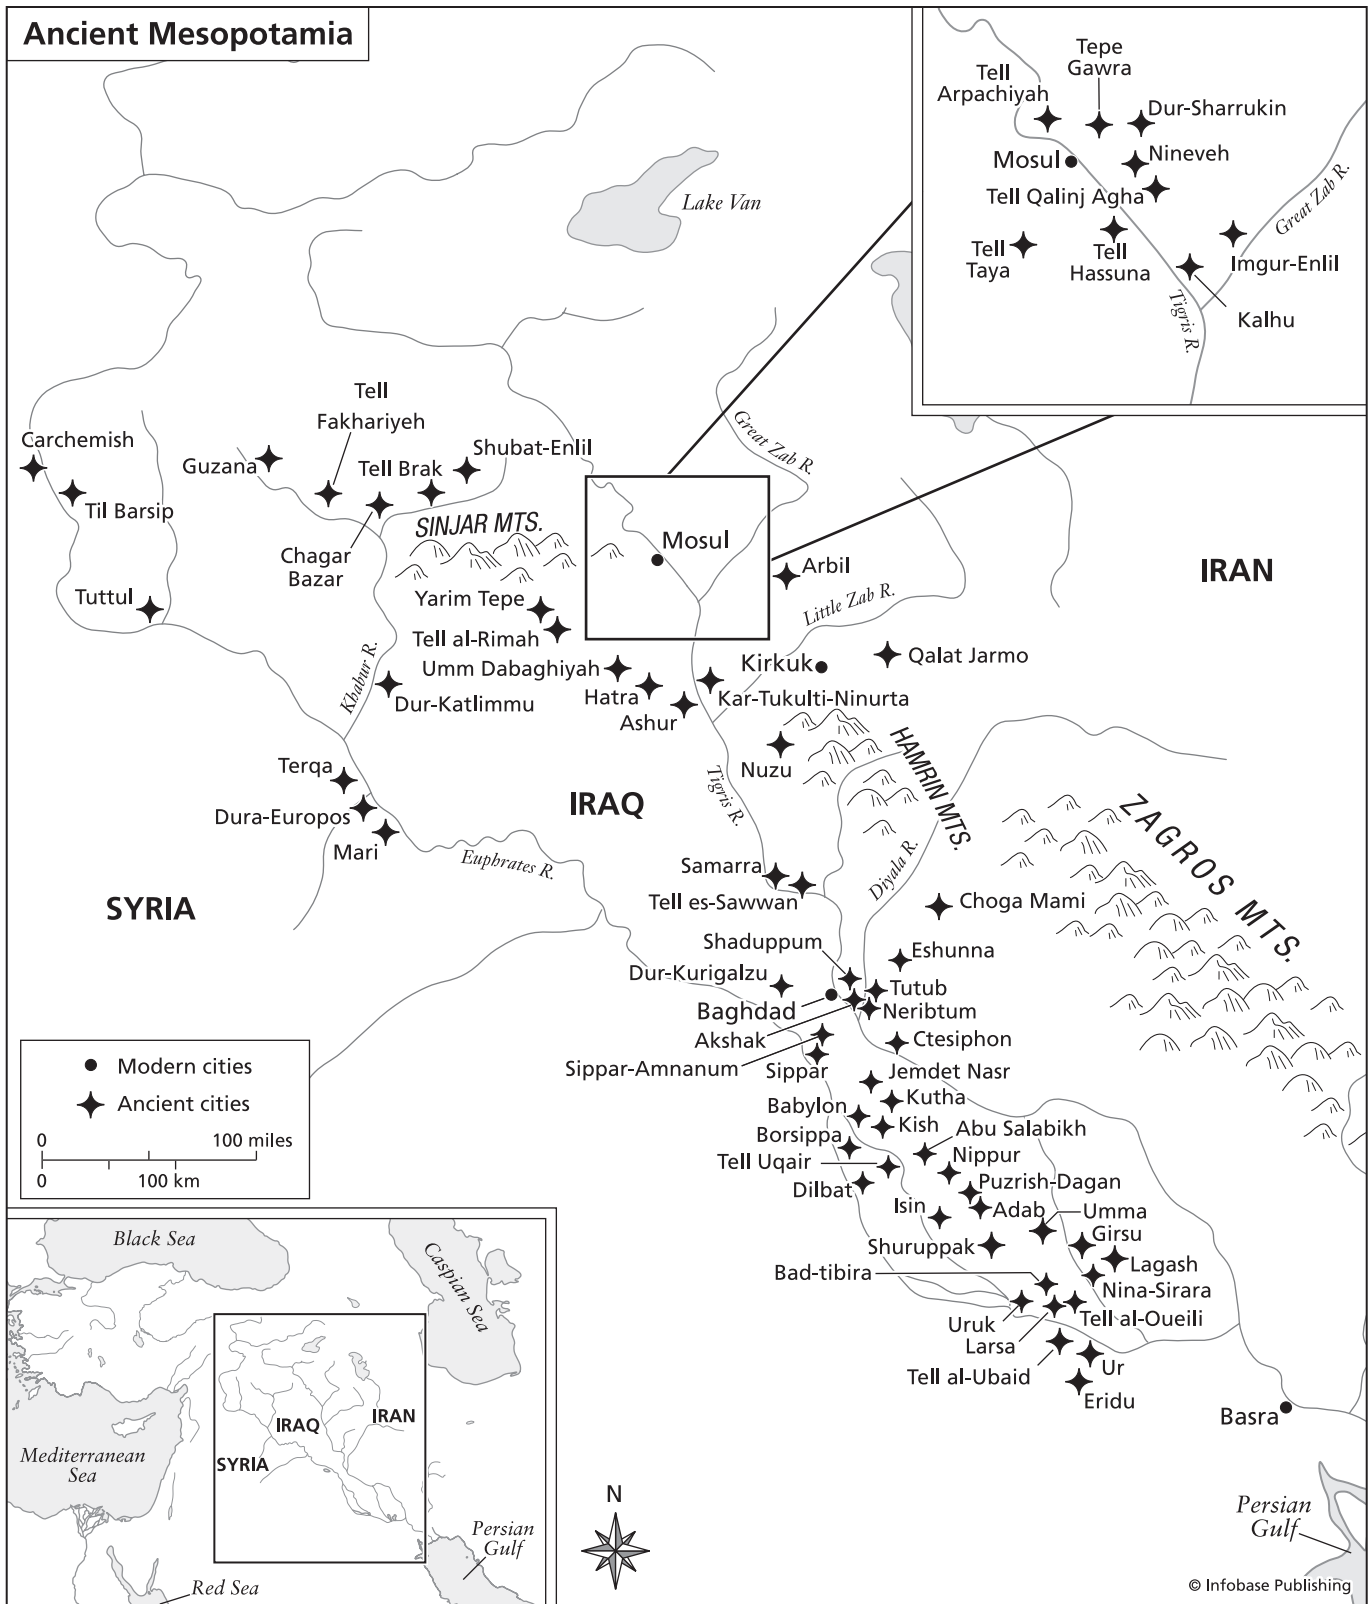

Indeed, such usurpation was not uncommon. Nor did a usurper have to be a member of the royal family. Strong, ambitious men made themselves king, particularly when the monarch they replaced was seen by the city populace as an ineffective or bungling leader. A king who was seen to have lost the favor of the gods—if, for example, famine ravaged the land or a war was lost—might face open rebellion and the loss of his throne to a usurper. A usurper normally claimed that the city’s patron deity had ordered him to become king.

Rarely did a daughter, wife, or sister inherit the throne. The queen, the king’s chief wife, generally had no real power. Even so, a strong-willed queen, or even one of the king’s other wives, occasionally exerted much influence over her husband. Further, during the rule of the Akkadian dynasty (2350–2100 B.C.E.), one of the king’s daughters often became the head priestess of the temple of Nanna, the moon god, in the city of Ur. Although the political function that the high priestess fulfilled is unclear, her installation was considered a major event, and clearly the post was considered important to the ruling monarch.

IN THE MESOPOTAMIAN PALACE

The center of the kingship, and consequently of the government, was the palace. Here, the king had his and his family’s living quarters. That family was often extensive and included not only his many wives, concubines, and children but also brothers, cousins, uncles, and nephews. Sometimes members of the royal family, particularly the royal heir, had their own, smaller palaces.

Also living and working in the palace, though separated from the royal living quarters, was the king’s staff. Many of these people were household servants, but also present were scribes, whose ability to read and write made them the clerks, secretaries, and accountants of the king. The scribes were thus the record keepers, among whose chief duty was keeping track of tax collection. They also composed tributes promoting the king’s character and achievements and made copies of myths, hymns, and epics, which often glorified the king’s ancestors and their relations to the gods.

Settlements and their accompanying governmental organizations in the ancient Middle East were heavily concentrated in the basin of the Euphrates and Tigris rivers.

BEING A MESOPOTAMIAN KING

The king's duties were many. In times of peace he had to see to the administration of the city, the dispensation of justice, the reception of ambassadors from other states, the collection of taxes, and the construction and maintenance of public buildings and irrigation canals. In times of war he had to ensure that the army was prepared for defending the city and for campaigning against the enemy. Additionally, he had religious obligations, overseeing the main temple and participating in religious rites.

To help him, the king had a host of aides, many of whom also lived in the palace. Among the foremost officials were a chief adviser and a chamberlain, or chief of staff. The former aided the king in formulating policy and in handling diplomatic missions from other states, while the latter supervised the operations of the large palace staff. In addition to the chief adviser and the chamberlain, the king was also served by a commander in chief of the army, along with an officer corps, and the head priest and the rest of the priestly hierarchy of the city's main temple. None of these officials had any more authority than that the king chose to give him. Some kings left much of the mundane details of governing in the hands of his staff, while others did not. Hammurabi, for instance, insisted on receiving exhaustive daily reports, particularly those relating to the collection of taxes. Perhaps such intimate involvement in government affairs led some kings to be given the title of "accountant."

On the whole, however, most kings contented themselves with the larger issues of policy and to some extent the implementation of that policy. In making decisions, kings took into account practical matters, such as the need to feed their sizable urban populations, the advisability of extending the all-important irrigation system that fed water to cropland, and the state of commercial relations with neighboring cities.

One other important factor played a role in royal decision making: the reading of omens. A good omen acted as a stamp of approval of royal action. However, a bad omen, such as a mongoose running underneath the king's chariot, could cause a monarch to change his policy completely or to have to endure a purification ritual. Among the later Assyrian kings, who kept a stable of 16 astrologers to read the signs, ill omens caused the monarch to fast for several days and, then clad in a white robe, spend more days confined to a small reed hut, a typical practice for isolating the sick.

The reading of omens was also used to protect the king. Royal activities and events would be postponed and audiences with the king cancelled if the omens predicted injury to the monarch. If the omens foretold the possible death of the ruler, a temporary substitute king took his place. While the real king hid, the substitute lived in the palace, wore the king's robes, and even had an appointed queen. In this way the real king hoped that the substitute would be the one to die. If the ill-omened time passed without harm to the substitute, he was then killed.

THE AKKADIAN STATE

Throughout the fourth and much of the third millennium B.C.E. Mesopotamian city-states were small enough for the entire administration to be located within or close to the palace. However, when the Sargon the Great (r. 2334–2279 B.C.E.) conquered Mesopotamia and other surrounding territories and created the first large unified state in the ancient Near East, there was no way that the Akkadian kings could directly control the affairs of all the city-states in their realm from their capital of Agade. Instead, they left local administration in the hands of the original family, which had ruled prior to conquest; if such families could not be trusted or proved disloyal, the Akkadians appointed a governor to administer the conquered city. Orders from the Akkadian king were passed by the bureaucrats in Agade to these governors. How tight the control from the Akkadian capital was is debatable, but governors, particularly those most distant from Agade, may have been free to act with a fair degree of freedom as long as the king received his annual tribute.

OUTSIDE MESOPOTAMIA

In general, other ancient Near Eastern states had governmental organizations similar to that found in Mesopotamia. Kings, such as the Israelite monarchs David and Solomon, ruled single city-states or more extensive domains, though the latter were generally more modest than that of the Akkadians. In like manner to the Mesopotamian kings, other Near Eastern rulers were served by advisers and staffs of scribes acting as clerks, secretaries, and accountants. To what extent these other realms were influenced by Mesopotamian governmental practices and to what extent these states reinvented Mesopotamian forms are not known. Only among the Phoenicians were matters different. Although the Phoenician city-states were originally headed by kings, they eventually came to be governed by councils made up of wealthy merchants. The bureaucracy below them, however, was the same as those found in other ancient Near Eastern domains.

ASSYRIA

All of these ancient states would eventually come under the rule of the Assyrian Empire (1000–626 B.C.E.). Twelve hundred years after the time of Sargon of Akkad, the Assyrians followed something of the same governing pattern as the Akkadian state, although with more complexity. The Assyrians ruled from a central state, located in northern Mesopotamia and made up of four cities, Ashur, Kalhu (modern-day Nimrud), Nineveh, and Arbela (modern-day Erbil). These four cities were favored in that they were exempt from taxation and their citizens could not be drafted into the army. The remainder of the empire was divided into provinces. Each province was further split into districts, which were centered on a city or a large town.

The Assyrian capital, which at different times was Ashur, Kalhu, or Nineveh, was the home of the king. Even more than previous Mesopotamian kings, the Assyrian monarch was the

absolute ruler of the state; indeed, it could be said that he *was* the state, since no one was allowed to question his decisions. His power came from Assur, the chief Assyrian god, though the king made no claims to be a god himself. Absolute the Assyrian king might be, but he still required aid in running an empire that contained much of the ancient Near East. The central Assyrian state was governed by the crown prince, and each province was administered by a governor and each district by a district chief. Both governors and district chiefs were Assyrians appointed by the king. Most governors were military men and often took part in campaigns to capture new territory or to suppress rebellions. To supervise a province in the governor's absence, there probably was a lieutenant governor.

The king also had his advisers. His chief source of advice came from a council made up of high-ranking army officers, some of whom were also provincial governors. The chief advisor was the *turtanu*, that is, the commander in chief of the army. Swift communication was essential in order for the king to maintain his control and to spread his orders throughout the empire. Consequently, he was served by a corps of mounted messengers. Riding the royal roads, the main highways of the empire, messengers changed mounts at posts every 20 to 30 miles, thus efficiently tying the empire together. Swift communication helped not only in spreading royal commands but also in stopping the occasional rebellion. Troops from the central Assyrian state or other provinces could be ordered relatively quickly to the trouble spot.

Once a rebellion was put down and its leaders tortured and executed, the Assyrian king might order some of the rebellious population's merchants, craftspeople, and aristocrats relocated as a further punishment. Such deportees found themselves far from home and surrounded by strangers. The threat of gruesome death and lifelong exile did not end rebellion, but they made such uprisings less likely.

ACHAEMENID PERSIA

Half a century after the collapse of the Assyrian state, in the middle of the sixth century B.C.E., a new empire, the Achaemenid Persian (538–331 B.C.E.), arose. For the next two centuries the Achaemenids would govern a territory considerably larger than Assyria, encompassing not only the entirety of the ancient Near East, including upper Egypt, but also the regions that are now Iran, Afghanistan, parts of Central Asia, and Pakistan as far east as the Indus River valley. The Achaemenids were hereditary kings, and like their Assyrian predecessors, they claimed absolute authority over their realm. Since the king was the representative of the Iranian god and creator of the world Ahura Mazda, the Persian monarch also claimed that he had the divine right to rule the entire world. The Achaemenids thus took the titles Great King and King of Kings to differentiate themselves from other rulers.

To emphasize the king's authority, he wore a long-sleeved purple robe embroidered in gold and much gold jewelry, including on occasion a golden crown. Four pillars supported his throne, which sat beneath a purple canopy, and he walked through his palace on purple carpets that no one else could use.

Despite his claim of absolute power, the king was expected to seek the advice of important officials and members of the aristocracy, particularly since no one person could have governed a state the size of the Persian Empire without advice and help. The king, however, did not have to heed advice if it conflicted with his own desires. The chief Persian official beneath the king was the *hazarapatish* ("commander of a thousand"). This official, who belonged to the highest ranks of Persian nobility, was the supervisor of the palace staff and commander of the royal bodyguard. He arranged audiences with the monarch and personally delivered messages to the king.

The *hazarapatish*, along with other palace officials, aided the king in administering the various conquered territories of the empire. From the beginning the Achaemenid tolerated a fair amount of local rule in conquered territories. Indeed, initially, the founder of the empire, Cyrus II (r. ca. 538–ca. 529 B.C.E.), known as the Great, did not appoint Persians as governors of the empire's various conquered states. Instead, he chose those native to each region. Darius I (r. 522–486 B.C.E.), however, revamped Cyrus's system. He wanted to make the overall governing of the empire more unified and to emphasize the dominance of Persia. For this reason Darius divided the empire into 20 provinces, known as satrapies. Persia itself was not a satrapy; only conquered territories were.

Each satrapy included a number of former states and a diversity of ethnic groups. Thus the satrap of Abarnahara ("beyond the river," referring to the Euphrates) included all of Syrio-Palestine with its Phoenician cities and Jewish states along with the island of Cyprus. The capital of this satrap was probably Damascus. Except for Persia, which was under the direct rule of the king, each satrapy was administered by a governor, or satrap, who was always a Persian. This governor was rewarded for his service with rich lands and a palace in the satrapal capital. Both the satrap and his holdings were a visible reminder that the Persians had ultimate authority in the empire.

Below the satrap, government continued to be mostly in the hands of local rulers, generally, like the satraps, appointed by the Persian king. Merchant councils continued to oversee the Phoenician cities along the Mediterranean, and tyrants still ruled the Greek cities in Asia Minor. These local rulers even enjoyed some degree of autonomy. The chief duties of the satrap and of the local authorities below him were to implement royal decrees, keep order, and collect the annual tribute, which was then sent to Persia. Only Persia itself was exempt from this taxation, one of its privileges of not being a satrapy.

In order to collect the tribute and to keep order, the satrap had the help of a garrison of Persian soldiers. However, he did not have command of this military unit. Instead, it answered only to its commanding officer, who in turn was responsible only to the king. It was the king rather than the satrap who appointed this military chief. This division of power was meant to lessen the risk that an ambitious satrap would use the forces at his disposal to set himself up as an independent ruler. At least one satrap during the reign of Darius was killed by Persian soldiers on the orders of the king when he was suspected of treason.

There were further safeguards to check the ambition of satraps. First, like the chief military officer, the treasurer and secretary of each satrapy were appointees of the king and were not subject to orders from the satrap. Second, the king had a corps of inspectors, known as the king's eyes and ears, who roamed the empire examining tax records, interrogating both members of satrap staffs and the general public, and making regular reports to the king. None of these measures completely stopped rebellion, and the final safeguard was to get word to Persia as quickly as possible when trouble broke out. The Persian kings had a series of signal fires placed on the top of hills. When a fire was lit, it was visible to the next station, which would then light its own fire and so on in a string that led to a Persian military outpost.

For more detailed information and orders the Persians, like the Assyrians, had a corps of mounted messengers. By changing horses every 15 miles along the excellent road system maintained by the empire, a courier could average 250 miles a day. The 1,500-mile trip from the western Asia Minor city of Sardis in Lydia to Susa, an important administrative center in southwestern Iran, normally took three months. The king's messengers made it in seven days.

AFTER PERSIA

Despite these safeguards, by the time that Alexander the Great (r. 336–323 B.C.E.) conquered the Persian Empire, many satrapies had shaken off much of the Great King's control and were operating virtually as independent states. Establishing himself if not in name at least in practice as the successor to the Achaemenid, Alexander kept most of the Persian governmental organization, particularly the satrapy divisions and much of the protocol that surrounded the Persian ruler.

After Alexander's death a series of large kingdoms—the Seleucid (311–140 B.C.E.), the Parthian (250 B.C.E.–226 C.E.), and the Sasanian (224–651 C.E.)—ruled large sections of the old Achaemenid lands, most notably the Persian heartland and Mesopotamia. These realms retained much of the Persian governmental organization, though the Seleucid added some Greek elements and eliminated the division of authority in the satrapies by giving the satrap both civil and military power. The Sassanians even revived the title of Great King. Meanwhile, Syrio-Palestine came under the rule of Rome in the last century B.C.E. Cut up into several provinces, this part of the ancient Near East would remain under Roman and later Byzantine control until the Muslim conquest in the seventh century of the Common Era.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

CHINA

The first government recorded in Chinese historical records was that of the Xia Dynasty, a Bronze Age kingdom that existed from approximately 2205 to 1500 B.C.E. The Xia, like the

mythical kingdoms that were said to precede them, had hereditary monarchs, with members of a single family controlling the entire country. China's first legal codes were written during this time, defining crimes and creating punishments for them. The Xia Dynasty was said to have ended when the last king, the corrupt Jie, was overthrown by the Shang people.

The Shang Dynasty (1500–1045 B.C.E.) is the first dynasty for which there is historical information, though historians know little about it. During this period rulers appear to have been hereditary kings who were also considered gods and spiritual leaders. Kings performed divinations with oracle bones (bones used to determine the wishes of spirits and dead ancestors) and led rituals as part of their state duties. They believed that keeping the gods happy was an essential part of maintaining a healthy state. The rulers lived in cities that were centers of government and court life. The Shang territory encompassed a small portion of modern China's territory around the Yangtze River. Outside the capital cities the countryside was divided into territories under the control of nobles. Common people raised crops, livestock, and silkworms, which they used to pay tribute to their local nobles. The local lords maintained armies within their territories in order to render military aid to the kings. Kings controlled the armies, which were often deployed to fight neighboring kingdoms and nomadic barbarians. The Shang Dynasty ended after its army lost a war with the Zhou people, who had invaded from the west, and the king committed suicide. The survivors of the ruling family changed their name to Yin and went to work as administrators in the Zhou Dynasty.

The Zhou Dynasty (1045–256 B.C.E.) was the longest of China's dynasties. It is divided into two portions, the Western Zhou (1045–771 B.C.E.) and the Eastern Zhou (770–256 B.C.E.). It was founded by hereditary monarchs of the Ji family, who justified their power by claiming that the gods gave them the right to govern. They also claimed that if a king was dethroned, it was a sign that the gods no longer wanted him in power. The government was organized into a group of city-states that each had its own local government. Each territory was ruled by a hereditary nobleman, or duke. Within territories, each duke's land was divided into nine equal portions arranged in a square; the commoners worked all the land, but the produce of the center square belonged to the duke. This was called the well-field system. In return, the dukes were expected to pray to the gods and ancestors to ensure that the entire territory had a good harvest.

Initially, the Zhou Dynasty had no real central government. Each duke paid tribute to the king out of loyalty, but the king did not directly control dukes or their territories. As the dynasty progressed, the central government became stronger and implemented a uniform scheme of taxation on crops. The system resembled the feudal system of medieval Europe, with warlords protecting and taxing their local residents and in turn giving tribute and aid to the monarch.

In the late 700s B.C.E. western barbarians sacked the capital city, so the king moved the capital to Luoyang in Henan

Province. The first half of this period, the Eastern Zhou, is called the Spring and Autumn Period (722–481 B.C.E.). During this time the central government lost the power it had gained during the Western Zhou period. Smaller city-states led by dukes began acting on their own again, going to war with one another and annexing weaker neighbors. Dukes had the power to collect their own taxes and raise armies. Several powerful states emerged; the most important were Qin, Jin, Qi, and Chu. Eventually, the overlords of these states stopped recognizing the nominal authority of the king and instead concentrated on running their own states and local administrations. The overlords promised military aid to smaller neighboring states and gradually ended up annexing most of their smaller neighbors. These states appointed officials who handled internal administration, particularly the taxation of territories.

During the fourth and third centuries B.C.E. seven strong states emerged as major powers: Qi, Chu, Yan, Han, Zhao, Wei, and Qin. Their leaders began to call themselves kings instead of dukes, declaring themselves equal to the Zhou king. This period, called the Warring States Period, saw endless conflict between the seven major states. Rulers built walls around their kingdoms to keep out invaders. States formed alliances with one another in the hope of defeating common enemies. The overlords of this period carried out various reforms to strengthen their governments. The state of Qin did away with the older feudal system by getting rid of hereditary ranks. It abolished the well-field system and legalized private land ownership. It created counties to replace the feudal land-management practices that had accompanied the well-field systems; counties answered to the state government instead of to hereditary feudal lords. This new stronger government was able to organize large-scale agriculture and irrigation projects. By the end of this period the state of Qin had emerged as the most powerful of the states and the house of Zhou was nearly extinct. From 230 to 221 B.C.E. Qin marched through the other six states, conquering them one by one. By 221 Qin was in control of all China.

The Qin Dynasty was short-lived, lasting from 221 until 207 B.C.E., but it left a lasting impression on Chinese government; for the next two millennia China followed the pattern of rule set up during this time. The ruler Qin Shi Huang turned China into a true empire. He set up a centralized government with uniform laws and procedures, specific weights and measures, standardized road widths and axle sizes, and unified coinage. He organized the empire into 36 prefectures, each of which was further divided into counties. Each prefecture had both a civil and a military governor. Counties were likewise ruled by a pair of magistrates, a civil one and a military one. County magistrates owed allegiance to their prefectural governors.

Qin Shi Huang even defined the types of philosophy that were acceptable. He embraced the school of thought known as legalism, which taught that laws must be clearly written and uniformly enforced. Legalism taught that rulers must ensure that others do not take control of the state away from them. Qin Shi Huang took this advice to heart, to the extent that

many people, particularly former ruling nobles, considered him a ruthless tyrant and hated him. He had a very hands-on governing style and did not tolerate criticism or rivals. He banished critical Confucian scholars, burned Confucian books, forced his former enemies to deliver their weapons to the capital city, and destroyed most of the defensive walls that his rival states had built during the Warring States Period; the ones on the northern border he kept and connected together to fend off northern barbarians. He set up a system of national conscription to keep his own army filled with soldiers; conscripts were also forced to work as laborers on projects such as the Great Wall and his mausoleum. He made several trips around the country to inspect conditions with his own eyes. When Qin Shi Huang died, his son lost control of the kingdom, the disgruntled nobles of the other six states began fighting again for several years, and people of all social levels rose up against their rulers.

The Han Dynasty (202 B.C.E.–220 C.E.) restored order and prosperity to the empire. The dynasty's founders, the Liu family, immediately went to work to reclaim control of China and to restore the people's faith in their rulers. They renounced legalism and its harsh controls and replaced it with Confucianism as the state philosophy. Confucian scholars were allowed to return, and criticism of the government was no longer punished harshly. Confucianism taught that the king should be the calm and virtuous center of the kingdom; if the king was stable, the whole kingdom should run smoothly. Confucianism encouraged the king to do as little as possible, in contrast to the micromanagement of legalist rulers. Confucianism also encouraged promotion based on merit; an ideal king was supposed to pass down the throne to the most qualified of his sons, not the oldest.

The Han reduced taxes, got rid of the harsher Qin laws, and removed some of the restrictions the Qin had placed on individual speech and actions. The Han did not entirely end conscripted labor, but they did not require nearly as much of the people as the Qin had. They kept most of the governmental institutions implemented by Qin Shi Huang, but they gave up some central control and allowed vassal states to govern themselves to a greater extent. The emperor himself maintained control of much of China, including the region around the capital city, which continued to be governed by the Qin system of governors and magistrates.

The region directly around the capital was run by three governors, called the Three Guardians. The central government was headed by one or two chancellors, several dukes, and a board of secretaries that handled administrative matters. Law enforcement and the running of the imperial household were delegated to a chamberlain and the Nine Courts. The army was divided into several branches, each headed by a general; a single general in chief was in charge of them all. The general in chief gained increasing influence with the emperor as the Han Dynasty progressed.

Outlying states were given to the princes of the imperial family; these states were run as vassal states of the emperor.

Princes were given the power to create nobles within these territories and were allowed to pass their titles and lands to their own sons. They owed allegiance to the emperor, but the emperor did not interfere with their local operations. In order to keep track of local government activities, the emperor created regional inspectors who, along with governors, monitored magistrates and princes.

The Han returned control of property to private landowners and then taxed them based on the size of their holdings rather than on the crops they produced from year to year. Initially, many families owned their own small farms. In bad years small farmers had difficulty paying their taxes, and most of them ended up selling their land to larger landowners and working for them as virtual slaves; gradually this resulted in the growth of a separate class of wealthy landowners. This problem was exacerbated by ever-increasing taxes, as the emperor and landlords both tried to raise money from the land. Landlords were supposed to provide their peasants protection from various hazards in return for the peasants' labor in their fields. The Han government had to put down periodic rebellions by peasants frustrated with their meager existence.

The Han government is credited with creating China's civil service system. The government required many officials to run its various levels. Initially, civil service officials received their jobs through recommendations and family connections. The most famous Han emperor, Wu Ti, remembered for his efforts to make China into a true Confucian state built on education, personal talent, and loyalty, is also known for his reforms to the civil service system. To reduce the threat from nobles who wanted to keep power in their own hands, he created an administration where positions were awarded based on merit, not on family. He founded a national school system designed to identify and train intelligent boys in the Confucian classics. The graduates of this school system could then take examinations that would allow them to enter the large and complex civil service bureaucracy. Once in the government, officials could hold a variety of offices administering the government's many projects, including the several levels of government; inspections of local governments; taxation; unifying and minting of coins; producing iron, salt, and liquor; trade missions west along the Silk Road; building projects; building a state library; chronicling court events, and maintaining relations with neighboring peoples.

The Han Dynasty began collapsing after a large peasant rebellion. The last years of the Han were marked by rivalries within the civil bureaucracy, a massacre of the court eunuchs (castrated men used as civil servants whose loyalty was supposedly assured because they would have no sons to advance), and barbarian invasions. By 220 C.E. the Han were out of power and three major states—Shu, Wu, and Wei—vied for control of China. Government during the Three Kingdoms Period (220–263 C.E.) was based on military might. The three states spent years fighting with one another, and most government institutions fell into chaos.

The emperor Wu unified China and again brought the country under control of the Jin Dynasty, which lasted from 265 C.E. until 420 C.E. Wu set up his capital in Luoyang. Although the Jin government ostensibly claimed to have renewed the Han system of government, in fact, it created a new feudal system. It kept many of the government titles of the Han and continued to run civil service examinations, but instead of exclusively awarding positions on merit, the emperor also rewarded families who helped him. Local noble families became very influential in court matters. The emperors made their relatives into kings or princes of various territories. As under the Han, the empire was divided into regions, governed by governors and overseen by inspectors, smaller commanderies, run by governors, and small districts run by magistrates. These existed alongside the territories governed by princes and other nobles. The highest officials were the Eight Dukes, who included ministers of education, works, and a general in chief.

CENTRAL ASIA

Modern Mongolia, Siberia, and western Asia were home to various nomadic peoples. For the most part they lacked a central government. Most of them were organized into tribes led by chiefs and shamans. These leaders decided when the groups would move, where they would hunt, and which tribes they would fight. The leaders also enforced rules about marriages and funerals and organized religious ceremonies. Chiefs were hereditary; several families related to one another by marriage held power.

In 209 B.C.E. a group of nomads called the Xiongnu formed a confederation under the leadership of a man called Modu Shanyu. Historians do not know what prompted this move; some believe it was the influence of the neighboring Han Dynasty that inspired the Xiongnu to organize. Modu divided the Xiongnu territory into several portions. He kept the central portion to rule himself, setting up a capital in Longcheng, Mongolia. He called himself *chanyu*, or supreme leader. A few noble clans related by marriage to the *chanyu* shared authority with him. During the first century B.C.E. the Xiongnu had difficulty maintaining their administration and unity. The succession of the *chanyu* became a problem because it was not always feasible for the throne to go straight from a father to his eldest son, especially when the son was still young. The Xiongnu solved this problem by deciding that the throne should pass from elder brother to younger brother as well as from father to son.

The state government was not sophisticated, and it was at the head of a confederation, not a true kingdom. The Xiongnu people remained in their tribes and continued to operate as they always had at the tribal level. The *chanyu* kept control of them through force, using military domination and the distribution of gifts to make other tribes fight alongside him. Instead of organized taxation, groups that needed funds or goods raided their neighbors and took what they could. The leaders of the confederation regularly conquered neighbor-

ing tribes to the south and west. When they took a tribe or a city-state, they typically enslaved it. Local and regional government of these areas consisted mainly of exacting tributes of grain, fruits, and vegetables from agricultural peoples and taking horses, cattle, and sheep from nomads. The Xiongnu called the military leader in charge of such operations the “general in charge of slaves.”

JAPAN

Little is known about the government of Japan in ancient times. Most information on the subject comes from contemporary Chinese accounts. The first highly organized societies appeared during the Yayoi Period, approximately 300 B.C.E. to 300 C.E. During this time Japanese people built villages and grew rice. They gradually adopted the use of bronze tools and weapons. From the available evidence it appears that governments were organized entirely at the local level and that there were not strong central governments anywhere. Chinese visitors to Japan (at that time they would have sailed from Korea and visited only the island of Kyushu) reported that the nation contained about 100 different states or kingdoms, though it is likely that the visitors did not know the exact number. Local governments collected taxes. Each district had a center of trade. There was social stratification, and some people clearly had higher status than others because some were buried in better graves than others. A few people owned large areas of land, and the peasants who lived in that area farmed on their behalf and gave their landlords annual tributes of rice. Villages were organized enough to store surplus food in granaries.

The main community or tribal leaders of the time were shamans (people thought to have spiritual powers) who performed sacrifices and relayed messages between humans and gods. Little is known about how these shamans worked, though it appears that many of these leaders were women. The best account comes from a Chinese description of an important Japanese ruler of the time was the woman Himiko, a female shaman who is said to have ruled in the early third century C.E.

The kingdoms near Nara developed into the Yamato kingdom, which thrived from about 250 to 710 C.E. in central Honshu. It was ruled by “great kings” who were buried in giant mounds after they died. Rulers continued to support their power by claiming that the gods wanted them to rule; as the years went by, however, they placed more emphasis on military power. These kings controlled sizable armies that allowed them to extend their power over most of Japan and into southern Korea. This brought them into contact with Chinese culture. In peacetime, Yamato kings worked to improve local conditions, building massive irrigation systems to ensure large crops of rice. Clans who belonged to the military aristocracy handled most matters of local government, including organizing the details of building irrigation systems, gathering laborers to construct massive tomb mounds for themselves, collecting tributes of grain from their local peasants, collect-

ing any required taxes and passing them on to the kings, and organizing local military bands.

Within each clan, the oldest man was responsible for performing religious rituals to placate the family’s gods and ensure prosperity for the whole locality. These clans had hereditary chiefs who cooperated with the Yamato kings in military matters. Groups of people who shared the same occupation also played an important role in government, holding duties such as guarding the palace or supplying water to the court. The Yamato kings’ greatest effort of expansion came during the fifth century, but they soon began suffering from challenges to their authority and military setbacks that disrupted the monarchy.

INDIA

The ancient empires of India were all located in the north, around the Indus and Ganges valleys. The Indus Valley was the home of the Harappan civilization, which flourished between about 2600 and 1500 B.C.E. Harappan people lived in several large urban centers. The cities were heavily fortified and the land around them was intensively farmed and irrigated, evidence of strong rulers within the cities. Historians believe that communities were led by powerful kings. The kings initially had limited power and had to consult tribal councils before making decisions, but as the Harappan civilization progressed, the kings’ position became stronger.

Kings were believed to be responsible for maintaining spiritual order and ensuring the fertility of the soil. To accomplish this, kings performed a ritual called the Ashvamedha, or horse sacrifice, as a means of ensuring local prosperity and acquiring more territory. The king would release a horse to wander free for one year accompanied by 100 young men; if the horse entered foreign territory, the king was supposed to conquer it. After a year the horse was brought back and sacrificed.

The Ganges plain was home to numerous tribal kingdoms that transformed into 16 major kingdoms called *mahajanapadas* in the fifth century B.C.E. Each kingdom had one or two capital cities. The capital cities were heavily fortified with moats, ramparts, and brick walls. Rulers made coins for people to use as currency and regulated weights and measures. The kings controlled the area immediately surrounding their capitals. Affairs through the rest of the kingdoms were governed by local chiefs. These chiefs were expected to join their kings if he needed military assistance, but otherwise they had a good deal of autonomy.

Much of what historians know about government organization of this time comes from the Arthashastra, an instruction manual for kings written around 300 B.C.E. According to this book, an ideal king ruled a kingdom in the center of a circle of states; the close states were his natural enemies and the more distant ones his natural allies. A king’s success depended on the quality of his advisers, his provinces, his army, his finances, his fortifications, and his allies. To improve these

things, the king was instructed to build up his own fortifications, encourage trade, dig mines for metals, police the forest, improve irrigation systems to ensure regular crops, and build enclosures for elephants. Military success was a direct result of economic prosperity, so the king was to oversee all aspects of the economy, including agriculture, trade, crafts, and mining. Success also depended on a contented citizenry, so the king was to keep taxes low and burden his people as little as possible. The book describes the ideal structure of the administration, which included ministers, regional governors, priests, inspectors, and various other officers.

The king Asoka was one of the most important rulers of the Maurya Empire (ca. 321–185 B.C.E.). He ruled the central part of it himself. The rest of his territory he divided into four large provinces, each under the rule of a prince who acted as governor. The provinces themselves were subdivided into districts with their own rulers. Individual towns had local leaders, judges, and other officers. The entire system was centralized, with Asoka at the top. Rulers could be harsh, and punishments for crimes were cruel; death sentences were common. The government controlled trade and no one was allowed to travel without first registering with the government and carrying a passport.

The Gupta Dynasty ruled northern India from 240 to about 550 C.E. The structure of this empire served as a pattern for several subsequent centuries of Indian kingdoms. Gupta kings had a different philosophy from that of their predecessors. They believed that the ruler should serve his people and make their lives better. Within the kingdom, all people were classified according to caste. Most land was held by wealthy families and worked by peasants or slaves who were under their noble patrons' control; these workers were poor, but their patrons were also expected to care for them and not allow them to starve. The government provided numerous services to the people, including free hospitals that were paid for by charitable contributions from the wealthy. The government ran rest houses along highways so that travelers would have a comfortable place to stay. Punishments for crimes were reduced and people were allowed to travel freely. People were allowed to run businesses if they so chose.

The Gupta emperor lived at the center of the empire, having destroyed the governments of the kings who had lived there earlier. Royal officers administered this area directly. The edges of the empire contained several border kingdoms ruled by kings who paid tribute to the Gupta monarchs and were required to attend the imperial court. Some of these border kings had fought against the Guptas as they were establishing the empire, but they were reinstated by the emperor. Border kingdoms were not required to assist the emperor in his wars; they functioned as tributary princes but not as true vassals in the European sense. Between the border kingdoms and the central kingdom were some wilderness areas, home to tribes that were never subdued. Outside the borders of the empire lived independent kings with whom the Guptas engaged in diplomatic relations.

SOUTHEAST ASIA

Several kingdoms existed in Southeast Asia in ancient times. Most of them were heavily influenced by either India or China or both. Vietnam was colonized by Chinese people from the Qin Dynasty in 208 B.C.E. The Qin general Zhao Tuo created a country on the Red River delta called Nam Viet. For the next 1,000 years Chinese people controlled Nam Viet as a subject state. Chinese rulers decided how to use the land and native Vietnamese occasionally rebelled, but they did not gain their independence from China until 939 C.E.

The Mon people of Burma built the kingdom of Suvarnabhumi around 300 B.C.E., but little is known about that kingdom. The Pyu people came to Burma two centuries later and created several city-states that never coalesced into a central government. Powerful cities demanded tribute from less powerful ones; the most powerful city was Sri Ksetra. The rulers passed laws against crimes and punished criminals by whippings or death.

Funan was a kingdom that arose around the Mekong Delta in southern Cambodia and Vietnam sometime around 1 C.E.; at its largest extent, in the third century, it encompassed parts of Malaysia and Burma. Its capital was near modern Phnom Penh. It was run as an empire headed by a royal family; the Chinese said this family came from India. Sanskrit was the official court language, and the royal family practiced Hinduism. Citizens paid taxes to the monarchs in the form of gold, silver, pearls, and perfumed wood. The rulers built up a large commercial fleet that traded with both India and China. Provinces were allowed to continue governing themselves as long as they remained loyal to the monarch.

The Malay kingdom called Srivijaya arose on the island Sumatra around 200 C.E. Some historians believe that it took over an earlier kingdom, the small Hindu kingdom called Pan Pan. Srivijaya was led by a king who functioned mainly as a military ruler. The island was divided into smaller states that were led by their own chiefs, who were organized by the king and came to his aid when needed. This kingdom was a thalassocracy, that is, one based on dominance of the local seas—a control that did not necessarily extend into the interior of the island.

The Philippines did not develop large kingdoms during the ancient period. People lived in kin groups of about 50 families led by chiefs who settled disputes and made major decisions for the community. Within the groups people were classified as nobles, freemen, or slaves.

AUSTRALIA AND OCEANIA

The ancient people of Australia, called Aborigines, did not have a formal government. They built no cities or even smaller settlements, instead living in open camps that could easily be moved from place to place. Individuals did not own anything; possessions belonged to the group as a whole. People belonged to clans that traveled together, but groups were usually small. The only leaders in the community were tribal elders, who

created rules for social interactions, had the best memories for sources of food and water, and knew all the tribal mythology. Clans claimed territory based on sacred sites that were special to them, but territories could overlap; no clan claimed exclusive rights to any piece of land.

The islands of Oceania were separated from one another by huge distances, so they tended to function independently. Each one had its own chiefs and rituals considered essential to the well-being of the community. Chieftains gained their position through a combination of family position and skill. As populations grew, governments became more centralized as a way of regulating competition for land and ensuring that everyone could be fed. Chiefs implemented intensive agricultural systems, organizing groups of islanders to dig terraces and irrigation ditches and harvest crops. Priests and religious leaders also appeared; in many cases, the priests helped chiefs keep power by proclaiming them descendants of gods.

Eventually, many islands developed several layers of government bureaucracy, with intermediate chiefs to run regional and local settlements. Class stratification appeared, with people of lower status expected to give food and goods as tribute to their chiefs and priests. Warfare was common, especially on the more densely populated islands. Chiefs trained soldiers, led war parties, and built fortifications. Some groups engaged in cannibalism and headhunting as part of their war practices. Most islands were sufficient unto themselves, but some island groups developed semicentralized governments. In Micronesia, for example, individual islands began by governing themselves. The islanders gradually developed a more centralized system of government with the island of Yap at its center.

EUROPE

BY MICHAEL J. O'NEAL

Government organization was not as advanced in ancient Europe as it was in, for example, ancient Greece or Rome. Europe was slower to develop, primarily because civilization expanded outward to the north and west from Africa, the Middle East, and regions around the Mediterranean Sea. For much of prehistoric time Europe's population remained small and isolated until ice from the last ice age receded and Europe became habitable. Accordingly, through much of the ancient period Europe was populated by tribes and clans that had no central governing authority. Put simply, Europe took a while to catch up with much of the rest of the world in social, political, economic, and cultural development as successive waves of tribes migrated into Europe and created civilizations.

The principal form of political organization in ancient Europe was thus the tribe. In general, people lived in communities that remained isolated from one another because of geographical features such as mountains and rivers. The Alps, for example, were a formidable obstacle to contact between peoples in central Europe, and the tribes of Scandinavia remained isolated because of surrounding seas. While explor-

ers and traders made contact with other communities, it was difficult for rulers to maintain authority over a wide region. Thus, kings and chieftains who held power locally ruled the communities of ancient Europe. These kings, though, were not like the pharaohs of Egypt or the emperors of Rome, who ruled vast empires with the aid of a large bureaucracy, including administrators, census takers, tax collectors, governors, and the like. Their names are largely lost to history, and to the extent that their names are remembered, they are surrounded by legends that are difficult to verify.

In reconstructing forms of ancient government, historians have to rely on a good deal of indirect and third-party evidence. The nations of ancient Europe left little in the way of written records, so historians in many cases must make educated guesses about their governmental systems. Greek and Roman writers left behind descriptions of the societies they encountered, but these descriptions were usually biased because these writers regarded the European tribes as barbaric and uncivilized enemies to be conquered. Otherwise, some archaeological evidence in the form of inscriptions, tablets, and coins has been found. Finally, historians often work backward, starting with what they know from early medieval European life. Since medieval Europeans did not spring from nowhere, it is reasonable to conclude that their governmental structures originated hundreds of years earlier.

A good example of this form of government is provided by the Scythians. These were a people who occupied the Pontic-Caspian steppes, the vast treeless grasslands north of the Black Sea and extending to the east of the Caspian Sea; the area corresponds with modern-day Ukraine and parts of Russia and Kazakhstan. The term *Scythian* is a catch-all for a number of nomadic pastoral tribes that inhabited the region over a period of many centuries. Little is known about the ancient Scythians, who first appeared sometime around 1000 B.C.E., other than what was reported by Greek historians. It is known, however, that the Scythians had little in the way of a central governing authority. The political organization was that of the tribe. There were several major tribal groups. In the modern-day Poltava region was a major tribe of agricultural Scythians. Other major tribes included the Callipidae, the Alazones, and the Arotres.

Historians refer to the dominant tribe as the Royal Scythians, who occupied the lower region of the Dnieper River and the Crimea. This tribe established a dynasty of rulers. The region under their control was divided into four separate provinces. Each was ruled by a governor whose job it was to collect taxes, administer justice, ensure the equitable distribution of land, and collect tribute payments from city-states in the Pontic, a region on the Black Sea inhabited by Greeks. The Scythians had no system of coinage. The administration of the region was loosely conducted by tribal elders. In time, power came to be held by social elites, including kings and their military followers. These tribes maintained a loose federation for purposes of defense and trade, with herdsmen trading with agriculturalists for food.

THRACE

Other than ancient Greece, one of the oldest civilizations to form a central government in Europe was Thrace. The people were called the Thracians, though the region was home to a number of tribes, including not only the native Thracians but also the Edones, Bisaltes, Cicones, Bistones, and others. Thrace historically was a region that occupied modern-day Bulgaria, northeastern Greece, portions of Turkey and Serbia, and the eastern portion of the Republic of Macedonia.

Ancient Thrace provides a good example of the evolving nature of government in Europe. The Thracians were a collection of warlike tribes. These tribes had little connection with one another. Each occupied a fortified town and was ruled by a tribal leader. Over the centuries Thrace came under the domination of various other peoples, including the Greeks, the Macedonians, and the Romans. Until the arrival of the Romans in particular, “Thrace” as a government entity did not really exist. There was little in the way of an administrative structure, though coinage developed under the influence of the Greeks. Tribal rulers exercised power over the people in their tribes. Often these tribes went to war with one another, bringing one tribe under the sway of a stronger, more dominant neighbor. Because these tribes did not have settled systems of agriculture, they did not have to establish mechanisms for land allocation, the distribution of food, tax collection, and the like. The law was administered by the sword. Eventually, the Thracian tribes were driven out of the region by invading Celts. What they left behind was a region devoid of written records about day-to-day government activities.

CELTS

The history of the ancient Celts in many respects parallels that of the Thracians. Again, the terms *Celt* and *Celtic* refer not to an empire in an organized sense of the word. The Celts were essentially an ethnic group that spread throughout much of the European continent and into the British Isles. At no point in history was there a Celtic capital, though some Celtic tribes created an *oppidum*, or fortified town that served as a central hub. Nor was there a ruling dynasty or succession of kings and emperors. The Celts, much like the Thracians, consisted of scores of largely independent tribes—at least 118 distinct tribes are known—each ruled by its own minor king or chieftain. These tribal divisions were largely an accident of geography and history. Individual tribes remained isolated from one another by geographical barriers.

As a vast conglomeration of tribes, the ancient Celts had no real governmental organization. Each of the tribes was ruled by a chieftain who gained his (or her) power by force of arms, by providing access to valuable resources, or by having been elected by members of the tribe. Beneath the chieftain was a warrior aristocracy, followed by a class of freemen farmers. The names of some of these chieftains, about whom little is known, include Orgetorix, Sinorix, Dunmorix, Cartismandua (a woman), Prasutagus, Amborix, Clondicus, Luernios,

Ariamnes, and Adiatorix. The suffix *-rix* on many of these names suggests that the person was a supreme chieftain and is related to the Latin word *rex*, meaning “king.” Throughout most of continental Europe there was little sense of empire or of nation-states. Small communities of people, in many cases sharing culture and language but living independently of one another, were ruled locally. There was little in the way of administration, public works, and all the other trappings of government. Leadership was exercised by force. Alliances were forged from time to time out of mutual necessity, particularly for defense. Each tribe had more or less fixed and recognized borders.

Land was held in common and consisted of forested land, wilderness, and agricultural land. Celtic societies tend to have complicated systems of land tenure. Laws governing this tenure specified the rights and responsibilities of each land holder. Sometimes the land was worked for the benefit of the particular clan that held rights to it. Sometimes it was work in common for the benefit of the clan’s chief, the tribal ruler, or the priestly class. Land was also worked in common to benefit the old and sick. Foraging and grazing rights tended to be held in common rather than apportioned to individuals.

By the medieval period legal codes had developed in such Celtic countries as Ireland and Wales; in Ireland, the code was called the Brehon laws, from an ancient Celtic word for “judge.” In Wales, the legal code was called the Hywel Dda. These legal codes developed from ancient law codes, usually referred to by historians as common Celtic law. These codes probably dated back to the Bronze Age, certainly to the Iron Age (from about 200 B.C.E. to 100 C.E. in that part of the world). These law codes were not written down but rather were oral. Also, no single code applied in all Celtic societies. Rather, each community developed its own code based on its own local needs, though in time these codes coalesced into a common code. In general, the code was administered by Druids, members of the ancient Celtic priestly class.

In fact, Druids and the priestly class were in many instances the chief form of government organization. This group was thought to be in possession of spiritual wisdom, so Druids were placed in charge of such matters as the calendar, the scheduling of festivals, ceremonies, and religious holidays, and other matters of concern to the tribe as a whole. Tribal business was discussed and settled at yearly meetings attended by clan leaders and directed by Druids. During these assemblies the Druids settled land disputes, conducted trials for those accused of crimes, and supervised the election of chiefs and their retainers by popular vote.

THE GERMANIC TRIBES

Historians use the term *barbarian monarchy* to refer to kingship among the ancient Germanic tribes—that is, those tribes that inhabited northern Europe, including the Scandinavian countries. They use this term to distinguish the nature of the Germanic monarchy from later monarchies under the feudal

system of medieval Europe as well as the national monarchies that continue to exist in modern life.

Like the Celts, the Germans were members of a large number of tribes, some of whose names remain familiar: Angles, Saxons, Jutes, Vandals, Visigoths, Franks, Huns, and numerous others. Many of these tribes, particularly the Huns, became inveterate enemies of the Roman Empire, defeating them in battle and eventually forcing the collapse of the empire in the west. Each of these tribes was ruled by a hereditary king who had three primary functions. One was to serve as a judge during assemblies of his nobles. The second was to serve as the high priest of his tribe. The third was to serve as a commander during times of war. Outside these functions, the power of ancient Germanic kings was fairly limited. When a king died, the throne passed to his son, but when the king had more than one son, each of the sons could lay claim to the throne, often leading to co-regencies, where two sons ruled jointly. Incidentally, after the Germanic regions became Christianized, the word *kaiser* arose to refer to a king; *kaiser* is derived from the name Caesar, suggesting that later Germanic kings thought of themselves as the descendants of the Roman emperors.

The Germanic regions of ancient Europe had a more complex governmental structure than did the Celts. The foundation of the system was the clan, called the *sibbe*. Clan relationships were so important that most ancient Germans knew the names of their ancestors going back at least seven generations. A typical *sibbe* consisted of about 10 families, including members of both the father's and mother's families, and sometimes even slaves. The English word *sibling*, referring to a brother or sister, derives from this Germanic word. Typically, *sibben* were formed by the noblest families. Not every family formed a separate *sibbe*, but rather many joined the *sibben* of more influential families.

Several *sibben*, then, composed the tribe, and each tribe had its own king. Sometimes coalition tribes formed for mutual protection and benefit, and the king of the most powerful tribe led the coalition. Each tribe exercised control over its own province, which was divided into districts called *gauen*. A *gau*, analogous to a county, was ruled by an earl, who collected taxes and raised troops. Earls who governed border provinces had the additional duty of defending the border and therefore were given more rights and privileges than ordinary earls. The word used to refer to these border provinces was *mark*, a word that survives in the name of modern Denmark, which literally means "border province of the Danes." Multiple *gauen* formed a dukedom led by a duke. These nobles did not necessarily inherit their titles from their fathers. Ancient Germanic societies were meritocracies, meaning that people achieved high positions because of merit, often success in war, rather than strictly inheritance.

At the top of the governmental system was the king, who was advised by a council. Among the Anglo-Saxons, for instance, this council was called the Witenagemot, or "Meeting of the Wise." While kingship was hereditary, kings ruled with

the consent of their people and were chosen from the tribe's most important families. It was customary for the king's loyal followers to present him with gifts, including cattle, part of a harvest, or manufactured items useful in the home. Only later, during the medieval period, did this custom evolve into obligatory taxes paid to the king.

Additionally, the Germanic tribes had a *þing*, or folk assembly, which consisted of all the free people in the community, including women and often older children. (The word *þing* begins with an alphabetic symbol called the thorn, usually pronounced like the *th* in either *thick* or *though*.) Historians describe the governmental structure of the ancient Germanic tribes as a mixture of a dictatorship and a democracy. While the king during times of war and crisis was a stable ruler, endowed with far-reaching powers, he remained subject to the will of his people and the rulings of the *þing*. Vestiges of the ancient *þing* can be found in modern-day European parliaments. In Norway, for example, the parliament is called the Storting, or "Great þing," while in Denmark it is called the Folketing, or "People's þing."

The *þing* dealt primarily with judicial matters, standing in judgment when people were accused of crimes or when disputes arose between them. Additionally, the *þing* determined whether to declare war and even intervened to solve personal problems and to decide who was being truthful in a matter of importance to the tribe. The *þing* usually met on a fixed date, often shortly after a new moon or shortly before a full moon, though the body met at other times if the need arose. In the event of a dispute, the parties assembled to tell all sides of the story. Anyone, particularly influential members of the community, could speak and offer an opinion. Sometimes these assemblies became rowdy, as people who agreed with a speaker signified their agreement by stamping their feet and clanging the weapons together; the greater the noise and hubbub, the more the assembly agreed. Usually once a year larger coalitions of tribes met to discuss the state of the larger kingdom.

The Germanic tribes did not maintain standing armies. The king, with the help of his nobles, raised an army when it was necessary. This typically was not difficult. The Germanic peoples tended to be warlike, and young men were expected to be skilled in the arts of warfare and eager to join in the bloodshed. The best of these warriors became personal bodyguards for the king. The guards swore an oath that they would protect him at all costs; in turn, the king swore that he would provide for the warrior and his family. Later, the warrior was often given land in exchange for his service. Additionally, a class of warlords led military forces in battle. These warlords were elected based primarily on their bravery, giving rise to what was called the retinue system, meaning that a powerful warlord attracted around him a retinue, or gathering, of intensely loyal followers. Meanwhile, the king was always the leader of the army. A king could be deposed for not showing courage in battle. Very few Germanic kings died of natural causes; most were killed in battle.

GREECE

BY JEFFREY S. CARNES

The famous quotation from Aristotle “Man is a political animal” actually means “Man is an animal that lives in a polis”—that is, in a relatively small city that is self-governing and not subject to the control of a larger governmental entity. (*Polis* is usually translated as “city-state.”) The entire history of Greek self-government from the earliest records (ca. 1200 B.C.E.) to the time of Alexander (late fourth century B.C.E.) is the history of such poleis, over 1,000 in number and ranging in size from a few thousand inhabitants to perhaps 300,000 in Athens at the height of its power in the mid-fifth century. There must have been a tremendous variety of systems of government, the details of which are mostly lost to us, but they can be broken down into three basic types. Cities were ruled by a single individual (whether a king or a *tyrannos*, a word which did not yet have the negative connotations of “tyrant”); by a small group, either a hereditary aristocracy or an economic elite (typically called an *oligarchy*, literally “rule by the few”); or by the entire citizen body, the *demos* (democracy, a Greek invention).

THE AGE OF KINGS

Our information about Greek political systems before about 700 B.C.E. comes primarily from the epic poetry of Homer and Hesiod. These poems show us a world in which poleis are ruled by individuals known as *basileis*, or kings. There is evidence for kingship dating back to Mycenaean times (ca. 1600–1100 B.C.E.) in the form of inscriptions in the early Greek syllabic writing system known as Linear B, and since Homer’s *Iliad* (probably written down in its current form around 700 B.C.E.) was the result of a long oral tradition, we can be confident that much of the material there reflects earlier practices.

The Greek *basileus* (king) differed in many respects from the kings more familiar to us in European history. To begin with, given the relatively small size of most poleis, the area and resources controlled by even a powerful *basileus* were not large. Based on the (probably exaggerated) figures for troop strength in the *Iliad*, combined with what can be surmised about ancient population sizes, the most powerful leaders of the Homeric era ruled over kingdoms of perhaps 100,000 individuals, and most of them substantially fewer. Moreover, the power of these kings seems to have been limited both in peace and in war. The version of the Trojan War told by Homer has a Greek expeditionary force made up of several dozen *basileis*, each leading his own contingent of troops, with Agamemnon in command by virtue of having brought the largest army. He is shown using whatever force or persuasion he can to get the leaders of the coalition to follow him, but nowhere does Homer suggest that Agamemnon has absolute legal or moral authority over them. When Achilles quarrels with Agamemnon and withdraws from the war, the other Greek leaders are displeased with his action, but none questions his right to take his ships and go home.

Kings seem to have ruled with a certain degree of consent from their subjects; in both the *Iliad* and *Odyssey* they call assemblies to seek advice from other nobles. Hesiod, in his *Theogony*, explicitly values kings for their wisdom in judging and settling disputes: “In the assembly . . . wrongs are righted [by kings] with gentle persuasion”; elsewhere he speaks of bad kings as “devourers of bribes.” As Greeks’ conceptions of justice evolved, their views of the gods came to be influenced by their views of kingship, with Zeus serving as a representation of the ideal king. By the seventh century B.C.E., however, kingship was essentially unknown in Greece and was considered a form of government practiced by foreign peoples.

THE AGE OF TYRANTS

The word *tyrannos*, apparently of non-Greek origin, first appears in the mid-sixth century B.C.E. applied to Gyges, the ruler of Lydia, a non-Greek kingdom in Asia Minor. Unlike its modern derivative *tyrant*, the word was not necessarily pejorative: A tyrant was simply an individual who held sole power in the state. The *tyrannos* was in many ways similar to a king, the chief difference being that a tyrant generally possessed no hereditary claim to his position. Of course, most tyrants wished to pass on power to their descendants: Gyges, for example, after acquiring power by murdering the king, founded a dynasty that ruled Lydia for over 100 years, and he is usually referred to as a king himself despite his illegitimate acquisition of the throne.

Tyrants were a varied lot, with different reasons for coming to power and widely varying styles of rule. In the early days tyranny seems to have been a response to a change in social conditions that was driven largely by a change in warfare tactics, namely, the switch to hoplite warfare in the early seventh century. Hoplites were heavily armed foot soldiers who fought in tight formation, making the cohesiveness of the army of paramount importance. Hoplites came from neither the richest classes (who could afford to keep and train horses and therefore formed the cavalry) nor the poorest (who could not afford hoplite armor). This “middle class” naturally wanted a greater share of political power, and came into conflict with the established aristocracy. In this situation tyrants arose—paradoxically enough—as champions of the middle class. This theory, first put forward by Aristotle in his *Politics*, is confirmed for some poleis and quite plausible for others. In Athens the reforms of Solon in the 590s B.C.E. gave the lower property classes more power, and Solon specifically rejected taking on the role of tyrant—yet when these reforms proved insufficient to maintain harmony, a tyranny arose some 30 years later under Peisistratus. In Sparta, by contrast, the hoplite class was officially composed of equals and had a large share in ruling the state; this may be the reason there was never a tyranny in Sparta. At any rate, the Age of Tyrants can be seen as a necessary precondition for the creation of democracy, since it was an era in which political rights were being given to ever-increasing segments of the population.

The Age of Tyrants was an age of growing material prosperity, and many tyrants used their wealth to glorify themselves and their cities. Peisistratus and his sons (collectively known as the Peisistratids) were responsible for a major building program in Athens, for the promotion of great festivals such as the Panathenaea and City Dionysia, and possibly for the start of Athenian coinage. Polycrates, tyrant of Samos, was the patron of the lyric poets Anacreon and Ibycus, and the Sicilian tyrant Hiero supported such notable poets as Pindar, Bacchylides, and Aeschylus.

Tyrants could also be feared, and it is their reputation for capricious cruelty, discussed in particular by Plato and Aristotle, that eventually gave the word the entirely negative connotations it bears to this day. Tyranny was seen as the chance to exert unbridled power—tyrants lacked the traditional restraints that kings operated under and could do whatever they pleased. In the popular imagination this included various forms of sexual predation. In Athens, for example, the expulsion of the Peisistratid tyrants was popularly thought to have resulted from a murder committed by a citizen named Aristogiton to defend his lover Harmodius from the unwanted advances of the tyrant's brother. Still, opinion on tyrants varied greatly. Thucydides (who tells the story of Harmodius and Aristogiton) praises the Peisistratids for their good works for the city and the general mildness of their rule. Even more dramatic is the case of Periander of Corinth. He is said to have been ruthless in eliminating potential rivals, to have killed his own wife, and to have sent 300 Corcyraean youth to Lydia to be made eunuchs; yet he is routinely listed among the canonical Seven Sages of the Greek world.

ATHENIAN DEMOCRACY

Athens was not only a rich and powerful state but also a center of learning and the arts. For this reason we have far more information about the Athenian democracy than about any other ancient government. But the factors that led to the development and growth of this political system were by no means unique, so that an examination of Athenian democracy will allow us to learn much about how Greek cities faced the challenges of self-governance.

Democracy was essentially an Athenian invention, with several of its key institutions put in place by Cleisthenes, who served as archon (leader) in 508–507 B.C.E. It lasted, with various changes and two brief interruptions, for nearly 200 years, until Athens was conquered by Philip of Macedon in 322. It was, however, quite different from any modern democracy in certain key respects. First, it was a direct democracy rather than a representative one: Almost all decision making was done by the citizens of Athens, who voted in popular assemblies. There were no long-term elected officials (offices were held for one year only), nor was there a bureaucracy with offices to oversee public functions (no departments of defense or the treasury and the like). Second, the Athenian democracy deliberately excluded from participation a large proportion of the population: all noncitizens, a group that would include

slaves, women, and the many foreigners resident in Athens. Although the key concept of Athenian democracy was *isonomia*, meaning “equality under the law,” decision making rested in the hands of perhaps a quarter of the population. (It should be noted, however, that all Greek states restricted participation to citizen males.)

The reforms of Cleisthenes were designed to promote cohesion among the citizen body and to reduce the power of older aristocratic institutions. Attica (Athens and its surrounding countryside) was divided into 139 demes, or districts, which after Cleisthenes formed the most basic units of citizenship. At age 18 a young man would be enrolled by his father into his deme register, signifying his admission to full citizen status; his full name included an indication of his deme (for example, Sophocles Labdakou Koloneus: Sophocles, son of Labdakos, of the deme Colonus). This system overrode earlier aristocratic institutions based on kinship; to diminish the geographical rivalry among city, rural, and coastal demes, Cleisthenes created ten “tribes,” each composed of demes from each of the major geographic divisions.

Although the deme was the basic unit of citizenship, tribal membership lay at the heart of the most important civic institutions. The tribes were the basis for the selection of citizens for the boule, or Council, made up of 500 citizens, 50 from each tribe. Although the *ekklesia* (Assembly), composed of all men 18 or older who had been enrolled in their deme registers, was responsible for all major decisions of the city during much of the fifth century, voting on both policy matters (declarations of war, taxes, and the like) and laws, the boule had the administrative responsibility of seeing to it that these decisions were carried out. It also served as a sort of steering committee for the *ekklesia*, determining its legislative agenda: All decrees brought before the *ekklesia* had to be proposed first by the boule (though amendments could be made during the debate on the legislation). Members of the boule were male citizens over the age of 30 and served for one year (with a lifetime maximum of two terms). Each deme nominated a certain number of citizens for membership in the boule (the number varied according to the size of the deme), who were chosen by lot. Thus all citizens had not only a theoretical chance to serve in this body but also a fairly high mathematical chance of actually doing so.

During each of the 10 months of the Athenian year a different tribe supplied 50 *prytaneis*, who served as presidents or overseers of the boule during their month in office. They lived at public expense in a special building in the Agora, the city's central market and governmental area, where they were on round-the-clock duty to deal with emergencies that might arise, in which case they were empowered to call a full meeting of the boule or even the *ekklesia*. Each day a different *prytanis* was chosen by lot as chair, so that any given Athenian citizen had a reasonable chance of being, in effect, head of state for at least one day during his lifetime.

After a brief period of tyranny under the so-called Thirty Tyrants, democracy was restored to Athens in 403. In the new

government the passing of laws was reserved for a smaller body known as the “lawgivers.” The *ekklesia* met four times per month (at least by the mid-fourth century), with the first of these meetings being considered the most important, for it dealt with military matters, the grain supply, and the tenure of officeholders (who might be removed if charged with corruption or incompetence). Anyone who wished was entitled to speak, though the historical sources indicate that in practice most of those who addressed the *ekklesia* were accomplished politicians.

The extent of popular participation in the *ekklesia* is the subject of some debate. Certain procedures required a quorum of 6,000 citizens and were held in the Agora instead of the usual meeting place on the nearby Pnyx. From this we can infer that most meetings were smaller—one source claims that no regular meeting was ever attended by more than 5,000 citizens. Modern demographers estimate a citizen population for Athens of between 20,000 and 50,000, and given the difficulty of getting to the city from outlying districts as well as the need of most Athenians to work for a living, it seems likely that most citizens attended only occasionally. By the late fifth century there were inducements for them to do so: They were offered a modest amount of pay for attendance, and before meetings Scythian slaves (who served as the police force of Athens) used a red-dyed rope to herd stragglers from the Agora toward the Pnyx. This seems to have worked, for the Pnyx was enlarged twice during the fourth century, indicating growing attendance even in an era of reduced population.

Aristotle suggested that in an ideal polis citizens would have the opportunity to govern and be governed in turn. Athens met this criterion well: Counting the members of the boule, there were perhaps 1,000 officeholders at any one time. Thus, at any given moment 2 to 5 percent of the citizen body held public office, and most of whom would be replaced by new officeholders the subsequent year. The vast majority of offices were appointed by lot, the most notable exception being the office of general (*strategos*), of whom 10 were elected each year, one per tribe.

The generalship was also unusual in allowing those who held it to run for reelection, with the result that skilled politicians such as Pericles could remain in office for years. (In fact, he was elected for 15 years running). In the hands of an able politician the office of general was concerned with more than military matters: Pericles was responsible for the building of the Parthenon and for the revision of Athenian citizenship laws, and he was the de facto leader of Athens at the height of its empire. Nevertheless nothing could be accomplished in Athens without the will of the people: Pericles’ dominance of Athenian political life depended on his ability to maintain popular approval and to persuade the *ekklesia* to do what he wanted. On one occasion, at least, he failed badly and in 430 was fined by the *ekklesia* and possibly removed from office. He did not, however, suffer the fate sometimes meted out to successful public figures, that of ostracism.

The greatest strengths of Athenian democracy—its encouragement of mass participation and its insistence on direct popular sovereignty—were in some cases also its greatest flaws. The institution of ostracism involved an annual meeting of the *ekklesia*, held in the Agora to accommodate the required number of 6,000 voters. Citizens would write on a potsherd (*ostrakon*, hence “ostracism”) the name of prominent fellow citizen they wished to send into exile for 10 years. Originally designed as a check against tyranny, ostracism was used frequently in the years down to 450 and occasionally after that until 418. For critics of the democracy (and there were many, both within and outside of Athens) it stood as a symbol of the fickleness of the demos, the people.

Similarly, the emotions of the people could be easily swayed in times of crisis: Thucydides reports a vote in the *ekklesia* to put to death the citizens of Mytilene (an ally that rebelled in 427 B.C.E., during the Peloponnesian War), followed by remorse and a vote to rescind the decree on the very next day. A ship sent in pursuit of the one bearing the original order reached Mytilene just in time to prevent the mass execution. Nor was the power of the *ekklesia* subject to effective checks and balances: In 406 B.C.E. the trial of the victorious generals at the naval battle of Arginousai (for failing to rescue survivors from the water) was clearly unconstitutional, yet the generals were condemned and executed. Nevertheless, the vast majority of Athenian citizens seem to have been happy with the basics of their form of government and with the ideology of *isonomia*.

THE SPARTAN CONSTITUTION

As the implacable enemy of Athens during its democratic era (particularly in the fifth century), Sparta is generally thought of as an oligarchy. In fact, the Spartan constitution was a mixture of oligarchic, regal, and democratic elements that together represent a unique solution to the problems faced by the polis.

The Spartans traced their form of government to the legendary lawgiver Lycurgus, who was thought to have lived in the early seventh century B.C.E. (though his historical existence is subject to debate). He is said to have authored (with advice from the oracle of Apollo at Delphi) the Great Rhetra, a set of pronouncements that set out the basic principles of Spartan law. The Spartans’ favorite word to describe their system of government was *eunomia*, “good laws” (contrasted with the Athenians’ *isonomia*, “equality under the law”), emphasizing the collective excellence of the Spartan citizen body as brought about by their unique way of life.

The democratic element in Sparta appears in the process by which all Spartan men became equal citizens and in their participation in the Assembly. The Spartan state maintained a precarious hold on power over its neighbors from Messenia, who had been conquered in a series of wars in the eighth and seventh centuries; their land was taken and distributed in supposedly equal shares to all Spartan citizens. (In reality, land distribution seems to have been uneven from the begin-

ning and to have become more so over time.) In order to keep this noncitizen population (known as helots) subjugated, Spartans devoted themselves to military life to an astonishing degree. Boys were taken from their families at age seven and put under the care of a magistrate in charge of education; they spent their time engaged in military pursuits, including night raids designed to spread terror among the helot population. Boys were divided into groups of *syssitia* (“eating clubs”) who ate communal meals together; as adults, each contributed food to his eating club from his allotment of land (which was worked by helots, since citizens were barred from agricultural labor). Citizens owed primary loyalty to their *syssitia* rather than to their families, and the *syssitia* (along with tribes and *obes*, units whose composition remains uncertain) formed the basis of the Assembly, which consisted of all Spartan citizens age 30 and over.

Like the Athenian *ekklesia*, the Spartan Assembly decided the major questions of state policy and could debate only questions put to it by an independent body that determined its agenda. There were two major differences, however: In Sparta the Assembly was supposed to vote yes or no on questions, with essentially no discussion (in effect, giving them something amounting to a veto power over items on the agenda), and the agenda-setting body, the *gerousia* (literally, “the old men’s group”), was not representative of the citizenry as a whole. The 28 members of the *gerousia*, while elected by the Assembly, came from the leading families of the polis; all were over the age of 60 and served for life. In addition to setting the agenda for the Assembly, the *gerousia* heard criminal cases and, eventually, gained the power to overturn decisions of the Assembly.

Sparta also had two kings, who claimed direct lineal descent from two different legendary ancestors and were thought to be semidivine. Although they were exempt from the rigorous military training imposed on Sparta’s citizens, the kings led Spartan troops in war. Providing a check on the kings’ power was a group of five ephors, selected annually by the citizens. Each month the kings swore an oath to the ephors to uphold the city’s laws; the ephors in turn swore to support the kings. Two ephors accompanied the kings on military campaigns, and their powers of oversight included the ability to prosecute the kings before the *gerousia*. They were also responsible for supervising the system of military training and for presiding over meetings of the Assembly.

OTHER GREEK CITIES

In practice, most Greek cities before the fifth century were oligarchies, which is to say that some portion of the citizen body was excluded from full political rights. The evidence suggests a wide variety of oligarchic practice: Some cities restricted political participation on the basis of birth, others on the basis of wealth. (In most poleis wealth seems to have eventually won out as the main criterion for participation.) Cities other than Sparta had ephors and a *gerousia*; it is unclear how similar these were to their Spartan counterparts.

By the middle of the fifth century the imperial ambitions of Athens led to a spreading of democracy throughout the Greek world: Athens encouraged its allies and subject states to adopt democratic constitutions (but did not always insist on it). Sparta, while having a mixed constitution that contained democratic elements, put itself forward as the champion of oligarchic states. The great alliances that led to the Peloponnesian War (431–404 B.C.E.) were based in large part on this ideological division. Ironically, the Athenians suffered their greatest military defeat in that war at the hands of Syracuse, which was itself a democracy.

Aristotle’s claim that oligarchy was government of the rich and democracy the government of the poor has much merit, yet there were democratic elements in oligarchies and a tendency for the rich and well connected to dominate political life in democracies. The cases of Athens and Sparta can give us a glimpse of the complex strategies used in Greek poleis to distribute power and resources among their citizens.

ROME

BY AMY HACKNEY BLACKWELL AND CHRISTOPHER BLACKWELL

The fundamental organization of the Roman government depended on the distinction between two classes of citizens—patricians and plebeians. This distinction predated the early period of the kings. From what historians can tell of the earliest period of Roman history (before the fifth century B.C.E.), the patricians (Rome’s aristocracy) alone held the offices, civil and religious, that constituted the government of Rome. Over the course of Roman history, particularly between the fourth and first centuries B.C.E., the rules limiting certain offices to the patrician class became looser, but this social distinction is nevertheless important for any understanding of the branches of Roman government and how they worked.

THE MONARCHY

The earliest period of Roman history is mostly the subject of myth and legend. Romans said that kings had ruled them before the Roman Republic was established in 509 B.C.E. Information about the period of kingship comes mostly from Roman writers of the first century B.C.E. and is therefore mostly traditional, but it is possible to make a few conclusions about Roman government under the monarchy.

The office of “king” (*rex*) was an elected office, not a hereditary one; the patrician Romans would choose a new king. The kings almost certainly served as supreme military commanders and acted as the final authority in matters of judgment and interpretation of laws. Otherwise, though, the king probably shared governmental duties with the various “colleges” of priests, with the patrician Senate, and with the *Comitia Curiata*, an assembly of all the people (not the patrician class only). The important governmental concept of imperium, the authority to lead an army and the power of life and death over citizens, was first vested in the Roman kings; later, under the republic, imperium would be the possession

of elected officials and, finally, of the emperor alone. (The word *emperor* comes from the Latin word *imperium*).

THE REPUBLIC

The Roman Republic lasted from 509 B.C.E. until approximately 27 B.C.E. It began with the overthrow of the monarchy and ended with a civil war that dissolved the republic and began the period modern historians call the Roman Empire. The republic took its name from its republican form of government. The word *republic* comes from the Latin words *res publica*, which mean “public thing” or “affairs belonging to the people.” The Romans gave their government that name to contrast it with the earlier monarchy. The republic belonged to the people as a whole, and its government was elected by the people rather than being controlled by hereditary kings.

Only adult male Roman citizens could vote in elections. Rules of citizenship varied over time. At some periods both of a child’s parents had to be citizens in order for their child to be one; at other periods it was necessary only for the child’s father to be a citizen. These male citizens exercised voting power—choosing officers and approving or disapproving certain kinds of laws—through several different kinds of assemblies. The most ancient of these was the *Comitia Curiata*, whose job eventually was reduced to that of confirming the appointment of certain priests and witnessing adoptions and the execution of wills. The *Comitia Centuriata* (Centuriate Assembly) handled the election of the most senior officials and declarations of war. The *Comitia Populi Tributa* (Assembly of the People) oversaw the election of the lesser magistrates, and the *Comitia Plebis Tributa* (Assembly of the Plebs) elected the most minor magistrates and handled some of the least pressing issues of legislation.

The day-to-day governing of the city, and later the empire, of Rome was not in the hands of these assemblies, however, but in the hands of the magistrates and the Senate. The Senate was a body of 300 men, all of them wealthy but including both patricians and plebeians in their numbers. The senators were formally known as the *patres et conscripti*, the “fathers and enlisted men,” with the former being the patrician senators and the latter being the plebeian ones. After 339 B.C.E. the senators were chosen by public officials called the censors, who considered the wealth, amount of property, and (supposedly) moral character of various Roman citizens; once chosen for the Senate, service was for life unless subsequent censors decided otherwise. Being removed from the Senate by the censors was a disgrace.

The Senate met in the *Curia Hostilia* within the Roman Forum normally, but it was authorized to meet in any public place within a mile of the city, once the proper prayers had been said. The senators debated policy, speaking in order of rank. The Senate did not pass actual laws. Its votes could result in advisory decrees that it presented to the *Comitia Populi Tributa* Rome’s actual legislative body. The Senate did have certain powers, however. It had authority over the treasury, and no public money could be taken from the trea-

surey for any purpose except by decree of the Senate. In the period when Rome’s political power extended beyond the city to include provinces abroad, the Senate decided which officials would be sent to govern which provinces; it also decided which serving governors would have their terms of office extended and which would be recalled. Since governors were often engaged in military operations in their provinces or from their provinces to neighboring ones, this power over governorships amounted to the Senate’s having considerable authority over military affairs. Furthermore, the Senate had to grant permission for a governor to raise an army before going to his province and could set limits on his efforts at recruiting.

The Senate received and ratified any treaties with foreign powers. This body was also given news of any religious portents or omens and could institute special religious rituals seemingly called for by these signs. The Senate could not actually veto laws passed by the *Comitia Populi Tributa* or the *Comitia Centuriata*, but it could declare procedural errors that would render laws invalid. In the late Republican period (the second half of the second century B.C.E. and the early first century B.C.E.) the Senate did give itself a kind of supreme veto: In times of crisis the Senate could pass a *senatus consultum de republica defendenda*, a decree that established martial law and put the Senate solely in charge of the government. This was rarely done, and each *senatus consultum* was invariably controversial. By the middle of the first century B.C.E. such decrees were likely to be ignored by certain political factions or actively opposed by serving magistrates with military force.

While the Senate dealt with the public economy, military affairs, government of the provinces, and religious portents, much of the actual legislating was in the hands of the various assemblies. These groups could vote on matters introduced by magistrates but could not introduce new measures “from the floor” or make any changes to motions brought before them. The *Comitia Plebis Tributa* included no patricians—patricians were not even allowed inside its meeting space. This body elected the ten *Tribuni Plebis* (Tribunes of the Plebs), who were important magistrates, as well as some more minor officials, the “plebeian” aediles, officials responsible for maintaining certain aspects of the city of Rome, such as roads. This assembly also conducted trials where the defendant was not at risk of capital punishment. Finally, the group could vote on measures introduced by the *Tribuni Plebis*, which, upon approval, became “plebiscites.” Plebiscites were originally valid and binding on Roman citizens only after the Senate had approved them, but after 287 B.C.E. they had the force of laws. During the late Republican period the *Comitia Plebis Tributa* and its tribunes were increasingly likely to use plebiscites to confront the authority of the Senate.

The *Comitia Populi Tributa* was a relatively late creation, formed sometime in the early fifth century B.C.E. in imitation of the *Comitia Plebis Tributa*. All Roman citizens, both patricians and plebeians, could participate in this assembly. While

the Comitia Plebis Tributa was called together by the ten Tribuni Plebis, the Comitia Populi Tributa was convened by the officials called consuls or praetors. This body could pass laws and elect other government officials—quaestors, curule aediles, and military tribunes. It could also conduct trials for cases less serious than treason or homicide.

The Comitia Centuriata also included all Roman citizens. This assembly could enact laws, but it met only infrequently and so rarely did any legislating. This body elected the most important magistrates: the consuls, the praetors, and the censors. It also conducted important trials, for cases of treason or murder or in cases where a Roman citizen had been sentenced to death by another court but exercised his right of appeal. Because the issues brought before the Comitia Centuriata were so important, it was required to hold several formal discussion periods before actually voting on matters.

The way the Comitia Centuriata voted explicitly favored the rich citizens. The Roman citizen body was divided into 193 “centuries” (divisions that, despite their name, had many more than 100 members), and these centuries were divided across five property classes. The top property class had the most centuries assigned to it, and each of those centuries included very few Romans citizens. Each lower property class included fewer centuries, and each century included more citizens, so most citizens were packed into a small number of centuries in the fifth property class. Voting in the Comitia Centuriata proceeded by class, with the centuries in the top class voting first. In this way, a small number of very wealthy Romans could almost always determine the outcome of voting on the important laws and offices that were the concern of this assembly.

REPUBLICAN MAGISTRATES

Every year Rome held elections to choose new officials, or magistrates. These public offices served a dual purpose; they provided Rome with people to run its affairs, and they gave ambitious men a means of ascending the political ladder. All magistrates except the Tribuni Militum (Tribunes of the Soldiers) were members of the Senate.

The lowest office was that of Tribunus Militum. This office was held by 12 young men in their late 20s. They were responsible for managing the legions of soldiers under the command of the two consuls. Next were quaestors. Between 12 and 16 men held this office every year. They handled Rome’s financial matters: collecting customs or duties at ports, collecting rent for Rome’s public lands, running the city’s treasury, or helping a provincial governor administrate his province. Traditionally, a man tried to get elected quaestor at the age of 30, which was also the proper age for entering the Senate. Some quaestors were already senators when they were elected, and the censors usually admitted to the Senate any quaestor who did not already belong.

Aediles handled public matters. Originally, the aediles were assistants to the Tribuni Plebis and were mainly responsible for taking care of certain temples. In the fourth century

B.C.E., however, the Romans added two new offices, the curule aediles, held by patricians. These were called curule because these two aediles were entitled to sit in the chair of office, the *sella curulis*. After this period all the aediles, both the curule aediles and the plebeian aediles, were responsible for taking care of the city of Rome and its inhabitants. They cared for Rome’s streets, traffic, water supply, and markets and organized religious festivals and cult observances. Curule aediles were also responsible for organizing the public games called the *ludi Romani*. These games were very expensive, and aediles often had to pay many of the costs themselves. They were willing to do this because it helped them get elected to further offices. Four aediles were chosen each year, two plebeian aediles elected from the plebeian class by the Comitia Plebis Tributa and two curule aediles elected from the patricians by the Comitia Populi Tributa.

Praetors held the second-highest office in Rome (not counting censors). Six to eight praetors were elected every year. Praetors were in charge of litigation and courts of law. The urban praetor (*praetor urbanus*) handled litigation within Rome. The foreign praetor (*praetor peregrinus*) traveled around Italy performing the same role. The other praetors took care of legal matters in the provinces. The normal age for serving as praetor was 39 or 40. Praetors held imperium, which gave them the right to execute Rome’s laws and to command an army. Normally, after serving a year as praetor, a man would be sent off by the Senate to govern a province.

Consuls were the highest-ranking magistrates in Rome. They also held imperium. The Comitia Centuriata elected two consuls every year, and they took their oath of office on New Year’s Day. The consuls served together and alternated months in which they would run Rome, convening the Comitia Centuriata and bringing laws before it and speaking first at meetings of the Senate. Consuls could command any of Rome’s armies and hold power in any part of Rome’s territory. The normal age to be elected to the consulship was 42, two years after being elected quaestor. After a year as consul, Romans expected to be sent by the Senate to govern a province. The Senate generally gave consuls one of the provinces that required military authority for its governance. Former consuls were known as *consulares* and were held in high esteem, having navigated to the top of the political system.

Censors were the most senior magistrates, though they had less power than consuls because they lacked imperium. Only men who had already been consul could become censors. The Comitia Centuriata elected two censors at a time, each serving five-year terms. They conducted a census of all Roman citizens, regulated the memberships of the various bodies such as the Senate, and issued state contracts. Because censors had the right to deprive men of their citizenship and deprive Senators of their (otherwise lifetime) office, the office was both respected and feared, and candidates for the censorship were held to very high standards.

The Tribuni Plebis, those magistrates charged with calling together the Comitia Plebis Tributa, were magistrates

elected by the plebeians to defend the lives and property of plebeians. During the Republic 10 such tribunes were elected each year. They did not hold the same power as other magistrates because they were not elected by all the Roman people, but they had one important right that made them very powerful: They had the right to veto any law, act of government, decree, or election.

In times of emergency the Senate could appoint a special kind of magistrate called a dictator. The dictator had almost unlimited power but was supposed to be limited to six months in office. The paradigmatic dictator was Lucius Quinctius Cincinnatus, a former consul who, in 458 B.C.E., was called from his farm by the Senate and made dictator. He then defeated Rome's enemy of the moment, the Aequi, laid down his office, and returned to his farm in the space of 15 days. In the late republic Lucius Cornelius Sulla (138–78 B.C.E.) and Julius Caesar (100–44 B.C.E.) both made themselves dictators and ignored all the official restrictions, which led the Senate to abolish the office after Caesar's death.

If a man aspired to high political office, he had to take certain steps in an order called the *cursus honorum*, or “way of honor.” First he had to serve in the army as a young man. After joining the Senate at the age of 30, he had to hold each of the major offices: quaestor, praetor, and consul. He did not have to be a curule aedile, but holding that office was considered advantageous to those with political ambition. He might then become a censor. It was considered proper for a man to serve as a provincial governor at some point along the way, too. Rome had numerous provinces. To keep them in order, the government appointed Romans to serve as governors. Governors had to live in their provinces and might spend several years away from Rome while in office.

THE EMPIRE

After a period of civil war from around 44 B.C.E. to 31 B.C.E. Julius Caesar's nephew and adopted son, Gaius Julius Caesar Octavianus, assumed more or less complete power over the workings of the Roman government. He did this by winning the support of the Roman armies to such an extent that their loyalties were to him personally more than to any notion of a Roman state or the Roman people. This marked the end of the Roman Republic and the beginning of the Imperial Period.

This change was not marked by any official alteration in the constitution of the Roman government. The Senate remained the official governing body, men still pursued the offices of the *cursus honorum*, the various assemblies still met, the aediles still took care of the city, and so forth. Gaius Julius Caesar Octavianus, known simply as Octavian, simply asserted that he was the “first citizen,” *princeps*. But everyone knew that with the army loyal to him alone, the Senate and assemblies legislated at the pleasure of Octavian. No law could be passed, much less enforced, without his approval, and no funds would be released from the treasury except by his permission. After the chaos of the preceding decades, the Roman Senate welcomed this new authority, which brought

order to the governance of Rome. The Senate granted Octavian various honors, including the title Augustus, and passed laws giving him perpetual powers like those of a consul.

The structure of Roman government during the Imperial Period was, therefore, at once stable and unpredictable. The old republican offices remained in place for centuries, with their formal and official powers intact. But the day-to-day functioning of the government depended largely on who sat on the throne. Since no formal laws defined the office of emperor—in fact, there was no official rule, or even unofficial custom, for determining the imperial succession upon the death of an emperor—each emperor assumed different powers, for different purposes.

The focus of imperial power was always twofold: the treasury and the army. Emperors could (and did) choose to spend Rome's income, sometimes on lavish parties for the royal court and at other times for programs of road building, harbor construction, and civic architecture. Much of this work was done by the army, always at the beck and call of the emperor.

Upon assuming power over the other arms of the Roman government, Octavian focused his energies on governmental reform, to reestablish order after decades of unrest and gradual undermining of the principles of Roman government. Because the army had been instrumental in perpetuating the state of civil war, Augustus reduced its size; elevated certain units, of certain loyalty, to be his “Praetorian Guard”; and assigned them the task of keeping order in Rome and Italy. Formerly, public order was the concern of the consuls, neither of whom had the necessary authority to bring an army inside the city of Rome and who, serving two at a time, often had conflicting interests. Octavian and his ally, the general Agrippa, arranged to be appointed censors in 28 B.C.E. and used this opportunity to revise the rolls of the Senate, getting rid of any senators who did not support them. In 27 B.C.E. the Senate, now made up of senators chosen by Octavian himself, granted to the “first citizen” the title of Augustus, “Honored One.”

With large amounts of public treasure freed by this reduction in the standing army and with Roman victories in Egypt, Augustus worked, through the Senate and the aediles, to reinvigorate the city of Rome through a project of public works. By exercising some control over whom the Senate chose to govern the provinces of the Roman Empire, Augustus was able to ensure that the taxes collected in those provinces made their way to Rome rather than into the pockets of the governors, further enhancing public revenues. Thus the Senate and the magistrates were better able, under Augustus's supervision, to make improvements to the city. Augustus claimed at the end of this life to have found Rome a city of bricks and to have left it a city of marble.

Subsequent emperors and their administrations made other efforts to increase revenues for the city. During the first century of the Common Era, Vespasian, for example, increased the Senate's membership from 200 to 1,000 members,

and most of the new senators came from the provinces. These new senators paid the treasury for the privilege of serving Rome, and their position in Rome's governing body brought greater stability to the empire. Vespasian also increased taxes, built up a surplus in the treasury, and used the money for public works. He gave the provinces more rights and allowed the army to recruit from Gaul and Spain instead of just Italy.

During the first few centuries of the Common Era the emperor continued to hold almost total power. He was the rule maker and judge of the ultimate court. He was assisted by an advisory body, the *Consilium Principis* (Council of the First Citizen) drawn from Senators and nobles, and the Senate continued to meet, but ultimately the emperor retained real power. The Praetorian Guard sometimes supported the emperor but at other times worked against him. Provinces continued to have governors, assisted by officials called procurators. Very few real Romans were sent to govern, so most provinces were really governed by local bodies. Roman officials primarily concerned themselves with censuses and tax collection. Local officials handled criminal justice, public works, religious festivals, and diplomatic relations with Romans.

Between 235 and 284 C.E. Rome descended into chaos. The government had never satisfactorily decided what to do about the succession of emperors, and this failure now came home to roost. Various soldiers decided they wanted to be emperor, and so for 50 years they fought over the office. Twenty-five different soldier-emperors took control during this period; all but two of them were murdered or died in battle, defending their positions. Citizens stopped participating in government; barbarians encroached on the borders, and the military did not stop them; and inflation destroyed the economy.

To a large extent, by the second and third centuries of the Common Era the government in Rome was increasingly irrelevant except in certain very specific ways. The Senate and magistrates continued to run the city itself, and the emperor, through the army, guaranteed peace in the provinces (for failed to do so, more and more). The bureaucracy and especially public finance were handled at a very local level throughout the empire. Local magistrates in each district of each province—some of whom might have had Latin titles like aedile or quaestor and others Greek or Egyptian titles—oversaw local political affairs, and detachments of Roman soldiers kept the peace and handled recruiting for the Roman legions. By the third century C.E. the Roman Empire's army was almost entirely made up by non-Romans and even by non-Italians and non-Europeans.

Taxation under the empire was not handled by the Roman government. The Roman quaestors auctioned off contracts for taxation to private companies. Whichever company bid the most money for the right to collect taxes in a particular province won the auction and became the tax collectors for that province. In this way the state was paid a lump sum at once and was spared the expense of a large bureaucracy. The

tax-collecting company, the *publicani*, then proceeded to tax the inhabitants of their territory. This taxation was supposed to be governed by laws. In theory, the *publicani* were supposed to judge how much tax they could collect, legally, given the size of a year's harvest and base their bids to the Roman treasury on that estimate. Companies of *publicani* tended, however, to bid much too high—the Roman quaestors did not complain—and then try to recoup their investment by seizing far more from the citizens of a region than was legal. Theoretically, the citizens could expect the provincial governor to protect their rights and to enforce the law by means of the soldiers at his command. But governors were easily bribed or actively in league with the tax collectors. The injustice of these practices, carried out far from the eyes of the Senate and emperor of Rome, contributed much toward the dissolution and collapse of the Roman Empire.

Corruption, more generally, undid good government, as did, ironically, efforts on the part of emperors to stem it. In the second and third centuries C.E. almost every governmental service required a bribe. As emperors and provincial governors from time to time tried to quell this corruption by punishing corrupt officials, the result was simply an increase in the amount of money demanded of each bribe—magistrates came to assume that they would eventually be caught and punished and so tried to collect as much illicit profit as possible before their careers ended. Taxation and corruption eroded government at a local level, while the emperor's efforts to manage the governance and defense of the vast empire became increasingly difficult at the highest level.

Diocletian (285–312 C.E.) tried to make the Roman government more efficient by dividing the empire into eastern and western empires, each with its own emperor. Each emperor was called Augustus, and each Augustus had an assistant emperor called Caesar, who was also his successor; this solved the perennial problem of succession. This form of government was called a tetrarchy, or rule by four.

The tetrarchy worked well at first, mainly because the first four rulers got along with one another, but it collapsed in 306 C.E. when Augustus Constantius Chlorus died. Over the next several years different men aspired to the throne, resulting in claims to places in the tetrarchy by five or six people at a time. After a brief civil war, in 313 C.E. two Augustuses divided the empire again. Constantine became Augustus of the Western Roman Empire, and Licinius became Augustus of the Eastern Roman Empire. This division lasted until 324 C.E., when Constantine defeated Licinius and became the sole emperor in the city of Constantinople (modern Istanbul, Turkey). Constantine declared Christianity to be the Roman state religion.

THE AMERICAS

BY KEITH JORDAN

Conclusions about the nature of ancient Native American governments are based for the most part on reconstruc-

tions—meaning educated guesswork—derived from archaeological data. With the exception of the Classic Maya (ca. 250–650 C.E.), these cultures either did not employ writing at all or left written records that we cannot yet decipher (as is the situation with the Olmec). Although we can now read the titles and personal names of Mayan rulers and brief descriptions of their coronation rites, military conquests, and religious duties, we lack such information for most other ancient Native American governments and must rely on other kinds of evidence.

For example, differences in grave goods, tomb construction, and other burial practices within a culture can reveal something about the nature of its government. The finding of relatively small number of burials with richer offerings or more substantial tombs than those of the majority indicates that some people were considered more important than most others. The presence of a few graves containing scarce or luxury items suggests unequal access to valued resources, indicating the presence of elite individuals or ruling classes. A burial holding the remains of human sacrifices to accompany the deceased reflects his or her importance in the community and power over life and death.

Similarly, differences in residential architecture—such as in the size, building materials (for example, stone versus wood), and location of housing structures—across a culture imply differences in social status. The existence of a few large residences in a separate or elevated area of a community points to the presence of rulers—especially if these residences are near the main structures used for civic and ceremonial purposes by the community. Large-scale public works and monumental architecture do not necessarily indicate the existence of a centralized government or a ruling class, but they do point to a high degree of social organization and cooperation. So does evidence of concentrated settlements with large populations, necessitating a system for maintaining social order.

A more direct kind of evidence comes from sculpture and paintings portraying rulers, usually in elaborate costumes, often on a massive scale, and typically engaged in actions indicating their rank, such as vanquishing captives, receiving tribute, or performing important religious rituals. The existence of monumental images of such figures also demonstrates their command of labor power and raw materials. Human remains can provide clues to social ranking. For instance, anatomical evidence of inherited illnesses or deformities can disclose familial connections among those with special access to wealth as revealed in their graves. In Mesoamerica ruling groups used artificial deformities, such as head flattening and jade-inlaid teeth, to distinguish themselves from their subjects. A riskier and more speculative approach is to interpret patterns of archaeological information from the distant past in light of accounts by European explorers and colonists after 1492 describing the Native American governments they encountered. The problem, of

course, is that a lot can change in a few hundred years, let alone millennia.

EARLY DEVELOPMENTS

From the available evidence it is apparent that the earliest settlers of the New World from Asia at the end of the last ice age did not possess government in the sense of centralized institutions and sharply stratified hierarchies of command. They were small migratory bands of hunter-gatherers who, like most other peoples at a similar level of social organization, were relatively egalitarian. Certain individuals may have been especially consulted in decision making because of their experience in such pursuits as hunting, and there is some evidence of ritual specialists or shamans, but there were no social classes and no formal leaders. Similar conditions seem to have prevailed for several thousand years.

The adoption of limited agriculture to supplement wild-food collection and the expansion of trade networks in eastern North America during the period from roughly 1000 B.C.E. to 500 C.E. led to greater social complexity. This change shows up in the archaeological record in the form of elaborate burials for some people and evidence of large-scale community projects, like the construction of large earthen burial mounds and ritual enclosures. However, settlements remained small and scattered, and there is little evidence of hereditary elites, suggesting that any status differences were based on individual achievements in trading or ritual activity rather than on class or a stable hierarchical structure.

MESOAMERICA

Only with the expansion of population and formation of permanent villages and towns permitted by the development of intensive agriculture in Mesoamerica in the last few millennia B.C.E. did conditions emerge for the rise of centralized hierarchical governments. The earliest of these seem to have been what anthropologists call “chiefdoms.” Chiefdoms are small-scale (population in the thousands) class societies ruled by individual, usually male chiefs, whose position is inherited. The chief’s family constitutes the wealthiest and most powerful social class, while the majority of the population consists of agricultural laborers living on family farms. Chiefdoms lack complex bureaucracies. Permanent political offices are limited to the chief and a few subordinate positions, such as war captains or priestly authorities.

Chiefs maintain their power by public ritual, conspicuous consumption of luxury goods, and bestowing rewards on loyal followers. They control the surplus wealth of the society (such as stores of grain) and its distribution and may also control trade with outsiders. They are able to organize their subjects to labor on such public construction projects as elite residences and shrines. They often function as war leaders, but they do not have a monopoly on the use of force and usually lack absolute power over their subjects. Their influence depends to a great degree on their wealth and personal charisma. Bad fortune may lead their followers to abandon

Jade perforator, Olmec, 1200–400 B.C.E., from Mexico; such instruments were used by rulers in bloodletting ceremonies to ensure the fertility of the land and the well-being of the community. (© The Trustees of the British Museum)

them. Chiefs usually govern from a large central settlement (population up to the thousands) that dominates surrounding smaller villages (populations in the hundreds or less) by military force or by co-opting local leaders through rewards and alliances. People living within an individual chiefdom are usually of the same ethnicity and speak the same language. Boundaries, however, are poorly defined and vary with the chief's influence and success.

Such institutions emerged in the present-day Mexican states of Oaxaca and Chiapas by the end of the second millennium B.C.E. At sites such as San José Mogote in Oaxaca, large settlements with public architecture such as platform mounds maintained control over surrounding small villages. Differences in grave goods and in house size show the existence of different social classes, with a chiefly elite at the top. Chiefs used force to maintain control over surrounding communities. An early stone carving from a public building at San José Mogote shows a sacrificed war captive with his heart cut out.

These early Mesoamerican chiefdoms evolved over the next millennium into archaic states or kingdoms. Anthropologists define states as systems controlled by several layers of officials and administrators serving a hereditary ruling class or, in kingdoms, a single supreme ruler. A wide range of social classes exists, and occupations become increasingly specialized. Religion takes a highly organized form, with a hierarchical priesthood, and rules of conduct may be formalized into official codes of law. The ruling class, and in kingdoms the king, has absolute power of life and death over the subjects. Government becomes concentrated in large cities, with several levels of smaller settlement types serving regional administrative needs. States usually have firm boundaries defended by a well-organized military. Trade within the state and with other areas is extensive. The territory of states expands via conquest and colonization of surrounding areas

and can encompass millions of people of markedly different linguistic and ethnic backgrounds

From 1500 to 400 B.C.E. the Olmec civilization flourished on the Gulf coast of Mexico in the modern states of Veracruz and Tabasco. Whether Olmec government represents an advanced form of chiefdom or an archaic state under kings was a matter of dispute among 20th-century archaeologists. However, most scholars today consider that the huge scale of Olmec architecture and the colossal stone images of rulers reflect greater power over people and resources and a more complex organization of labor than any known historical chief ever commanded. The Olmec kings apparently ruled over small polities of some 5,000 to 20,000 people, each organized around a primary town that served as both royal residence and religious center. Kingship was already no doubt an inherited office, as in later Mesoamerican states, and rulers seem to have been exclusively male. They controlled the surplus of their simple farming economies. The kings functioned predominantly as religious and war leaders and had a trade monopoly over exotic luxury materials that could be redistributed as gifts to reward allies and followers. They commanded both small groups of specialized artists and massive public works projects to create and decorate their capitals.

In ancient Mesoamerica there was no distinction between politics and religion, no issue of sacred versus secular rule as developed in the West over the last half of the 20th century. The Olmec rulers apparently attempted to legitimize their claim to power by serving as ritual specialists. They had themselves portrayed on their monuments engaging in ritual activities and wearing elaborate costumes, suggesting that they had usurped the role played by shamans in earlier, more egalitarian societies. Like shamans, the Olmec kings mediated between the human world and the worlds of gods and ancestors and were thought to be able to travel to supernatural realms to maintain the well-being of their subjects, magically ensuring adequate rain and good harvests. Some sculptures show them transforming into powerful animals like jaguars and birds of prey, as shamans are believed to do, or emerging from caves, viewed in Mesoamerica as portals to the underworld.

At the early Olmec center of San Lorenzo (ca. 1500–900 B.C.E.) the rulers lived on the highest ground in huge palaces fitted with columns and drains of stone, in contrast to the pole-and-thatch houses of their subjects. Sculptors labored in workshops attached to these royal residences to create colossal carved portrait heads and thrones for their kings from blocks of stone brought from some sixty miles to the north—all evidence of the Olmec lords' extensive command of human labor and raw materials. At other royal workshops at the site specialized craftsmen created royal regalia and ornaments with exotic materials such as magnetic iron ore imported from faraway Oaxaca. The massive monuments were the equivalent of modern political propaganda, illustrating the ruler's power by their scale and intensive use of labor. The iron ore was ground into mirrors and worn as pendants that

could be used to start fires or reflect images, no doubt underlining the king's powers as chief shaman.

Some 20th-century archaeologists claimed that the Olmec unified into an empire that conquered peoples in other parts of Mesoamerica, but there is little evidence for this claim. The spread of Olmec art objects and styles beyond the Gulf coast seems better explained by trade and imitation. Rulers at the central Mexican site of Chalcatzingo, however, seem to have enhanced their status by alliance and possibly even intermarriage with the Olmec of the site known today as La Venta, adopting La Venta's sculptural style for their monuments. Chalcatzingo's rulers are distinguished in the archaeological record by burial in stone crypts alongside precious materials like jade. Artistic representations at the site may indicate that some rulers were female.

Around 500 B.C.E. residents of Zapotec communities in the three branches of the Valley of Oaxaca joined together to create a new central capital atop an easily defended mountain. The site, known today as Monte Alban, was not on good agricultural land but nonetheless rapidly grew in population and in the scale of its temple and residential architecture. These facts suggest that it was founded with the presumption that the surrounding communities would supply it with food. The smaller chiefdoms may have merged into a larger political system to defend against enemies from outside the area or to put an end to conflicts among themselves, choosing Monte Alban as a neutral ground on which to build a regional capital. If so, this system would resemble a form of political organization in ancient Greece in which several villages joined together to create a new central city, usually for defense.

Initially, Monte Alban contained many elite residences but lacked clear-cut royal palaces or tombs. However, during the Late Formative Period (ca. 400 B.C.E.–150 C.E.) royal tombs and large palaces appeared. At the same time, the scale of collective labor on construction projects at the site increased; most impressively, the top of the mountain was leveled to build a ceremonial plaza. Carved stones from this period identify towns outside the valley that had been conquered by the rulers of Monte Alban. All of this evidence indicates that the city had evolved into the center of a state.

In the Maya area, kingdoms probably existed by about 600 B.C.E., as evidenced by the massive scale of construction at sites like Nakbe, Guatemala. The size of Mayan cities increased as more sophisticated and intensive agricultural techniques, such as elaborate irrigation systems, developed. From these beginnings the unit of political control among the Maya became the city-state, meaning an independent regional kingdom governed from a prominent city or primary center that was the seat of the royal family. Among the Maya the primary cities dominated smaller, secondary centers and sought to conquer other city-states in a pattern of ongoing warfare and shifting political alliances that persisted until the end of the Classic Period (ca. 650 C.E.).

Unlike the Olmec rulers, the first Maya kings appear not to have advertised their status in colossal portraits. In-

stead, they built pyramid-temples decorated with huge plaster masks of deities associated with kingship to bolster their rule through art. By the Late Formative Period the hieroglyph signifying the holy lord or king of a city-state began to be used on royal monuments depicting individual kings. Most important among these monuments are stelae, upright stones with images or inscriptions carved in relief. During the Early Classic Period these stelae became the predominant form of Mayan political art, showing portraits of individual rulers conquering enemies, performing religious rituals, and engaging in such important passages as royal marriage and accession to the throne. These stone images functioned as doubles or copies of the king and bolstered his right to rule by showing him as a shaman like the Olmec lords, able to conjure up his ancestors' spirits and bring their blessings to himself and his people. He was also seen as a divine being, equated with the Maize God.

The enormous metropolis of Teotihuacán, north of present-day Mexico City, was the center of a state that reached its height of power and influence between 1 and 650 C.E. The precise grid system of the city, the immense scale of public architecture, and the evidence for standardized systems of measurement all point to strong centralized planning and coordination of labor. One feature unique to Teotihuacán in Mesoamerica, the construction of massive, collective public housing, also points to a state bureaucracy. The exact form of rule at Teotihuacán, however, remains unclear. There are no individual portraits of rulers at the site. Teotihuacán art shows smaller humans behaving deferentially toward large deities, but there are no explicit scenes of humans dominating bound captives, as in Olmec or Maya art. Fresco paintings show elite figures in profile processions, facing a frontal deity image on an adjoining wall. They are not distinguished from one another by signs that could represent individual names until late in the city's history. However, they wear elaborate regalia, including a distinctive tasseled headdress that might signify rulership or at least high military or priestly rank. Their images are sometimes bordered by representations of the mythic deity the Feathered Serpent, associated with kingship in later Mesoamerican cultures, including the Aztec and Toltec.

The lack of images of individually named rulers in Teotihuacán has led some scholars to conclude that rather than having a single divine ruler like the Mayan city-states, Teotihuacán was governed by a collective, perhaps of warrior-priests or elite families. However, archaeological evidence gathered over the past 20 years casts doubt on this model. At the Pyramid of the Feathered Serpent, the remains of more than 100 sacrificial victims were interred as offerings. The bodies were richly ornamented, and differences in the quality of the grave goods suggest that they represented members of distinctive social ranks. These mass executions reflect a very powerful and centralized government with the power of life and death over its subjects, and the burials may have been intended to accompany an individual king in a (now looted) central tomb.

One interpretation seeks to reconcile this evidence of individual rulership with the lack of such evidence in the city's art by positing two stages in Teotihuacán's political history: An earlier despotic kingship, reflected in the Pyramid of the Feathered Serpent finds, was overthrown around 350 C.E. because of its excesses and replaced by a more collective leadership. But societies from other parts of the world show that individual ruler portraits are not a necessary feature of centralized monarchies. The Incas, for example, did not develop individual portraiture to any great degree and made few images of kings, yet they created an empire ruled by divine monarchs.

At its height Teotihuacán had a population of 125,000 to 200,000 and certainly controlled the Basin of Mexico. Whether Teotihuacán created an empire, or how far its political power extended, is another controversial topic. Imported Teotihuacán objects and local copies of the city's architecture occur across Mesoamerica, but most probably represent the attempts of local rulers to legitimize their power by emulating Teotihuacán's prestige rather than Teotihuacán conquests. Foreign rulers may have sought the endorsement of Teotihuacán's government and made pilgrimages to the city to stress their claims to power in the same way medieval European monarchs obtained the pope's blessing in Rome. Archaeological evidence indicates that Teotihuacanos did conquer and colonize part of the Pacific coast of Guatemala, 200 miles away from the city. They probably wanted to control this area in order to procure local luxury materials such as chocolate, jade, and the beautiful iridescent green tail feathers of the indigenous quetzal bird, which were used to make headdresses and other garments for ancient Mesoamerican rulers. The nature of their political relations with local Maya city-states remains unclear. At Tikal recent interpretations of hieroglyphs indicate that in 378 C.E. Teotihuacán directly intervened in the politics of this city-state, sending a military force to kill the ruler Great Jaguar Paw and install the next king, Yax Nuun Ayin. However, not all scholars accept this reconstruction, and Teotihuacán may have simply backed a faction in a local struggle for power rather than directly invading Tikal.

PERU

Although large-scale building and irrigation projects involving thousands of laborers took place in Peruvian agricultural towns as far back as 2700 B.C.E., there is not much other evidence for rulers during this time. Huge temple platforms reflect strong social organization, but there are no real differences in grave goods to suggest big differences in status among the population. Perhaps collective organizations like those still found today in indigenous Peruvian communities, based on extended family ties and reciprocal work obligations, constituted the only government. On the other hand, the presence of two types of housing suggests at least two levels of society, and the temples atop the platform mounds were small, suggesting access restricted to a few. At Kotosh in the Andean highlands as early as 2000 B.C.E. members of some families were

preserved after death as mummies, indicating special positions in society, but supporting evidence for ruling classes is scanty from contemporary sites. At the coastal town of Cardal individuals buried in a shrine about 1400 B.C.E. were probably not members of noble families but religious specialists honored for their individual achievements. There is no evidence for state control in these places, despite the size of the buildings.

Between about 900 and 200 B.C.E., however, strong evidence of rulers emerges. At the religious center of Chavín de Huántar the bones of individuals living close to the main shrine during the New Temple Period (ca. 400–200 B.C.E.) show that these folks ate a more varied diet, with more meat, than people buried farther from the temple. A class with preferential access to food resources, perhaps priests, had emerged. At the contemporary site of Kuntur Wasi some burials contain gold jewelry and regalia—clearly some members of this community had higher status than others. Cemeteries from the same time near Paracas, on the south coast, provide clear evidence for powerful nobles. Some mummy bundles contain hundreds of feet of elaborately woven textiles, enclosing rich grave goods of ceramics and gold jewelry, and sometimes occupy the central position in tombs, surrounded by the smaller bundles of their subjects. Anthropologists believe that these early Peruvian elites were akin to the hereditary nobles of later Inca times, who presided over clan-based collective groups and served as religious specialists mediating between their subjects and the deities of fertility responsible for agricultural success.

NORTH AMERICA

Little is known of the governmental organization of ancient groups in North America. During the Paleo-Indian period (ca. 13,000–ca. 8000 B.C.E.) the earliest inhabitants of North America were organized into very small, highly mobile, and presumably egalitarian hunting bands ranging over the landscape in search of prey. There is no evidence from burials of any type of social stratification or hierarchy; as with historically documented modern hunter-gatherers there was probably no centralized leadership, though older band members would have been looked to for guidance based on their experience. Archaeological traces of ritual activity hints at the possible presence of shamans among these small groups, but certainly no priestly class or caste with governing power. Through the subsequent Archaic Period (ca. 8000–ca. 1000 B.C.E.) band size grew larger, and there is archaeological evidence for longer occupation of campsites based on seasonal exploitation of natural resources, but again there is nothing to suggest the presence of elites or ruling classes. Like other hunter-gatherers, these bands seem to have been simply organized without any evidence of fixed or centralized leadership positions.

During the Early and Middle Woodland periods in the Midwest, cultures participating in the Adena (1000 B.C.E.–200 C.E.) and Hopewell (300 B.C.E.–500 C.E.) burial and ritual traditions were sufficiently well organized to bring communities together for the construction of burial mounds and cer-

emonial earthworks, some of them of massive size. The large quantities of luxurious grave goods accompanying some mound burials point to the emergence of status differences. However, there is still no evidence for any formal governing structure. Settlement patterns remained diffuse, with small groups, probably based on family ties, scattered into very small villages. The high-status individuals buried in the mounds probably did not represent hereditary or formal positions of leadership, but they acquired their wealth and influence by individual achievements, perhaps as traders, hunters, or shamans. There is no evidence for formal government in the form of chiefdoms in North America until the beginning of the second millennium of the Common Era.

Greece

~ Xenophon: "The Polity of the Spartans," ca. 375 B.C.E. ~

I recall the astonishment with which I first noted the unique position of Sparta among the states of Hellas, the relatively sparse population, and at the same time the extraordinary powers and prestige of the community. I was puzzled to account for the fact. It was only when I came to consider the peculiar institutions of the Spartans that my wonderment ceased.

When we turn to Lycurgos, instead of leaving it to each member of the state privately to appoint a slave to be his son's tutor, he set over the young Spartans a public guardian—the *paidonomos*—with complete authority over them. This guardian was elected from those who filled the highest magistracies. He had authority to hold musters of the boys, and as their guardian, in case of any misbehavior, to chastise severely. Lycurgos further provided the guardian with a body of youths in the prime of life and bearing whips to inflict punishment when necessary, with this happy result, that in Sparta modesty and obedience ever go hand in hand, nor is there lack of either. . . .

Again, as regards food, according to his regulation, the *eiren*, or head of the flock, must see that his messmates gather to the club meal with such moderate food as to avoid bloating and yet not remain unacquainted with the pains of starvation. His belief was that by such training in boyhood they would be better able when occasion demanded to continue toiling on an empty stomach. . . . On the other hand, to guard against a too great pinch of starvation, he did give them permission to steal this thing or that in the effort to alleviate their hunger. . . .

When Lycurgos first came to deal with the question, the Spartans, like the rest of the Hellenes, used to mess

privately at home. Tracing more than half the current problems to this custom, he was determined to drag his people out of holes and corners into the broad daylight, and so he invented the public mess rooms. As to food, his ordinance allowed them only so much as should guard them from want. . . . So that from beginning to end, till the mess breaks up, the common board is never stinted for food nor yet extravagantly furnished. So also in the matter of drink. While putting a stop to all unnecessary drink, he left them free to quench thirst when nature dictated. . . . Thus there is the necessity of walking home when a meal is over, and a consequent anxiety not to be caught tripping under the influence of wine, since they all know of course that the supper table must be presently abandoned and that they must move as freely in the dark as in the day, even with the help of a torch.

It is clear that Lycurgos set himself deliberately to provide all the blessings of heaven for the good man, and a sorry and ill-starred existence for the coward. In other states the man who shows himself base and cowardly, wins to himself an evil reputation and the nickname of a coward, but that is all. For the rest he buys and sells in the same marketplace with a good man; he sits beside him at a play; he exercises with him in the same *gymnasion*, and all as suits his humor. But at Sparta there is not one man who would not feel ashamed to welcome the coward at the common mess-tables or to try conclusions with him in a wrestling bout; . . . during games he is left out as the odd man; . . . during the choric dance he is driven away. Nay, in the very streets it is he who must step aside for others to pass, or, being seated, he must rise and make room, even for a younger man. . . .

(continued)

(continues)

Lycurgos also provided for the continual cultivation of virtues even to old age, by fixing the election to the council of elders as a last ordeal at the goal of life, thus making it impossible for a high standard of virtuous living to be disregarded even in old age. . . . Moreover he laid upon them, like some irresistible necessity, the obligation to cultivate the whole virtue of a citizen. Provided they duly perform the injunctions of the law, the city belonged to them each and all, in absolute possession, and on an equal footing. . . .

I wish to explain with sufficient detail the nature of the covenant between king and state as instituted by Lycurgos; for this, I take it, is the sole type of rule which still preserves the original form in which it was first established; whereas other constitutions will be found either to have been already modified or else to be still undergoing modification at this moment. Lycurgos laid it down as law that the king shall offer on behalf of the state all public sacrifices, as being himself of divine descent, and wherever the state shall dispatch her armies the king shall take the lead. He granted him to receive honorary gifts of the things offered in

sacrifice, and he appointed him choice land in many of the provincial cities, enough to satisfy moderate needs without excess of wealth. And in order that the kings might also encamp and mess in public he appointed them public quarters, and he honored them with a double portion each at the evening meal, not in order that they might actually eat twice as much as others but that the king might have the means to honor whomsoever he wished. . . .

Close by the palace a lake affords an unrestricted supply of water; and how useful that is for various purposes they best can tell who lack the luxury. Moreover, all rise from their seats to give place to the king, save only that the ephors rise not from their throne of office. Monthly they exchange oaths, the ephors on behalf of the state, the king himself on his own behalf. And this is the oath on the king's part: "I will exercise my kingship in accordance with the established laws of the state." And on the part of the state (the ephors) the oath runs: "So long as he (who exercises kingship), shall abide by his oath we will not suffer his kingdom to be shaken."

Greece

~ Plutarch: excerpt from *The Life of Theseus*, ca. 110 C.E. ~

Now, after the death of his father Aigeos, forming in his mind a great and wonderful design, he gathered together all the inhabitants of Attica into one town, and made them one people of one city, whereas before they lived dispersed and were not easy to assemble upon any affair for the common interest. Nay, differences and even wars often occurred between them, which he by his persuasions appeased, going from township to township and from tribe to tribe. And those of a more private and mean condition readily embracing such good advice, to those of greater power he promised a commonwealth without monarchy—a democracy, or people's government—in which he should only be continued as their commander in war and the protector of their laws, all things else being equally distributed among them; and by this means brought a part of them over to his proposal.

He then dissolved all the distinct statehouses, council halls, and magistracies, and built one common statehouse and council hall on the site of the present upper

town, and gave the name of *Athens* to the whole state, ordaining a common feast and sacrifice, which he called *Pan-Athenaia*, or the sacrifice of all the united Athenians. He instituted also another sacrifice called *Metoikia*, or Feast of Migration, which is yet celebrated on the sixteenth day of Hecatombaion. Then, as he had promised, he laid down his regal power and proceeded to order a commonwealth, entering upon this great work not without advice from the gods. . . . Farther yet designing to enlarge his city, he invited all strangers to come and enjoy equal privileges with the natives. . . . Yet he did not suffer his state, by the promiscuous multitude that flowed in, to be turned into confusion and he left without any order or degree, but he was the first that divided the Athenian Commonwealth into three distinct ranks, the noblemen, the farmers, and the artisans. To the nobility he committed the care of religion, the choice of magistrates, the teaching and dispensing of the laws, and interpretation and direction

in all sacred matters; the whole city being, as it were, reduced to an exact equality, the nobles excelling the rest in honor, the farmers in profit, and the artisans in number. He also coined money, and stamped it with the image of an ox, either in memory of the Marathon bull, or of the Minotaur, both of whom he vanquished; or else to put his people in mind to follow animal husbandry; and from this coin came the expression so frequent among the Hellenes, of a thing being worth ten or a hundred oxen. After this he joined Megara to Attica. . . .

About this time, Menestheos (the son of Peteos, grandson of Orneos, and great-grandson of Erechtheos), the first man that is recorded to have affected popularity and ingratiated himself with the multitude, stirred up and exasperated the most

eminent men of the city, who had long borne a secret grudge to Theseos, conceiving that he had robbed them of their several little kingdoms and lordships, and having pent them all up in one city, was using them as his subjects and slaves. He put also the meaner people into commotion, telling them that, deluded with a mere dream of liberty, they were actually deprived of both that and of their proper homes and religious usages and that instead of many good and gracious kings of their own, they had given themselves up to be lorded over by a newcomer and a stranger. . . . and after Theseos death—by accident or misadventure—Menestheos ruled in Athens as king.

Rome

~ Polybius: "Rome at the End of the Punic Wars," ca. 200–after 118 B.C.E. ~

The three kinds of government, monarchy, aristocracy and democracy, were all found united in the commonwealth of Rome. And so even was the balance between them all, and so regular the administration that resulted from their union, that it was no easy thing to determine with assurance, whether the entire state was to be estimated an aristocracy, a democracy, or a monarchy. For if they turned their view upon the power of the consuls, the government appeared to be purely monarchical and regal. If, again, the authority of the senate was considered, it then seemed to wear the form of aristocracy. And, lastly, if regard was to be had to the share which the people possessed in the administration of affairs, it could then scarcely fail to be denominated a popular state. The several powers that were appropriated to each of these distinct branches of the constitution at the time of which we are speaking, and which, with very little variation, are even still preserved, are these which follow.

The consuls, when they remain in Rome, before they lead out the armies into the field, are the masters of all public affairs. For all other magistrates, the tribunes alone excepted, are subject to them, and bound to obey their commands. They introduce ambassadors into the senate. They propose also to the senate the subjects of

debates and direct all forms that are observed in making the decrees. Nor is it less a part of their office likewise to attend to those affairs that are transacted by the people; to call together general assemblies; to report to them the resolutions of the senate; and to ratify whatever is determined by the greater number. In all the preparations that are made for war, as well as in the whole administration in the field, they possess an almost absolute authority. For to them it belongs to impose upon the allies whatever services they judge expedient; to appoint the military tribunes; to enroll the legions, and make the necessary levies, and to inflict punishments in the field, upon all that are subject to their command. Add to this that they have the power likewise to expend whatever sums of money they may think convenient from the public treasury; being attended for that purpose by a quaestor; who is always ready to receive and execute their orders. When any one therefore, directs his view to this part of the constitution, it is very reasonable for him to conclude that this government is no other than a simple royalty. . . .

To the senate belongs, in the first place, the sole care and management of the public money. For all returns that are brought into the treasury, as well as all the payments that are issued from it, are directed by their

(continued)

(continues)

orders. Nor is it allowed to the quaestors to apply any part of the revenue to particular occasions as they arise, without a decree of the senate; those sums alone excepted which are expended in the service of the consuls. And even those more general, as well as greatest disbursements, which are employed at the return every five years, in building and repairing the public edifices, are assigned to the censors for that purpose, by the express permission of the senate. To the senate also is referred the cognizance of all the crimes, committed in any part of Italy, that demand a public examination and inquiry: such as treasons, conspiracies, poisonings, and assassinations. Add to this, that when any controversies arise, either between private men, or any of the cities of Italy, it is the part of the senate to adjust all disputes; to censure those that are deserving of blame: and to yield assistance to those who stand in need of protection and defense. When any embassies are sent out of Italy; either to reconcile contending states; to offer exhortations and advice; or even, as it sometimes happens, to impose commands; to propose conditions of a treaty; or to make a denunciation of war; the care and conduct of all these transactions is entrusted wholly to the senate. When any ambassadors also arrive in Rome, it is the senate likewise that determines how they shall be received and treated, and what answer shall be given to their demands.

In all these things that have now been mentioned, the people has no share. To those, therefore, who come to reside in Rome during the absence of the consuls, the government appears to be purely aristocratic. Many of the Greeks, especially, and of the foreign princes, are easily led into this persuasion: when they perceive that almost all the affairs, which they are forced to negotiate with the Romans, are determined by the senate.

And now it may well be asked, what part is left to the people in this government: since the senate, on the one hand, is vested with the sovereign power, in the several instances that have been enumerated, and more especially in all things that concern the management and disposal of the public treasure; and since the consuls, on the other hand, are entrusted with the

absolute direction of the preparations that are made for war, and exercise an uncontrolled authority on the field. There is, however, a part still allotted to the people; and, indeed, the most important part. For, first, the people are the sole dispensers of rewards and punishments; which are the only bands by which states and kingdoms, and, in a word, all human societies are held together. For when the difference between these is overlooked, or when they are distributed without due distinction, nothing but disorder can ensue. Nor is it possible, indeed, that the government should be maintained if the wicked stand in equal estimation with the good. The people, then, when any such offences demand such punishment, frequently condemn citizens to the payment of a fine: those especially who have been invested with the dignities of the state. To the people alone belongs the right to sentence any one to die. Upon this occasion they have a custom which deserves to be mentioned with applause. The person accused is allowed to withdraw himself in open view, and embrace a voluntary banishment, if only a single tribe remains that has not yet given judgment; and is suffered to retire in safety to Praeneste, Tibur, Naples, or any other of the confederate cities. The public magistrates are allotted also by the people to those who are esteemed worthy of them: and these are the noblest rewards that any government can bestow on virtue. To the people belongs the power of approving or rejecting laws and, which is still of greater importance, peace and war are likewise fixed by their deliberations. When any alliance is concluded, any war ended, or treaty made; to them the conditions are referred, and by them either annulled or ratified. And thus again, from a view of all these circumstances, it might with reason be imagined, that the people had engrossed the largest portion of the government, and that the state was plainly a democracy.

Such are the parts of the administration, which are distinctly assigned to each of the three forms of government that are united in the commonwealth of Rome.

► health and disease

INTRODUCTION

Many common themes run through discussions of health and disease in the ancient world. The first is low life expectancy. Infant mortality rates were extremely high by modern standards, and many women lost their lives in giving birth. Among those who survived their first year of life, the prospects for a long life were limited. In most ancient civilizations people in their mid-thirties would have been considered old. Among the most ancient cultures death by starvation was a constant threat; even when food was somewhat plentiful, diets were often unbalanced, leading to medical conditions that result from the lack of essential vitamins or minerals.

A second common theme is a lack of sanitation, usually reflecting ignorance about the causes of infectious diseases. In many parts of the world clean drinking water was scarce. As human communities grew and became more crowded, unsanitary conditions were commonplace. Even the ancient Romans, known for their plumbing and water systems, often lived in unsanitary conditions, with latrines located in kitchens and water wells dug in the vicinity of cesspools. Further, insects and rodents frequently invaded homes and food-storage facilities, bringing waste and therefore diseases with them. These conditions gave rise to a host of infectious diseases, such as malaria, as well as parasites. Before the development of antibiotics, a person could die as a result of a simple infection from an unhealed wound.

A third theme is that ancient cultures sought cures for the diseases that afflicted them. Many of these treatments

involved substances derived from plants, including herbs, thought to have medicinal value. In some cases, the ancients were correct. Chewing the bark of a willow tree relieved pain, and modern scientists discovered that willow bark contains a chemical that is closely related to the chemical in aspirin. Healers who acquired knowledge about medicinal substances occupied a high place in most ancient cultures, the ancient Chinese providing a good example. They were often thought to possess special wisdom from the gods. In some cases, these healers were sought out, giving rise to the earliest hospitals. The earliest-known hospital dates to the fourth century B.C.E. in modern-day Sri Lanka.

A fourth theme concerns the role of shamans and medicine men (and women) in ancient cultures. At a time when people believed that they were subject to mysterious forces in nature and that their afflictions were the work of the gods, shamans were often looked on as healers because it was believed that they could read the will of the gods in omens and signs. In a sense, these early healers were the world's first psychologists, for they often linked illness with the mental condition of the patient. In ancient Africa illness was seen as the result of a combination of physical, mental, and even social factors. While their cures may have lacked medicinal value, they provided patients with the will to fight their illnesses. In many instances, the patients' improved mental state helped them recover.

AFRICA

BY JULIAN M. MURCHISON

Health and disease in African prehistory has been largely understudied. As a result of historical stereotypes and miscon-

ceptions, non-Africans often think of the African continent as dark, dirty, and diseased. However, a detailed look at the prehistory of the continent and an examination of information derived from research that sheds light on the past shows that Africans have developed long-standing and flexible systems of health that have allowed them to treat and cope with a wide range of diseases and other health concerns. What we know about Africa today and about the past suggests that some of the most important concerns of the residents of Africa in ancient times included the health and welfare of infants and children, fertility, calamitous events, and their relationship to the environment in which they lived. Many healing practices undoubtedly addressed these types of concerns, along with broken bones and the specific, widespread diseases such as malaria, schistosomiasis (infection with a parasitic worm), and sleeping sickness that probably affected some inhabitants of the continent during the ancient time period.

As in modern times, diseases were closely connected to the environment in which humans lived on the African continent. Understanding the human inhabitants' natural and cultural environments is crucial to comprehending the experiences with health and disease that those humans had during the ancient era. The fact that humans and their biological ancestors have a long history of residence on the African continent probably means that the viruses, parasites, and other causes of diseases in humans have an equally long history on the continent. These diseases and their carriers have evolved in concert with the human populations that they infect. The natural environment—whether tropical forest, savanna grassland, or arid desert—shaped the nature of health and especially disease. Different conditions either did or did not lend themselves to specific diseases and other health concerns.

Water, as a direct carrier for diseases and as a breeding ground for other carriers of disease, especially mosquitoes, was a key part of the environment that directly affected Africans' ability to remain healthy. Malaria and schistosomiasis are both closely linked with the presence of bodies of water and were probably particularly prevalent in communities engaged in agriculture, especially agriculture involving irrigation. The absence of water, in the form of drought, was also a frequent health concern. In the search for a healthy balance with their environment, Africans probably used healing practices both to ensure enough water to support their lives and to treat illnesses associated with water-borne illnesses.

Africans also shaped their environments culturally in terms of their settlement patterns, their economic activities, and their beliefs and associated behaviors. These cultural environments created circumstances that helped reinforce the likelihood of health or disease. Many of the inhabitants of the African continent during this time period lived in relatively small groups that were often fairly mobile. These cultural characteristics meant that they were less subject to large-scale epidemics and other health concerns associated with bigger settlements and the domestication of plants and animals. On

the other hand, their health was often a direct product of the unpredictable natural environment, which was sometimes unfriendly. Residents of the continent who depended on domesticated plants and animals may have had more protection from some of the vagaries of the natural environment, but they most likely also experienced more problems with malnutrition and the transmission of disease among humans and between animals and humans.

The study of human cultures and historical evidence suggests that African cultures tended not to compartmentalize health by separating it completely from other important activities and concerns. It seems reasonable to assume that many African cultures in ancient times had a similarly broad understanding of health and healing. Health tended to be thought of in physical, mental, and social terms. Healers who were sought out to treat diseases and physical ailments probably often provided other services, such as protection from witchcraft, magic to ensure success in hunting or agriculture, and medicines to protect infants from harm. The fact that healers frequently dealt with a wide range of issues signals the ways in which health blended together with issues of economics and politics as well as religion and spirituality. Sometimes the medicines and treatments were widely known by members of a particular society; in other cases, medicines and treatments were known only by specialist healers. Individuals with specialized healing knowledge often occupied positions of political and religious authority. Therefore, healers were important figures in many African societies during ancient times.

Healers seem to have practiced both imitative (or "sympathetic") and contagious magic, where certain magical acts are performed or formulas followed in the hope of effecting the desired end, whether it is to improve crops or heal illness. In sympathetic magic, for example, it is thought that acts performed on ritual objects (such as a doll that stands in for an actual person) will transfer to the person. Prehistoric art forms have been interpreted to indicate that art was part of the practice of imitative magic, designed to ensure the success of the hunt or other desired outcomes. In contagious magic it is thought that things or persons that have once been in contact can afterward influence each other. Along these lines, it seems likely that healing practices involved elements of imitative and contagious magic as well as detailed knowledge of the medicinal properties of locally available plants and minerals and other resources. These healing practices, supported by substantial knowledge, are indicative of the sorts of cultural responses to disease and ill health that would undoubtedly have been found on the African continent in ancient times. Humans on the continent sought to ensure their health and to treat diseases using a combination of spiritual and physical means.

In all, the physical and cultural environments shaped both health and disease for residents of the African continent during ancient times. Healing practices designed to ensure or to restore health responded to elements of nature as well as to

social and cultural concerns. The diseases that afflicted human inhabitants at the time were also a product of the physical environment, which determined whether certain viruses or parasites existed to infect humans. Human activities, like agriculture or pastoralism, often altered the environment in certain ways that directly or indirectly helped spread or control certain diseases. Through cultural knowledge and cultural practices, inhabitants of the African continent in ancient times sought to maintain or restore health by focusing on a combination of balance with the environment, relationships with neighbors and ancestors, and personal illness.

EGYPT

BY CHRISTINE END

Mummies, artistic representations of human beings, and medical papyri all contribute to what Egyptologists know about the quality of health and hygiene in ancient Egypt. While examining mummies remains the most thorough means of investigating diseases and illnesses of the ancient Egyptians, protecting these irreplaceable time capsules of the ancient world is of paramount concern. Radiography, CT scanning, endoscopy, and small-scale tissue sampling are scientific methods of examining mummies with a minimal amount of damage.

Contrary to popular belief, ancient Egyptian physicians did not master the study of human anatomy. What was known of physiology was largely based on the butchery of animals. Many ancient Egyptian words for human body parts or concepts have a determinative (a hieroglyph that depicts the meaning of a word) showing animal's body parts following such words. The removal of organs by the embalmer during mummification was limited to a tiny opening in the flank of the deceased person and did not provide much visual anatomical information. Dissection of humans simply did not take place and was taboo. According to the histories of Diodorus Siculus, the man who made the mummification incision was ritually stoned after finishing his work, for defiling the body.

By modern standards ancient Egyptian life spans were relatively short. Living to the mid-30s was considered living to a good age, though some individuals (including the pharaoh Ramses II of the 14th century B.C.E.) lived well into their eighties. Signs of arthritis and hardening of the arteries are apparent in mummies of older people; documented complaints relating to these conditions also survive. Infant mortality was high in ancient Egypt, and death during childbirth was common. Both pregnancy and menstruation appear to have been viewed with a certain amount of suspicion and considered unclean. Fertility problems, contraception, and pregnancy are topics discussed in the Kahun Medical Papyrus (dating to ca. 1900 B.C.E.) and the Berlin Papyrus (dating to the 1200s B.C.E.). Birth defects were common but not often depicted, aside from cases of dwarfism. Dwarfs were accepted, if not embraced by ancient Egyptian society.

Coffin with skeleton of a child, from Speos Artemidos, Egypt, Twenty-second Dynasty, around 850 B.C.E.; the skeleton shows clear signs of "brittle bone" disease. (© The Trustees of the British Museum)

According to physical and pictorial evidence, circumcision for males was common, possibly for reasons of hygiene. Circumcision appears to have taken place not in infancy but at an age just before puberty.

The Greek historian Herodotus, of the fifth century B.C.E., remarked on the general cleanliness of the ancient Egyptians. Washing the body with animal or vegetable oils and the mineral natron as "soap" was routine. Persons of the upper class would bathe in an indoor shower powered by servants who poured water over the bather's body. The commoners washed their bodies and clothing in the waters of the Nile. Perfumed oils applied to the body masked unwanted odors and was

thought to promote youthful skin. The washing of clothing was also frequent; a clean, white outfit was the indication of high status. Funerary trappings portraying the deceased depict them in fine clothing of this type to perpetuate an elite appearance for all eternity.

Maladies and their causes varied. Sand brought about several physical ailments for the ancient Egyptians. The dental health of the Egyptians was enormously poor, owing to sand and not sugar. Teeth cleaning may have been done with twig “toothbrushes” or a cloth. Sand within food and particles of stone from stone-ground grains were the culprits in the wearing down of teeth. Over time, such wear would cause abscesses (a collection of pus and related inflammation) and infections. The eye makeup worn by men and women to help with the glare of the sun also had antiseptic properties to prevent infections of the eyes caused by blowing sand. Another result of sand in the air was pneumoconiosis, a disease of the lungs caused by inhalation of sand and other irritating particles.

The Egyptians suffered from skin ailments as well. Head lice found in the hair of mummies suggest that shaving the head and wearing wigs may have been an attempt to prevent this, but the Egyptians were also known to wear wigs over their natural hair. Shaving body hair may also have been practiced for hygienic reasons. Lice on the head or body would have caused rashes prone to infection from persistent scratching. Other conditions of the skin may have included the highly contagious smallpox. Smallpox may be the cause for the skin condition visible on the face of the mummy of King Ramses V (r. 1156–1151 B.C.E.).

Parasitic infection was a serious problem in ancient Egypt. The Nile’s waters also harbored hookworms, guinea worms, and the schistosome worms. Ingesting these parasites or allowing them to gain entrance into the body by wading in the Nile or through contact with soil from the river, insects and animals harboring the worms, or an infected person were sources of much illness in the population of Egypt. Schistosomiasis, with symptoms ranging from fever and cough to fatigue, abdominal pain, and enlargement of the liver and spleen, is evident in the examination of ancient mummies. This disease is still a great problem to modern-day Egyptians who venture into the still areas of the Nile.

Other parasites came from the land. Feces, which was used as fertilizer, was also the source for parasitic illness in ancient Egypt. Hookworms, roundworms, and tapeworms transferred to humans via crops grown in manure. Heat can encourage the breeding of flies, thus promoting the spread of disease. The hot climate of Egypt also made a breeding ground for filarial worms, which can cause blindness in humans harboring the parasites.

Even the home could be an unsanitary environment. Overcrowded living quarters, sometimes shared with livestock, promoted the spread of such illnesses as tuberculosis. (Representations of humpbacked people may indicate sufferers of spinal tuberculosis.) Bedbugs and fleas were certainly

frequent household pests, causing chronic skin irritations. Rodents invading household food storage were also responsible for spreading illness of all types, including plague.

Treatments for ill health took the form of a combination of prescribed medicines and magical rituals. Cures may have involved something as simple as wearing a magical amulet, or charm, in conjunction with taking a prescribed medicine. This dual physical and spiritual approach to health is especially apparent in the cases recorded in the London Papyrus (dating to the early 14th century B.C.E.). That both methods of treatment were contained in the one document suggests that the Egyptians did not consider either approach to be the sole cure. The occurrence of physical injury and first aid is the focus of the Edwin Smith Medical Papyrus (dating to the 1600s B.C.E.). This papyrus records the injuries of several laborers, including diagnoses of their injuries, decisions concerning whether they should be treated, and the prescribed course of treatment, if any.

THE MIDDLE EAST

BY MARKHAN J. GELLER

Our information about medicine in the ancient Middle East derives almost entirely from Babylonian sources. One of the noticeable differences between the Hippocratic medicine of Greece and Babylonian medicine is the lack of any texts dealing with diet and health regimens. While Greek medicine invested a great deal of interest in diet and exercise and ways to preserve one’s good health, Babylonian medicine was primarily focused on how to treat or alleviate symptoms and distress caused by disease that had already been diagnosed. Disease, in Babylonian terms, could be either physical or psychic and could express itself through symptoms such as pain and fever and loss of appetite or through anxiety, insomnia, impotence, or other *maladies d’esprit*, or “illnesses of the soul.”

One reason why Babylonian medicine did not address itself to health regimens or healthy living is that prevention was considered to be the bailiwick of magic and exorcism, rather than medicine. Incantations were essentially intended to ward off demons and misfortune that might arise in the future. Hence, Babylonian health therapy was divided between the activities of the *ashipu*, the “exorcist,” and the *asû* the “physician,” each operating within his own area of expertise though not in a way intuitively obvious to modern medical practitioners. The *ashipu* was responsible for magical prevention of attacks by demons, angry gods, or even witchcraft and unfavorable omens, but he also acted as the attending physician who visited the patient on his or her sickbed to give a prognosis, predicting the nature and course of the disease. The *ashipu* also had the social advantages of being a priest. The *asû*, on the other hand, was more of an apothecary who prepared the complicated recipes for healing treatments and drugs, though we have little information regarding his contacts with patients. As a layman, he had no access to the tem-

ple and presumably operated from a corner shop in the street or from his home.

The respective positions of these two health professionals affected their approach, to some extent. The *ashipu* operated primarily under the assumption that disease was ultimately caused by divine will or fate; the *asû*, while generally agreeing with this position, concentrated more on natural causes of symptoms (bites, excessive exposure to draughts or sunlight, kidney stones, and so on). In essence, magic focused on disease, while medicine concentrated on symptoms.

It is not particularly easy to classify diseases within Babylonian medicine, but they fall generally within categories similar to diseases within Hellenistic medicine. Some diseases are simply associated with parts of the body, such as head disease, tooth disease, eye disease, nose disease, and even foot disease as well as kidney disease and anus disease. Even baldness was treated as a disease. There were a variety of skin diseases, including rashes and pox, as well as leprosy-like conditions affecting the nose and mouth, but it is impossible to diagnose these conditions according to modern disease terminology.

Other diseases are listed as being “caused” by the hand of a particular god, with special attention being given to “Hand of the Ghost disease.” Although the diseases may have, at one time, been thought to have originated from the actions of a particular god, ghost, or demon, by the time we see such terminology within Babylonian medical literature, these labels identify specific diseases, without much in the way of religious overtones.

Typical medical texts in the Babylonian medical literature often consist of a brief statement of the problem and a remedy. For urinary problems, one treatment stated that a man “should keep drinking one *sila*-measure of ash of the hoof of a spring lamb, one *sila* of ash of male mandrake, on an empty stomach in water for five days.” This was thought to be curative. Medical literature from Babylonia always leaves the impression of being optimistic, in the sense that most medical remedies end with the positive statement that once the drugs are administered, the patient will recover from the illness. Such statements are hardly realistic, since other diagnostic texts, which list symptoms from many different types of diseases, often give a rather grim prognosis, saying that the patient will die or that the disease will persist for a time and then the patient will die. The Babylonian *Diagnostic Handbook* lists all symptoms from head to foot, in the following case also referring to symptoms associated with the urinary tract: “[If] his [urine] is red, it is the hand of his god, (his disease) will be prolonged; . . . [If] his [urine] is black, he is affected by the fatal disease, he will die; . . . [If] his urine is continually blocked up, he will die; if his urine keeps flowing, [he will die].”

The question often asked is whether any part of Babylonian medicine was actually effective. Did it work? Hundreds of drugs are cited in Babylonian medical recipes, in addition to long lists of plants and minerals used for medicinal pur-

poses, often with descriptions of the drugs and the diseases for which they could be used. We have no idea, however, how such data was compiled, since there were no such things as clinical trials. How would ancient physicians know which plants were effective against which diseases? In the absence of any information, we can surmise that plants were identified over a very long period, perhaps going back to Neolithic times, and the use of such plants was determined by the hit-or-miss means of trying something to see what happens and then keeping careful records of the results. The crucial point was to remember, later on, if the drug seemed to work.

We have little evidence of surgery, since almost all medical texts deal with pharmacological preparations administered as potions, salves, ointments, fumigations, or suppositories or as drugs blown into the urethra or ears through bronze tubes. Surgery would have been dangerous without either proper antiseptics or anesthesia. Nor is there any evidence of bloodletting, an ancient remedy used in other cultures. For this reason, the Babylonian physician probably caused less harm to his patient than his colleagues in later medieval Europe.

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

In India the system of medicine using professional healers dates to at least 2000 B.C.E. and probably developed in China at about the same time. The earliest Indian literature, the Rig-Veda, mentions herbal and other remedies. It also accredits the divine twin gods known as the Asvins (“horsemen”) with the power to heal the sick. Gradually the role of doctors came to be officially recognized.

Medical concepts appear in the Indian Vedas, dating back to the second millennium B.C.E. As early as 800 B.C.E., when many of these ideas were written down, treatments were listed for various diseases, along with “charms” that served to expel demons from the body—an early interpretation of the root of diseases. One writer attributes the origin of Indian medicine to the god Brahma, who gave the ideas to Dhanvantari, later deified as the god of medicine.

King Asoka, ruler of the Maurya Dynasty of eastern India, is reported to have founded some 18 hospitals throughout his kingdom in about 230 B.C.E. An inscription notes that Asoka “established gardens and hospitals for man and beast,” suggesting that there were also veterinary clinics. Certainly, medical care in India was well advanced, and many medical treatises were published, including two attributed, respectively, to a physician called Caraka and a surgeon called Suśruta. The former treatise dates to the first century C.E. and the latter, in its present form, to the seventh century C.E., though parts of it are undoubtedly much older.

One of the major problems with Indian medicine was that Hindus were prevented by their religion from conducting surgery on dead bodies. This meant that they had a weak knowledge of internal organs, believing that bodies were

made from spirit, phlegm, and bile, with health relying on the balance of the three substances. Medicines later took the form of herbal drugs, animal remedies, and even mineral concoctions. Drugs were often used to sedate patients, some of them made from such plant extracts as cardamom and cinnamon. In 2001 archaeologists found evidence from a burial ground in the Indus Valley that dentists had been at work in about 2000 B.C.E. and had managed to deal with problems in molar teeth. It is unknown exactly how they did this, but it is presumed that they used quite advanced dental hand drills.

China has had a long history of the use of medicine. Much of it was herbal, and many early treatises survive that describe the use of various herbs for curing particular diseases. The first emperor of China, Qin Shi Huang (r. 220–207 B.C.E.), ordered the “burning of the books” in 213 B.C.E. and particularly excluded works of a medical nature, showing the importance of them at that time. Indeed, he helped put together the major medical work the *Nei ching su wen* (Yellow Emperor’s Classic of Internal Medicine). This treatise still forms the basis of many other Chinese medical tracts, such as the *Mo ching* (Pulse Classic), written in about 300 C.E.

Chinese medicine essentially relied on the dualist cosmic concepts of the yin and the yang—the “hot” and the “cold.” The former is the female principle, represented by the earth; the latter, the male principle, is represented by the heavens. The body itself is made up of five elements, wood, fire, earth, metal, and water, which are associated with five planets. As with the Indians, most Chinese were forbidden by religious beliefs from dissecting dead bodies, and hence the knowledge of many diseases remained limited. However the *Nei ching* did refer to circulation of the blood, anticipating the discovery of the English physician and anatomist William Harvey by 13 centuries.

Chinese doctors traditionally relied heavily on herbal cures, especially using *Ephedra vulgaris* (mahuang), and *Cannabis sativa* (Indian hemp). The root ginseng has also been used in China, Korea, and Japan for many years. Early Chinese medical practices likewise included diet regimens, the use of mineral “cures,” and acupuncture. Acupuncture has a history dating to 2500 B.C.E. and, it is thought, was discovered when several soldiers were hit by arrows in battle and found themselves cured of other ailments. The idea behind using needles inserted into various points in the body was essentially to free blocked energy, bringing the yin and yang back into balance. The needles would work on particular nerves or cause activity in another part of the body, which would allow the person’s inbuilt defenses to cure the body naturally. Starting in about 180 B.C.E. hydrotherapy was also used, with cold baths serving as a cure for some fevers.

Mention should also be made of Chinese alchemy. The practice seems to have started at least as far back as the Warring States Period (the fifth to the third centuries B.C.E.); it was closely associated with the Daoist philosophical ideas of Laozi. One early alchemist, Ge Hong (382–343 B.C.E.), came up with a large number of potions from which to make elix-

irs. Some of the many mineral elixirs in ancient China were poisonous, and several emperors died from taking them in search of immortality.

The first-known hospital where patients were brought for treatment was developed by King Pandukabhaya during the fourth century B.C.E. in modern-day Sri Lanka. An ancient Sinhalese royal chronicle, the *Mahavansha*, records that the king established hospitals for ill people in parts of his lands and also at his capital, Anuradhapura. Many people believe that the Sri Lankan hospital at Mihintale may be the oldest in the world for which a site is known. Located in north-central Sri Lanka, near the city of Anuradhapura, the remains of the buildings have inscriptions on the walls showing that the institution had a bone and muscle specialist and also a leech doctor.

While Korean medical practices were similar to those in China, in Japan diagnoses were based on expelling evil spirits from the bodies of sufferers. Gradually, however, the Japanese began to follow Chinese medicine. Similarly, in Southeast Asia, many people used Chinese and Indian medicines and practices, and some doctors from China and India settled in the area. None of these practitioners were able to deal with what is thought to be the main cause of death in the region, malaria. Some Chinese and Indian medical practitioners may also have lived on various Pacific islands, but medical care in the Pacific remained well behind that on mainland Asia. Although ancient medical practices have long been dismissed by 19th-century and early-20th-century historians, archaeological work has unearthed a far more advanced state of medical treatment in India and China, as well as in other parts of Asia, than was previously thought to exist in ancient times.

EUROPE

BY MICHAEL J. O’NEAL

The health of the ancient Europeans was not especially good. Among prehistoric peoples life was precarious, a constant struggle against starvation, famine, accident, disease, and early death. And this state of affairs assumes that a person lived long enough to carry on the struggle. The rate of infant mortality was extremely high, with perhaps as many as a quarter of children either stillborn or dying shortly after birth and as many as a quarter more dying during their first year of life. Things were not much better for women, many of whom died while giving birth.

A person who survived the first year of life had a life expectancy much lower than life expectancies in the modern world. Archaeologists, for example, have discovered a burial pit in Austria that dates to the Bronze Age. The pit contains seven skeletons of people whose ages are estimated at three, six, eight, nine, 30, and 40, respectively. In Scotland an Iron Age burial chamber yielded skeletons of people estimated to have been 10, 19, 30, 35, 40, and 45, respectively; three additional skeletons were of people who were older than 45.

Throughout ancient Europe, living past age 40 would have been an unusual accomplishment.

Disease was rife among ancient Europeans, primarily as a result of poor hygiene combined with ignorance about the causes of disease and about bodily processes. Of course, infections were common, for people did not bathe or change and wash clothing very often, and they lived in close proximity to livestock and domesticated animals, along with their waste. Communicable diseases, such as smallpox and measles, were an ever-present threat, and infections from wounds could easily turn deadly. People suffered from a host of complaints, including intestinal parasites (often from unsanitary water and poor waste disposal), eye disorders, respiratory infections, and dental disease. All of these relatively simple complaints could have dire effects. Intestinal disorders, for example, could lead to diarrhea and consequent dehydration, shock, and death. Eye problems contributed to accidental injuries and death; at best, they severely limiting the sufferer's quality of life. Respiratory infections could turn into pneumonia, and tuberculosis was common. Dental disease made it difficult for older adults to chew food, with resulting consequences to their health.

Further, diets were not always well balanced, given that the availability of foodstuffs was dependent on the seasons. During the summer, fruits, vegetables (primarily roots and leafy vegetables), and berries would have been available, providing people with essential vitamins, but during the long winters people relied primarily on meat (preserved by salting or drying), dairy products from livestock, and stored grain. Some diseases were genetically based. One example is a disorder called Dupuytren's disease, a genetically transmitted deformity of the fingers. This disorder was relatively widespread among the ancient Scandinavians and later extended to the rest of Europe after the Viking invasions in the Common Era.

None of this is to say that the ancient Europeans did not make efforts to practice a form of medicine. One form of "medicine," of course, involved religious beliefs put into practice. To cure their disorders, people turned to the gods, usually enlisting the help of shamans (native healers) and priests, many of whom were thought to have magical powers. Examples of shrines, with replicas of human organs, suggest that people went to such shrines seeking cures. Another common practice was the sacrificing of an animal, such as a bull, to effect a cure. Also popular among the ancient Europeans were healing springs, including numerous springs in Gaul (modern-day France) and in Bath, England. People believed that the waters in these places had medicinal properties. In some respects, they may have been correct. The warm, soothing waters of these springs and baths undoubtedly provided at least some psychological benefits, giving the sufferer relief from pain and the will to get better.

Herbal remedies were also popular. Among the ancient Celts, for example, mistletoe was thought to have healing properties; in fact, mistletoe contains chemicals that have

been shown to reduce blood pressure, and it is the basis of several modern-day homeopathic remedies. Ancient Roman historians who traveled in such places as Gaul wrote about the healing properties of various plants, including "samolus," "selago," and "anguinum," though modern historians have been unable to identify these plants. Celery and parsley were also thought to have medicinal properties.

In general, ancient Druid healers among the Celts were familiar with a wide range of plant substances that had beneficial health effects. Examples include the bark of the willow tree, which contains a substance that is chemically similar to the active ingredient in aspirin, though it caused a great deal of stomach pain because it was not "buffered," as modern aspirin is. They probably gathered these substances according to a strict schedule based on the phases of the moon, in the belief that all the powers of nature worked hand in hand. They were also familiar with poisons and thought that a poisonous plant was not harmful if it was picked with the left hand. In

many senses, these ancient healers functioned as experimental scientists, observing symptoms, trying herbal treatments, and assessing what seemed to help.

The ancient Europeans also practiced a form of surgery. Near Munich, Germany, archaeologists discovered the tomb of a “warrior-surgeon” that contained a number of medical and surgical implements. This tomb dates to about the third or early second century B.C.E. Among these instruments were probes, retractors, and a trepanning saw, or a saw used to cut holes in the skull. Trepanning was a widely used technique for treating head injuries and psychological disorders, and healers used both saws and drills to make their holes. A large number of skulls have been found that have neat holes drilled or cut into them. While many people died during this type of surgery, a surprising number did not, for the holes in some skulls show evidence of healing. Trepanning evolved from the notion that the health of the body was based on a balance of substances. Allowing substances that caused ill health to escape the body could, it was believed, lead to a cure. For the same reason, blood-letting (opening a vein to let blood flow out) was a common early practice.

GREECE

BY TOM STREISSGUTH

Asclepius reigned in ancient Greece as the god of health and medicine. According to Greek myth, Asclepius was the son of Apollo and was taught the arts of healing and surgery by the centaur Chiron. His daughter Hygieia was the goddess of cleanliness and good health; his daughter Panacea was the goddess of healing. In ancient Greece the *asclepeion* was a sanctuary built to honor Asclepius and as a health retreat, to treat the sick and the injured. There were *asclepia* in Athens, Corinth, Trikkala, Pergamon, Kos, and Epidauros in the Peloponnesus, the traditional center of the cult. *Asclepia* were also built in distant Greek colonies and throughout the Mediterranean region. Patients arrived to receive the god’s blessing through healing waters and treatment, through offerings at the temple altar, and through the interpretation of their dreams by the priests of the sanctuary. The fame of the healing god spread to the early republic of Rome, where sanctuaries were built in imitation of the Greek *asclepeion*. On the outbreak of a plague in the early third century B.C.E., the Romans appealed directly for his services. The Greeks responded by sending the god in the form of a snake; in many depictions of the god, a snake adorns the Rod of Asclepius. This symbol of the healing arts survives in medical emblems to the present day.

Traditional Greek medicine relied on the use of herbs and other natural remedies and on incantation and prayer to the gods. Greek medicine began to pass from religious belief to scientific observation at a school of medicine at Cnidus in the seventh century B.C.E. Historians believe that Egyptian medicine, which had some supernatural elements and which prescribed very strict courses of treatment for every occur-

rence of a disease, had an important influence on the early medical practices of the Greeks. (The skill of Egyptian healers and the power of their medicines are mentioned in the *Odyssey* of Homer.)

Alcmaeon (fl. sixth century B.C.E.), a member of the school of Cnidus, was the first Greek to set down in writing his observations of the human body. His surgical experiments led to the first rational debates over the structure and functions of the human body. On performing the first eye operations, Alcmaeon theorized that the brain was the seat of memory, thought, and emotion. Empedocles (fl. fifth century B.C.E.), a philosopher from the island of Sicily, advanced the notion of the four elements—earth, air, fire, and water—and extended this idea to the human body in the four “humors.” The Greeks believed that a combination of four elements, or humors, made up an essential balance within the human body. The humors originated in the physical location of the person and the place of his or her birth, with the ideal balance being found in the civilized people of the Greek world. The humors were blood, phlegm, yellow bile, and black bile. Through their proportions, the humors shaped the human intellect and personality and also affected life’s physical existence from birth to maturity and on to old age and death. A balance of the humors was needed to keep the body free of disease, and achieving or repairing that balance was the task of a physician. A patient suffering from disease could be put right by purging, by bloodletting, or by some other method of relieving the body of a humor found to be in excess.

The theory of the four humors was followed by Hippocrates (460–377 B.C.E.), the most renowned Greek physician. Hippocrates was a native of the island of Cos who founded a new school of medical practice, which for a time became the most important center of healing in the Greek world. Using case histories, Hippocrates took a scientific approach to disease, discarding religious superstitions and investigating causes, symptoms, and *physis*, or the overall state of the body, including its inner functioning as well as environmental effects. In dealing with their patients, physicians at Cos carried out observation, diagnosis, prognosis, and treatment—the basic elements of clinical medicine that survive to this day. They discarded the Egyptian notion of strictly prescribed treatment; all patients were considered individually through careful observation and treated accordingly.

Medical students at Cos served a paid apprenticeship of several years, which involved classroom teaching, study of medical texts, and observation and treatment of patients. The most enduring product of the school was the *Corpus Hippocraticum*, a collection of essays by several authors that described case histories and accounts of treatment. This work included essays on nutrition, surgery, and obstetrics, as well as the Hippocratic oath, a lengthy instruction on proper care and treatment of patients that survives as the foundation of modern medical treatment and ethics.

After the conquest of North Africa by Alexander of Macedon (r. 356–323 B.C.E.) and the founding of Alexandria

Ivory figure of a hunchback thought to show signs of Pott's disease, Hellenistic, about first century B.C.E. (© The Trustees of the British Museum)

by his general Ptolemy, the seat of medical research moved to this new city on the Mediterranean coast, which attracted scholars and physicians from all over the Greek world. Famous Alexandrian medical scholars include Herophilus, who lived in the early third century B.C.E. Herophilus investigated the eye and brain and deduced the usefulness of the pulse in the diagnosis of disease. His written work on the topic of dissection (which has not survived) described his study of human anatomy. A contemporary of Herophilus, Erasistratus, made a famous study of the brain, nerves, arteries, and veins and went further than Herophilus in understanding the structure of the brain and the nervous system.

The theory of the humors was further advanced by Galen, a physician of Pergamum (129–200 C.E.) in Asia Minor, who was renowned for his public dissection of pigs, apes, dogs, and goats. His works include *On the Elements according*

to Hippocrates and a work in 17 volumes, *On the Usefulness of the Parts of the Body*. Galen explored the nervous system and the spinal cord, demonstrated the function of the veins and arteries, and showed that urine originated in the kidneys. Galen's works circulated widely in the Arab-speaking and Persian-speaking world as well as in Europe, where physicians relied on his theories and practices for the next 1,500 years.

ROME

BY BROOKE HOLMES

The Romans considered health to be both a private and a public affair. The majority of responsibility for maintaining health rested with the individual and the family, and patients had access to a range of options in their pursuit of health, depending on their location and their resources. The health of the populace also benefited from the construction and maintenance of public aqueducts, sewers, latrines, and baths. Official interest in public health, however, was largely restricted to the army.

Life was precarious in the ancient Roman world. The average life expectancy at birth was about 25 years of age, and infant mortality rates were high. The risk of death remained serious during the child's first year, although those who survived had better odds thereafter, with a life expectancy extended into their thirties and forties. The analysis of skeletal remains has shown that environmental and demographic factors determined the unique disease profiles of individual settlements. Dental health, for example, could be affected by fluoride levels in the water, and low-lying areas were prone to malaria. Poor sanitation, particularly in the overcrowded areas of Rome, fostered the spread of ailments such as diarrhea, pneumonia, jaundice, parasites (such as tapeworm), and infections of the liver, bladder, and kidney.

Malnutrition, caused by an irregular food supply, posed a serious threat everywhere, affecting poor women and children particularly hard. Childbirth, too, exacted a heavy toll on women. For Romans who survived past their twenties, degenerative diseases such as arthritis would have made later life difficult and painful, and chronic pain was a problem at any age, especially for slaves and free laborers. Roman remedies are considered largely ineffective by modern standards, though they may have had a placebo effect. Patients may have improved because of their positive expectations rather than as a result of the remedies themselves.

In the early Roman Republic, the health of the household, both free persons and slaves, was overseen by the *paterfamilias*, the male head of the family. The remedies recommended by Cato the Elder (234–149 B.C.E.), who wrote in this tradition, are primarily herbal and magical, drawn from Italic folk medicine. Cato saw medicine as an internal affair that did not require professional expertise. He was writing, however, at a time when Romans were becoming Hellenized, that is, more Greek, following their military conquests across the Mediterranean and the influx of Greek ideas, goods, and

persons into Rome. A vocal critic of these changes, Cato's defense of traditional medicine coincided with a denunciation of professional Greek physicians as greedy and even murderous. Cato's remedies nevertheless show his familiarity with Greek medicine.

Ambivalence characterizes the Roman experience with Greek medicine. In 293 B.C.E., after three years of plague, the Roman Senate summoned the healing god Aesculapius from his shrine in Epidaurus, in the Greek Peloponnese. According to the myth, the god traveled in the form of a snake to Rome and promptly ended the plague. His cult was established on Tiber Island, where the river Tiber takes a double bend through the city of Rome, and later spread throughout the Roman world, attracting patients from all backgrounds. Romans also continued to appeal to the healing gods of their native pantheon and patronize older shrines, such as that of Diana Nemorensis at Nemi in central Italy, established perhaps as early as the eighth century B.C.E. about 16 miles from Rome.

The first mortal Greek doctor, Archagathus (later known as Caecilius of Calacte), who arrived in Rome in 219 B.C.E. on

the invitation of the Roman Senate, did not assimilate as easily. He was granted citizenship, and a practice was set up with public funds. Soon, however, his harsh techniques earned him the nickname "the executioner," and he left Rome. Greek medicine found a more successful representative in Asclepiades of Bithynia (fl. ca. 120–50 B.C.E.). Asclepiades arrived in Rome toward the end of the second century B.C.E. and gained renown for his gentle therapies. His teachings were modified by his student Themison of Laodicea (fl. ca. 50 B.C.E.), who identified three causes of disease, called the commonalities: "tightness" in the body, "looseness," and a mixture of the two; the physician simply noted the state of the patient's body and prescribed the appropriate cure. His ideas were elaborated in the next century by Thessalus of Tralles, the founder of the "Methodist" school of medicine, which essentially saw disease as an imbalance of solid particles and spaces in the body. By this time Greek medicine was well established in Rome. Julius Caesar had granted citizenship to all physicians in 49 B.C.E., and the emperor Augustus exempted them from taxes in 23 B.C.E. Yet while many elite men consulted physicians, they continued to value self-sufficiency, and the care of the body was an important component in Roman practices of self-mastery.

While the Methodist school was popular at Rome, practitioners competed for patients with physicians loyal to medical doctrines developed in Hellenistic Alexandria. Empiricists believed that physicians should rely on past experiences with a disease when determining the proper response to symptoms. Others, called Dogmatists by their adversaries, argued that the physician needed knowledge of the human body and the hidden causes of disease to treat patients successfully. Galen of Pergamum (129–200 C.E.) brought the theory and practice of medicine together. He was an expert anatomist, well versed in philosophical debates about health and disease, the emperor Marcus Aurelius's personal physician, and a prodigious writer. Galen's version of medicine, which developed Hippocratic ideas about the importance of balance between humors, elemental fluids inside the body, influenced Byzantine, Arabic, and medieval Western medicine.

Imperial expansion brought physicians into contact with new medicaments and herbs. Exotic substances were in high demand as both remedies, such as mithridatium, a drug composed of thirty-seven different ingredients, and cosmetics. The most famous treatise on pharmacology, or the study of drugs, was written in Greek in 64 C.E. by Pedanius Dioscorides of Anazarbus (fl. ca. 40–90 C.E.). His five-book *De materia medica* is an attempt to provide a complete list of known medicinal substances, organized according to their effects. Dioscorides' work was consulted for the next 1,500 years.

The Roman army benefited from some of the most advanced medical care under the empire. With the establishment of a permanent military presence on the frontiers, care became more institutionalized. Production of Greco-Roman surgical instruments sharply increased in the first century C.E., and many of the new fortresses included hospitals. Ci-

vilians had no equivalent until Christians in the east began to establish shelters for the poor, the sick, and travelers, which spread under the emperor Julian in the third century C.E.

The organization of the Roman household did not observe basic principles of sanitation. Latrines were often situated in kitchens; wells were dug near cesspits. Public works projects made the city cleaner but did not always improve hygiene. Rome's sewer system, the Cloaca Maxima, was first laid out in the sixth century B.C.E. by the Etruscans and covered in the third century B.C.E. The statesman Marcus Agrippa (64–12 B.C.E.) directed extensive repairs to the system in 33 B.C.E. and had it paved and vaulted. Sewage emptying into the Tiber was, however, a source of pollution for those downstream and could back up with changes to the water level.

Although water from the aqueducts provided residents with a relatively safe water supply, opportunities for contamination remained—some as a result of the use of lead pipes. Aqueducts also supplied public latrines and baths. Across the empire, baths were popular social hubs. Physicians also prescribed them for their patients, and medical services, massages, and beauty treatments would have been available onsite. While they were unhygienic by modern standards, the baths ensured a relatively high level of cleanliness in the population.

THE AMERICAS

BY KIRK H. BEETZ

Of the many controversies involving the interpretation of ancient American history, the matter of health and disease is one of the most heatedly debated, more because of what the history may mean to modern politics and society than what it may mean in terms of the actual archaeological evidence. At present historians believe that syphilis originated in the Americas, and there is skeletal evidence that indicates that syphilis afflicted ancient Mayans by 1000 B.C.E. Still, a minority of archaeologists suggest that syphilis already existed in Europe when Columbus reached America in 1492, though documents indicate a spread of syphilis from Columbus' home port in Spain through Spain and then to the rest of Europe. What gives the debate its heat is the notion that someone is to blame for the disease, an issue that matters nothing to the facts of the disease itself.

Not as contentious an issue is the origin of tuberculosis. This disease seems to have afflicted ancient Americans as well as people in the Old World; its DNA has been found in naturally mummified corpses in Peru dating from the 900s C.E., and lesions are evident on lungs of ancient peoples. Some archaeologists argue that the disease could have started in only one place or the other and thus disagree about whether tuberculosis began in the Old World or the New World. One possibility is that tuberculosis was carried into the Americas by people during one of the ancient migrations from northeast Asia into Alaska. Another is that it was carried by an unknown contact between ancient Americans and Asians or

Europeans. Perhaps the likeliest possibility is that tuberculosis first developed in rodents and eventually developed into a disease that could pass from rodents to humans in both the New World and the Old World, perhaps at different times.

Many severe diseases developed in the Old World that were unknown in the New World until the coming of Columbus, but ancient Americans were afflicted various diseases anyway. There were vitamin deficiencies, especially of vitamin C. Some North Americans of the Southwest learned to eat wild garlic cloves to treat the problem, but it seems to have afflicted Mayans without successful treatment. Other vitamin deficiencies caused poor tooth enamel growth, a problem detected by archaeologists more among ancient Mesoamericans than among other ancient Americans. By 7000 B.C.E. Chagas disease affected early settlers in the Andes. Chagas, a disease that leads to fever and swelling of the lymph glands and can progress to serious nervous system and heart damage, among other symptoms, is caused by a protozoan and carried from host to host by mosquitoes. The protozoan burrows into body tissues, eventually overwhelming the body and causing death. About 41 percent of tested mummies from about 7000 B.C.E. had the disease. Another disease was yaws, a tropical skin infection that causes infection of the skin, bones, and joints.

Some of the health problems suffered by ancient Americans were caused by their own activities. For instance, archaeologists have reported throughout the Americas that ancient Americans had trouble disposing of human waste. From large settlements in North America to South America, communities were troubled by the buildup of human waste, though after the ancient era some cultures developed sewer systems. Archaeologists debate the cause of the collapse of Mayan cities, and one theory is that disease made their cities unlivable, forcing them out of lowland cities into highland cities and then out of cities altogether. Poor disposal of human waste is often cited as a possible source of diseases of the skin that would make life in the cities unbearable. Further, poor disposal of waste may have attracted animal carriers of disease. American rodents carried, for example, viruses that could attack human hearts and cause severe fevers. Poor nutrition may have resulted from expanding human populations that put too much stress on the land's ability to provide enough food for everyone, which would have resulted in vitamin-deficiency diseases. Studies of Mayan skeletons indicate that prior to 400 B.C.E. Mayans were taller than those after 400 B.C.E., which may indicate poor nutrition caused by overpopulation after 400 B.C.E.

The ways in which ancient Americans dealt with their health problems are best known for the regions of the Andes, Central America, eastern North America, and southwestern North America. The peoples of southwestern North America may have been influenced by the cultures of Mesoamerica. The use of smoke for curative power seems to be very old in ancient American cultures. A large smokehouse dating to about 3700 B.C.E. has been found in Canada. At its center was a large hearth. Inhaling fumes thick with smoke may have

been thought to cure breathing diseases and perhaps skin diseases. The Mayans seem to have been using smoke for similar purposes by 650 B.C.E. An ill person would be cloaked in smoke, which was supposed to draw the disease out of the body. Sweat houses were also used by Mayans because it was thought that the sweating caused by heat would carry poisons out of the body.

Other cures and treatments came from plants. In North America it is likely that shamans, or native healers, had practical knowledge of how to use certain plants to treat illnesses. Headaches could be treated with powdered Indian turnips and upset stomachs with a drink of boiled mint. A therapy for asthma might have been powdered skunk cabbage root. Even tuberculosis seems to have had a treatment, the eating of black nightshade. A salve from yarrow could be used to treat cuts. Energy could be recovered by eating the peyote cactus. In Mesoamerican cultures herbs were used to treat illnesses, and surgery was used to amputate diseased bones. In the Museum of the Bank of the Pacific in Ecuador is a sculpture showing a man chewing coca; it dates from about 1500 B.C.E. Coca was probably used to renew energy.

In ancient American cultures disease was not only physical but also spiritual. Some ancient Americans may have believed that diseases resulted from the loss of part of the soul.

A shaman would “suck in” the missing part of the soul and blow it back into the patient. Often, diseases were thought to be spiritual poisons. In North America and Central America eggs were passed over a patient’s body to suck out the spiritual poison. The egg would then contain the poison and would be disposed of. Ancient Mayans would place the egg underground.

In Central America caves were thought to be sources of illness. Breezes from the caves were believed to carry diseases to humans. Thus, placing charms at the entrances of caves might prevent the spread of disease by keeping it contained in the caves. On the other hand, a patient might have been treated in a cave, perhaps to send his or her illness back into the cave. Among the Maya, shamans engaged in “earth magic,” using crystals in their healing rituals, probably as a way to draw on the power of the earth from which the crystals had come.

The Middle East

☞ *Tabu-utul-Bêl: “Ludlul Bêl Nimeqi,”*
ca. 1700 B.C.E. ☞

I advanced in life; I attained to the allotted span.
Wherever I turned there was evil, evil—
Oppression is increased, uprightness I see not.
I cried unto god, but he showed not his face.

I prayed to my goddess, but she raised not her head.
The seer by his oracle did not discern the future
Nor did the enchanter with a libation illuminate my case.
I consulted the necromancer, but he opened not my
understanding.
The conjurer with his charms did not remove my ban.

How deeds are reversed in the world!
I look behind, oppression encloses me.
Like one who the sacrifice to god did not bring
And at meal-time did not invoke the goddess
Did not bow down his face, his offering was not seen; . . .

Into my prison my house is turned.
Into the bonds of my flesh are my hands thrown;
Into the fetters of myself my feet have stumbled.

With a whip he has beaten me; there is no protection;
With a staff he has transfixed me; the stench was terrible!

All day long the pursuer pursues me,
In the night watches he lets me breathe not a moment
Through torture my joints are torn asunder;

My limbs are destroyed, loathing covers me;
On my couch I welter like an ox
I am covered, like a sheep, with my excrement.
My sickness baffled the conjurers
And the seer left dark my omens.

The diviner has not improved the condition of my
sickness—
The duration of my illness the seer could not state;
The god helped me not, my hand he took not;
The goddess pitied me not, she came not to my side
The coffin yawned; they [the heirs] took my possessions;

While I was not yet dead, the death wail was ready.
My whole land cried out: “How is he destroyed!”
My enemy heard; his face gladdened
They brought as good news the glad tidings, his heart
rejoiced.
But I knew the time of all my family. . . .
This is the dream which I saw by night:

[He who made woman] and created man,
Marduk, has ordained that he be encompassed with
sickness. . . .

He said: "How long will he be in such great affliction and
distress?

What is it that he saw in his vision of the night?"

In the dream Ur-Bau appeared

A mighty hero wearing his crown

A conjurer, too, clad in strength,

Marduk indeed sent me;

Unto Shubshi-meshri-Nergal he brought abundance;

In his pure hands he brought abundance.

By my guardian-spirit he stopped,"

By the seer he sent a message:

"A favorable omen I show to my people." . . .

He sent a storm wind to the horizon;

To the breast of the earth it bore a blast

Into the depth of his ocean the disembodied spirit

vanished;

Unnumbered spirits he sent back to the underworld. . . .

The sea-flood he spread with ice;

The roots of the disease he tore out like a plant.

The horrible slumber that settled on my rest

Like smoke filled the sky. . .

With the woe he had brought, unrepulsed and bitter, he

filled the earth like a storm.

The unrelieved headache which had overwhelmed the

heavens

He took away and sent down on me the evening dew.
My eyelids, which he had veiled with the veil of night
He blew upon with a rushing wind and made clear their
sight.

My ears, which were stopped, were deaf as a deaf man's

He removed their deafness and restored their hearing.

My nose, whose nostril had been stopped from my
mother's womb—

He eased its deformity so that I could breathe.

My lips, which were closed he had taken their strength—

He removed their trembling and loosed their bond.

My mouth which was closed so that I could not be
understood—

He cleansed it like a dish ; he healed its disease.

My eyes, which had been attacked so that they rolled
together—

He loosed their bond and their balls were set right.

The tongue, which had stiffened so that it could not be
raised

He relieved its thickness, so its words could be understood.

The gullet which was compressed, stopped as with a
plug—

He healed its contraction, it worked like a flute.

My spittle which was stopped so that it was not secreted—

He removed its fetter, he opened its lock.

the Bible*, 3rd ed. (Philadelphia: American
Sunday School, 1920), pp. 392-395.

Asia and the Pacific

~ The Yin Fu Ching, or Clue to the Unseen, excerpts ca. 1200 B.C.E. ~

*To observe the TAO of Heaven, and grasp its method of
operation, is the limit of all achievement.*

The root of Heaven is in TAO; and TAO being
fixed, Heaven secures it and so brings about its
transmutations. Principles have their root in
circumstances, or facts; and facts being determined,
it is Principles by which they are modified or varied.
Thus Principles have no unvarying course, and facts
no essential uniformity; both belong to the region
of the unlimited. It is only by observing the TAO
of Heaven, and grasping that, that the limit can be
reached.

*Thus Heaven has Five Despoilers: and he who perceives them
will flourish.*

There is no benefit intended towards man when the
Five Atmospheric Influences are set in motion; how,
then, can there be any intentional injury to things?
Observing the nourishing and beneficial results of these
Influences, men call it virtue; observing the injury and
ruin they cause, men call it spoliation. As soon as we see
a thing produced, it is destroyed; and having witnessed
its destruction, we see it come into being again. The
Afflatus of the East is antagonistic to the Centre; the
Afflatus of the Centre is antagonistic to the North; the

(continued)

(continues)

Afflatus of the North is antagonistic to the South; the Afflatus of the South is antagonistic to the West; the Afflatus of the West is antagonistic to the East. When these Five Afflati promote the growth of one another, they move freely; but the very ease with which they flow leads to their exhaustion. When they act in antagonism to each other, their motion is arrested; but if such arrest be counteracted, they are re-established [in their course]. Man is in the centre of Heaven [and Earth]; the heart is in the centre of man. When anything occupies a central position, it may be removed to the outside. If one wishes to control much by means of a little, it is necessary to use contrivances—or, to employ one's faculty of contrivance—in manipulating the material under one's hand. Nevertheless, let the mind be once set in motion, everything under Heaven may be accomplished; while by using antagonistic agencies, that which is complete and permanent may be produced. . . .

When Heaven sends forth its engines of destruction, the stars are moved out of their places and the constellations metamorphosed. When Earth sends forth its engines of destruction, dragons and snakes appear on the dry land. When Man puts forth his faculties of destruction, Heaven falls and Earth is overthrown. When Heaven and Man do so in concert, all the disorganised phenomena are re-established on a new basis.

The stars and constellations are the countenance of Heaven. In like manner, when a man is angry, his countenance will surely change. Dragons and serpents are the breath and blood [the hidden agencies] of earth. In like manner, when a man is sick, his breath and blood will surge up, or overflow. Man, situated in the centre of the Universe, is as it were the abdomen of Heaven and Earth. When the viscera are injured, the effects are manifest from top to toe; everything, from the head down to the feet, is thrown into disorder. When Earth is in harmony with Heaven, Man occupies the same relation towards each. For Heaven to respond to human requirements, or affairs, it is necessary to wait until such affairs be brought to a state of completion. If any one such affair be uncompleted, even the Sage will be unable to undertake its achievement; but when it is perfected—in such a forward state as to be prepared for the co-operation or assistance of Heaven—the response of Heaven will come. . . . This may be compared to the capture of Wu by the Prince of Yueh.

The Five Despoilers pertain to the Heart, but their operation is diffused all over the world. The Universe is in one's Hand; all transmutations take their rise from the body.

Thieves, or despoilers, are so called because they are unseen; if, in acting as thieves, they are perceived, their depredations are put an end to. The antagonism which exists between Water and Fire is turned to advantage when brought into contact with matter, and eventual welfare is the result. The Five Despoilers of Heaven are identical with the Five Despoilers of men. These Five Despoilers residing in the human heart, their agency is diffused far and wide; but is Heaven within the range of my—[i.e., any man's—activity]? Now cooperation implies the same object being held in view by two persons. If the other man acts, it is as though I myself acted; just, for instance, as in riding,—the rider is identified with his horse; and where the horse arrives the rider arrives too. Therefore a journey of a thousand li may be said to be held in the hollow of one's hand; for if a desire arises in the mind to go, say, from Yen in the north to Yueh in the south, you will be able to reach your destination supposing you make proper use of your intellectual faculties. . . .

The Abuse of the Nine Openings of the Body having specially to do with the Three which are most important, action and rest are both possible.

The Nine Openings are, all of them, the organs of intelligent perception; even those which have least capacity serving as passages for air. Eight of these openings are channels for the exercise of sagacity; it is only the private part behind, which is without any such faculty. The implication [in the text] that they are all liable to misuse, is simply made as applying to the majority, [the one exception] being wrongly included for the sake of convenience. But it is the Ear, the Eye, and the Mouth, which are the most liable to deception and abuse; therefore their action should be confined within certain limits, and subjected to the will of their owner. Then they may be made to act and abstain from action; by which means the body may be nourished and provision made [for any exigencies that may arise].

The diseases to which men are subject are the result of abuse. It is only the Sage who knows how to value this abuse [of the bodily organs], for, when it becomes violent, it is only the Sage who is able to hinder its operation. Then [the man's] action becomes in accord with the principle Yang, and his repose in accord with the principle Yin; [the man himself] developing mental powers of superhuman excellence.

Greece

≈ *Galen: Medicine, ca. mid-second century C.E.* ≈

There are in all three branches of the study of medicine, in this order. The first is the study of the result by analysis; the second is the combining of the facts found by analysis; the third is the determining of the definition, which branch we are now to consider in this work. This branch of the science may be called not only the determining of the definition but just as well the explication, as some would term it, or the resolution, as some desire, or the explanation, or according to still others, the exposition. Now some of the Herophilii, such as Heraclides of Erythrea, have attempted to teach this doctrine. These Herophilii and certain followers of Erasistratus and of Athenaeus, the Attalian, studied also the doctrine of combination. But no one before us has described the method which begins with the study of the results, from which every art must take its beginning methodically; this we have considered in a former work.

Chapter 1. Medicine is the science of the healthy, the unhealthy, and the indeterminate, or neutral. It is a matter of indifference whether one calls the second the ill, or the unhealthy. It is better to give the name of the science in common than in technical terms. But the healthy, the unhealthy, the neutral, are each of them subject to a threefold-division: first, as to the body;

second, as to the cause; and third, as to the sign. The body which contains the health, the cause which affects or preserves the health, and the sign or symptom which marks the condition of the health, all these are called by the Greeks *hygienia*. In the same way they speak of the bodies susceptible to disease, of causes effecting and aiding diseases, and of signs indicating diseases, as pathological. Likewise they speak of neutral bodies, causes, and signs. And according to the first division the science of medicine is called the science of the causes of health; according to the second, of the causes of ill health; and according to the third, of the causes of neutral conditions.

Chapter 2. The healthy body is simply that which is rightly composed from its very birth in the simple and elementary parts of its structure, and is symmetrical in the organs composed of these elements. From another point of view, that is also a healthy body which is in sound condition at the time of speaking.

Greece

≈ *Hippocrates: Aphorisms, ca. fifth century B.C.E.* ≈

SECTION I.

1. Life is short, art is long, occasion sudden, experiment dangerous, judgment difficult. Neither is it sufficient that the physician do his office, unless the patient and his attendants do their duty and external conditions are well ordered.

6. In extreme diseases extreme and searching remedies are best.

13. Old men easily endure fasting, middle-aged men not so well, young men still less easily, and children worst of all, especially those who are of a more lively spirit.

14. Those bodies that grow have much natural heat, therefore they require good store of food or else the body consumes, but old men have little heat in them; therefore they require but little food, for much nourishment extinguishes that heat. And this is the reason that old men do not have very acute fevers, because their bodies are cold.

20. Those things that are or have been justly determined by nature ought not to be moved or altered, either by purging or other irritating medicine, but should be let alone.

SECTION II.

4. Neither satiety nor hunger nor any other thing which exceeds the natural bounds can be good or healthful.

51. It is dangerous much and suddenly either to empty, heat, fill, or cool, or by any other means to stir the body, for whatever is beyond moderation is an enemy to nature, but that is safe which is done little by little, and especially when a change is to be made from one thing to another.

SECTION III.

1. Changes of seasons are most effectual causes of diseases, and so are alterations of cold and heat within

(continued)

(continues)

the seasons, and other things proportionately in the same manner.

SECTION IV.

37. Cold sweats in acute fevers signify death, but in more mild diseases they mean the continuance of the fever.

38. In what part of the body the sweat is there is the disease.

39. And in what part of the body there is unusual heat or cold there the disease is seated.

SECTION VII.

65. The same meat administered to a person sick of a fever as to one in health will strengthen the healthy one but will increase the malady of the sick one.

SECTION VIII.

6. Where medicines will not cure incision must be made; if incisions fail, we must resort to cauterizing; but if that will not do we may judge the malady incurable.

18. The finishing stroke of death is when the vital heat ascends above the diaphragm and all the moisture is dried up. But when the lungs and heart have lost their moisture, the heat being all collected together in the most mortal places, the vital fire by which the whole structure was built up and held together is suddenly exhaled. Then the soul leaving this earthly building makes its exit partly through the flesh and partly through the openings in the head, by which we live; . . . thus it surrenders up this cold earthly statue, together with the heat, blood, tissues, and flesh.

► household goods

INTRODUCTION

The household goods of ancient peoples were in general made of nondurable materials, so few of these goods, other than those made of metal and, to a lesser extent, clay pottery, survive. Archaeologists know about the kinds of household goods found in typical homes primarily from surviving paintings and mosaics that depict these goods as well as from surviving household goods placed in the tombs of royalty and prominent people. In some cases, written descriptions of household goods survive.

Nothing is mysterious or unpredictable about the household goods of ancient people, for no matter where or when they lived, they had roughly the same needs that modern people do. People needed to rest, so they had beds and chairs. To keep warm, they used blankets woven from local fibers or comforters stuffed with down, and in colder climates they had tools for tending a fire. They needed to eat, so they had a table for dining as well as plates, bowls, and cups—but not always utensils like forks and spoons—for food. They needed

to store and preserve food and beverages, so they had jars, pots, and flagons, sometimes kept in a pantry, sometimes in what amounted to a basement below the house. They needed to cook food, so they had pots and pans, ladles, and cook stoves and ovens, in a kitchen or outdoors, depending on the region's climate. They needed to dress, so they had not only clothes but also places to keep them, and they had mirrors to check their appearance. They needed to eliminate waste, so they had some type of privy or toilet. When it was dark, they needed lamps to provide light. Because most households had to provide many of their own goods for personal use, household goods usually included tools for carving, cutting, polishing, sewing, weaving, sharpening, butchering, gathering crops, cultivating, and any other necessary task.

The ancients constructed household goods out of the materials at hand. In some cases, furniture was made of mud brick and incorporated into the structure of the building itself. Thus, a mud brick bench might have been built into an interior wall. In many cases, though, furniture was made of wood. Early furniture was crude, consisting of branches woven together or small logs assembled into a chair, table, and the like. As time went on, though, and civilizations became more developed, many craftsmen throughout the world became expert carpenters and wood carvers and created furniture that was not only functional but also decorative. Even the most luxurious of homes did not contain a great deal of furniture. In ages before machinery and mass production, furniture and other household goods were made by hand, one piece at a time. Rich people could perhaps have afforded more household goods, but the goods often were simply not available.

Other materials were used to fashion household goods. In addition to clay and local wood were metal (including primarily copper, bronze, and iron but also silver and gold). In time, luxury goods made of such materials as ivory, glass, precious and semiprecious stones, and exotic hardwood from other regions of the world became available to the elite through trade.

AFRICA

BY KIRK H. BEETZ

It is challenging to determine the sorts of household goods used by ancient Africans, because the wood and reeds most Africans would have used to make most of their furniture and other household goods decays quickly in much of Africa. Thus, archaeologists have only rock paintings, pottery, stone, and metalwork to study to gain an understanding.

At one time all Africans were hunter-gatherers. In about 27,500 B.C.E. these ancient hunter-gatherers began painting on rocks in southern Africa and in the Sahara. The people of southern Africa were the San, also called Bushmen, while the Saharans were a mixture of ethnic groups. As the Sahara became drier, its residents changed their ways of life, shifting from hunting and gathering to herding cattle. After 3000

B.C.E. some of these herders began settling at oases and adopted agriculture. Rock paintings offer glimpses of what the Saharans owned. Herders are shown using sticks to guide their animals. Sometimes they wear robes, probably for special occasions. One painting from about 1000 B.C.E. is a diagram of two men drawing water from a well. They use what appears to be a leather bucket. This image suggests that leather was used to store water, perhaps for use in homes, though this is not known for certain.

As the Sahara dried, many of its people moved eastward. Others were probably already part of a culture that included the forests of West Africa and probably moved south to live among their own people. Among their descendants may have been the Bantu speakers. These were an agricultural people, which meant that they had homes where they lived year round. This contrasts with the San, who were mobile and ranged far over the land where they lived. The San had some household goods, mostly clay vessels for cooking. These they made themselves if clay was available, or they traded for the vessels. On the other hand, the Bantu could accumulate goods because they did not have to carry them far afield. Perhaps by the 400s B.C.E. they had pottery, woven baskets, and metalwork they could call their own. By the 100s C.E. Bantu households had iron utensils for cooking, iron spearheads for hunting, and iron hooks for fishing.

Ancient Bantu speakers apparently had little or no household furniture. People sat on the floors of their houses, which would have been dirt, perhaps covered by matting. Mats were made out of loosely woven reeds or other grasses. Bantu speakers' houses were usually circular, with hearths or ovens in their centers. Ovens were ceramic, apparently with one chamber for baking. Most cooking would have been done on top of the oven.

Cooking utensils seem to have varied from place to place, with ceramic, copper, iron, or presumably wooden spoons being used to stir, serve, or eat some foods. The Bantu speakers had a fairly wide range of foods to cook, including cereals, roots, milk, and meats, both from domesticated animals such as cattle and sheep and from wild animals such as elephants and monkeys. Stew would probably have been common, cooked in ceramic pots on ovens or in open fires. Ceramic cups found in Kenya are associated with the Bantu speakers.

Other household goods included grinding stones for making flour. In western Africa people made ceramic pots as large as human beings to store grain. These pots were elevated above the ground to keep them safe from termites. Still other household items included toys, which were small ceramic animals probably made by children, perhaps to introduce them to an important craft or because children often will make their own toys when none are available.

Somewhat more is known about the household goods of the major civilizations of eastern and northeastern Africa: Kerma (ca. 2400–ca. 1550 B.C.E.), Kush (ca. 900 B.C.E.–ca. 350 C.E.), and Axum (ca. 500 B.C.E.–ca. 900 C.E.). Kerma and Kush were Nubian nations, occupying an extensive region south

Stone chopping tools from Olduvai Gorge, Tanzania, dating to the Lower Paleolithic, almost two million years ago. (© The Trustees of the British Museum)

of Egypt, whereas Axum developed near the Red Sea in the region of modern Ethiopia. In Nubia of Kerma's era, people favored Egyptian-style jars for storage of grains and perhaps beer. For cooking and eating they used copper utensils that were either imported from Egypt or copied from Egyptian designs. Household objects included brushes, perhaps for cleaning house, and cups and bowls.

More is known about Kush's household items, partly because of Kush's long association with Egypt and also because Kush made more extensive use of metal, which is not as perishable as most other substances used in manufacturing household goods. The homes of wealthy Kushites had bowls as thin as eggshells that were made of very strong, well-fired clay. These bowls compare well with the best ceramics of China and Korea of the same era. Glass bottles, jars, and vases were common; the bottles apparently contained beer. Goblets of glass, bronze, and iron were used for drinking beer or wine. That beer was popular is shown by the numerous pots made for fermenting beer found just about everywhere in Kush. Large jars were used to store wine. Even poor households had beer pots and heavy ceramic cups for drinking beer. The bowls and pots of poor households tended to be heavy, even bulky.

Ceramic jars for containing healing ointments were common, as were spoons for dishing out the ointments. These spoons were usually decorated with small figures following the Egyptian fashion, especially swimming girls, though the Kushite swimmers are plainly Kushites in color and features. Mirrors of copper or bronze were used for grooming. These tended to be well decorated on one side and may have been more common in homes of the well-to-do than in poorer households.

Stone was often used for housewares even after Kush became Africa's most important manufacturer of iron in the 600s B.C.E. There were grinding stones for turning grain into flour and simple implements of stone such as cleavers. Lamps were made of copper in many homes, while bronze or silver lamps were rarer. Razors of copper or iron were in homes, as well as combs of metal or wood. Furniture varied according to the wealth of the household. In the houses of city dwellers and the wealthy, furniture included chairs and stools. Beds were

sometimes made of masonry. Boxes and chests were used for storage. In poorer households in farmlands, people might have had no furniture or only baskets or boxes for storage.

Much has yet to be discovered about everyday household goods in Axum. Axumites had chairs and chests, probably made of wood. The region was a center for trade between Africa and Asia, and it is reasonable to suppose the people had many consumer goods from around the world. They did have jewelry, especially beads, from Egypt, Asia, and of their own manufacture.

EGYPT

BY CHRISTINE END

The ancient Egyptians built their homes with sun-dried mud brick. Because of the highly degradable nature of this material, domestic architecture is scantily preserved. Tombs, however, had to last an eternity, so the Egyptians furnished them with an abundance of household goods for use in the afterlife. They produced many of these objects especially for mortuary use, while others give indications that they were well-used favorite items of the deceased. The depiction of household items of many types on tomb walls magically provided their services for the deceased as well. It is from this evidence that Egyptologists know most about the trappings of an ancient Egyptian home.

Oil lamps provided light for the home. Such a lamp may have been as simple as a wick inserted in a small, oil-filled clay bowl. Salt added to the oil would have kept the home from becoming unpleasantly smoky. Other, more elaborate, lamps decorated with patterns or the heads of household gods such as Hathor and Bes also survive. Larger "floor lamps," which provided even more light, stood on top of tall stands.

Some mud-brick furniture incorporated into the structure of the house itself eliminated the need for expensive, freestanding wooden furniture. A low dais, or platform, may have functioned as a kitchen table for dining. Ingredients and preserved foods were stored in clay jars of many sizes. A cellar near the cooking area normally served as a pantry for the largest of these storage vessels. The preparation of food took place inside another set of clay vessels. Meals were cooked outside, perhaps in a courtyard, to keep cooking fires from making the house too hot. Open fires or ovens made of clay were fueled by wood, coal, or manure. Aside from the oven, a silo for storing barley or emmer and a large stone surface for making bread were all usual "appliances" of the ancient Egyptian kitchen. Pottery plates, bowls, and cups served as tableware. Eating food from these dishes using only the hands was the norm, regardless of the social status of the diner. However, an upper-class Egyptian banquet may have included a good set of dishes and cups, possibly including fancier items made of faience (a type of glasswork), stone, or metal.

In the earliest periods of ancient Egyptian history furniture created hastily and unskillfully from local woods and plant lashing was common. Over time, however, the Eryp-

tians became highly skilled carpenters. Although the household was never overly furnished, furnishings made from wood were highly valued possessions. In early times native woods such as acacia, tamarisk, and sycamore fig were relatively inexpensive compared with imported woods, but these trees were not large enough to produce sizable lumber, nor were they strong enough for furniture. Gypsum, gesso (a type of plaster), and paint applied to the surface of the furniture covered the imperfections of inferior woods and created a clean exterior for painting the furniture. Expensive imported woods, such as beech, elm, ash, fir, maple, juniper, oak, pine, cedar, ebony, and yew, provided better quality wood for furniture. Ivory was another luxury material craftsmen used to make furniture.

A bedroom may have had a vaulted ceiling over the bed to capture excess heat, making the sleeping area more comfortable. Examples of high, boxed beds made from mud brick survive from the workmen's homes in Deir el-Medina. A reed mat rolled out on one of these platforms provided a surface for sleeping. The height of this type of bed may have also protected the sleeper from poisonous creatures during the night. The sleeper could create the illusion of privacy as well as gain additional protection from insects by the use of a bed canopy.

The Egyptians slept in wooden beds if they could afford to own one. Wooden beds were low and slightly slanted. The wood frame contained reed matting or leather in the center to create a flexible, more comfortable sleeping surface. The mattresslike cushioning of the bed, provided by folded sheets

of linen cloth or a cushion of linen casing stuffed with bird feathers, gave the sleeper additional comfort. Wooden headrests, consisting of a curved surface to support the neck atop a column upon a base, cradled the sleeper's head. Headrests discovered under the heads of mummies within their coffins mimic the sleeping postures of the ancient Egyptian. For the living, headrests wound with linen provided additional padding for the sleeper's head.

Low, sturdy stools were the most popular piece of furniture in the Egyptian home. Many varieties of stools survive from ancient Egypt. Three- and four-legged stools were both used, though the latter were more common. The ancient Egyptians also invented convenient collapsible stools much like the modern-day folding chair. A curved seat, perhaps made of woven plant material or leather, provided a comfortable place for sitting. Cushions upon the seat of the stool created a softer seat. Stools survive in alternate materials as well, including those fashioned from limestone surviving from the site of Amarna.

Chairs were used by the Egyptians, but not as frequently as stools. Their rarity suggests that chairs were more of a luxury item. Seats of surviving rush chairs are contoured, as were the chair backs. Armless models of chairs were more common than chairs with arms. Chairs were elaborately decorated more often than stools; some chairs are embellished with legs resembling a bull's or lion's legs, intricate inlays, carvings, and gilding.

Bathrooms were part of the Amarna Period (ca. 1350 B.C.E.) Egyptian household, along with toilet seats constructed of clay, wood, or, for the wealthy, stone. A chamber pot filled with sand changed by household servants would suffice for waste removal. Indoor showers, another luxury of the elite, consisted of a low walled area where water poured on the bather could drain outside.

The ancient Egyptian home lacked closets, cupboards, or dressers. Household items such as clothing, bedding, and other items not in constant use were stored in wooden chests, boxes, or baskets. Cosmetics, worn by both men and women from the earliest periods of Egyptian history, as well as other toiletry items were often stored in elaborate wooden boxes along with a mirror for application. Many examples of exquisitely designed and embellished containers, storage chests, and cosmetic storage containers survive.

THE MIDDLE EAST

BY DAVID KELLY

The area between the eastern Mediterranean, the Taurus Mountains, the northern Arabian Desert, and the Zagros Mountains is often considered the cradle of civilization. Innovations as basic to household life as the domestication of animals, cultivation of crops, weaving, and the potter's wheel first occurred there. Exotic woods and metals that were unavailable locally came to the area from Anatolia, the Plateau of Iran, the Indus Valley, Central Asia, the Persian Gulf, and

A folding wooden headrest, from Akhmin, Egypt, late Eighteenth Dynasty, around 1225 B.C.E.; the head of Bes, protector of the home, shows on the neckpiece. (© The Trustees of the British Museum)

Syria, but there were plenty of readily available materials in this region to use for the fashioning of those everyday items used by most households. Clay, reeds, bitumen, wood, horn, hides, bone, and some types of stone (limestone, basalt, obsidian, and flint) provided the raw materials necessary to make most things.

The houses and campsites of the region's earliest hunter-gatherers have yielded stone mortars and pestles for the grinding of wild grains, necessary for seeds to be turned into flour and eventually bread. In addition, stone tools for cutting and bone tools (often from the long bones of wild sheep and goats or slender, hollow bird bones) for sewing cloth and leather were often abundant. Wooden bowls and basketry were used as containers; even in cases where these materials have completely deteriorated owing to humidity and poor conditions unsuited to preservation, basket impressions frequently exist. Furthermore, textiles of both wool and linen have been found in some of the drier environments, like caves in Israel and Palestine. Horn, too, was used to fashion basic tools used around the house.

From about 8000 B.C.E. onward these sorts of materials began to be accompanied by another, more durable material, namely, fired clay. Many early houses had simple pits in the ground, lined with plaster or mud to keep out the damp and the ever-present rodents, and these were sometimes burned, accidentally or intentionally. The added heat made the interior of these pits stronger, and for this reason pits served as places of storage. But it was probably not a very great conceptual leap from a fired clay or plaster pit, set in the ground, to the idea of creating a fired clay container above the ground in which to hold seed, flour, or water; in this way the earliest pottery may have been "discovered." The earliest examples of pottery were found at Mureybet, on the Euphrates River in Syria, and at Ganj Dareh, in western Iran, in about 8000 B.C.E. Archaeological evidence indicates that the potter's wheel, which made it quicker and easier to produce pottery vessels, probably first became commonly used in Mesopotamia around 3500 B.C.E.

Houses often had built-in features, like benches along the walls; steps up to the roof, where most people would have slept in the hotter months; and bins to hold things. Niches in walls served as shelves. In Mesopotamia most houses were built of mud bricks, both sun-dried and baked, with wooden rafters, often of poplar or ash, and reed matting between the bricks above the ceiling and the rafters themselves.

Archaeologists have the clearest view of what life was like in a typical urban household from excavations and texts found in Mesopotamia. The durable objects—pottery, grinding stones, stone and metal knives, and the like—survive well in the soils of Mesopotamia. Even wood is sometimes preserved. But for many types of objects, cuneiform texts give us additional details that archaeology cannot provide. Dowries, marriage contracts, and inheritance documents, for example, from the early second millennium B.C.E., itemize all sorts of goods that were deemed necessary to a well-furnished home.

These goods include items made of wood, including looms, spindles, beds, chairs, footstools, tables, trays, combs, pot racks, bowls, spoons, and chests. Some types of wood, such as poplar and ash, was available from the gallery forest—the trees growing along the Tigris and Euphrates rivers and their associated irrigation canals. More exotic woods came from the Persian highlands, Lebanon, and even India. Under the Assyrians, in the first millennium B.C.E., ivory imported from Africa and India was used for inlays in elite furniture made for royal and high-status families. Other goods included pottery and metal vessels, sets of stone weights, basalt grinding stones for herbs and spices and others for flour, leather bags, and bronze scrapers. Blankets and other textiles were included too. The kitchen was outfitted not just with equipment but also with specific ingredients, like linseed oil, scented oil, barley mash (for making beer), flour, peas, and groats.

Domestic crockery came in many sizes and shapes, and until the late first millennium B.C.E. the pottery used in Mesopotamia was almost always unglazed. Because it was fired at a high temperature, however, Mesopotamian pottery was not too porous to hold liquids. The kitchen contained large jars that were used for storage, jars for water, bitumen-lined jars and vessels for storing oils and clarified butter (ghee) or beer and sometimes wine. The ancient Mesopotamians used a wide variety of cups and bowls, sieves, and basins. Archaeologists have documented hundreds of different pottery shapes, but few can be associated with a particular activity. Occasionally, though, we see pottery being used in scenes illustrating daily life, for example, on limestone plaques mounted on the walls of temples.

These scenes show, for example, a typical large jar with a pointed bottom (therefore unable to stand by itself) being carried in a sling supported by a long wooden pole by two men, who each balance the pole on one shoulder. Such a jar probably held large quantities of beer or oil being brought to a banquet. In early partly pictographic texts from the late fourth millennium B.C.E., small drawings of pottery with straight spouts sticking up from the shoulder of the vessel are associated with different types of oils, beer, and wine. Similar, spouted vessels have been found in excavations. Finally, Assyrian reliefs portray the king and his entourage drinking from a very carefully depicted bowl with lobes emanating from a disk in the center of the base. Exactly this type of bowl has been found, in pottery, silver, and bronze, at sites dating to the first millennium B.C.E. The study of ancient Mesopotamian households is therefore an area in which written sources, images, and archaeological finds complement each other.

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

Although few household goods from Asia and the Pacific have survived from ancient times, evidence about them survives from goods found in graves, including small-scale models of

houses and furniture, some drawings, and written descriptions in China and India. Generally these are the household goods of the wealthy, but it is possible to extrapolate what other people may have had, or not had, in their houses.

The earliest surviving household goods in India are from excavations in the Indus Valley from the 1920s. From 2500 to 1800 B.C.E. civilization centered on two large cities, Harappa and Mohenjo Daro, as well as some 100 nearby towns and villages. Some of the houses were large, but others were more modest. The function of the various rooms was revealed by artifacts found in them, including figurines of deities and other mythical characters, including the famous bronze “dancing girl” and other sculptures and terra-cotta figures. A large number of small personal seals have also been found, as well as remains of plates, water containers, vessels for storing grain, and pots, often decorated with geometrical designs or showing images of animals in black ink. These provide evidence of the large range of crops grown in the Indus Valley, which, in turn, would have required families to own large numbers of farm implements. The most common pieces of furniture in houses were wooden storage chests, with fasteners fashioned from bronze or copper. There were also chairs—carved chair legs have been found—and beds and benches.

Apart from the Indus civilization, the earliest descriptions of Indian furniture are of thrones, and they can be seen in Buddhist reliefs from the second century B.C.E. Many have a flat and rectangular seat with four legs and sometimes an upright back but no arms. There are even images of the Buddha sitting on a similarly designed throne. Also appearing in reliefs are beds that, in the first century C.E., had a wooden frame and a mattress. Gradually both became more elaborate, but drawings continue to show Indians sitting on chairs with crossed legs.

In China many early graves have been excavated, along with sites of houses from the Han Dynasty (202 B.C.E.–220 C.E.). These sites have revealed many details about Chinese household goods connected with cooking: pots, bowls, and plates. These items varied from the cheap clay pots of the poor to better quality terra-cotta vessels and on to elaborate and delicate porcelain. In addition, utensils, especially remains of knives, have been found. For larger items some representations of early Chinese furniture have survived, and tombs contain some of the deceased’s possessions, including small models of houses and miniature models of furniture. Chinese furniture was manufactured without nails, and dowels were used only when a repair had to be made. Furniture was constructed with mortise and tenon joints largely because, especially in northern China, wide differences in temperature between summer and winter caused expansion and contraction of the wood. Other Chinese items in houses included floor coverings; storage boxes, especially for food during the winter; and personal ornaments or jewelry. These vary from simple to intricately carved items made from gold and silver, sometimes inlaid with precious stones, or from jade.

Korean furniture was similar to that in northern China, again because of the need to cope with the differences in temperature. Some potsherds have also survived, and they, once again, show the heavy cultural influence of China on the Korean peninsula. Unlike the household goods in China and Korea, those in Korea tended to be much less obtrusive. With regular earthquakes, many houses were made with light walls that could be easily moved or reassembled. Many people slept and ate on the ground, and thus many household items included armrests, pillows, and small writing desks and cabinets for valuables.

In Southeast Asia wooden artifacts generally have not survived because of the wet climate. Pottery uncovered at many sites shows Indian and Chinese cultural influences. Many early Vietnamese people had musical instruments. The excavations at Dong Son, in northern Vietnam, show a highly developed Bronze Age culture from about 300 B.C.E., where a large number bronze drums have been found indicating an early importance placed on music. Some historians have suggested that the drums were solely for burying with the dead, but this seems unlikely. Numbers of miniature drums, bowls, *situlae* (bronze vessels similar to buckets), bells, and bronze tools have also been recovered. If the Dong Don culture rested heavily on music, so also did the reputation of the empire of Funan from the first through the fifth centuries C.E. Chinese chronicles describe a Funan delegation to China in 243 C.E. that brought along expensive gifts made by musicians, whose music was highly praised. Excavations of houses at Oc-Eo (in modern-day Vietnam), believed to have been the capital of Funan, have indicated that there was room for large amounts of furniture, but because the furniture was made from wood, it has not survived.

In the Pacific household goods, except for pots and tools, were probably made from wood. Carved stools, tables, wooden drums, figurines, fly whisks, and ornaments survive from later periods, and it is highly probable that these would have existed in earlier times, with a major focus being on boats and fishing equipment. In Australia the climate is good for preserving material, but the nomadic life of the aboriginal peoples limited their possessions to hunting weapons and a few other basic necessities.

EUROPE

BY JUSTIN CORFIELD

Large numbers of household goods surviving from ancient Europe reflect changes in society and technology, starting with the forming of stone implements of the Paleolithic a million or more years ago. These items, mostly flints, were used for hunting, cutting meat and crops, and cleaning animal skins. Archaeological finds around the lakeside site of Bilzingsleben in Germany, which have been dated to the Paleolithic, have shown that the devices of the hunter-gatherers there included flints, wooden tools, and bone implements. Similar discoveries in eastern Europe have established that

carved bone harpoons were used for fishing in rivers. Few cooking implements have survived.

Of the stone and bone ornaments that have survived, the figure of a woman's head with what appears to be plaited hair found at Brassempouy, France, and dating to around 20,000 B.C.E. and a female figure carved from mammoth ivory found at Lespugue, France, and dating to as early as 25,000 to 18,000 B.C.E. show people making nonessential items for the household. The numbers of surviving pots and figurines dating to 4500 B.C.E. or later increase dramatically, as does the sophistication in the design on the pots that have been found.

Changes in household goods appeared with the spread of agriculture during the Neolithic Period. Bowls from about 4000 B.C.E., such as those from Fussell's Lodge, Britain, show simple decorations, while ones from about 600 years later from a Newgrange megalithic tomb in eastern Ireland depict more complicated geometric patterns. It also seems probable that there were many wooden implements from this period that have not survived.

The advent of the Copper Age in Europe, from about 2500 B.C.E. in southeastern Europe and from circa 1900 B.C.E. in Britain, saw the increasing ease of making purely decorative items such as copper collars worn on ceremonial occasions as well as copper and pottery bowls and pots. Many artifacts have been found at a Copper Age cemetery in Tiszapolgár (also called Polgár), Hungary. With so many objects buried with the dead, it is possible to work out how many possessions people may have had, with some graves containing large numbers of artifacts. Indeed, a few of the graves of children also contain expensive items, suggesting that they might have inherited them.

Much weaponry and armor of ancient Europe, including helmets, breastplates, shin plates, spearheads, arrowheads, and swords, survive from the Bronze Age, with artifacts dating to about 1800 B.C.E. until 1200 B.C.E. Many urns, pots, cooking implements, and decorative items have been found. Although wooden furniture was used, little has survived. At Cologne, Germany, a small wooden chair and bed were uncovered in the grave of a boy, and a folding stool from the Bronze Age was discovered in a grave in Denmark.

The Bronze Age was a period of comparative affluence, during which many large communities formed. By this time there were clearly greater contacts between the various peoples of Europe, with trade needed for the acquisition of some items and commodities, especially tin. Some of these traders were Phoenicians, who brought with them items to exchange, and various statuariers from the period have a distinct eastern Mediterranean style. Although there are local variations, a greater uniformity in design and similar household items has been found across the whole of Europe as a result of widespread trade.

One of the more elaborate items of the period is from an excavation in the Trundholm bog in Zealand, Denmark, in which was found a model of a horse pulling a partially gold-plated disc—possibly a mirror—dated to about 1650 B.C.E.

Another significant find is a razor from Solberg, Jutland, that has been dated to 1000 B.C.E.

Further changes in ancient European household goods occurred during the Iron Age (1000 B.C.E.–150 C.E.). Many highly stylized pieces of bronze ware and ironwork from the fifth century B.C.E. survive. The appearance of such items coincided with the introduction of wine into the diet of the Celts, and the result was the production of many elaborate flagons, a type of drinking vessel with a handle and spout and typically a lid. One discovery from an archaeological excavation at Basse-Yutz, in the east of France, dated to the late fifth century B.C.E., includes intricate flagons, involving bronze work combined with enamel and Mediterranean coral. Others follow Etruscan (characteristic of the ancient civilization in modern-day central Italy) or Greek designs, with a hydria—a vessel for water mixed with concentrated wine—found at Grächwill, near Bern, Switzerland, showing a distinct Spartan pattern.

In addition to flagons, there were many different styles of drinking containers. One style, a bronze vessel designed to look like a boot, has been found in Hungary dating to the third century B.C.E., soon after the Celts moved to that region. There have also been iron frames such as those found at Welwyn, Hertfordshire, England, which were probably used for holding amphorae (a two-handled vessel with an oval shape and slender neck) and flagons. Pottery was also developing considerably. During work on the Hallstatt Cemetery in Austria, which was discovered in 1846, many pots were found along with decorated ritual axes and sword scabbards depicting scenes of battle and everyday life.

The influence of the Etruscans is clear in many household items from the fifth century B.C.E. until the second century B.C.E. These items can be seen in the La Tène culture, which flourished at the eastern end of Lake Neuchâtel, Switzerland. A mirror, following Etruscan designs, was found at La Motte-St.-Valentin, Haute-Marne, and an Etruscan-style bronze vessel with a tripod was found in the tomb of a Celtic prince at Bad Dürkheim, in Rhineland, Germany. Gradually, however, a new style of mirror made from polished metal started to be produced in workshops in southern England from the first century B.C.E. until the first century C.E. They were particularly distinguished with an openwork handle and a pattern that has plain, smooth areas with grooved basketwork-style motifs, as seen in the Desborough Mirror, which has been dated to the first century C.E. and was found at Northamptonshire, England, in 1908.

With the rise of the Roman power in Italy, Roman artifacts started to be traded throughout the area settled by the Celts. There were also many more similarities between the goods in northern France and southern Britain. The most celebrated “find” from this period was the Aylesford Bucket, found in 1886 at the cemetery of a Belgic tribe that had settled in Kent, England. The “hinges” of the bronze bucket's handle show a human face with bulging eyes in a La Tène design. It seems likely that furniture became more ornate, but being

made from wood, little has survived apart from chairs and tables in some images of the period.

GREECE

BY JEFFREY S. CARNES

The most striking feature of Greek household goods is that the Greeks had significantly fewer possessions of every sort (furniture, clothing, cooking implements, decorative objects) than those found in a typical modern house. This was partly because of the difficulty of manufacturing goods. In an era with little machinery and no mass production, virtually everything was made by hand and thus relatively expensive, limiting most people's ability to accumulate material possessions. In addition, an ideology of equality (even in many oligarchic societies, that is, those ruled by a few) discouraged ostentatious displays of wealth.

Furniture and other household objects were both functional and, when possible, decorative. Ancient furniture differed from modern furniture in size and portability: Most pieces were designed so that they could be moved easily from one room to another or, for the wealthy, from one house to another. The main items of furniture were chairs, tables, stools, couches, and beds. Greek houses usually did not have large cabinets, dressers, or armoires, nor were rooms built with closets. Clothing was folded flat and stored in small, movable chests and boxes. Since most people had few or no changes of clothing, the need for storage space was limited. Greek furniture was made primarily of wood, which does not survive well at archaeological sites, so most of the information we have comes from pictures (in particular, vase paintings) and from literary sources. Metal was used for fastenings, for locks on storage chests, and sometimes for the legs or feet of couches, chairs, and tables. Some of these items, in fact, have survived long after the wood to which they were attached decayed.

Chairs were simple. The most basic type was the *diphros*, or stool, which had no back or armrests and four straight legs. A common variation on this was the folding stool with legs

that crossed in an X pattern, similar to a modern director's chair without arms or a back. Such chairs were easy to store and transport. More substantial was the *klismos*, which featured curved legs and a curved, slightly reclined back; the word *klismos* derives from the Greek verb *klino*, meaning "to lean." The examples on Greek vases often have graceful curves. At the top end of the scale was the *thronos* (the source of the word *throne*), a solidly constructed, upright chair with armrests, often highly decorated, and more likely to be found in temples or palaces than in households.

One of the most versatile pieces of furniture was the *klinē* (a word also derived from *klino*), which combined the functions of bed, couch, and dining couch. It was common for food and drink to be consumed in a reclining position, particularly on formal occasions. The *klinē* was backless and designed for reclining rather than sitting on, with one end slanted upward. Legs were either straight or with a slight curve and in some cases could be carved to look like animal legs or paws. The frame of the *klinē* was wooden and light enough to allow it to be carried easily from one room to another or outdoors or onto the roof for sleeping in the warmer months. The weight of the occupant was borne by a surface of webbing, consisting of interlaced leather or rope, which was typically covered by a thin mattress. On top of this were blankets, pillows, and coverlets or tapestries, which could be highly decorated luxury items in wealthy households. Evidence for the weaving of pictures and designs into tapestries is found as early as Homer's *Iliad*, in which Helen weaves her own story into a tapestry; skilled weavers were considered among the more valuable spoils of war. There is no evidence for the use of sheets, and mattresses were typically stuffed with straw, so an ancient bed would seem uncomfortable by modern standards.

Tables were either three-legged or four-legged (*trapezai*, the source of our word *trapezoid*), and tended to be few in number, since there simply were not that many things to put on them. Most tables were used for dining and, like all Greek furniture, were light enough to be carried away when not in use. Books were rare (and typically stored in chests), and

Stone bowl and pitcher (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

lamps were normally placed on separate stands. In wealthy houses tables were sometimes used for displays of decorative objects. These objects might include the beautifully painted vases now displayed in museums and reproduced in art history textbooks. Pottery for practical purposes—for storing oil and grains and for use as cookware—was much plainer, and Greek cookware consisted of these and simple iron pots and skilllets.

Decorative objects, such as tapestries and bronze plaques, could also be hung on walls, which were themselves painted, either quite simply—plain red or white was popular—or extravagantly. The packed-earth floors of the typical Greek house could be covered with rugs or mats, which were probably highly decorative in wealthier households, though little direct evidence supports this notion. In addition, dining room floors were sometimes covered with decorative mosaics.

Indoor lighting depended on the use of oil-burning lamps, which were either placed on stands or suspended from the ceiling or walls by means of cords or chains. Some were metal, but most were made of fired clay, which survives extraordinarily well when buried in the ground, so countless thousands of oil lamps survive from antiquity. These typically contained a reservoir for fuel (usually olive oil) and a nozzle into which a wick was inserted and lit. Such lighting was by no means ideal. Lamps of this sort do not produce much light and produce heat as well, which, given the warm Greek climate, would be unwanted for much of the year. The cheaper grades of olive oil used for fuel tended to produce smoke, and in addition to the obvious fire hazards of using an open flame, the mere lighting of a lamp could pose problems. Kindling a fire was not easy, and the usual practice was to keep a flame or embers burning so that a fire could be easily rekindled. Outdoor lighting (for example, for making one's way through dark streets) was often accomplished with torches, which could produce a brighter flame through use of flammable materials such as pitch, which were not suitable for indoor lighting. Poor lighting technology was only a minor problem for the Greeks, however, since they, like most pre-industrial peoples, tended to rise at dawn and spend only a small percentage of their waking hours in the dark.

ROME

BY FRANCESCA C. TRONCHIN

A number of sources of information about Roman furniture and household goods are available. Archaeological material, especially from such sites as Pompeii and Herculaneum, includes actual remains of objects of everyday use in the Roman world. Secondary visual sources, such as paintings and mosaics, depict Roman interiors. Finally, evidence from ancient literature also provides information about the types of furniture and domestic implements used in antiquity.

Because the rooms in most Roman houses were often few, small, and designed for multiple uses, furniture needed to be relatively portable. A space that functioned as a bedroom at

night might also have been used for work or study during the day, so the required furniture for these activities was brought in and out of the space at different times of the day. Folding stools, for example, were very practical because they were portable and could be stored in small spaces when not in use. An exception to this rule was the *arca*, or chest, which was most frequently found in the main hall of a Roman house, the *atrium*. These cupboards functioned as strongboxes to protect household valuables and could vary in size and material from a large wooden chest to a tall iron or bronze armoire.

By far the most prevalent pieces of furniture in the Roman house were chairs, tables, and couches. Stools and chairs made of both ordinary materials such as wood and exotic materials such as ivory were common and could be used for a great number of activities. Stools were more common than the chairs with backs derived from the Greek *klismos*. Couches with turned legs and topped with cushions were common in both the bedrooms and dining rooms of Roman homes. At dinner parties guests reclined on one of three couches placed at right angles to one another in a Roman dining room, whose name, *triclinium*, comes from the Greek words for “three couches.” The most elaborate couches could be inlaid with ivory and colored glass or decorated with bronze and silver animal heads on the headboards. In describing luxurious dinner parties Roman authors note the use of beautifully embroidered silk cushions on these dining couches.

Both utilitarian and luxurious tables have survived at Roman archaeological sites. Tables came in a variety of shapes and sizes. Benchlike tables made of wood and with four legs could be used for working or for dining in more modest homes. Round tables supported by three sculptural legs in the shape of animal legs or mythological figures were popular in the dining rooms of the very wealthy. This type of table was usually cast in bronze; an example in the National Archaeological Museum in Naples, Italy, is a table with three legs in the shape of satyrs with goats' legs. A rectangular table with sculpted supports in marble seems to be a Roman invention without precedent in Greek furniture. The supports terminate on both ends with animals such as griffins or lions in an opposing stance. These marble tables were popular in Roman gardens, where they were a relatively permanent part of the landscaping and decoration of the exterior space.

Utensils, tableware, and cooking vessels in the Roman world were made from a variety of materials. Terra-cotta was most popular for cups, plates, and storage containers. These fired clay objects were fairly durable and could be produced in both utilitarian and decorated varieties. Large storage containers for wine, oil, and other foodstuffs were usually made of coarse pottery, but finer tableware could be of a very high quality. Varieties of Roman terra-cotta, such as African red slip ware, red gloss, and Arretine, were frequently ornamented with stamped or molded decorations in the shapes of floral forms, mythological figures, and even gladiatorial scenes. Many of these finely decorated terra-cottas were influenced by even more costly vessels in glass or metal.

Roman jug, two-handled cup (the handles now missing), strainer, ladle, and stirrer, dating to about 100–75 B.C.E., from Arcisate, near Como, northern Italy. (© The Trustees of the British Museum)

Glass was used in the Roman world for such household objects as drinking vessels and containers for precious commodities like perfume. Colored glass imitated gemstones, while clear, colorless glass may have been developed to imitate more costly rock crystal. Glass could be blown or cast in a mold and was frequently decorated with reliefs of floral motifs. The sumptuousness of glass vessels was second only to that of gold or silver objects. Trimalchio, a fictional character based on wealthy Romans in Petronius's *Satyricon*, states that he would prefer glass cups to gold ones, were they not so fragile.

Tableware made of luxurious materials has been found in both the archaeological and literary records of the Roman world. Diners in the homes of the very wealthy would have eaten and drunk from silver plates and cups decorated with figural scenes in relief, like the famous examples from the Boscoreale Treasure found near Pompeii. It is this type of tableware that decorated pottery was most likely reproducing.

Boiling, roasting, and techniques akin to modern grilling were the most popular cooking methods in Roman domestic kitchens; baking was typically done in one of a number of bakeries throughout a given city. Pots and pans made of bronze or iron have been found among the remains of ancient kitchens. These implements were similar to modern-day pots and pans, with flat bottoms, straight or slightly angled sides, and either one or two handles based on their size and use. Bronze braziers, sometimes finely decorated, were used in Roman homes to grill food over hot coals.

The illumination of interior spaces in the Roman world was often difficult. While architects and engineers developed features that allowed natural sunlight into their buildings, lighting spaces at night was impossible without the use of artificial light. Lamps in terra-cotta and bronze were made in all periods of Roman antiquity and could take on many forms. Olive oil was the most common fuel for the lamps that illuminated public and private spaces alike. Most terra-cotta lamps had a small ring handle; a covered, bowl-shaped container for the fuel; and a rounded nozzle to hold the wick. The majority of lamps had one wick, but some had multiple nozzles to maximize illumination. A wide variety of stamped or molded imagery decorated the covers of terra-cotta lamps. Floral designs and mythological scenes were popular, but crosses came into fashion when Rome converted to Christianity. Bronze lamps were more durable and costly than the terra-cotta versions but were made in the same general shapes. The more elaborate versions in bronze (or even gold and silver) had large handles, usually in the shape of a palmette or other kind of leaf. Lamps in metal could be hung from chains or cords on tall candelabra; all lamps could be placed on a stand.

These are by far the most common items found in a Roman household—furniture, lamps, and receptacles for cooking and eating in a variety of materials. Although they are usually not preserved in the archaeological record, baskets, tapestries, rugs, curtains, and screens made of perishable fabrics and wood had functional and decorative roles in the ancient Roman house.

THE AMERICAS

BY KIRK H. BEETZ

The ancient Americans of the far north learned how to adapt their frigid environment to their needs. For instance, they built their beds out of frozen ground, laying animal skins on the bed to provide comfort. They made cradles out of wood and hung them from sturdy wooden poles in their homes. Later Arctic peoples used a mesh of branches covered with animal skins for their floors, and some of the ancient Arctic American peoples probably did, too. Their household tools tended to be focused on what they needed to prepare food. This meant that they had scraping tools made out of bone, wood, or stone for removing fat and flesh from animal hides. Their eating utensils, such as spoons, tended to be made out of bone.

In North America south of the Arctic and north of Mexico, many cultures rose and fell, and archaeological studies of their remains have only begun to form a picture of their lives. Stone mortars and pestles have been found at many sites. Some large stone outcrops have dish-shaped impressions caused by people grinding into them, but there are also mortars and pestles small enough to be used in homes, including ones barely bigger than a hand that could have been carried by nomads. Given how small they are, they were more likely used for grinding ingredients for medicines than food.

Many ancient North Americans probably made spoons and scoops out of bone. The extent of the use of wood in making home utensils is not known but probably was extensive wherever wood was available. This can be inferred from the wide use of wood for building homes, which suggests that wood would have been used for other household purposes. Ceramics were used broadly for making pots, bowls, plates, and cups. Woven baskets were probably used to store grain and for other household purposes, but pottery would have been favored for carrying liquids and for cooking. Furniture was sparse, and most people slept on mats or blankets on dirt floors.

A multitude of cultures developed in ancient Mexico and Central America, but only a few are at all well known. The earliest Americans were hunter-gatherers who used wood and bone for tools. In Guatemala stone tools dated to 8760 B.C.E. include scrapers and blades, probably for preparing meat for cooking. The most famous of the ancient Mesoamericans are the Olmec and the Maya. Little is known of the everyday habits of the Olmec, though their household goods were probably similar to those of the Maya, whom they seem to have influenced.

The Maya did not use much furniture. They slept on mats on dirt floors unless they were of the nobility, in which case their floors may have been stone. The mats were made of woven reeds. When they were not sleeping, Mayans usually used their sleeping mats as seats. In some homes, raised earth may have been covered with sleeping mats and used as seats. Chairs were made of wood and wicker and may have had backs, but they were probably used only by nobility and royalty. The homes of important people might have contained

stone benches. Archaeologists imagine that those who sat on the stone benches were family patriarchs conducting important business with family or outsiders. Baskets have been found in homes. Chests of wickerwork may have been used for storing clothing or valuables. Low wooden tables may have been used in some homes. They would have been small and portable, because the Maya might sit to eat almost anywhere.

Food preparation involved stone goods such as grinding stones. It is possible that every home had a grinding stone and a cylindrical stone grinder, used primarily to process maize. Nuts may have been cracked on small, stone hand mills. Mayans used stone tools extensively in their preparation of food, using them for chopping vegetables, cutting meat, and scraping pulp from gourds. Food would have been cooked in ceramic pots, with wooden utensils that had been made with obsidian cutting tools. Food was either boiled in ceramic pots or grilled over open fires.

The majority of household goods recovered from Mesoamerican archaeological sites have been ceramic, varying from coarse bowls for soaking maize to artfully shaped plates for holding food during meals. Bottles, jars, bowls, cups, and plates were used regularly. The bottles held liquids, usually drinks. Maize beer was often poured from bottles into plain cylindrical cups that fit easily in the hand. By about 400 B.C.E. Mayans used jugs with spouts.

The populating of South America probably occurred in waves, with perhaps the first human inhabitants being people who moved along the coast of modern Argentina in small boats. Others migrated into the Andes, and more is known about the ancient Andean peoples, partly because the climate is cold and dry, meaning that goods made of wood, reeds, and cloth decay much more slowly than they do in other parts of South America.

These peoples began as hunter-gatherers but learned to cultivate maize and many varieties of sweet potatoes. Ceramic bottles appeared first on the coast and then moved inland. By about 1200 B.C.E. bottles varied considerably in shape, from balls to cubes to ornate shapes of animals or even houses. The stirrup bottle seems to have been important as a religious object as well as popular for its design. Ancient South Americans believed the stirrup represented their connection with their ancestors. The stirrup bottle derives its name from its handle, which arches far out in the shape of a stirrup from the main part of the bottle. Sometimes the bottles had two such handles, and the stirrup-shaped handle design often shows up on jugs and bowls.

The principal drink of the ancient Andeans was probably maize beer. Their housewares include many examples of fermentation jars, bottles for pouring beer, and cups intended to be used for drinking beer in particular. Their bottles began as boxy shapes with spouts in the 1200s B.C.E. and became ever more intricately shaped and colorful. By the 200s B.C.E. the Andeans were using bottles in which the spout projected out of the stirrup, so that the liquid flowed through the handle and out the spout. Another form during

the first century C.E. was the double bottle, which linked two main vessels with a tube. Cups sometimes resembled those used by the Mayans, but a long, narrow, cylindrical one was in use by the mid-400s C.E.

The furniture of the ancient South Americans is not yet well known. Beds seem to have consisted of blankets, and pillows may have been used to rest sleepers' heads. Tables were low on four legs, with raised edges as if to prevent objects from slipping off. Dates for such artifacts have yet to be firmly assigned.

► hunting, fishing, and gathering

INTRODUCTION

In modern life, many people hunt and fish as a form of recreation, and even gathering crops from a household garden is often more of a hobby than a necessity, at least in the devel-

oped nations. By contrast, among ancient peoples, especially before the development of agriculture, hunting, fishing, and gathering were serious pursuits. People lived in small bands and tribes, moving about as the seasons changed in the constant search for food. To the extent that they foraged within a limited area, they had to be careful not to deplete the food resources in their area; otherwise, they could face starvation later. They often had to compete with other species, making sure, for example, that they harvested berries before birds ate them.

Ancient hunters, who relied on such weapons as spears, had to hunt cooperatively, and they learned how to read the signs of nature that told them where they could find game and in which direction that game might be moving. In early hunter-gatherer societies, considerable emphasis was placed on sharing. In general, the food acquired in a hunt or gathered from the ground was communal property, not the property of the individual who found it. Women played an important role in acquiring food, especially as gatherers.

Game meat was the chief source of protein among early hunter-gatherers, as was fish for those who lived in coastal regions or along the banks of freshwater rivers. Early fishermen became adept at fashioning nets and underwater traps for fish and seafood. Additionally, ancient hunter-gatherers consumed nuts, acorns, seeds, herbs and spices, roots, fruits and berries, and mushrooms—always depending on what was available in the local region at a particular time of year. The most common sweetener was honey. Many common domesticated crops, including wheat, rice, and legumes (that is, beans), originally grew wild and only later were domesticated to become staple crops.

After the development of agriculture, hunting, fishing, and gathering by no means disappeared. While people who lived in sedentary communities (that is, more or less fixed communities, where people remained in one place) derived most of their food from agriculture, including livestock production, people in remote areas continued to rely on the hunting, fishing, and gathering skills learned by their remote ancestors. Even people who lived in settled communities continued to hunt and fish as a way of introducing variety into their diets. Poor people, for example, supplemented their diets by hunting rabbits and game birds.

As civilizations became more advanced and food production became more organized and even commercialized, hunting became more of the sport that it is in modern life. The elite hunted prestige animals such as wild stags, usually on horseback and with the aid of dogs bred for the purpose. Hunting, fishing, and gathering provided ancient peoples with more than just food. Animals large and small afforded hides for clothing and blankets as well as bones, horns, and teeth from which tools and decorative items could be made. Birds supplied feathers, and many plants were valued not as food but for their medicinal properties or as the source of dyes. Even fish bones could be useful for such household items as needles.

AFRICA

BY MARK ANTHONY PHELPS

Hunting, fishing, and gathering activities are collectively known as foraging. Foraging was the only economic option for all humans prior to the Neolithic Revolution (ca. 9000 B.C.E.). Given that *Homo sapiens sapiens* appeared around 40,000 years ago, the bulk of human existence has been spent foraging. The primary sources for Africa from antiquity are sparse. Written sources, aside from the Nile Valley and its immediate cultural neighbors, are foreign and are unconcerned with recording the lives of foragers. Oral sources rarely extend back beyond the 18th century C.E. One is thus left with archaeological evidence to reconstruct this aspect of human history, along with models based upon historical foraging groups.

The advent of the Neolithic Revolution is manifested in the archaeological record in the form of domesticated plants, domesticated animals, the beginnings of a sedentary lifestyle, and the appearance of ceramics as a means of storing domesticated products. However, the African evidence does not correspond neatly with this model. In Africa there is evidence of ceramics before domestication. There is also evidence of hunting, gathering, and fishing among settled groups as well as evidence of pastoralism side by side with gathering.

The Nile Valley provides the earliest evidence for sedentarization. At the delta site of Merimda Beni Salama, by 8000 B.C.E. foragers were living in houses with hearths and had large pottery vessels for water storage. In the Faiyûm there is evidence of a settlement on a shrinking lake from the seventh millennium B.C.E. Foragers lived in this settlement, with silos built to store excess food. Farther south, around Khartoum, there is evidence from around 7000 B.C.E. of a foraging society with ceramics, silos, and net weights for fishing. Evidence of a number of hunting and fishing camps has been found in modern-day Sudan. Throughout the Nile Valley the dominant fish species harvested were the Nile perch and catfish. With the development of the harpoon around 8500 B.C.E. (appearing first in Sudan), deepwater fish were exploited as well. A wide variety of species was hunted, including aurochs, hippopotamuses, crocodiles, and a number of smaller species. Birds were also harvested. Tubers seem to have been the dominant flora food source. Domestication reached the Nile Valley in the fifth millennium B.C.E.

Ceramics had appeared throughout the Sahara by 6000 B.C.E. The Sahara supported plant life until around 4500 B.C.E., when a prolonged desertification process began; through this process the basic climatic patterning of today emerged around 2500 B.C.E. During the wetter period permanent streams as well as a number of lakes were found in the Sahara. The faunal representation was more Sahel-like, with many types of wild grasses. Herding was being practiced at Ti-n-Torha (Libya) by 7000 B.C.E. It is not confirmed in the western reaches of the Sahara until the third millennium B.C.E.

As the Sahara dried, the herders apparently moved south into western Africa. Their influence is discernible all over the region from the second millennium, as herding became a staple. They also brought domesticated millet and sorghum with them. The date of the domestication of the latter two is not known but is fixed at no later than around 1800 B.C.E., evidenced by African species that are present in India.

Along the Niger yam cultivation may have begun as early as 4000 B.C.E., based upon the presence of a new type of hoe, though paleobotanical evidence is lacking. However,

INSULTING THE MEAT

Although meat accounts for a relatively small proportion of the caloric intake of the Bushmen (estimated between 15 and 30 percent), it is still the prestige food item produced by foragers. Meat distribution is among the most important issues that occupy the attention of foragers. A !Kung woman stated that the primary gender status gap appears because men are “masters of the meat.”

The anthropologist Richard Lee experienced a social leveling mechanism in the course of purchasing a bull to be slaughtered for a Christmas feast for the band of !Kung he was researching. Once word of the particular bull chosen became known to the members of the band, the men began to complain to the anthropologist of his repulsive choice of animal. Thoroughly depressed by the continuous complaining concerning his choice, Lee watched the killing of the bull and the unmistakable joy the animal brought the crowd. The animal’s flesh appeared to be in perfect accord with what he had been told was the ideal. Confused, he was told by an informant that he had experienced the mechanism of “insulting the meat.”

For the !Kung, there is a fear that a good hunter could become vain, begin to hoard meat, and try to assert his will upon others. Thus, when an animal is killed, those who go with the hunter to retrieve the carcass will complain about investing so much work for a useless “bag of bones.” The hunter will apologize profusely. Likewise, when a hunter announces that he has had no real luck but may have injured a little animal, the rest of the band knows to get excited, as a large animal must have been hurt. Hunters engage in self-deprecation when announcing their luck. In an environment in which death is a constant threat, bands must take care that all their members freely share risks and resources. It is impossible to assert that such was the case among ancient African foragers, but the logic behind the mechanism probably was at work in these societies as well.

throughout most of the valley, to the middle of the first millennium B.C.E., data point to semisedentary foragers, existing on riverine fish, or more mobile groups of foragers. Along Lake Chad, by 2000 B.C.E. herding, fishing, and hunting occupied people dwelling in permanent wooden buildings. Shell middens (piles or refuse heaps) dating to the sixth millennium B.C.E. have been discovered in Mauritania. By the middle of the second millennium B.C.E. the oil palm may have been domesticated. By the end of the millennium millet was clearly being cultivated. The Kintampo culture of central Ghana from the second millennium B.C.E. seems to have been a point of cultural fusion between Saharan traditions and rain forest gathering cultures.

Eastern Africa was a zone of foraging until the second millennium B.C.E., as pastoralism became the dominant economic activity around the lakes and along the Rift Valley highlands. The Ethiopian highlands became a place of domesticated farming, primarily with species native to the region. Before the advent of pastoralism, the fishers on the lakes harvested a wider variety of species as the lake levels dropped. At Lake Turkana the fishers used boats. Nile perch was the dominant species, but catfish and cichlids and soft-shelled turtles were also present. Crocodiles, elephants, gazelles, giraffes, hippopotamuses, rhinoceroses, warthogs, and zebras were among the species hunted. As throughout most of Africa, foragers in the east had ceramics before the advent of agriculture, around 4000 B.C.E.

Southern Africa consisted exclusively of foraging societies throughout all but the last four centuries of the ancient period. Herding and agriculture entered the region at the beginning of the Common Era. Ceramics, domesticated plants, domesticated animals, and iron all arose in the region roughly at the same time as Bantu peoples. There is no firm evidence of the ancient foraging way of life, but we can make what are widely evidenced generalizations about historic foraging societies, which may or may not be an accurate embodiment of their ancient forbearers. Foragers live in bands for at least part of the year, often in areas of marginal climate, meaning that they must not overuse the resources at their disposal, or they might not have these resources in the future. Thus, foragers are intimately tied to nature. The !Kung of the Kalahari are aware of seven distinct seasons in an area in which climatologists distinguish two. They consume at least 80 distinct floral food sources. They are able to recognize each band member's footprint. From animal droppings, they can discern the size, gender, and health of each animal, where an animal has recently been, what time of day it passed, which direction it was heading, and the number of animals that have passed by.

Foragers have an understanding that they are but bit players in an intricately balanced world. Religion traditionally has taken the form of animism. The chief value in foraging societies is sharing. Both the risks and the resources of the group must be shared to facilitate survival in marginal areas. Hoarding is the most heinous act one can commit. Gift giving and gifting are important social mechanisms to prevent ac-

cumulation of items and to establish ties among members, as items are briefly possessed by all members of the band.

Not only are males relatively equal, but women are indeed nearly equal to men in foraging societies. Anthropologists attribute this gender equality to the role women play in food production, as gathering provides some 80 percent of the calories consumed by the band. Given that there is no property to inherit, men are not concerned with controlling women's reproduction. Thus, women are decision makers in their marriages and divorces. Women interact freely with men, including in public discussion. Men will help women gather. In some societies women can hunt larger animals, and in most, women can hunt small animals or use traps.

EGYPT

BY LINDA EVANS

The ancient Egyptians observed their surroundings closely and drew upon aspects of the natural world to form many of their religious and philosophical concepts. By using various methods and technologies, they also exploited the plentiful food sources that could be found in the fertile Nile River valley and adjoining deserts.

Petroglyphs, or rock carvings, in the cliffs that border the Nile provide clear evidence that animals were hunted extensively during the Paleolithic and Neolithic Periods. In these images, men armed with harpoons and bows and arrows pursue a variety of game, including hippopotamuses, Nile crocodiles, scimitar oryx, giraffes, and African elephants. Bones and scales recovered from prehistoric settlement sites also show that the indigenous population consumed a great deal of fish, especially Nile catfish. Later, during the Predynastic Period (before ca. 3000 B.C.E.), art objects, such as ceramic pots, knife handles, and palettes, were often decorated with images of game. By the dawn of the Egyptian state, however, many prey species had become extinct locally owing to the combined effects of climate change and human disturbance.

With the development of agriculture, the Egyptians were no longer dependent upon hunting for their survival. Nevertheless, images that were carved into and painted upon the walls of tombs reveal that the practice continued throughout the historical period, during which it achieved a ritual significance. Hunts took place in both the desert fringes and the marshes of the northern delta region. In desert scenes from the Old Kingdom (ca. 2575–ca. 2134 B.C.E.), hunting dogs are commonly used to attack prey. These slender, greyhound-like animals, with tightly curled tails and pricked ears, are shown pulling down and savagely biting a range of species, including scimitar oryx, hartebeest, dorcas gazelles, Nubian ibex, striped hyenas, red foxes, golden jackals, and Cape hares. The dogs are often accompanied by a hunter wearing a striped tunic who, while kneeling beside his pack, points out potential victims.

Other hunting practices are also depicted. In a few tomb scenes men use lassos to rope wild cattle or wrestle desert

Archery case painted with a hunting scene, from Thebes, Egypt, Middle Kingdom, (2040–1640 B.C.E.). (© The Trustees of the British Museum)

ungulates by hand; it is possible that such animals were captured alive and then killed later for ritual purposes. At first only the king is shown using a bow and arrow. Scenes from the late Old Kingdom, however, show private tomb owners using this weapon to bring down various species of antelope as well as wild ass, Barbary sheep, dama deer, and ostriches. The sparsely vegetated rocky landscapes in which these depicted hunts take place are occasionally bordered by netting fences, suggesting that the animals were sometimes captured first and then released into a corral before being set upon. The necessity for such “hunting parks” may reflect a gradual decline during the Dynastic Period in the populations of some species in their natural habitats.

Tomb paintings also show men hunting in the marshes. Set within impenetrable papyrus thickets, these images usually feature an abundance of birds, such as ducks, Egyptian geese, sacred ibis, pied kingfishers, and little egrets. In a scene that was popular from the Old Kingdom until the New Kingdom (ca. 1550–1070 B.C.E.), the tomb owner, while holding “decoy birds” in one hand, hurls a throwing stick at wild fowl to knock them to the ground. In other scenes, groups of hunters employ a “clap net” to catch large numbers of waterbirds. This device consisted of netting panels laid out across the water surface. Once a sufficient number of birds had alighted upon the submerged trap, the men, while hidden from view, pulled on a rope to close the panels over the animals. Scenes from the Old Kingdom frequently show a gray heron standing prominently nearby; the heron was used as a decoy to attract birds to the trap.

Wild birds were also captured in the surrounding countryside. For example, wall scenes show that common quail attracted to harvests were flushed into weighted nets, which teams of running workmen dragged across grain fields. Similarly, golden orioles drawn to orchards were caught in nets

slung over fruit trees after the shouts of waiting men caused them to fly upward.

Both pictorial and physical evidence has provided details about ancient Egyptian fishing methods. Spear and harpoon points made of bone, ivory, and copper have been recovered from archaeological sites dating from the Predynastic to the Greco-Roman Period. These objects are also represented in wall paintings that depict tomb owners using a bident (a two-pronged spear) to stab fish while canoeing in the marshes and in scenes where men hunt hippopotamuses with barbed harpoons. Wall scenes often illustrate large-scale fishing operations in which long seines (a type of large net) overflowing with tilapia, Nile perch, gray mullet, catfish, and European eels are hauled in to shore by groups of fishermen. However, small wooden models found in tombs dating to the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) show that the seine could also be dragged through the water while slung between a pair of boats. In some scenes weir traps (basket traps) are deployed in shallow canals to intercept fish swimming upstream, while in other images workers strain to lift from the water large dip nets filled to capacity with a variety of species. Hand lines were also used, and fishhooks of bone, ivory, shell, and copper have been recovered from many sites. Simple barbless hooks were common at first, but barbed examples became popular during the Middle Kingdom, a time when the first depictions of fishing rods also appear.

Once the catch was brought to land, tomb scenes show that the fish were gutted and then the flesh was dried by either hanging it from lines or laying it out on the ground, often with the heads and spines still intact. Mullet roe was especially prized; this was also removed and eaten either fresh or dried. Despite occasional religious restrictions, fish were consumed throughout Egyptian history. The remains of a fish-processing plant have been found in a Fourth Dynasty (ca. 2575–ca.

2465 B.C.E.) workers' village at Giza, and documents show that soldiers, priests, and artisans were often paid with quantities of fish. During the Roman period, dried catfish were exported from Egypt to many parts of the Mediterranean.

Although their early development of agriculture enabled the Egyptians to cultivate most vegetables, they nevertheless continued to gather important wild plants. For example, wall scenes show men carrying large bundles of papyrus back from the marshes. This aquatic plant had multiple uses, particularly in the production of paper, but the rhizomes were also eaten. The rhizomes of white and blue lotus plants were also consumed, and their petals, which have narcotic qualities, were used in medicines. The sweet fruits of the wild sycamore fig, the thornbush, and the doum palm were so relished by the Egyptians that they were frequently included among tomb offerings left for the dead to enjoy in the hereafter.

THE MIDDLE EAST

BY LYN GREEN

The Fertile Crescent of the Middle East is usually regarded as one of the areas where humans first domesticated plants and animals. However, the earliest cultures of the region relied on hunting, fishing, and gathering for their subsistence. These activities continued to be important sources for foodstuffs to supplement people's diets and for trade. Although many types of plants and trees would eventually be cultivated in some way or another, wild plant gathering continued to be the usual way to obtain various herbs for medicine and cooking and for certain types of food.

Nuts and seeds or kernels were a significant part of the subsistence diet throughout ancient Near Eastern history. Acorns could provide both animal fodder and food for the poorest classes of people. Almonds, pine nuts, pistachios, and kernels from the fruit of the terebinth tree were widely eaten throughout Mesopotamia and Persia. Greek authors such as Strabo and Plutarch, of approximately the first century C.E., mention pistachios and terebinth kernels as particular foods of the Persians. Although some varieties of trees eventually were cultivated in orchards or gardens, in areas where these trees grew plentifully on their own it was often much easier just to gather the nuts, fruits, and kernels in the forests. Some varieties of mushrooms also did not lend themselves easily to cultivation and continued to be gathered in the woods. Truffles were considered a delicacy by the Babylonians.

Even after the rise of agriculture, fishing was part of food production throughout the ancient Near East. Archaeological finds and texts recording trade or rations for workers show that both saltwater and freshwater fish were a part of the diet. It is also clear that many varieties of freshwater fish were raised in ponds for easy access. Saltwater fish, of course, would still have been caught by fisherman in boats. Once caught, fish of all types might be dried, salted, or otherwise preserved for

trade. The bones of a saltwater fish called a tunny have been excavated in the ruins of the inland Sumerian city of Ur in southern Iraq, showing that preserved fish might have been traded over long distances.

There is some evidence that in Israel during the Iron Age fish were both salted and pickled. Fishing was done with hooks of bone or metal much like modern ones. Nets were also used: Individual fishermen cast nets with stone or lead sinkers, and groups of fisherman used dragnets to catch fish in rivers or in the sea. These nets were originally made of plant fibers, but eventually linen and cotton became more common. Clams and other mollusks were gathered and eaten by most of the cultures of the ancient Near East. However, seafood was often considered food for the poor. The well-off preferred to show their wealth by eating red meat, especially from large animals that were either were expensive to raise or dangerous to hunt.

Although the domestication of animals such as sheep, goats, and cows proceeded at the same time as the development and spread of agriculture, there was always a place for hunting in food production. However, as hunting is a time-consuming and unreliable method of meat production compared with the slaughter of domesticated animals, hunting tended to provide meat for two widely disparate classes of people. At one end of the social scale, hunting would still have been important in the lives of those fringe groups who lived outside the urban centers.

A group of early cuneiform tablets called the Yale Cuneiform Tablets (housed at Yale University in Connecticut), dating to about 1700 B.C.E., includes a number of recipes for various types of meat, including stag. The recipes on the Yale

Impressions of cylinder seals on clay, depicting hunting scenes; found in the treasury of the palace at Persepolis. (Courtesy of the Oriental Institute of the University of Chicago)

tablets were those used by the upper classes of society, and the mention of venison shows that they valued game. The Greek authors also mention venison when describing the diet of the Persians, and at Persepolis both antelope and gazelle are shown among the animals prepared for a feast. It is also likely that rabbit and other small wild animals were hunted by the poorer country dwellers—everywhere but in Israel, where religious rule prohibited people from eating them. Onagers (wild donkeys) were also hunted for their skins. Other wild game, including wild oxen and wild boar, were hunted and eaten in most of the Near East. Both wild bulls and wild boar were dangerous animals, and those who hunted them gained both prestige and protein after a successful hunt. Hunting, especially lion hunting, became a symbolic activity of kings to promote an image of bravery.

Not all hunting activities were equally prestigious. Birds and small game such as hares and rabbits were hunted or trapped, but without the fanfare that surrounded other game hunting. Among the wild birds eaten were partridges and duck. Other birds used for their meat, feathers, and eggs were sometimes raised on farms, including geese, pigeons, and chickens. The chicken was a latecomer to the Near East, arriving from the Indian subcontinent around the time of the Assyrians (1813–609 B.C.E.). Even in classical Greek times chickens were sometimes still called the Persian Bird.

Apart from obvious food sources, such as domesticated cattle, both wild and domesticated birds, and fish, the ancient Israelites also gathered and ate insects, specifically grasshoppers and locust. A taste for locusts was apparently shared by others in the Near East: Assyrian reliefs show attendants carrying long skewers of (presumably roasted) locusts or very large grasshoppers to a royal banquet. These, too, were probably gathered from the fields where cultivated crops were sown. Locusts and grasshoppers were not only a useful protein supplement to the diet but also reduced the depredations caused by these pests on other food sources.

A number of ancient Near Eastern cultures, including the Persians, ate camel. Although camels were more or less domesticated by the first millennium, their use as food undoubtedly began when these animals were still wild. They would have been hunted for their meat. Some cultures, such as the Babylonians, also caught and ate mice, jerboas, turtles and wild hare. Gazelles and similar animals (such as ibex) were hunted and eaten as delicacies. The trapping or hunting of wild animals gradually evolved from a necessary means of subsistence to a source of luxury foodstuffs.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The Asia and Pacific region is vast, with many different climates that affect what sort of food is available from place to place. At one time all people were hunter-gatherers, people who moved around the landscape learning what to eat and

what not to eat. Some of them settled in one place or chose to migrate between winter and summer homes. Others chose to follow herds of animals. Still others chose to press ever onward. This last group continued until they reached Australia. Their descendants remained primarily hunter-gatherers.

For the ancient Australians, the landscape offered vast, open lands where spears, arrows, and boomerangs were effective in bringing down game. For other peoples of Oceania, there were small islands with big mountains, vast rain forests, and much open water. One group, by far the most ancient, was ethnically similar to the Dravidians of southern Asia and to the Australian Aborigines. Another group, only beginning to colonize the Pacific islands near the end of the ancient era, was the Polynesians. Both groups had a dramatic effect on wildlife.

The migration of people through Indonesia and across the Pacific to Australia is just beginning to be studied, but one aspect of it stands out: Wherever these ancient peoples went after leaving the Asian mainland, they tended to exterminate the wildlife. They would reach an island, feed off its game animals until they were gone, and then move on to the next island. They used spears with fire-hardened tips, stone tips, or bone tips. The ecological catastrophe such habits of hunting could cause can be seen in Easter Island (settled in the 400s B.C.E.), where the people exterminated edible native land animals and plants, leaving mostly fish to eat, and even trapped themselves by destroying the trees from which they could build boats, using the trees for timber for the roofs of their homes and as logs for rolling massive stone monuments from their quarries to the edges of the island.

Among the Polynesians, special hunting skills were developing during the early Christian era. The Polynesians hunted game not only on land but also in the sea. They made harpoons tipped with stone or coral. They learned to use nets to gather in fish in shallow waters and to hunt dolphins and large fish out at sea. When foraging on land, they sought out tubers, perhaps because starchy tubers were filling and supplied energy. The people on every island in the Pacific near Asia, such as the Philippines, Indonesia, and Japan, learned to harvest shellfish. On the Japanese island of Honshū, people ate so many shellfish that they were able to pile the shells into large burial mounds.

The first fishhooks were used even before the last great ice age. The first may have been gorge hooks—double-pointed hooks with a line attached in the middle. Bone, antlers, and stone were used throughout southern Asia. Fish from freshwater streams were an important source of food. The earliest depictions of bows and arrows may be in rock paintings in North Africa from about 20,000 B.C.E., but some paleontologists believe that the bow and arrow developed much earlier. Prior to the development of the bow and arrow, hunters used spear launchers to maximize the force of their throws. These launchers were hollowed out wood, stone, or antlers in which the base of the spear would rest. With an overhand motion,

the spear could be flung hard enough to pierce the flesh of elephants and rhinoceroses. The bow and arrow allowed a hunter to increase the force of an attack by using the stored energy of the bent bow and string. Among hunters of large game from at least 1500 B.C.E. the bow and arrow were the weapon of choice.

Little is known about the customs for hunting in India before 500 B.C.E., though the Aryans who migrated into India in the 1500s B.C.E. esteemed hunting prowess. Hunting and fishing became controversial in India after 500 B.C.E. By 300 B.C.E. hunting and fishing had become detestable acts that only outcasts (those people who had no caste status and were thus at the lowest end of the social order) were permitted to do, yet hunting and fishing were recognized professions under the laws of India, and the restrictions on eating meat were often ignored or explained away. For instance, Buddhist priests could eat meat so long as they did not kill the animal themselves. Fishing was excused because the fish was partly at fault for choosing to bite the fishhook. Further, hunters were expected to capture animals alive to transfer to parks owned by monarchs and nobility, who hunted the animals for sport.

Ancient Indian professional hunters lived near forests, sometimes in villages of nothing but hunters. Farmers who lived near wild lands also hunted, even though doing so was against the rules governing the castes. The primary weapon in hunting was the bow and arrow. Hunters would station themselves near trails used by deer and other animals and strike with poisoned arrows. Sometimes they incorporated traps into their hunt. A pit would be dug large enough for an elephant, and the pit would be covered to look like normal ground. Poison arrows would finish off a trapped elephant, and then its tusks would be sawed off and carried away for sale.

Other animals were also trapped. Loops of rope attached to trip wires would wrap around an animal's legs, hobbling it. An unusual method for capturing deer and antelope involved attracting deer with the scent of tasty food and then letting the animal see the hunter. This activity could go on for days until the deer had become used to the hunter and was unafraid. Then the hunter would scoop up the animal and carry it away.

In China monarchs and noblemen would go hunting with their retainers and servants. The monarchs and nobles rode on chariots during the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) and were traveling on horseback by the Han Dynasty ca. 202 B.C.E.–ca. 220 C.E.). They used dogs and servants to stir up game, which they hunted with bows and arrows. Such a hunt was intended to be a grand entertainment, during which the nobility would win honor by killing animals. Sometimes they used trained falcons to bring down game.

Even peasants could use trained hawks, usually to bring down game birds. While peasants hunted mostly to feed themselves and their families, professional hunters brought

their kills to city markets to sell. They hunted birds with bows and arrows and brought ducks, geese, and pheasants to market. Fishermen salted the fish they caught to preserve it until they brought it to market. They used nets made of hemp in rivers and the sea. Under law and by custom, the ancient Chinese valued their game animals. When a Chinese hunter had the opportunity to kill two deer, he would kill only one. The Chinese believed that enough game animals should survive from year to year to keep their numbers sufficiently high to feed people indefinitely.

EUROPE

BY RICK SCHULTING

Until the arrival of domesticated plants and animals from the Near East, prehistoric populations in Europe relied upon hunting, fishing, and gathering for their subsistence. The Mesolithic Period began at the end of the last ice age, around 12,000 years ago, and ended with the arrival of farming, which began around 7000 B.C.E. in southeast Europe, around 4000 B.C.E. in northwest Europe, and even later in the more northern parts of Scandinavia.

Great changes took place at the end of the last ice age, as the large herd mammals—horse, reindeer, bison, and mammoth—became extinct or moved to the far north. With the retreat of the ice came the forests, with an entirely different set of animals, including red and roe deer, elk (the European moose), aurochs (wild cattle), and wild boar. These now formed the main prey species sought by human hunters, who by this time were well acquainted with the use of the bow and arrow. Domestic dogs were present as well and may have helped in the hunt. In some parts of Europe different animals, such as ibex and chamois in the Pyrenees and the Alps, were found and were also hunted. A great variety of smaller game was also hunted or trapped, some, including pine marten, fox, and wolf, mainly for their furs.

Where people had access to rivers, lakes, and coasts, fish and shellfish often featured in the diet. Much evidence for coastal settlement at this time has been lost to rising sea levels, but where the ancient coastlines do survive, and most particularly in southern Scandinavia, there is abundant evidence from ancient kitchen middens (accumulations of food and other debris of human occupation, such as discarded tools and ashes from hearths) of the exploitation of marine foods. The largest of these middens contain many cubic yards of oyster shells and other shellfish as well as the abundant remains of a variety of fish. Eels and flatfish appear to have been particularly important here. A relatively new technique known as stable carbon and nitrogen isotope analysis has been used to test surviving human bone from burials at these sites. These tests show that in many cases the great majority of the protein in the diet came from the sea. But the bones of terrestrial mammals in the same sites show that these animals were also hunted, as were such sea mammals as seals and porpoises. It seems that on occasion even small whales

Harpoon tips made of antler from the cave of Courbet, Penne-Tarn, France, and dating to about 10,500 B.C.E. (© The Trustees of the British Museum)

were actively hunted, though more often these animals were probably found and used when they were stranded.

The waterlogged conditions of some of these coastal sites led to the preservation of wood and plant fibers only very rarely found elsewhere. This evidence shows that ancient peoples had developed a complex technology, including stationary fish traps of wooden stakes and woven withies, as well as eel baskets that differ very little from those still in use today. Dugout canoes and paddles have also been found, though mainly these items seem suited for calmer waters near the shore.

Many species of birds were also exploited, some in large numbers, taken when their migration routes brought them within reach. Others, such as the white-tailed eagle, were used less often, but their feathers may have been important for arrow fletching as well as for ornamental and ceremonial purposes. Nets, small fragments of which survive from some sites, were probably as useful for capturing birds and other small game as they were for fishing.

A great variety of plants was gathered, for a variety of purposes, including food, medicines, and raw materials for clothing, basketry, and dyes. Unfortunately, rather less is known concerning the exploitation of plants than of animal resources, partly because plant remains do not survive as well as animal bones and are more difficult to recover during ex-

cavations. An exception is the hazelnut, the charred shells of which are ubiquitous on Mesolithic sites across Europe. The stones of wild fruits, such as plum and apple, and the pips of many types of wild berries have also been found where preservation conditions were favorable. Far less well represented are herbs and other greens that would have added flavor and variety to the diet and would have been of medicinal importance as well. A greater abundance and variety of edible plants would have been available in southern than in northern Europe, including sweet foods, such as figs and honey. Indirect evidence of their use is seen in the much higher rates of caries (cavities) in the teeth of human skeletons from this period in southern Europe.

A reliance on hunting, fishing, and gathering does not mean that people wandered endlessly over the landscape. Their use of the environment was both highly knowledgeable and highly structured, often following a distinct seasonal round, with return visits to, for example, productive berry patches or animal migration routes year in and year out. In areas that were favored with especially rich and varied resources, communities were able to live in larger and more permanent villages, comparable in many ways to the earliest farming villages. There is evidence of such settlements patterns in parts of southern Scandinavia and on some stretches of the Danube River, most famously at the site of Lepenski Vir.

Based on comparisons with people practicing a hunting, fishing, and gathering economy in more recent times, we can surmise that different activities were often carried out by different age and gender groups but that there was at the same time a considerable degree of flexibility in these arrangements. Thus, in many cases, young men were probably the most active hunters, while young women may have ranged farthest in gathering plants and shellfish as well as seeking out or taking any small game that opportunistically presented itself. Young children and older men and women likely stayed closer to the camp or village, contributing in other ways. Many men probably also gathered, especially at certain times of the year, such as when the berries were ripe and would soon be lost to birds and bears if not gathered quickly. And no doubt some women enjoyed and were skilled in hunting larger game. Other activities, such as game drives, or preparing and setting nets for migratory fish or birds, would have required the participation of everyone.

GREECE

BY CHRISTOPHER BLACKWELL

Hunting figures prominently in the mythology of ancient Greece. Several of the famous Twelve Labors of Heracles (Hercules to the Romans) involved hunting: his killing of the Nemean Lion, his hunt for the Ceryneian Hind and the Erymanthean Boar, and his killing of the Stymphalian Birds. The famous Boar Hunt of Meleager, which ended in tragedy, brought together a number of mythological heroes. The hunter was a romantic figure who existed outside the normal

life of the farm and town. Artemis was the goddess of the hunt and is often portrayed as an untamed spirit, exotic but dangerous.

Most hunting by real people of the ancient Greek world was for food rather than for sport. Since the main source of protein for most people came from legumes such as lentils, meat was a welcome addition to the table. Our best source for techniques of ancient hunting is the work by the fourth-century philosopher, historian, and adventurer Xenophon. *Cynegeticus*, literally Dog Leader but often translated as *Hunter*, describes techniques for hunting rabbits and hares, deer and hinds, and the most challenging prey, the wild boar. He writes of how dogs or human “beaters” were employed to drive animals out of the brush and into the open. Many of the other techniques Xenophon describes are clearly those of a practical-minded hunter rather than a sportsman. He mentions using pits and snares to trap animals, setting out clogs (blocks of wood intended to trip a running animal) and nets to impede animals until dogs could take them down, and even capturing young animals, holding them, and beating them so that their cries would draw their larger mothers to the dogs or the spear.

Boar was prized as a catch both for its meat and because of the danger and difficulty of hunting it. Even when hunting from horseback and with dogs, a human being had ultimately to face the boar and kill it with a spear. An enraged animal could move quickly, dodging the spear or even impaling itself on the weapon so deeply that its tusks could wound the hunter. An alternative was to kill the beast with thrown javelins, but this had its own risks; the historian Herodotus describes how the son of King Croesus of Lydia was killed by friendly fire during a boar hunt on Mount Olympus in Mysia.

Dogs were indispensable assets for a hunter, as the title of Xenophon’s treatise indicates. The Greeks kept various breeds of hounds. The most common of these was the Laconian hound (named after the southern region of Laconia, near Sparta), which was bred into a larger breed, the Castorian hound (perhaps like a modern greyhound), and crossed with foxes to form a smaller breed called the Vulpine hound, which may have resembled a modern whippet. For hunting boar, the ancient Greeks preferred so-called Indian hounds, which may have been akin to the modern mastiff. For the most part, hunting was not conducted from horseback except among Greek communities of Asia Minor.

Xenophon’s writing on hunting, as well as references in the works of Plato and those of Greek writers from later centuries, tend to support an elitist distinction between aristocrats, who could afford to hunt for sport, and the lower classes, who hunted for profit. This reflected a general bias toward land ownership and agriculture as the proper pursuit of the upper classes, while any activity aimed at financial profit was considered a base pursuit for the masses.

Fishing appears widely in the art of the Bronze Age, particularly that of the Minoan palaces on Crete dating from the second millennium B.C.E. Nonetheless, seafood was not a par-

ticularly important part of the ancient Greek diet. The water of the Mediterranean Sea is too salty and too clear to support the variety of fish found in the Atlantic Ocean. Fish populations around areas inhabited by Greeks in antiquity were migratory and variable, making them an unreliable source of food. In fact, ancient literature tends to portray fishermen as figures of excess, swinging from utter poverty to wild, temporary wealth, with comic effect.

But the ancient Greeks liked fish, which provided a welcome change of taste from the regular diet of bread, olive oil, and beans. Because of its relative scarcity and the difficulties of transporting it fresh, fish was most often pickled and used as a relish to enhance the taste of bread. The ancient Greek word for relish is *opson* or *opsarion*, and the modern Greek word for fish, *psari*, is derived from this ancient word.

Fish were often salted and dried by laying them out in shallow lagoons of seawater, which the sun would evaporate; the increasing salinity of the evaporating water would preserve the fish, which would end up very salty, dried, and easily stored. The salts and trace minerals in this dried fish were probably as important nutritionally as the protein.

There were few rivers in the world of the ancient Greeks, and most rivers dried to mere trickles during the summer months. There is virtually no evidence for freshwater fishing of any kind. The Greeks caught fish close to shore with hand nets whose hauls included small octopuses and shellfish, from small boats offshore with cast nets, and in the deeper ocean with spears for larger fish such as tuna. Fishing in deepwater was dangerous, since the seas of the Greek world were subject to sudden violent storms. These storms were particularly dangerous for boats because of the relative shallowness of the sea

Fragments of a fresco from Tiryns, showing hunter and dog (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

and the proximity of rocky coasts. Paintings on ancient vases depict boats with lanterns hanging from prow and stern, suggesting that fishing was conducted by night.

Various straits and narrows in the seas around the Greek world were known as rich sites for fishing. The straits of Messina, the Hellespont, and the Bosphorus all saw populations of fish pass by, closely packed, during their annual migrations. Certain bays and inlets along the convoluted eastern coastline of Greece were rich in populations of eels, another prized delicacy.

Most of the vegetables in the ancient Greek diet, such as onions, leeks, garlic, and turnips, were the produce of gardens or small farms, but wild greens and herbs were prized as seasoning. Fennel, particularly, grows wild all around the Aegean Sea, and it was valued for its seeds and its stalks. Other herbs that were probably gathered wild were basil (whose name comes from the Greek word *basileus*, meaning king) and the pungent, sulfurous asafetida, a plant originally from Iran but common throughout the ancient world and frequently used in cooking. Honey and some fruits, such as figs, could be gathered in the wild, but both of these sources of sweetening were domesticated by the historical period, after the seventh century.

ROME

BY MICHAEL J. O'NEAL

The civilization of the ancient Romans developed later than most ancient civilizations. The first inhabitants of the area around Rome arrived in about 1400 B.C.E. Then, by about 625 B.C.E., numerous settlers had arrived and drained the marshes around what would become the city of Rome, along the banks of the Tiber River. The Etruscans and Greeks settled portions of the Italian peninsula, but the political entity known as the Roman Republic did not emerge until about 500 B.C.E. The Roman Empire refers to Rome and its many colonies beginning in 27 B.C.E.

Because Rome was a late arrival, its people were never hunters and gatherers as most ancient peoples had been during some period of their early history. Rome was a civilization in the fullest sense of the word, so Romans quickly came to sustain themselves through manufacture, agriculture, and especially trade and military conquest. The entity now called "Rome" was never a Paleolithic, hunter-gatherer, tribal society. This is not to say that some people in rural regions did not live by hunting and gathering or, more likely, supplement their living by these activities. Rome encompassed a wide region, so people under its control in North Africa, in the Middle East, in Europe, and around the Mediterranean Sea undoubtedly hunted, fished, and gathered nuts, berries, fruits, tubers, leafy vegetables, and other products of nature. But no respectable Roman citizen living in one of the empire's cities would have survived in this way. Rather, Romans lived in large part by imported luxury foods and massive supplies of imported grain.

Fishing in ancient Rome was either a sport or a commercial activity. Roman men, particularly those from the affluent classes, often traveled to the countryside, where they hunted and fished for sport. Fly-fishing was an especially valued form of recreation. The bulk of fishing, though, was commercial in nature. The Italian peninsula thrusts deeply into the Mediterranean Sea and is surrounded by water on three sides, so it comes as no surprise that fishermen plied its waters, as had the ancient Greeks before them.

Much of the evidence for ancient Roman fishing practices comes from references in literature and from surviving artwork. These demonstrate that Rome and its colonies around the sea maintained a thriving fishing industry, both from boats and from the shore. They caught fish primarily with nets, though sometimes they used traps. Some of these nets were relatively small and could be managed by just two men. Others were quite large and required a crew of men to handle. Some nets required draw ropes to close the nets; others required the fishermen simply to gather the edges of the nets and pull. The technology of nets was advanced, and Roman writers refer to a wide range of net types, each suitable for fishing under different conditions—in shallow water or deep water, for example. Unfortunately, these nets were made from organic materials, such as flax, so none have survived the ravages of time.

Catches were sold in marketplaces in Roman cities. In comparison with modern life, transportation was relatively slow, and the Romans did not have the advantage of refrigeration, so the fish that arrived at markets was sometimes "fishy," suggesting that it was getting old and on the verge of spoiling. For this reason fish by itself was not always a major portion of the Roman diet, though wealthy people were able to get fresh fish specially delivered to their doors. Fish was consumed primarily in the form of a processed sauce called *garum*. The empire maintained numerous fish-processing plants along the coast for producing this sauce, and people who lived in these coastal regions often made their living by supplying the plants.

Hunting, like fishing, was primarily done for sport, again by affluent men who journeyed to the countryside to hunt game animals, usually with the aid of dogs. Hunting was also memorialized in the Roman pantheon of gods and goddesses, most prominently by Diana, who evolved from the Greek goddess Artemis. Diana, the virgin goddess of the hunt, is usually depicted with a bow and arrow and accompanied by a hunting dog and a stag.

Hunting as a sport was so popular that it actually became a spectator sport called the *venatio*. In ancient Rome this term had different meanings, depending on the context in which it was used. Sometimes it referred to big-game hunting in places like Africa. Sometimes it referred to spectator hunting that took place in Roman arenas. And because such "beast hunts" were often conducted in connection with gladiatorial contests, *venatio* became a general term for these spectator sports taken together.

Thus, at Rome's Circus Maximus, for example, a gladiatorial contest would be scheduled for the afternoon; the hunt, or *venatio*, would serve as a warm-up act in the morning, though sometimes the *venatio* went on for a period of days. Wild animals, such as lions and tigers that had been captured and kept in cages below the arena, were raised by ropes and pulleys and then released in the arena, where trained hunters called *venatores* stalked and killed them, often as the animals were being goaded by assistants. The spectators were protected from these animals by large nets or polished metal rollers attached to the tops of the surrounding walls that separated spectators from the killing ground. Archers were positioned on balconies around the arena as a last line of defense.

These trained hunters held a position high in the public's esteem, just below that of gladiators. Sometimes expert hunters from Africa and other regions were imported; in 79 B.C.E. the Roman statesman Pompey organized games in which skilled desert nomads were brought in to kill 20 elephants. On other occasions slaves and prisoners of war with no training were forced into the arena in the expectation that they themselves would become the hunted, and their gruesome deaths would entertain the crowd. These people, called *bestiarii*, were frequently unwilling to face the wild animals in the arena. In one case, a slave managed to get his head through the spokes of a wheel in the cart carrying him and thus break his neck before the hunt began; in another, the writer Seneca tells the story of a German who killed himself in the lavatory rather than face the ferocious beasts in the arena.

THE AMERICAS

BY MICHAEL J. O'NEAL

The usual stereotype of early hunter-gatherer cultures suggests that they were primitive and unsophisticated, perhaps almost subhuman. They lived short lives that consisted of nothing but hardship as they engaged in a desperate, ongoing search for food. They had no property, no art, no government, no social organization—in short, none of the fruits of civilization that accompanied the advent of agriculture and the settled communities that agriculture produced. In the famous words of the 17th-century English philosopher Thomas Hobbes, their lives were “nasty, brutish, and short.”

This stereotype, like many stereotypes, had a grain of truth to it among ancient Americans. It is true that people tended to live in smaller bands of perhaps 50 to 100 people, with 20 to 30 being the optimal size; larger communities strained the carrying capacity of the band's territory, often leading to conflict and fissures in the band, as some members broke away to form new bands. It is also true that population densities were small, on the order of just one person per 30 to 50 square miles in resource-poor environments, perhaps as many as 10 to 30 people per square mile in more resource-rich environments, such as the Pacific Northwest. Early hunter-gatherers (including those who subsisted by fishing, a form of hunting) were often on the move, so they had few posses-

sions. Archaeological evidence such as that uncovered in the southeastern United States suggests that they also formed more permanent communities, with public buildings and burial grounds. These more permanent communities established a type of base camp to which groups returned at various points during the year. Otherwise, the band moved about according to changes in the seasons, exploiting resources as they became available.

The social organization of early foragers tended to be egalitarian, with everyone sharing in the fruits of the community's labor. The only specialization tended to be along gender lines, with men engaged in hunting and women engaged in gathering vegetables, fruits, berries, nuts, and even protein-rich insects. Both men and women gathered firewood, and both found small game and such food items as mollusks in marine settings. Artwork was a blend of craft and technology, as even ancient hunter-gatherer societies produced decorative clothing, masks, wood carvings, baskets, pottery, and other artifacts out of the materials available to them. While life expectancy was often low, primarily because of a high rate of infant mortality and high death rates among women giving birth, archaeological remains also suggest that a surprising number of people lived to a relatively advanced age, cared for by the larger community.

The earliest hunter-gatherers migrated to the Americas from Siberia to Alaska via a land bridge across what is now the Bering Sea. It is estimated that the sea level rose to cover the land bridge in about 8000 B.C.E. It is likely that the very first Americans crossed the land bridge to hunt, and after about 11,000 B.C.E. and perhaps much earlier, they hunted mammoths, mastodons, bison, and other large game. The chief archaeological evidence comes from the vicinity of Clovis, New Mexico, which gave its name to the Clovis peoples, bands of Paleo-Indian hunters who, many historians believe, were the first people to inhabit the Americas, arriving in the New Mexico region around 9500 B.C.E. and moving on from there to South America. So-called Clovis points, or stone spear points that historians believe were mounted on wooden hafts, have been discovered in this area. These points are unique in their design in that they snap off on impact, allowing the hunter to reuse the haft if the animal escapes.

In addition to hunting and foraging for food, the Clovis people exploited other natural resources, including stone (especially flint), bones, and ocher (for dye). Many historians believe that the Clovis people were the first Americans; however, many questions surround where they came from and what happened to them. Some of the richest archaeological Clovis finds have been in the southeastern United States, but no archaeological evidence has been found in Alaska. Further, while some disagreement exists about the cause of their disappearance sometime after 8500 B.C.E., when the archaeological record ends, most archaeologists believe that overhunting of big game contributed to their extinction.

Early hunter-gatherers naturally gravitated to environments that were rich in resources, including wild game, for-

ests, grasslands, and river valleys. The tribes of the American Northwest, for example, found abundant resources in the region's forests and along the coastlines. Salmon satisfied a large percentage of people's nutritional needs. In the grasslands of the North American Plains and the savannas of South America, large game animals, including prominently the bison in North America, provided not only meat but also hides for clothing, blankets, and shelters, as well as bones, hooves, and other remains that could be put to use. In regions where vegetation was sparser, evidence suggests that early hunter-gatherers burned grasslands and woodlands. This practice encouraged the growth of new, tender vegetation, which attracted game animals that could be hunted.

Hunting and gathering were done almost exclusively on foot. Muscle power was the only form of power available. The horse was not used for hunting in North and South America until much later. The primary exception was among people who lived in aquatic environments along coastlines throughout the Americas and eventually on the islands of Central America. These people relied more heavily on boats, rafts, and canoes to fish and hunt such animals as seals and whales in the far north.

These two subsistence patterns had relative advantages and disadvantages. Aquatic foragers were able to secure larger amounts of food with relatively little physical effort, so their communities became much denser with people. The disadvantage was that they tended to be dependent on a limited range of foods. A sudden change in weather patterns or a disease that wiped out an important food species could leave them vulnerable to starvation. In contrast, pedestrian foragers, because they moved about within a wide geographical region, relied on a much wider range of foods, making them less susceptible to climatic changes, changes in rainfall, and similar catastrophic events. However, they had to exert much more physical effort than did aquatic foragers, sometimes burning more calories in the quest for food than they were

able to acquire. Put simply, aquatic foragers had more than pedestrian foragers had, but the food supply of pedestrian foragers tended to be more secure and reliable.

► illumination

INTRODUCTION

Before the advent of electricity, people had to find ways to illuminate their homes at night. They also needed to light workspaces and caves and cellars where they stored food and other goods and to illumine their paths if they traveled at night. The technologies for providing illumination in the ancient world were remarkably similar from culture to culture. Fire, of course, was the source of artificial light. Among the most ancient peoples, bonfires provided light around which the community gathered, thus affording people an early form of social gathering where the events of the day could be discussed, stories and legends could be told, and successful hunts could be celebrated. But people needed more portable sources of light as well as sources of light that were relatively safe and controllable for use in their homes. This concern with safety, especially in crowded and poorly built tenements in ancient cities, led to the development of the *couvre-feu*, a cover for fires at night. The *couvre-feu* is the source of the modern word *curfew*.

Throughout the world, the oil lamp was the most common source of artificial light. These lamps were typically made of stone, clay pottery, or metal. For fuel, the earliest lamps relied on bark, wood shavings, and the like, but the preferred fuels in later lamps were oils derived either from animal fats or from plants. Typically, a wick was fashioned to soak up the oil, which then burned faster than the wick. To make such lamps less smoky, salt was added to the oil, which also had the advantage of causing the flame to burn more brightly. In addition to oil lamps, ancient people relied on torches, tapers, rushlights, and other forms of portable

lighting. The ancient Chinese were the first to mine coal for burning, and they even developed natural gas wells. Both of these fuels provided light.

Ancient lighting served a variety of purposes other than just to add illumination in homes and work spaces. The ancient Romans, for example, developed lighthouses along coastal regions, using mirrors to project light that provided guidance to ships at sea. Ancient military organizations also used light to send signals in stages over long distances. Cities in ancient China used lamps as streetlights.

Among many ancient peoples, illumination from the sun had religious meaning. The sun, as the source of warmth, light, and the growth of plants and crops, was often worshiped as a god. Most ancient religious texts highlight the separation of the light from the dark in stories about Creation, and light and fire played an important role in their mythologies. The story of how Prometheus stole fire from the gods is a good example. Accordingly, fire and light were central to religious rituals throughout the ancient world, and fires were often kept lit in honor of the gods.

Fire and illumination even played a role in ancient forms of entertainment. Ancient China and Japan developed magic lanterns and used light to form puppet shows by casting shadows that created the illusion of motion. In effect, the ancient Chinese and Japanese produced the world's first cinema.

AFRICA

BY KIRK H. BEETZ

For much of ancient Africa, light had both practical and religious purposes. Practical purposes included being able to see in the dark as well as marking the edges of a path. For

religion, there were many purposes, including marking sacred ground or altars and indicating places for worshipping the sun. Many Africans believed the sun to be sacred, and archaeologists have found evidence that a profound interest in the sun dates back several thousand years.

As in other parts of the world, management of light probably began with campfires. In modern times the San of southern Africa centered many of their activities on a fire that provided a central gathering place in their communities. In Saharan Africa there was a mix of ethnic groups for thousands of years, as their rock paintings make clear. For regions where different cultures mixed, the area around a campfire became a gathering place for people to share information and stories. Thus, the fire's light in the dark not only helped people to see but also drew them together.

When the Sahara was a fertile land, it was populated first by hunter-gatherers (perhaps 27,500–5095 B.C.E.) and then herders of cattle and sheep. They used torches of wood to light their way at night. The exact mechanisms of the torches have yet to be defined, but these early peoples probably just ignited sticks of wood at one end and then let them burn down. However, the ancient Saharans had at hand what they needed to make more sophisticated torches, such as sticks wrapped at one end with grass or cloth soaked in animal fat. Whether the Saharans used torches in their religious ceremonies is uncertain.

The history of ancient Africa is very incomplete, but here and there archaeology offers hints at how ancient Africans dealt with illumination. The management of light seems to have been very important for them by the time they begin to show up in ancient histories. Their homes show that sunlight was often an enemy. Whether the homes were woven huts, grass and wood huts, houses of clay, or houses of stone, throughout central and northern Africa, from west to east, houses tended not to have windows. They did not even have openings in their roofs to let out smoke from hearths. A single door was often the only source of outside light, perhaps because the sun can be harsh in Africa, and keeping cool inside one's home may have been more important than having light.

During the Meroitic Period (ca. 590 B.C.E.–ca. 350 C.E.), the Kushites (ca. 900 B.C.E.–ca. 350 C.E.) of eastern Africa south of Egypt developed a way of managing sunlight that would be duplicated in later cultures in West Africa. City dwellers built homes that consisted of a walled enclosure with rooms at its corners. A single door opened into the enclosure, giving the homeowners the privacy of a home, but the enclosure was open to the sun. The rooms had single doorways into the enclosure, and they were otherwise without openings. Those who lived in the house could have the benefits of sunlight for their daily activities but could retreat into cooler rooms when they wished to escape the heat.

The Bantu-speaking peoples of the third century C.E. seem to have used torches to light their villages at night. Some of their ancient altars consisted of a large uncut stone on which a statue or mystical symbol rested. To the sides of

these altars were torches, perhaps just to frame the altar in light. The torches may also have had a ritual purpose, now unknown. The Kushites were heavily influenced by the Egyptians, and they adopted Egyptian lighting techniques for their own homes, temples, and civic buildings. As early as the 2600s B.C.E. Egyptians were using indirect sunlight to illuminate interiors of underground tombs. An aperture was cut at an angle through the roof and ceiling so that direct sunlight did not fall into the passage below but a haze of light did. This construction may have been used in Kushite temple passages, keeping some of the heat of the sun outside while enabling sunlight to play on bright, glistening interior decorations of precious metals, creating a display of sparkling art.

The Egyptians are often credited with inventing the oil lamp. This method of lighting quickly became known to the peoples in touch with Egypt, called "Libyans" to the west of Egypt and "Nubians" to the south of Egypt, where the kingdom of Kush eventually arose. Archaeology has yet to reveal how extensive the use of oil lamps was in Kush, but it was probably widespread. The simplest oil lamps, shallow bowls made of clay with impressed lips for holding wicks of cotton, could have been used by even ordinary Kushite farmers. In Kushite cities there may have been stands of metal to hold them or niches in the walls of stone buildings. They probably did not entirely supplant torches, because torches made a dramatic image when arrayed in a large assembly hall or along an otherwise dark passage leading into the depths of a large temple.

An example of Kushites' managing light is the Sun Temple outside the city of Meroë, once the capital city of Kush. The temple is in a hollow in the ground but is raised above the ground at the bottom of the hollow, perhaps to accumulate rainwater, which was used to water a grassy lawn around the temple. The floor of the temple was yellow, and its walls were blue. Its sanctuary was surrounded by columns. On the back wall, facing the entrance, was a golden circle representing the sun. It would have dazzled people, with the reflected sunlight seeming to thrust out of the earth, while the temple seemed to float on yellow light.

By the time Kush fell out of history around 350 C.E., another ancient kingdom, Axum (ca. 500 B.C.E.–ca. 950 C.E.), was on the rise. The Axumites were a cosmopolitan people who were constantly visited by traders from Europe, the Near East, and southern and eastern Asia. They built houses with columns similar to those used in India's architecture. Short awnings of stone or wood extended over the columns, and behind them were windows, often arched at their tops. These windows had latticework shutters that would allow some light into the rooms beyond but that would keep the rooms somewhat shadowy. It is possible that the shutters were carved so that decorative patterns would fall on the floor as sunlight passed through. The windows probably had panes of glass. Glass windows inspired an explosion of creativity when Axumites converted to Christianity in the mid-fourth century C.E. Techniques for making colored glass were prob-

ably known from India, Syria, and Egypt, and Axumites demonstrated a mastery of creating religious images in glass for their churches. Their colored glass windows were feasts of radiant color for the eye.

EGYPT

BY LINDA EVANS

Light had great significance for the ancient Egyptian people. The sun was considered to be the preeminent source of life and was worshipped in the form of the solar god Re. One of the many Egyptian creation myths also declares that the world began when light in the form of a benu bird pierced a dark abyss of primordial waters, causing the earth and the sky to separate. Light thus created order out of chaos, a vitally important concept in Egyptian thinking.

While we can only speculate about how the prehistoric population of the Nile Valley used fire to illuminate the darkness, archaeological evidence indicates that by the dawn of Egyptian civilization, people had found ways to perpetuate flames and make them portable. Indeed, in ancient times Egypt was credited with the invention of the oil lamp. The most common form of lamp, which was used throughout Egyptian history, consisted of a shallow dish, made of metal or pottery, that contained a small amount of oil and a floating wick. The Egyptian term for both lamps and torches was *tekah*. When written in hieroglyphic script, this word often includes the image of such a lamp, rendered as a half-circle from which projects a snakelike wick. Olive and sesame oils, as well as animal fat, were used for fuel, while wicks were produced by first twisting a narrow length of linen or natural fiber and then folding the length in two and twisting it once again.

Although the dish lamp was the most enduring form, other shapes were also developed in Egypt during different eras. In the Old Kingdom (ca. 2575–ca. 2134 B.C.E.), for example, the rim of the bowl was sometimes pinched to form a small spout, the purpose of which was to hold the lighted wick in position. In another example recovered from the Old Kingdom, the wick of a metal lamp was supported by a series of strips projecting from the rim. Lamps dating to both the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) and the New Kingdom (ca. 1550–ca. 1070 B.C.E.) occasionally feature a broadly channeled rim. The purpose of this outer gutter is unclear, but it may have held water to act as a barrier and to prevent the oil from seeping into the fabric.

During the Middle Kingdom covered lamps began to be produced in order to contain the oil and to prevent spillage. The rim of these vessels was gradually extended to enclose the top of the bowl, leaving only a small hole by which to add the oil and position the wick. Some lamps of this kind included a second aperture in the wall of the vessel into which the wick was inserted. Many lamps of a similar design were imported into Egypt during the Greco-Roman era. However, in the third and fourth centuries C.E. “frog lamps” were pro-

duced in great numbers in Upper Egypt. These popular and distinctive ceramic vessels are so named because they display the features of a frog modeled in relief on their upper surface as well as palm branches and rosettes.

Pottery and metal lamps were common in Egypt, but some lamps were rendered in stone. Indeed, hollowed stone vessels probably was the earliest lamp type. For example, a limestone lamp in the form of a papyrus bud has been recovered from a tomb dating to the First Dynasty (ca. 2920–ca. 2770 B.C.E.). Two alabaster lamps were also found in the 18th Dynasty tomb of Tutankhamen (r. ca. 1333–ca. 1323 B.C.E.). One of these delicate objects is carved in the form of a lotus plant featuring two buds and an open flower, each of which acts as an oil reservoir. The other lamp, which resembles a lotus-shaped chalice, consists of two cups nested one inside the other. When the lamp is lit, a scene painted on the inner vessel displaying the king and his wife becomes visible.

Lamps placed upon the floor, on stands, or in wall niches were used in houses and temples, but they also illumined commercial operations, such as mining. Craftsmen probably relied upon lamps when working inside underground tombs. However, as very little smoke staining or soot has been found in these structures, the precise method that was employed has yet to be determined. Since individual handheld lamps would have provided insufficient light by which to carry out the delicate artwork, it has been suggested that many were placed together in a larger vessel and that salt was added to the oil to reduce the amount of smoke. It has also been supposed that an elaborate system of polished metal mirrors captured sunlight and streamed it deep underground, but this notion is not supported by archaeological evidence.

Lamps were not the only form of lighting technology used by the ancient Egyptians. Archaeological and textual evidence reveals that torches and tapers were also employed for both practical and ritual purposes. Tapers, which were made from strips of twisted linen soaked in fat, were either held by hand or placed in holders when lit. A linen taper was found in one of four bronze lamp holders, each rendered in the shape of an ankh symbol, that were discovered in the antechamber of the tomb of Tutankhamen. Wall reliefs and inscriptions in temples reveal that tapers were lit, carried, and offered to deities during daily rituals and that spells were recited to ensure that their flames endured. Torches, consisting of a conical bolus of fat or resin-soaked linen surmounting a pole, were also introduced in the 18th Dynasty and used extensively throughout the Ramesside Period (ca. 1307–ca. 1070 B.C.E.). Both tapers and torches played an important role in religious festivals, especially those associated with the arrival of the New Year.

The harsh climate in Egypt deterred the use of large windows to admit daylight into buildings, in favor of high, narrow apertures. Sunlight was instead cast obliquely into the rooms of houses and other structures via inner open courtyards. Recent evidence has hinted that artists may also have taken advantage of the strong light in Egypt to create special

effects in their work. Statues of King Khafre, builder of the second great pyramid at Giza, were originally placed in an open court of his pyramid temple, where they were exposed to the sun. Some of these royal effigies are rendered in anorthosite gneiss, a hard and rather unattractive stone. It has been revealed, however, that when placed in strong sunlight, the stone generates a deep blue glow, suggesting that it was chosen specifically for this purpose, to give the statues a mysterious, celestial quality.

THE MIDDLE EAST

BY KIRK H. BEETZ

Before the invention of the oil lamp, ancient peoples of the Near East used torches, candles, hearths, and ovens for artificial light. In many parts of the Near East sunlight was harsh and something to be escaped. Located in central Anatolia (modern-day Turkey), the city of Çatalhöyük (ca. 7000 B.C.E.) had no streets. Houses were joined together without space between them. People climbed through trapdoors onto their roofs and then walked from rooftop to rooftop. Although the roofs were flat, they were of different heights; thus, people used ladders to go from level to level. As a result, the interiors of homes were very dark and probably much cooler than the outside. Illumination probably came from hearths, with open trapdoors in roofs venting the smoke. Some buildings, such as temples or shrines, had windows. A small window high in a wall would allow sunlight to fall on an altar or on worshippers. In some cases, in large chambers, torches seem to have been used for light.

In ancient Mesopotamia houses were refuges from the sun. Brick houses with walls up to eight feet thick were usually built without windows. The thick walls were intended to keep out the heat. Usually the only opening a house had was a door, but some houses had a window. Windows were fitted with grillwork, probably wooden. Many well-to-do Mesopotamians had homes with courtyards; some such homes were in Babylon. In that city such houses varied in size from

18 feet long and 8 feet wide to 45 feet long and 17 feet wide. Palm-wood planks overlaid by rushes would cover much of the courtyard, providing shade and shielding interior doors from direct sunlight.

Mesopotamians made extensive use of oil lamps to illuminate the interiors of their homes. Torches were used to light fortifications, city streets, and temples at night. Interiors of temples were often kept shadowy, with torches barely illuminating the statues of gods within. This dim lighting added to the mystery of the temples. Interiors of palaces were usually lit by torchlight. Torches were typically made of bound reeds, though wood was used in parts of the Near East where trees were plentiful. One end of the torch would be bound with cloth that had been soaked in animal fat. For night travel torchlight would have been essential for seeing one's way.

Candles were made of wicks of cotton or flax dipped in tallow. Although candles were probably used in religious ceremonies, oil lamps were the preferred form of artificial light for everyday use. The first oil lamps in the Near East were very simple affairs made of fired clay. Finding oil suitable for lamps was difficult in Mesopotamia; sesame oil was usually used. In other parts of the Near East, palm oil or olive oil was used, with olive oil preferred by most people in the western regions of the Near East.

In about 2200 B.C.E. oil lamps were shallow ceramic bowls with four lips impressed on their sides. Onto the lips were laid wicks of cotton or flax. Most of the wick settled in the oil. Some archaeologists suspect that four wicks were used, one for each lip. At most, these lamps would have provided light for about an hour. For many hardworking Mesopotamians, an hour was about all they needed between quitting work for the day and going to bed. Oil lamps became more varied, with round or square shapes and only one lip. The lip began small, but over time it gradually lengthened until it became a spout. By 1200 B.C.E. oil lamps had become larger and were able to hold more fuel than before, and the spout had become pointed. The longer lip moved the flame farther away from the main body of the lamp, making the lamp somewhat easier to handle because the flame made the body of the lamp hot.

The bottoms of lamps were either flat or rounded. The rounded bottoms may have served a couple of purposes. First, rounded bottoms made the ceramic lamps easier to stack, with the rounded bottom fitting into the open bowl of the lamp underneath. Second, rounded bottoms may have fit lamps into holders. Lamps could be set atop platforms with legs, with the rounded bottom cradled in a circular band, perhaps of metal, at the apex of the platform. The lamps could be fitted into frameworks that were hung from ceilings. Lamps with either flat or round bottoms could be set into niches in walls. Lamps made of copper or bronze could be nailed to walls or hung from hooks from walls.

The development of metal lamps in the Near East is harder to trace than that of ceramic lamps because ceramic lamps were always more numerous and were in constant use

A bronze lamp found at the palace of Persepolis, Persia. (Courtesy of the Oriental Institute of the University of Chicago)

from the time of their invention to long after the end of the Roman era. Some molds for metal lamps have been found. The molds were made of stone, plaster, and ceramics. Plaster and ceramic molds were easier to make than stone molds, but plaster molds decay much faster than do ceramic ones; therefore, most of the surviving molds are ceramic. Archaeologists believe that they can tell the difference between lamps made with plaster molds and those made with ceramic molds. On metal lamps, plaster would leave speckles caused by tiny bubbles in the plaster; these bubbles occurred much less often in clay. The molds show that some metal lamps were mass-produced. These lamps would have had handles, and they were made not only of copper and bronze but also of brass, iron, and silver.

There were regional variations in style. For instance, during the Achaemenid Dynasty (ca. 600s–331 B.C.E.) of the Persian Empire, Persian lamps had a long, flat pinch in the side for holding a wick and thin sides, and they were large enough to hold about three hours' worth of oil. The Samaritans of about 100 B.C.E. to about 600 C.E. may have manufactured the lamps most esteemed in the ancient Near East. Their ceramic lamps were decorated with images of plants and religious symbols. Several religions in the Near East of that era used oil lamps in religious rituals, and the Samaritan lamps were well suited to temple use as well as home use. Among their designs were lamps with more than one nozzle. Nozzles were somewhat like spouts on jugs, but wicks were placed in them. Lamps with two nozzles, decorated with images of plants, were especially popular among the Hebrews. Some lamps looked like boxes with nozzles; others looked like horseshoes attached to a bowl.

ASIA AND THE PACIFIC

BY TOM STREISSGUTH

To the ancient Chinese, fire was one of the five elements. Fire corresponded to the summer and to the south. Its color was red; it was generated by wood, another element, and was overcome by a third, water. In ancient China a new light struck during the spring festival represented renewal and purification. The evils and misfortunes of the previous year were forgotten with the extinguishing of the old flame. In addition, the time before the new flame was struck was a time of fasting, as no cooking fire burned, and the family had to eat raw or uncooked food.

According to traditional belief, demons feared the home fires as well as loud and sudden noises. To contend with these bad spirits, the Chinese lit numerous small lanterns or torches in public places and set off fireworks—the noisier and more startling the better. They also protected their homes by painting doors with the color red, symbolic of fire.

The first lamps of Asia may have been stone containers holding dry wood, bark, leaves, or other kindling. Hollow shells could also serve as fuel containers. At some point, animal fat was separated from the carcasses of animals and

used as a source of lamp fuel—although one that burned with considerable smoke and smell. Torches were handheld lamps that burned bark, strands of bound and dried vegetation, or combustible cane or bamboo.

Lighting served military commanders as well as the keepers of religious ceremony. Signal fires were burned from mountaintops and walls to convey orders and messages. Commanders sent out spies to gauge the size of an enemy force by the number of camp fires it burned at night. By the same token, a commander could deceive his opponent by gradually reducing the number of evening fires, giving the false impression that he was retreating from the field.

Flammable oil from rendered animal fat served as the earliest fuel for lamps in China. The demand for lighting fuel supported a whaling industry, in which fleets of ships set out in northern waters in search of whale blubber, one of the most economical lamp fuels. These fat-based fuels were so abundant that the Chinese did not turn to oil pressed from plant sources, such as almond, sesame, and hemp oil, until around the first century B.C.E., making the use of fuel oil one of the few technologies in which imperial China lagged behind classical Greece and ancient Rome.

The Chinese were the first in the world, however, to mine and burn coal and to develop natural gaslights. The gas was collected from underground wells that were known occasionally to burn at the surface. Later the Chinese began sinking wells and building iron drill bits to extract gas as well as petroleum from underground reservoirs. They built pipelines of bamboo to transport underground brine, gas, and petroleum to nearby villages. Gas was first put to use to heat basins containing seawater, which when evaporated left a film of edible sea salt. It was also piped into sealed leather bags, which could be carried to the home and then lit for the purposes of heating, lighting, and cooking.

The basic design of Chinese homes and temples, with large eaves overhanging exterior porches and courtyards, allowed lamps to be hung from roof edges and to burn without the obstruction—and the fire danger—of nearby walls. However, these same overhanging eaves, and a lack of windows, made interior spaces dark. Each household had a few burning tapers, made from rendered animal fat, and terra-cotta lamps, but the expense of fuel and the danger of fire such lights posed made artificial lighting in private homes relatively rare.

In India one of the ancient religious texts known as the Upanishads names fire, or *agni*, as the first of the elements. This element is associated with butter, oil, and fat—three forms of basic fuel that were used in the ancient Indian lamps. Ghee, or clarified butter, was a common fuel for home lamps while torches and exterior lamps used castor or linseed oil. Natural petroleum was rare in India and too costly to use as lamp fuel.

The oldest lamps of India were found by archaeologists in Mohenjo Daro, a city of the Indus Valley that had been abandoned by 1700 B.C.E. These round or oval lamps had a small opening for placing a wick. As in all ancient lamps, the wick—

made of cotton, linen, or other dense woven fabric—absorbs the fuel at a steady rate. The fuel is distilled into carbon at the end of the wick, which burns with enough energy to give off a visible flame. In the making of lamp wicks, the Chinese took an important step forward with the invention of the asbestos wick in about the fourth century B.C.E. These wicks burned without being consumed, providing a steadier and more dependable light. They were more costly to produce, however, making the use of such permanent wicks a mark of wealthy and royal households.

The color and brightness of the lamp flame depended on the type of fuel and wick used; some ancient societies added salt to lamp oil to make it burn a brighter shade of yellow. A single lamp with a small reservoir might have burned for eight to 10 hours before its fuel ran dry. Some oils gave off pungent smells and created soot as they burned, covering the walls, ceiling, and furniture with a thin film of carbonized black dust.

Lamps were designed in various shapes and in terracotta, stone, and metal. The city of Mohenjo Daro also had street lights and lights illuminating gates and doorways. Public lighting was well advanced in China under the Han Dynasty (202 B.C.E.–220 C.E.), which was contemporary to ancient Rome. Such lighting remained a mysterious phenomenon closely associated with the otherworldly and the sacred. It was also a source of entertainment. The shadow play, in which hands or puppets are illuminated by a lantern and silhouetted against a sheet of linen, dates back more than 2,000 years. Shadow plays and “magic lanterns” were popular in ancient China and Japan. In the second century C.E. a Chinese inventor named Ting Huan created a device on which the figures of birds and animals moved, and sounds were created, in a shaft of projected light. The magic lantern, the ancestor of the modern cinema, spread in the following centuries to Southeast Asia, Malaysia, and Indonesia, giving rise to illuminated puppet theaters that remain a vital art form in many parts of Asia.

EUROPE

BY MICHAEL J. O'NEAL

The ancient world was a dark place at night. Throughout the lunar year the moon provided some illumination for a few nights each month, assuming that skies were not cloudy. But in common with modern people, ancient people had to find ways to provide artificial light to illuminate their world. Even during daytime illumination was needed in such places as caves, underground food storage facilities, and homes.

The ancient Europeans illuminated their world with fire. Archaeologists routinely find evidence of fire in the form of charred wood or smoke on the walls and ceilings of caves, such as the famous Lascaux cave in France, known for its ancient wall paintings. In the earliest human communities—in Europe and throughout the inhabited world—humans learned to harness fire to provide light. The earliest such fires were

probably communal bonfires, around which an entire community gathered at night. This communal fire was the source of fires used by individual families in their homes. Fire, then, became not only a practical way to provide light but also a key part of the social life of the community. People had to work together to provide fuel for the fire, tend it throughout the night so that it did not go out, and keep it smoldering during the day so that it could be rejuvenated the next night. Fire formed the center of an early form of social organization and provided a place where people met to discuss the events of the day and to transmit stories and legends about their community.

While many fires were set outdoors, many were built in caves, up against rock formations, and even in individual huts. Many huts in ancient Europe were round, with the fire built on the floor in the center so that smoke could exit through a hole in the center of the roof. The roundness of the hut ensured that the fire's warmth and light were somewhat evenly distributed throughout.

Early on, fire acquired symbolic and religious connotations. Fire was associated with light and warmth, and creation myths inevitably focus on the separation of the light from the darkness. Accordingly, even in ancient societies, light played a major role in religious observances, and fires in some form were kept lit at shrines and places of worship. The ancient Celtic Druids, for example, used fire in religious ceremonies and kept fires lit as a way of paying homage to gods and goddesses.

Bonfires, though, were unwieldy and potentially dangerous, and communal bonfires were less useful in windy, rainy, or cold conditions, so early Europeans learned to control fire for light in other ways. The principal light management tool was the lamp, which had the advantage of portability. Early lamps were made of stone, with a hollowed-out depression into which fuel could be placed. Some of these lamps were fashioned by hand, but sometimes a person was lucky enough to find a suitable rock with a depression. Limestone was a preferred rock for at least two reasons. Because limestone is soft, it was easy to fashion into a lamp by carving out a depression. Furthermore, limestone does not conduct heat well, so the lamp remained relatively cool to the touch and could be carried about. Many ancient European lamps, though, were made of sandstone, which conducts much more heat. Accordingly, sandstone lamps were fashioned with handles.

The most common fuel, other than such materials as bark shavings, was oil. Rendered animal fat (fat that has been melted down) from game animals and livestock was a good fuel, but it had the disadvantage of being smoky. Vegetable oils were efficient and less smoky, but archaeological evidence from ancient Europe shows that vegetable oils were not widely used. A third fuel was beeswax, or the waxy substance from which bees make honeycombs. Wicks were probably made of such materials as cedar bark (cedar contains its own oils that make it useful as kindling for a fire, and the bark tears off the tree in strips) or any other material that would readily absorb

Broken limestone lamp from the cave of Courbet, Penne-Tarn, France, dating to 10,500 years ago; it shows a blackened hollow that suggests it held animal fat to burn like a candle. (© The Trustees of the British Museum)

the oil and conduct it upward so that the fuel burned faster than the wick itself.

Another form of portable lighting was the torch. Any type of hardwood stick, often soaked in pine pitch (the sticky, tarlike sap from pine trees), would have burned to provide light for some hours. Another type of torch consisted of tree bark which comes off in sheets that naturally curl into tubes, such as the bark of birch trees. These tubes were stuffed with tinder and could be carried as torches. Also, ancient Europeans probably used rushlights, a kind of candle that consisted of the pith of plants (the spongy inside of the stalk) soaked in fat. Many marsh plants worked well for this purpose. The outer part of the stalk was peeled away, leaving the soft, fragile interior. This pith was then dried and soaked in fat. A one-foot length of rush candle would probably burn for about 20 minutes. Ancient Europeans used other plants in a similar fashion, sometimes by rolling their leaves, drying them, and soaking them in oil.

The question remains as to how the ancient Europeans started a fire in the first place. The technologies for starting fire are nearly as old as humankind. One way to start a fire was with friction. Hardwoods were the most useful materials

for this purpose. A pointed stick was inserted into a small hole in a block of wood and then rapidly twisted back and forth until the friction produced enough heat to ignite a small amount of tinder, such as dried grass. Later Europeans, who were especially knowledgeable about metals, learned that a piece of flint struck with steel produced sparks. Flint is a crystalline quartz often found primarily in the form of nodules of rock in limestone formations. Flint is found, for example, in the chalky White Cliffs of Dover, England, and all over the nearby beaches.

GREECE

BY LISA R. BRODY

Interior spaces in the ancient Greek world were often illuminated with natural light through windows and skylights, but various types of oil-burning lamps were also commonly used whenever artificial light was required, as for nocturnal activities. These lamps evolved from their first appearance in the Bronze Age (ca. 3000 B.C.E.) until the Roman conquest (31 B.C.E.) and beyond, into the Roman period. They could be made of terra-cotta, stone, or metal—usually bronze but in some instances also lead, silver, or gold. The simplest lamps were plain and purely functional, while more elaborate examples contained ornamental or figural relief scenes that often came from mythological or religious contexts. Even these decorated lamps were relatively inexpensive (with the exceptions of those made with precious metals) and soon were reproduced on a widespread scale by using molds.

A typical ancient Greek lamp was approximately 3–4 inches in length and 1 inch high. One of these lamps would have burned for two to three hours before running out of oil, though Greek legend spoke of a wondrous golden lamp on the Acropolis in Athens that burned for a full year. Linen was probably the most common wick material, but wicks could be also made of various plant fibers, such as flax, papyrus, and hemp. The twisted strand would be inserted into an oil-filled reservoir, with the end of the wick protruding from the nozzle so that it could be lit. The fuel of choice was generally olive oil, though animal fat or fish oil also were used.

The earliest oil lamps found in the Greek world date from the Bronze Age (ca. 3200–1200 B.C.E.); many examples of these lamps have been found at sites from Minoan Crete as well as from the Mycenaean Greek mainland. In this era and continuing through the ninth century B.C.E., common terra-cotta lamps were generally bowl shaped or saucer shaped, with the thickened rim pinched to form the nozzle spout for the wick. The earliest of these open lamps were made by hand and usually had four distinct spouts. In the Middle and Late Bronze Ages they were thrown on a potter's wheel, and their shape began to develop toward a single spout; these are sometimes known as “cocked hat lamps.” Such lamps were usually unglazed and undecorated.

By the onset of the Classical Period in the fifth century B.C.E., the Greeks began to make lamps with a more rounded,

closed form. This development was practical, in that it reduced the likelihood that the oil might spill. By the third century B.C.E. the lamp body was even more closed, with a small fill hole usually less than an inch in diameter. The typical classical and Hellenistic oil lamp had a globular body with a flattened base and a flat top. Centered in the top of the lamp was a pour hole or fill hole, through which oil was poured into the reservoir. The upper surface, surrounding the fill hole, is called the “discus” and was sometimes decorated with a geometric, floral, or figurative design. In some instances this design dictated an off-center placement of the fill hole.

Ancient terra-cotta oil lamps were decorated in a variety of ways. The surface could be burnished or covered with a slip or glaze. Stamped or raised patterns are often found on the shoulder of the lamp, around the fill hole. The fabric, manufacture, and decoration of these lamps reflect contemporary ceramics, and it is very possible that some potters produced lamps in their workshops along with other types of vessels. In Athens of the Classical Period, for example, lamps were made with the same reddish-orange fabric and glossy black slip seen in ancient Greek pottery. Once molds began to be used, even more elaborate lamps could be created. Often the lamp’s discus would be decorated with a relief design that could be floral, geometric, or figural. One of the simplest, most common motifs is a repetitive pattern of ridges and grooves radiating from the fill hole. Greek lamps with figural scenes could draw their inspiration from a wide variety of sources, including daily life, cult, literature, and myth. The images on such lamps resemble in many ways the compositions on contemporary coins. Mold-made lamps could also be created in the form of any other object or figure, such as an animal, a human or satyr head, or a sandaled foot; such lamps are called “plastic.”

Ancient lamps often had one or more elongated nozzles, through which the end of the wick could protrude for lighting. If there were many nozzles and many wicks, more fuel was consumed and more illumination provided. A lamp might or might not have had a handle; if there was one, it was generally modeled and attached to the lamp body opposite the nozzle. Some lamps had small pierced or unpierced projections, called lugs, in lieu of a handle. The pierced lug could be used to hang the lamp by a string when not in use, while the unpierced versions seem to have had no practical function. Classical Greek terra-cotta lamps were made on the same wheels that were used to make pottery, but artisans in the Hellenistic era developed the ability to fashion them by using plaster or clay molds; this became the preferred method of manufacture from the third century B.C.E. through the Roman period and allowed lamps to be even more easily mass-produced. Lamp molds are often found on archaeological sites along with lamps themselves, allowing for the identification of lamp workshops.

Another important source of information about lamp manufacture and trade in antiquity is the maker’s marks and owner’s signatures that were sometimes stamped on the un-

derside of the lamp. These signs, representing the potter or the workshop where the object was made, could range from a single letter or pictograph (a symbolic drawing) to a full word or name. Votive inscriptions also sometimes appear on examples that were dedicated to a member of the Greek pantheon of gods.

Lamps were used in a variety of contexts in ancient Greece, including private homes, public buildings, and religious sanctuaries. They were sometimes suspended from a wall or ceiling and sometimes placed on specially made lamp stands. Niches could also be constructed in a wall to hold a lamp and illuminate the room or hallway. Lamps, used or unused, were also typical offerings in temples and in tombs. Like pottery, lamps not only were essential objects in the daily lives of ancient Greeks but also provide invaluable archaeological artifacts for scholars. The ubiquity and relative indestructibility of both types of artifact (though easily broken, small pieces of vases and lamps survive well on archaeological sites) help us to “illuminate” various aspects of the ancient Greek world.

ROME

BY LUCAS G. RUBIN

The Romans employed a range of methods for generating artificial light, the most basic of which was the open fire. Torches were also used, fabricated in a variety of means from the simple to the elaborate. Some were simple wooden stakes while others were fastened bundles with a crown composed of a flammable material and soaked with a chemical accelerant, a substance that speeds the development of fire.

Candles were also used, probably inherited from the Etruscans. Because of their biodegradable and fragile nature, they have not survived well in the archaeological record, but there is sufficient evidence of their use in the form of extant candlesticks and candleholders. Candle shafts were made of tallow or beeswax as well as the reed of vegetable fiber. Beeswax was readily obtainable through apiculture, or beekeeping, an agricultural enterprise in which the Romans excelled. Because the manufacturing process was rather involved, widespread use of candles was restricted primarily to the wealthy.

By far the most common device for generating artificial light was the oil lamp, which was ubiquitous throughout the Roman world. The basic oil lamp consisted of a body (*infundibulum*) with a flat top (*discus*) bordered by an ornamental rim (*margo*), an opening for a wick near the front (*ellychnium*), and a handle at the back (*ansa* or *manubrium*). In the middle of the *discus* there was usually a hole for replenishing the fuel. Lamps were most commonly fueled with olive oil, though less expensive castor oil—which was particularly smoky—may have been more common among the poor. Many different types of wicks were used, including castor, mullein, asbestos, linen, and papyrus.

Lamps were typically made of clay, metal (gold, silver, iron, lead, and especially bronze), and stone. The most com-

mon material was fired clay, and large factories that manufactured mass-produced terra-cotta lamps were prevalent throughout the empire. Clay lamps were usually made with molds, the top and bottom halves pressed into hollow forms and joined together. Once assembled, they were often glazed. With this simple fabrication technique, elaborate decorative elements could easily be impressed into the surface of the clay. Decoration included patterns as well as images of a religious, mythological, or quotidian nature. In addition, manufacturers often stamped their names into the bottom of the lamp, a feature that permits archaeologists to look in some detail at patterns of production and distribution.

Analysis of these distribution patterns suggests that Italian lamps dominated the provincial markets in the first century of the empire but were later superseded across the empire by locally made products. Manufactured lamps could be shipped in bulk or perhaps used as filler with (or packed within) other commodities and sometimes transported over great distances. A wooden shipping box found at Pompeii in 1881 contained 37 lamps from southern Gaul, with a range of manufacturers' stamps that suggest that they may have been shipped as a consignment.

Lamp showing a chariot race, Roman, about 175–225 C.E. (© The Trustees of the British Museum)

There were numerous and frequent variations on the basic lamp design. Lamps with multiple wicks were manufactured, and models with as many as a dozen wicks arranged in a circle around the *discus* were not unusual. Portable lamps (lanterns), with bodies made of bronze, iron, clay, or wood, were also common. These had high, protected sides and windows covered with a translucent material, such as thinly shaved animal skin, horn, or parchment. Stationary lamps were frequently placed upon purpose-built stands or suspended from chains in order best to radiate their light.

The Romans utilized artificial illumination for a range of functions. Private residences and businesses (both commercial and industrial) required some degree of lighting in the evening, though the Romans chose as much as possible to organize their activities around the daylight hours. At night public spaces were often lit by torchlight, and the city of Antioch was reported to have had an organized street lighting system by 350 C.E. For certain industrial operations, such as mining and tunneling activities, extensive artificial lighting was required. Open-flamed torches would have presented problems, so portable lanterns and lamps placed within wall niches could have been used. The author Diodorus Siculus (ca. 90–ca. 30 B.C.E.), in his *Bibliotheca historica*, mentions that lamps were also mounted on miners' heads, but there is no other evidence of this practice.

Artificial illumination also played an important role in transmitting information. The Romans built many lighthouses along the coasts, both to mark harbors and to warn against shoreline hazards. During the day large mirrors were used to alert ships while fires were ignited at night. A number of these lighthouses survive, including well-preserved structures in La Coruña, Spain, and Dover, England. Additional information is provided about other major lighthouses—such as the one at Ostia—by surviving depictions on coins and in mosaics. The most famous lighthouse of antiquity, the Pharos of Alexandria in Egypt, was actually built by the Hellenistic rulers Ptolemy I Soter and his son and successor, Ptolemy II Philadelphus, but may not have been transformed into a lighthouse until the first century C.E. by the Romans. Although it was destroyed by earthquakes in 1303 C.E. and 1323 C.E., we are well informed about its size and appearance by later Arab chroniclers.

One especially sophisticated use of artificial illumination was its application to military signaling. Signaling was important in ancient warfare, and various communication systems permitted complex messages to be relayed by torches over great distances. The Romans adapted and modified systems from the Greeks and the Carthaginians, among others, and employed them both tactically (on the battlefield) and strategically (along the frontier). These systems were akin to an early form of Morse code, in which a patterned display of torches could relay letters, phrases, or codes.

Illumination also played an important role in several aspects of religious practice. Lamps were an important feature of the household altar (*lararium*) and were used in various

religious functions, including funerals. Among Jews in the Roman Empire, lamps were used in observance of the Sabbath, some even equipped with an additional oil reservoir to keep the light burning for the time required. A large candelabrum from the Great Temple in Jerusalem appears in relief on the Arch of Titus in Rome, a monument that celebrates the Roman victory over the Jewish revolt in 70 C.E. Similarly, the early Christians decorated their lamps with early symbols of their faith, such as the Chi-Rho.

Paradoxically, the widespread use of artificial lighting presented some considerable problems. The materials used as fuel (fats and oils) were also sources of food, and individuals—especially the poor—would have had to weigh the need for calories against the need for light. Further, open flames dramatically increased the risk of fire, and large, often rambling and jerry-built neighborhoods in cities like Rome would have been particularly vulnerable to accidents or negligence.

Although artificial illumination was used in a variety of contexts in the Roman world, the technologies for generating light remained fairly static. It was the Roman genius for production, distribution, and adaptation, however, that permitted the widespread and effective use of artificial illumination in various capacities among the populace.

THE AMERICAS

BY MICHAEL ALLEN HOLMES

Illumination was obtained in the ancient Americas as among the most ancient of all civilizations: with fire. With wood gathered from forests, which were especially ubiquitous in Mesoamerica, small fires could be made both for cooking purposes and for light by which to see at night. The more elaborate houses of the elite often included fireplaces. Especially at ceremonial sites, torches would be used. While incense made from copal, a tropical tree resin, was often burned at these ceremonial sites, its function was more aromatic than visual.

► inventions

INTRODUCTION

The topic of inventions among ancient peoples is a difficult one to compass, for the modern understanding of *invention* might not always be applicable to the ancient world. Throughout the Industrial Revolution in the West and the technological revolutions of the 20th and 21st centuries, inventions took the form of objects that were fundamentally new and that changed the way people thought about their world. While many of these inventions built on the scientific and technological discoveries of others, they themselves were a major leap forward as people learned to harness what they knew about the natural world.

In studying the ancient world it would be almost impossible to date the invention of a tool, process, or technique to a certain time and place. Rather, the world's ancient peoples took part in a process of discovering the principles of their world over a period of millennia, each new generation making tiny advances on the discoveries of the previous generation. Invention, then, was more of a process of uncovering the secrets of the physical world, finding ways to adapt human activities to the demands of the nature world, and discovering ways to modify that natural world to promote the comfort and security of people. Another complication in tracing ancient inventions is that the peoples of the world were exploring and innovating in isolation from one another. Thus, while the ancient Egyptians were discovering the uses of papyrus, particularly as paper, so the ancient Americans were also discovering an early form of paper. Who "invented" paper? No one can really know, especially since paper has so little durability over many centuries.

The world's earliest inventors were no doubt those anonymous hunter-gatherers who devised tools to make their hunts more successful: a type of stone that worked better as a spear point, then a way to slice or pound the stone to make it sharper, then a better way of affixing the point to the shaft of a spear, and finally a way to give the spear better balance and

heft. One can imagine a group of hunters who had to encircle their quarry until someone had the idea of using cord made from tree bark to make a kind of fence around the quarry; his descendants generations later would then have learned to weave cord into nets to make the process more effective. Perhaps that weaving of nets gave someone the idea of a way to make clothing out of fibers or some other innovation that can only be imagined.

Inventiveness was fostered as people began to settle into permanent, fixed communities with the advent of agriculture. Now they were in more direct communication with one another, observing others' techniques and tools, sharing them, and adapting them. Moreover, a critical mass of people could pool their efforts to come up with an innovative solution to a problem. Throughout ancient Mesopotamia, Egypt, and Mesoamerica, for example, people carried out massive public works projects that led to innovations in architecture (columns and arches), agriculture (plant breeding), irrigation (the water wheel), road building (the crowned road), sewage and drainage systems (the lead plumbing of the Romans), and the like. People interested in medicine could observe the successes and failures of others, over time developing know-how in the use of medicinal plants and even surgical techniques. Farmers could learn new ways of harvesting, threshing, and storing grain. Others who were more interested in crafts work could learn to make use of new tools, techniques, and materials as they collaborated with others. Miners could become skilled at new ways to find ores, mine them, process them, and forge metals.

This process continued as trade and commerce developed, bringing novel tools and materials to new regions of the world, leading to further innovation. One can only imagine the excitement of a European wood carver the first time he or she acquired a piece of ivory from an African elephant tusk or a jewelry maker encountering imported glass for the first time.

AFRICA

BY MICHAEL J. O'NEAL

Ancient Africa was the cradle of human civilization, the home of the world's first people, so it is no surprise that Africans were among the world's first inventors. As the earliest Africans struggled to adapt to and control their environment, they naturally learned how to modify that environment and use the resources that surrounded them to help ensure their survival and to make their lives more comfortable.

The word *invention* suggests thinking of something entirely new, the development of a tool or process that had not existed in the past and that fundamentally changes the relationship between people and their environment. Among the ancient Africans, and probably ancient peoples generally, invention was probably more of a process of discovery and adaptation. Over millennia people inherited the knowledge of their ancestors, but whether from necessity or from simple

Stone hand ax (Lower Palaeolithic, about 1.2 million years ago) from Olduvai Gorge, Tanzania, representing one of the earliest technological inventions. (© The Trustees of the British Museum)

curiosity they introduced innovations, refinements, and improvements to existing technology to make it work better.

The ancient Africans did not invent fire, for example. Fire is a process of combustion that already exists in nature. Rather, they discovered that fire could be put to human uses and learned to control it to keep themselves warm, cook food, weaken rock so that it could be split into pieces for use as tools, clear fields of stubble to encourage the growth of the next season's crop, and so on. Historians and archaeologists believe that the first human use of fire occurred some 1.4 million years ago in Chesowanja, near Kenya's Lake Baringo.

Many African developments had to do with the most basic necessities: food, shelter, and clothing. Africans were the first to develop Stone Age cutting tools, and in time they learned to produce handles for those and other tools. Later they developed a great variety of tools, including fishhooks, grindstones, awls, spears, and bows and arrows. They were the first to domesticate crops, some 15,000 years ago, and to domesticate and graze cattle. This took place in what is now the Sahara Desert but at the time—around 6000–3000 B.C.E.—was covered with grasses.

Ancient African inventors, many of them women, devised methods and devices for gathering, preserving, and preparing food (including the mortar and pestle for grinding and pulverizing foods), herbs, and medicines. They created devices for carrying both food and infants (often at the same time), including slings for infants. They learned to use sticks as levers for moving rocks, tree stumps, logs, and other objects. They created hoes and similar tools for digging plants and, later, for cultivating the earth for planting, and they invented one of the world's first plowshares (the metal blade of a plow). They learned how to tan and preserve animal hides for use as clothing and blankets, which they sewed with needles made of bone and dyed with natural substances such as henna. Later they learned how to weave and spin fabrics. They created the first pottery and learned to use kilns to fire the pots, which were then used for food storage or carrying water.

One important adaptation of fire in ancient Africa took place some 2,000 years ago in the region around Lake Victoria. There archaeologists have discovered ancient blast furnaces used in the production of carbon steel. (Carbon steel is an alloy of iron and carbon. Iron not alloyed with carbon remains relatively soft, but the introduction of carbon hardens the metal.) Carbon was introduced into the iron ore by an ingenious process. First a bowl-shaped hole was dug in the ground. The hole was then lined with soil taken from a termite mound, and a handle that rose above ground level was inserted so the steel could be removed. The chief innovation the Africans introduced to existing furnaces was to insert tubes or blowpipes through the walls of the mound into the pit. These tubes channeled air into the fire, creating a blast-furnace effect as the hot air from the fire rose, sucking air through the pipes into the fire. Grasses and reeds were then burned in the pit, and when the temperature reached a high enough level, charcoal and iron ore was added. The carbon from the burned grasses and charcoal added carbon to the iron, resulting in carbon steel. It is estimated that these furnaces could achieve a temperature of nearly 3,300 degrees Fahrenheit. Of course, the ability to produce carbon steel presupposes the existence of mining technologies, and the oldest-known iron mine in the world, dating back some 43,000 years, has been found in Swaziland.

Ancient Africans invented several systems related to calculation. The Yoruba tribe had a number system based on 20, and the so-called Ishango bone, dating to 8,000 years ago, has a system of notches that indicates a number system. In East Africa accurate calendars were developed in the first millennium B.C.E., and megaliths (vertical stone slabs) enabled ancient Africans to make accurate observations of star constellations. Ancient Africans also developed water clocks, an aerodynamic glider, and the game of chess.

In the area of health care, ancient Africans developed various medicines, including aspirin, a treatment for diarrhea, and a smallpox vaccination remarkably similar to the smallpox vaccine developed by Robert Jenner in the late 18th

century. Cosmetics invented in ancient Africa included eye shadow to reduce the glare from rivers, similar to the black patches modern-day football player use to reduce glare. Other cosmetics were fingernail polish, breath fresheners, wigs, pomades, perfumes, and various dyes to enhance skin color. To apply these cosmetics, African women invented the first mirrors, made of polished copper.

The drum, probably the world's first musical instrument, was invented in Africa and used on ceremonial occasions and for communication. Africans also crafted seaworthy boats, and some archaeological evidence suggests that ancient Africans were able to reach the coasts of the Americas. Petroleum, too, was produced around 4000 to 3000 B.C.E. To this list must be added the invention of civilization itself, for the Africans were the first to live in human communities that survived, grew, and spread in large part by passing their inventions down to future generations.

EGYPT

BY WILLIAM H. PECK

The inventions of the ancient Egyptians include ideas and innovations both great and small. One important innovation that still affects us today is the observation of the 365-day solar year. The Egyptians divided the year into 360 days—three seasons of 120 days, 12 months of 30 days—and added five days dedicated to the gods to complete the cycle. They also added the rough equivalent of a leap year to make the calendar correspond more closely with their observations of the sun. They divided the day into 12 hours of daylight and 12 of darkness, giving us the 24-hour division we also still use.

The Egyptians produced the first paper, which they manufactured from the papyrus plant, in contrast to the clay tablets used by the ancient Mesopotamians. With the introduction of papyrus as a convenient writing surface that was flexible and portable, they also developed the inks necessary for writing. Papyrus made possible a giant step forward in the creation and preservation of documents of all kinds.

With the use of papyrus, one of the most important inventions sometimes credited to the ancient Egyptians was the ability to make meaningful signs that could be understood to record sounds and ideas—a written form of language. Historians debate whether the Egyptians or the Sumerians in Mesopotamia came up with the idea first. Recent discoveries at Aswan in the south have led some scholars to reassert the idea that writing was first invented in Egypt. Not everyone agrees with this. In any case, before 3000 B.C.E. a method of recording lists of foodstuffs or other objects began to be developed in Egypt.

As with many other early written languages (such as Sumerian, Chinese, and Mayan), the first stages were essentially pictographs, pictures that stood for things. When this method was extended to convey ideas as well as objects, it was necessary to use pictures as phonograms, signs that conveyed

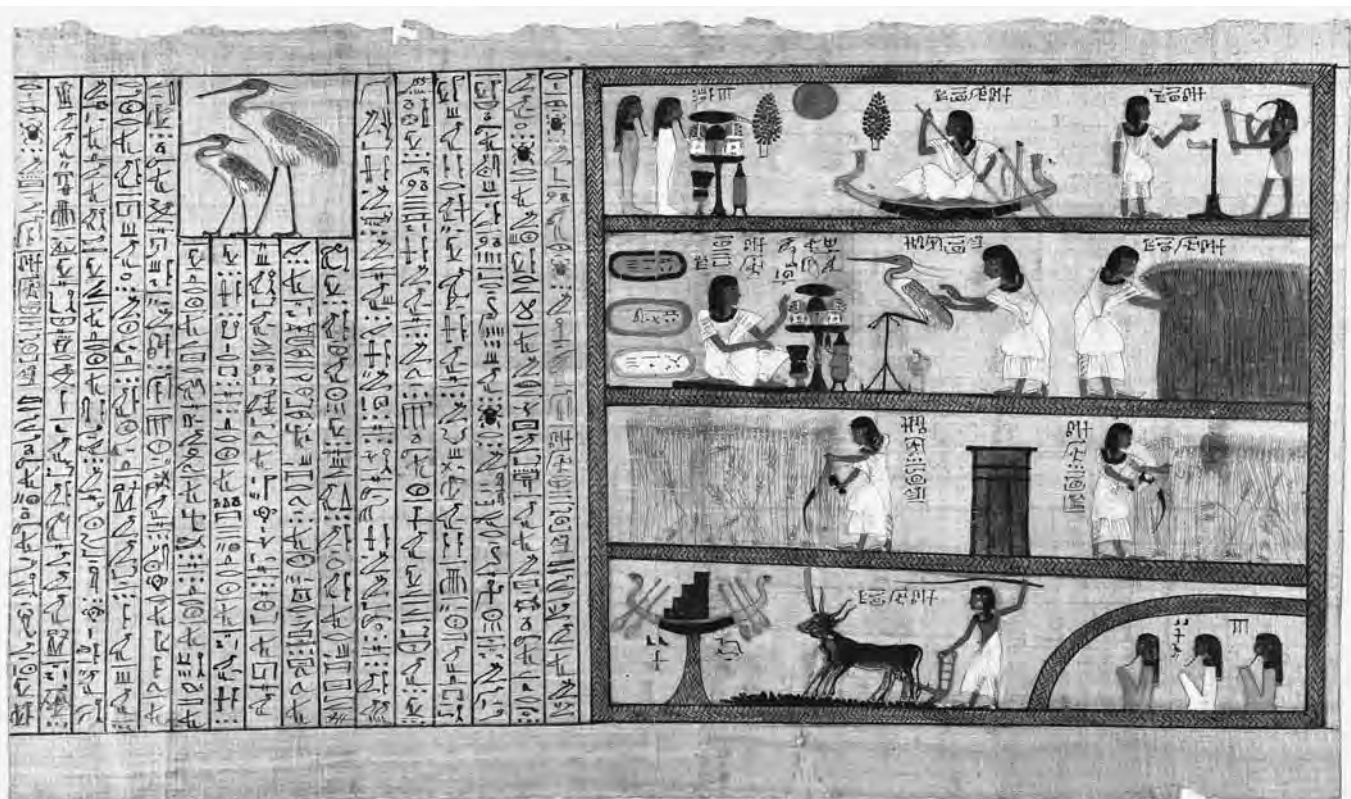

sounds. What is almost unique about Egyptian writing is that the pictures were never completely replaced by abstract signs. Throughout Egyptian history hieroglyphic writing was a combination of signs that expressed sounds with those that expressed ideas. Along with these two types of signs was a third that could be added to designate classes of related words. The ancient written language was complex and became highly developed to a level where it could be used to convey any kind of information, including poetry, prose, religious texts, and scientific, mathematical, and medical treatises. If written language was not an independent invention in Egypt, credit is due for a complex and comprehensive method of recording information.

Egypt was an agricultural country throughout its ancient history. The people were completely dependent on the annual flooding of the Nile for successful food crops. The yearly flood, or inundation, was the result of the winter rains in central Africa. When the flood waters reached Egypt, a new layer of silt was deposited, the land was thoroughly watered, and the natural buildup of salts in the earth was leached out. The Egyptians developed a system of basin irrigation that enabled them to retain the floodwater for a time and then release it into the fields. Because of the annual flooding, the river valley had gradually built up a system of natural dikes or levees made up of the fresh silt deposited by the waters each year.

These were pierced to help draw water through canals to the fields and then closed, creating temporary reservoirs. When it was time to begin planting, the dikes were pierced again to allow excess water to escape.

To move water from the level of the river to higher fields, the Egyptians invented a device called a *shaduf*. This was a simple lever pole with a bucket on one end, counterbalanced with stone or mud, which made it possible to lift water 5–6 feet. This was a highly labor-intensive method, but it was the only mechanical solution to raising water known to the Egyptians until late in their history. In the Ptolemaic Period (304–30 B.C.E.) a second method was introduced. The *sakkia* was an animal-driven waterwheel that increased volume and reduced human labor. Both the *shaduf* and the *sakkia* were still being used well into the 20th century.

Although glass was not widely manufactured in ancient Egypt, the basis for its production was known. Rare examples of glass objects have been found, but the principles used in glassmaking were also those used to make Egyptian faience. Blue or green glazed objects of all kinds were produced using this technique. Egyptian faience is a ceramic-like material composed of powdered quartz and a small amount of lime, usually with a copper compound to give it color. The powdered quartz—essentially crushed sand—was made into a paste that could be modeled by hand or pressed into a mold.

Papyrus from the Book of the Dead of Nakht with agricultural scenes, from Thebes, Egypt (1350–1300 B.C.E.); the introduction of papyrus as a convenient, flexible, and portable writing system made possible the preservation of many documents. (© The Trustees of the British Museum)

PYRAMID AND TEMPLE CONSTRUCTION

It is almost impossible to see an Egyptian pyramid or temple without wondering about the methods used in their founding and construction. Of all of the inventions ascribed to the Egyptians, some techniques have hardly been surpassed. The massive amounts of stone needed for such projects was cut from quarries, moved to the construction site, and placed with great precision. There has been a great deal of discussion and speculation about how the blocks of stone, often weighing many tons, were handled. Some of the theories have been very imaginative, but the simple answers seem to be the best. Egyptologists have used the scant information available to deduce the ancient methods. These clues consist of paintings in tombs and the remains of temporary ramps.

In a tomb in Middle Egypt there is a painting of a gigantic statue being moved. It rests on a sled being pulled with ropes by hundreds of men. Standing on the front of the sled is a workman pouring a liquid on the ground to lubricate the way. The liquid may be milk, oil, beer, or simply water. There is no written evidence to tell us, but there are also no rollers or wheels beneath the sled. In another tomb on the west bank at Luxor (ancient Thebes) is a representation of pieces of stone being moved up an inclined ramp. In the first court of the great temple of the god Amun at Karnak part of the mud-brick and rubble ramp used to construct the pylon gateway is still preserved. Taking the tomb paintings with the remains of actual ramps, it has generally been concluded that there was nothing particularly mysterious about construction techniques. It simply required careful planning, ramps that would later be dismantled, and the use of massive manpower.

The construction of a pyramid might have required long ramps that extended far into the desert or a series of shorter ramps that were placed against the four sides. This method is still debated by historians. However, scholars generally agree on the method of constructing a temple, with its gigantic walls and columns. The first course of stone for walls and columns was put into place, looking like a three-dimensional plan of the finished structure. Then the enclosed space was filled with earth and debris to the level of the tops of the stone. This made a flat platform on which the next layer of stone could be moved and placed. When that layer was finished, the filling was repeated, and this continued until the roofing blocks were in place. Then the process was reversed. The fill inside the top of the building was removed, and the decoration of carving and painting was begun. This continued downward until the building was completed, level by level. This technique was simple and slow, but it also made it unnecessary to use scarce wood for scaffolding during construction and decoration.

When heated, the material hardened, and the surface developed a colored glaze. The material is known from many examples of amulets (charms), scarabs (the figure of a beetle used as a charm), and small sculpture, as well as containers such as cups and bowls.

Probably the best-known and most characteristic invention of the ancient Egyptians was the process of mummification. The Egyptian belief in life after death required that the body of the deceased be preserved as a resting place for the spirit. Early in Egyptian history it was determined that the body had to be treated to prevent decay. This process, as it evolved, was essentially one of desiccation, or drying out. Since the internal organs were apt to decay rapidly, they had to be removed and treated separately. An incision was made in the side so the lungs, liver, intestines, and stomach could be taken out. The body was cleaned and packed in a material that would draw out any remaining fluids. When this was accomplished, it was wrapped in many layers of linen cloth and put into one or more coffins, usually with the face of the deceased on the lid. The organs were placed in a set of four containers and buried with the coffin. The process developed over the centuries of Egyptian history, generally becoming more elaborate.

THE MIDDLE EAST

BY MARK ANTHONY PHELPS

Inventions made in the ancient Near East encompassed agricultural processes, technology, and intellectual life. The Neolithic (or agricultural) Revolution occurred first in this region. The hallmarks of the Neolithic Revolution were the cultivation of plants and selective breeding of animals, which gave humans more control over the production of food.

Einkorn and emmer wheat were the first plants to be domesticated, the former by the Natufian culture of Israel and the latter at Umm Dabaghiyah in Syria, both around 9000 B.C.E. Wine appeared by 6000 B.C.E. in Iran and Mesopotamia, and by the same date lentils were prevalent throughout Southwest Asia. Goats and sheep were domesticated in Iran and Afghanistan by 9000 B.C.E., and pigs and cattle in Anatolia by 7000 B.C.E. Dogs had been domesticated in Israel and Kurdistan since around 12,000 B.C.E. The wheat domesticated by the early farmers may have included forms of the grain that were not intended as food, as one ancient source states that 40 percent of the harvest went for the production of beer, which had made its appearance by 8000 B.C.E.

The production of food begat a societal revolution, as humans would never live the same lifestyles as their foraging ancestors. Food production demanded that people stay in one place to care for fields. These fields were not interchangeable, as some plots were more productive than others. With the desire to control the more productive fields came the concept of property ownership. As the concept of private property evolved, society changed at its core. A prime example was that of the role of marriage. Concerns about the devolution of property from generation to generation spurred most agricultural societies to begin to monopolize access to women to ensure paternity. Many anthropologists believe the subjugation of women arose from this agricultural revolution.

Moreover, the ability to create surpluses meant that wealth, or surplus products, became common for certain members of society while remaining out of reach for others. Economic classes emerged that were mirrored in political structures as the economic elite created societal laws to protect their position. Another change was found in the collection, storage, and distribution of agricultural surpluses. Protecting these surpluses required city walls, which were first built in Jericho in Israel about 8000 B.C.E. Silos with lime plaster also appeared there for the first time.

It is assumed that public works demanded a centralized political system with enough power to coerce citizens into building and maintaining such works. Complex political systems tend to arise in such circumstances, and the first empire to encompass a number of ethnic groups was founded at the Mesopotamian city of Akkad by Sargon (r. 2334–2279 B.C.E.) in the 24th century B.C.E.

The need to keep track of property was clearly the motive in the development of cuneiform, the world's earliest form of writing. Fired clay tokens, as means of legal proof of ownership, first appeared in Syria in 8000 B.C.E. Seals, which by imprinting established ownership, appeared by 4000 B.C.E. The earliest clay envelopes came from Syria about 3500 B.C.E.,

An administrative text in cuneiform (the world's earliest form of writing) recording food supplies, probably from southern Iraq (about 3000 B.C.E.). (© The Trustees of the British Museum)

followed by the earliest cuneiform writing, Sumerian, around 3300 B.C.E. The oldest datable preserved contract is from 2700 B.C.E. The first decipherable alphabet appeared at Ugarit in Syria approximately 1500 B.C.E. The Phoenician alphabet, the precursor to European alphabets, was developed around 1100 B.C.E. Mathematical innovations, too, were tied to the need to keep track of economic actions. Geometry, for example, was developed for the figuring of taxes. The concept of positional values for numerical expressions emerged in the Near East about 2000 B.C.E.

The wheel made its first appearance at Ur in Iraq about 3500 B.C.E., at the same time that the pottery wheel was known to exist in Mesopotamia. The wheel is the prerequisite for most machines. One use of the wheel was in the creation of an astrolabe-like device, around 1250 B.C.E., for plotting items due south of the viewer from Babylon.

The Near East was the innovation center for early metalwork and glasswork. Copper was being cast by at least 6400 B.C.E. in Anatolia. Silver and gold were smelted in Sumer by 4000 B.C.E. By 3000 B.C.E. tin had appeared in Iran, and gold was being soldered at Ur. An iron dagger from Anatolia is dated to 2200 B.C.E., and large-scale iron smelting was undertaken by 1500 B.C.E. in Mitanni. The Assyrian army of the 10th century B.C.E. is the first army known to have used iron weapons. Lead glazing was being applied to bricks by 1000 B.C.E. Glass was manufactured by at least 2000 B.C.E. (though later Akkadian texts claim it was a Sumerian invention) and was manipulated while hot by 1500 B.C.E. Glassblowing was developed in Syria by 100 B.C.E. Coinage, which revolutionized economic systems, appeared first at Lydia in Anatolia around 700 B.C.E.

The need to corral the floodwaters of the Tigris, which came at harvest time, and to dissipate and store the waters of the Euphrates led to the development of irrigation by 6000 B.C.E. The Sumerians did large-scale work, with massive public works projects, including one preserved canal regulator at Girsu that required 750,000 bricks. The *shaduf*, a rotating lever for moving water from one canal to another, was developed in Mesopotamia by 2000 B.C.E.

One can make a case for Mesopotamia being the birthplace of modern science. The cosmos, according to local thought, was ordered by the gods. When an oddity occurred in nature, it implied to these cultures an indirect message that the gods could not reveal directly to humans. Thus, the practice of recording odd natural events (such as a malformed sheep liver) and associating the oddity in nature with an event in the human realm (such as the birth of a king) became a means of predicting the future by unraveling the clandestine communication of the gods. Searching for cause and effect by recording empirical observations in a universe that is understood to function regularly is the basis for Western science. All of these firsts were diffused to the rest of the world within centuries of their innovation in this region. Virtually every society can be considered the offspring of the ancient Near East on some level.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Tracing inventions, especially when they are from illiterate cultures, can be difficult. For example, ancient Australians, Indians, and Europeans all used the boomerang to hunt small game. Who invented it? The answer is that they each did, separately from the others. How they invented the boomerang is a mystery that puzzles engineers to this day because of its complex aerodynamics. Another example is the bronze making of the Shang Dynasty of China (ca. 1500–ca. 1045 B.C.E.): Did the Shang invent bronze making independently? The answer is that they probably did not. The techniques for making bronze probably were imported from the Near East. Ancient cultures were far more connected than modern people may realize, with inventions that were useful moving across great distances over hundreds of years.

The inventions of ancient China are far better known than for the rest of ancient Asia and the Pacific because the Chinese wrote about their inventions, and archaeologists have been able to trace when certain inventions arose. For Oceania archaeologists are fairly sure that the ancients invented harpoons with teeth pointing backward so that the harpoon would stick and not be shaken loose, but when or exactly where they arose is not known. People of the Philippines probably invented the yo-yo as a device for hunting game; a hunter could hide up a tree and send a heavy yo-yo spinning down onto his prey. Still, the details for when the yo-yo was invented are so vague that it could have been invented elsewhere and been taken to the Philippines, where it survived because it remained useful.

For Korea and Japan the rarity of written records hampers historians' efforts to identify their inventions. Both were notably creative in the manufacture of ceramics, but Korea's great era of invention in ceramics came in the 1100s C.E., long after the ancient era. Japan's ceramics were among the best of the ancient world, but what archaeologists have so far found of advances in ancient Japanese technology consist of innovations developed first in China and then transferred to Japan through Korea. On the other hand, there is one well-known Japanese invention that predates 200 C.E.: the *zori*, sandals with a strap next to the big toe that attaches to the sole and a strap that arcs over the top of the foot. This invention is worn throughout the world and is often called "flip-flops."

In most of the ancient world, technology was learned by being passed down from master to student. Over several generations the knowledge would become tradition that each new student was expected to learn. This tended to discourage inventions, because innovation would seem like tampering with unwritten laws for the manufacturing of goods. This meant that changes in technology were usually minor adjustments in technique, as when Indian metalworkers of the Maurya Dynasty (321–185 B.C.E.) of India figured out how to make iron that resisted rust. Moreover, passing on knowledge by word of mouth meant that innovations could be lost, as

was the case for making white ceramics during the Warring States Period (453–221 B.C.E.) of China, which was not reinvented until the 700s C.E.

The Chinese developed an appreciation of scientific research for its own sake, and inventors were often celebrated figures. In fact, the Chinese developed the practice of pure research, meaning learning about the natural world simply for the sake of acquiring knowledge. They believed that learning about the natural world contributed to a person's moral development. The impetus for research resulted in significant inventions before they even became notably useful. For instance, the Chinese knew that lodestone was magnetic and that when hung from a string the lodestone would point north and south. By the 400s C.E. they had carved lodestone into the shape of a spoon called *sinan* that was used to help miners know the direction in which they headed. It was several hundred years before the device was adapted for navigation by the Chinese, becoming a compass.

The Chinese were also good at taking an invention and reinventing it to make it more useful. For instance, the Scythians of central Asia invented the stirrup for horseback riding in the 380s B.C.E. It consisted of a loop of leather in which a foot was inserted, giving a rider stability. In about the 100s C.E. the Chinese transformed this into a metal loop with a flat bottom that allowed horseback riders to stand up in the stirrups and remain stable while firing arrows or throwing spears. Thus, in hunting and battle the Chinese stirrup gave riders an advantage they would not have had with the leather stirrup. Another Chinese innovation for horseback riding was the padded saddle in the first century C.E. Not only did it make riding more comfortable, it also enabled people to stay in the saddle for longer periods and cut down on the number of sores and injuries to the backs of riders.

Many Chinese inventions were practical, and while they may seem obvious now, they were world changing when they were introduced. For example, the Chinese invented the wheelbarrow in the first century C.E. It was basically a cart with only one wheel in front, but it was a remarkable labor-saving device that allowed farmers and construction workers to work faster and move heavier loads than they could by carrying them. It allowed a worker to quickly move loads that might have taken two men to move before. For ships the Chinese invented the sternpost rudder for steering in about 200 B.C.E. In the 400s C.E. they created transverse bulkheads. When a ship had a leak, the transverse bulkheads allowed sailors to seal off the leaking section of the ship and thus keep the ship afloat. For land transportation the Chinese invented carts with two shafts in the first century B.C.E. The shafts went outside instead of down the middle in front of the cart, making it possible to use only one horse or other draft animal to pull a cart rather than the two a single shaft would usually require.

Two of the most widely used inventions have been silk and paper. At present no one knows for sure when silk

Pair of fragments of silk, from Cave 17, Mogao, near Dunhuang, Gansu Province, China (third to fifth century C.E.); archaeologists believe that the Chinese invented silk thread. (© The Trustees of the British Museum)

thread was invented, though archaeologists and historians are sure it was originated by the Chinese. In ancient Chinese folklore the wife of the mythical Yellow Emperor Huangdi was drinking a hot beverage in about 2700 B.C.E. when the cocoon of a silkworm dropped into it. The cocoon unraveled, revealing strong strands of silk that the queen could twist together to make thread. The queen is almost certainly a mythological figure, but the discovery of silk may not have been much different from the tale because to make silk the cocoons were boiled and the strands carefully unwound. They were then twisted together to make a tough thread. Archaeologists disagree about when silk cloth was first invented, with many believing it did not occur until the Shang Dynasty, while some believe it occurred as early as 7000 B.C.E., based on an ivory cup with a silkworm design dated to that era. In Zhejiang, silk thread that may date to 3000 B.C.E. has been found.

Before the invention of paper, silk cloth and bamboo slats were used in China for writing. In the second century C.E. a eunuch in the emperor's court, Cai Lun, explained to his emperor that bamboo was too heavy and silk too expensive for writing, so he experimented with substances that he could substitute for silk. Through experimentation he hit upon combining hemp from fishing nets, old rags, and tree bark; chopping and pulping the combination; and then spreading the wet pulp on screens to dry. He is credited with making the first paper in 105 C.E., though some older examples of rag paper have been found dating to about 49 C.E., which suggests that he was building on preliminary work already done. The Chinese used the paper not only for writing but also for painting, wrapping, and clothing.

EUROPE

BY MICHAEL J. O'NEAL

The word *invention* in modern life implies a sudden breakthrough, a moment of inspiration when a curious inventor solves a problem in the physical world by creating something that was unknown before—a tool, a process, or a material—and thereby changes the relationship between humans and their physical world. The discovery can often be attributed to a particular individual or a team of researchers. In the ancient world, however, inventions cannot be attributed to particular individuals or even groups. Instead, technology advanced gradually in response to particular environmental or economic conditions.

In ancient Europe, where written records were largely absent until the end of the first millennium B.C.E., information about inventions could not be transmitted except by word of mouth. As a result, similar inventions arose independently at different times and places in ancient Europe. A key point to consider is whether an invention was an accidental novelty or was the platform on which a new and lasting technology was based. During the Paleolithic Period in central Europe (ca. 24,000 B.C.E.), for example, people developed the ability to fire clay, but they used it for only a short while to make clay figurines and other small objects. The use of fired clay to make ceramic containers would not be invented until thousands of years later.

Metallurgy was a key area for invention in ancient Europe. In southeastern Europe around 5000 B.C.E. prehistoric people developed the ability to produce very high temperatures to fire their pottery. They realized, perhaps accidentally, that copper could be smelted from its native ores at these temperatures as well, thus yielding a material that could be hammered and eventually cast into ornaments and tools. Subsequently, around 2500 B.C.E., they discovered that mixing the copper with tin or arsenic made a much harder metal called bronze. The demand for this metal triggered further inventions in casting and alloying to make more complex items.

The appearance of iron metallurgy around 1000 B.C.E. offered further opportunities for invention. While the Europeans did not invent the metal sword, for example, they carried sword-making techniques to new heights. One good example is the so-called Kilburn sword, discovered in East Yorkshire, England, and dating to about the third century B.C.E. The sword consists of more than 70 separate parts, including those made of iron, horn, and glass, each carefully engineered and assembled to create a weapon that represented the highest degree of technical innovation in metalsmithing.

An invention of process in ancient Europe was the use of domestic animals, specifically oxen, to pull plows and wagons. The first traces of plow use appear around 3500 B.C.E. The first plows, called ards, simply scratched the soil to create furrows in which seeds could be planted. These plows worked only on light, dry soils. To deal with heavier, wetter soils that

had not been cultivated previously, European farmers had to devise a heavier plow that turned over heavy clods of turf rather than merely scratching the top of the soil.

Animal power could also be applied to transportation. The earliest wheeled vehicles appeared around 3000 B.C.E. in central Europe. They were probably wagons used for hauling agricultural products and firewood from fields and forests into the settlements. Such vehicles were then improved with further inventions. The Celts of central Europe, for example, produced extremely high-quality carriages and wagons, many of which archaeologists have found in such places as Germany and Austria. An important innovation was the use of iron on wheels. Rather than relying on purely wooden wheels, which deteriorated rapidly and often broke if the driver hit a stone, the skilled metalworkers of central Europe learned to create an iron hoop that served as a kind of tire for wagon wheels. The hoop was heated and then rapidly cooled around the wooden portions of the wheel, shrinking it and thus binding it firmly to the wheel. These wheels were far more durable than anything that had been produced before.

Further inventions in transportation technology took place late in prehistoric times. One was the bearing, created by the ancient Scandinavians. By the first century B.C.E. the Vandals and Goths of northern Europe had invented a wooden roller bearing they used on wagons. This bearing was durable and provided a more reliable and comfortable ride than anything the more technically proficient Romans produced. To fill some of their wagons, the Europeans invented the wine barrel (as opposed to such containers as jars) to transport wine, a prestigious commodity, from the Mediterranean region.

To go along with their wheels and carriages, the ancient Europeans also developed engineered roads. The ancient Romans are often credited with the earliest and best road-building technology, but in fact the oldest known engineered road in the world—that is, a road that was built rather than simply cut through the forest—is the so-called Sweet Track, a causeway in Somerset, England, named after its discover, Ray Sweet. It was built in about the 3800s B.C.E. and was constructed with crossed poles of hardwood, along with lime, that were sunk in the spongy, wet soil to support a walkway. Subsequently, roads made from timbers laid side by side across the direction of the road were built across many of the wetlands of northern Europe and the British Isles, especially as trade flourished during the Iron Age.

The ancient Europeans, like people the world over, looked for ways to improve their physical conditions. In domestic architecture they developed new techniques of timber construction and joinery that enabled them to build warm and durable houses and barns. The cold northern climates of Europe created the need for heavy, durable, and warm clothing, so a precursor of knitting called *nålebinding*, or “binding with the needle,” emerged from the Danes. The Danes used this technique, which involved passing a needle through a loose loop to create a chain of loops, to make what may have been the world’s first true socks and mittens.

GREECE

BY JEFFREY S. CARNES

The technological contributions of the Greeks are somewhat difficult to measure, owing in part to the nature of our sources, in part to political and social circumstances, and in part to the Greeks’ own attitudes toward science and technology. There is, for example, little scientific literature—and essentially no technical literature—for the first four centuries for which we have historical records. Only in the Hellenistic Period (323–31 B.C.E.) do we find scientists discussing inventions, so there is only indirect evidence for the technical contributions Greeks may have made in the eighth through fourth centuries B.C.E. To some extent this is due to a certain disdain for practical matters among members of the upper classes: Typical is the contempt shown by Plato and Aristotle for the “banausic” (mechanical) professions for their negative effect on the soul. Theorists of science were generally drawn from the elite classes (there were no “pure science” occupations at which to make a living) and therefore tended to be ignorant of or unconcerned with technological developments.

Political and social conditions played a further role in slowing the progress of Greek technology. Necessity truly is the mother of invention, and in many cases the Greeks lacked the necessity that might spur technological innovation. There was little large-scale manufacturing of the sort in which costs might be reduced and profits increased by the invention of new machinery or processes. Further, Greece was a slave-owning society on a large scale—perhaps one-third of the population of Athens was made up of slaves—and with so much forced labor there would have been little incentive for labor-saving devices. Given the lack of records for all but the Hellenistic Period, we must content ourselves with noting aspects of Greek technology that do not appear previously elsewhere and speculating that these may be inventions.

In agriculture the main improvements probably attributable to the Greeks were in the area of processing. Various minor innovations in milling technology are known, mostly designed to mill more grain at once and allow more animal power to be applied to the mill. Presses for wine and olives show steady improvement, starting with primitive lever presses using stone weights and progressing to a variety of screw and lever-and-screw presses in the Hellenistic Period. The screw itself seems to have been developed in the third century B.C.E., making it the only one of the basic machines to have been invented in the historical period. The screw was also used in devices for lifting water, which had applications in both agriculture and mining.

The remains of the Athenian silver mines at Laurium include washing devices that represent an improvement on earlier washing techniques, allowing for more efficient separation of the metal from its ore. These machines also allowed the water to be recycled, a serious consideration in the semi-arid climate of Greece. Ironworking became more efficient with the development of the shaft furnace in about 500 B.C.E.

with the air supply now controlled by bellows and blowpipes. A much earlier metallurgical invention, however, was the lost-wax process for casting bronze, which dates to the Mycenaean Period (1600–1100 B.C.E.) and is still used by artists today. The making of a wax mold of an artwork into which molten bronze is poured allows for great detail, making the Greeks renowned throughout the ancient world for the quality of their bronze sculptures. Since bronze is easily melted down and reused, few artworks have survived. Another innovation of great artistic import was the development in Athens of a black high-gloss permanent glaze for pottery, which made Athenian vases highly sought-after exports throughout the Mediterranean.

The Hippocratic Corpus, a series of writings attributed to the physician Hippocrates (ca. 460–ca. 377 B.C.E.), contains numerous references to medical instruments: In this sense it is the earliest extant scientific work to discuss technology. Of particular interest is the Hippocratic bench, a device with posts, straps, and cords designed for traction and the reduction of dislocations.

As in the modern world, compelling state interests led to a great deal of innovation in military matters, and we are also well supplied with sources on military technology. In addition to archaeological finds, there exist treatises on military technology and descriptions of such innovations in the historical accounts of battles. The Greeks were the first to develop artillery (without gunpowder) by making use of a variety of mechanical means to launch projectiles. The gastraphetes, invented in 399 B.C.E., was a device for launching arrows or stones and resembled a medieval crossbow. Torsion catapults were developed later in the fourth century B.C.E. and underwent a steady series of technical improvements throughout antiquity. The Greek mathematician and inventor Archimedes (ca. 287–212 B.C.E.) is credited with the development of various siege engines and defensive weapons, including a pivoting crane to drop stones on enemy ships and scaling ladders, a crane with a claw for grabbing the bow of an enemy ship and overturning it, and a series of parabolic mirrors that could be focused on an enemy ship to set it on fire. (A recent experiment by students at the Massachusetts Institute of Technology has suggested that this was, in fact, feasible.)

A clever but entirely low-tech military invention developed in Sparta by the fifth century B.C.E. was the scytale (also spelled skytale), a device for transmitting messages in code. The scytale consisted of a rod around which a leather strap was wrapped in a long spiral. A message would be written across the strap, which would then be unrolled and sent to the recipient, who would possess a rod of equal size. When rolled around the recipient's rod, the strap would reveal the original message; anyone intercepting it without the decoding rod would find a string of apparently random letters.

The intellectual atmosphere at Alexandria was particularly conducive to innovation, owing perhaps to the combination of royal patronage for the sciences and access to Egyptian

learning. The most important of the surviving treatises are those of Hero (fl. first century C.E.), who wrote on a vast variety of subjects, giving details on the building of surveying devices, hydraulics, and pneumatics. Of these innovations, many are of practical value: the pump and the accurate water clock developed by his predecessor Ctesibius (fl. second century B.C.E.), for example, and the water organ (the world's first keyboard instrument). Others are clearly designed to be impressive rather than practical. Hero wrote an entire book devoted to automata (self-operating mechanisms), which include slot machines for dispensing water for ritual cleansing before entering a temple, pneumatically powered temple doors that would open automatically when a fire was lit on the altar, steam-powered tops, and a variety of devices for making small mechanical birds and other animals move. It is unknown how many of these devices were actually built or how widespread their use was, but the discovery of a complex, multigear mechanism for computing the positions of the stars and planets (the Antikythera device, named after the island near which it was found) shows that the Greeks were capable of precise engineering, building what was in effect a mechanical computer.

ROME

BY DAVID KELLY

Many of the inventions that are credited to ancient Rome are related to construction, travel, and water management. One of the principal reasons that Romans were able to build large-scale projects was their improvement in concrete. Starting in 237 B.C.E. the Romans developed a method of mixing traditional claylike building materials with such diverse elements as volcanic ash from Pozzuoli, a village near Naples, which was found to be a strong binding agent; horsehair, which gave the concrete flexibility; and blood, which helped inhibit frost. Roman improvements in concrete enabled them to make a product that could be molded to different shapes and yet was resistant to moisture. With this basic invention they could be more imaginative with architectural design, incorporating arches and domes to raise buildings up toward the sky, freed of having to rely on stone blocks as their main building material.

The improved concrete also enabled Romans to build hundreds of miles of water-transportation tunnels, or aqueducts, which are considered one of the greatest achievements of the Roman Empire. Roman aqueducts transferred water from sparsely inhabited regions to all of the urban capitals of the empire. In the city of Rome itself, for instance, roughly 300 million gallons of water were brought in from the surrounding countryside each day, all without the use of pumps or any machinery whatsoever, relying solely on the power of gravity. Besides the flexibility that concrete gave them, the Romans also developed a precision in their understanding of hydraulic engineering that made aqueduct technology possible: They calculated the downward angle needed to move

Roman aqueduct in Tunis; Roman improvements in concrete enabled them to build hundreds of miles of water-transportation systems, considered one of the greatest achievements of the Roman Empire. (© Board of Regents of the University of Wisconsin System)

water over hundreds of miles of channels without running into the ground before it arrived at its intended destination.

In addition to the aqueducts, concrete also enabled the construction of an unprecedented series of roads and highways throughout the Roman Empire. The Romans built approximately 53,000 miles of roads; by comparison, the U.S. Interstate Highway System had a total of about 47,000 miles at the beginning of the 21st century. Romans invented the layered method of building roads, starting with large stones at the bottom to absorb moisture and prevent shifts in the ground and ending with smooth stones held together with concrete. Many of the roads constructed during the Roman Empire are still in use today, such as the Via Appia (the Appian Way), which was begun in 312 B.C.E. Roman roads are found throughout Europe, Asia, and Africa, where many of the paths laid out before the birth of Christ have been paved over with modern materials and are still used.

Inside the home Romans are credited with the invention of the hypocaust heating system, a way of moving heated air through houses to warm them. This method, which is the basic design for modern-day heating and air conditioning systems, consisted of raising houses a few feet above the ground

and leaving space in the walls for air flow. Vents in the walls would pull warm air from a small fire under the house, distributing it throughout the entire building. Because a large fire would create smoke the fire had to be small, but it had to be constantly going or it would lose its effectiveness. The Romans relied on slaves to tend to the house fires throughout the day.

Many of the inventions credited to Rome are actually variations on designs developed by other civilizations, particularly the Greek culture that preceded Rome in history. Often adaptations were just the result of the natural process of improving on what works, though in some cases there were changes significant enough to consider the Roman version a new entity. This is true of the Roman version of the waterwheel, which captures the power of flowing water to move a heavy stone to grind grain into flour, credited to Marcus Vitruvius, an architect and engineer who served under Augustus in the first century B.C.E. His wheel improved on a similar concept from the Greeks: While the Greek wheel was moved horizontally as water flowed by, the Roman waterwheel stood horizontally and had water stream down onto it. Gravity gave the falling water much more force than its natural flow pro-

vided. At eight pounds per gallon, water is a fairly heavy substance; consequently, the Vetruvian waterwheel was the most powerful source of energy in the ancient world. Considering this fact, it should be expected that the vertical waterwheel would have been used widely throughout the Roman Empire, but that turns out not to have been the case. With slave labor inexpensive and abundant, the Romans simply were not interested in new energy sources.

A case where Roman invention does not appear to be a direct adaptation of another culture's design but rather a new product in itself is the Roman abacus. Modern people are perhaps more familiar with the Chinese abacus, which was in use well into the twentieth century. Records indicate that the Roman version predates the Chinese abacus by several hundred years. Interestingly, it is thought that the Babylonian abacus predates both cultures with indications that it may have been developed between 1000 B.C.E. and 500 B.C.E. Despite similarities in design, there is no conclusive evidence that any one was an influence on the development of the other. While both the Chinese and the Roman abacus used the manipulation of beads to help a person keep a running tally of whatever was being counted, the Chinese abacus held the beads on strings and the Roman version had slots in which the beads could roll loosely and quickly. Still, the Roman version is considered a significant innovation because it was portable and included spaces for fractions.

THE AMERICAS

BY LAWRENCE WALDRON

The people of the ancient Americas contributed countless inventions to the world as we know it today. They devised these technologies in response to a wide range of environments and circumstances. Some ancient American inventions were similar to those of other world cultures, such as weapons and hand tools, but other inventions, like the igloo, were uniquely suited to American needs and were found nowhere else. While it might seem surprising that ancient Native Americans had no carts, chariots, swords, or sailing ships, it is equally notable that they had the largest buildings in the ancient world, even larger than Egypt's; had invented paper in the first millennium B.C.E., more than one thousand years before the Chinese; and had developed counting systems that employed the numeral zero centuries before any other civilization. People in each ancient American culture developed technology that was influenced by the opportunities, necessities, and limitations of their lives and times.

Since the native cultures of the Americas seem to have developed with little or no contact with people from other parts of the world, the technological achievements of the ancient Americans seem all the more outstanding. Ancient Americans produced some of the earliest metalwork and sewn clothes, and they demonstrated some of the most innovative agricultural and medical techniques in the ancient world. In the first millennium B.C.E. Peruvian doctors occa-

sionally performed brain surgery with obsidian scalpels while the patient was under herbal anesthesia.

Although Native American discoveries could be similar to those from other parts of the world, they were not always used in the same ways. Metal tools and jewelry from the Great Lakes region of the United States date back to more than 6,000 years ago. Unlike metalworkers elsewhere in the world, however, the North American metallurgists showed little interest in making weapons. Similarly, archaeological findings in Mesoamerica show that Native Americans had invented the wheel but did not use it to make wagons or coaches. With no horses, cattle, or elephants to pull such vehicles, ancient Mesoamericans had little use for the wheel except on push toys for their children and in a few minor tools.

In many instances ancient Americans were the first to come up with ideas that would be either reinvented or adopted later by Asians, Europeans, or Africans. For example, the ancient Americans developed many kinds of waterproofing for their containers and vessels, using materials and methods unknown or undeveloped in other parts of the world: The ancient Chumash of California used asphalt from the La Brea tar pits to seal their boats, and the ancient Olmec used (non-synthetic) latex for similar purposes. There were many such inventions and innovations in the fields of art, architecture, agriculture, athletics, and urban planning.

The art of the ancient Americans was varied and ingenious. Given their great antiquity, many of these ancient artworks survive only in fragments. Pottery and metalwork are among the most durable of the ancient American arts, but some textiles and other arts also survive. Native North Americans of the Great Lakes had been annealing metal—heating and changing the shape of metal objects—since around 7000 B.C.E. Other ancient Americans throughout the continents hit upon the same techniques, and by the second millennium B.C.E. they had developed them substantially. Chavín Andeans hammered semiprecious and precious metals into thin foils to be used in decorating objects made of other materials. By 200 B.C.E. other Andeans had begun to cast and alloy metals into solid tools and weapon points. Eventually they refined their casting methods into what ancient Greeks would have recognized as the lost-wax method, a complex process of casting hollow metal sculptures shared only by a few ancient cultures.

Perhaps the most amazing Andean achievement in metallurgy was an early form of electroplating used by the Moche sometime in the very early Common Era. In Moche electroplating, an anode and cathode were inserted into an acidic solution (like the negative and positive poles of a battery) to produce an electric charge. This current caused the positively charged gold particles, intentionally dissolved in the acid, to migrate to the negatively charged copper artwork connected to the cathode. In this electrical process a copper object gradually becomes plated with gold. Thus we can credit Andeans not just with the discovery of electricity but with its use in the production of consumer items.

As textile artists, ancient Americans were great innovators. Peruvians and Bolivians began using looms for weaving sometime in the second or third millennium B.C.E. and pioneered a staggering range of textile techniques, including simple warp-and-weft weaves, scaffold weaving (discontinuous warp-weft), single-needle knitting, and a host of other demanding ways of weaving and decorating cloth. These textiles of animal hair and domesticated cotton were used by ancient Americans for clothing, shelter, wrapping the dead, decoration, and furnishings, and they were even used as containers. Even tie-dyed textiles, a kind of cloth associated with southern Asia today, were produced in the Americas by the ninth century B.C.E. The use of woven containers among Amazonians may have inspired their clever invention of the hammock, a swinging bed suspended off the ground between two trees or posts.

In the later part of the Pre-Classic period (nearing the start of the Common Era) the Maya civilization developed a full-fledged calendar system. Since the second millennium B.C.E. early Maya astronomers and their Zapotec and Olmec contemporaries had followed the movements of the sun, moon and Venus and had come to mark time by the movements of these celestial bodies. They invented three separate calendars to trace and regulate the lives, agricultural activities, dynasties, and mythic sagas of their civilization. The first was a 365-day *haab*, or solar year (much like our modern calendar), made up of 18 months. There was also a 260-day *tzolk'in*, or cycle of religious ceremonies and festivals, with each day assigned its own name and ritual significance. Finally, a great era or Calendar Round was celebrated every 52 years at the coincidence of the other two calendars. The Calendar Round, functioning much like the Gregorian century, was a large period used by historians and some religious leaders to mark ages, the return of rare celestial events, dynastic changes, cultural trends, and even the fulfillment of prophecies.

Many modern sports were born of early antecedents in the ancient Americas. Most notable of these sports is basketball, which was a ceremonial game played by religious devotees in eastern Mexico from about 1000 B.C.E. The very possibility of the bouncing ball originated in another Mesoamerican invention, that of vulcanized rubber. Both the rubber and sapodilla trees of eastern Mexico produce latex. The Mesoamericans were the first to put latex to use as a sealant and sculpture material. The Olmec developed the process of vulcanizing rubber, whereby it was heated to make it more malleable so the material could be fashioned into any shape desired. Thus, the ancient Olmec civilization contributed one of the most important materials to the development of the modern world.

There is evidence that soccer and football also existed in early versions among the ancient Mesoamericans as ritual games played at religious ceremonies. Both field and ice hockey have ancient origins in early versions of shinny, a sport played in the North American Great Plains region up to European colonial times.

The early urban centers of the Andes date back as far as the third millennium B.C.E. Many early cities such as Caral and Kotosh feature centrally located plazas, sunken courtyards, and pyramidal temples. The adobe pyramids at Caral and El Aspero in Peru were built around 3000 B.C.E., several centuries before the stone ones in Egypt. The ancient Olmec employed outdoor and indoor plumbing to conduct water through their cities. They installed carved canal blocks in three- to five-foot lengths to create aqueducts centuries before the Romans or Maya employed similar concepts in their urban centers. The so-called New Temple at Chavín de Huantar in Peru also shows knowledge of aqueduct technology.

The Chavín culture of the first millennium B.C.E. employed conduits for air as well as water in a fully functioning hydraulic system that drew both substances into the New Temple. This design created a constant roar of running water and a steady circulation of air that is still functioning today. Indeed, Native American structures from ancient Chavín's temple complex to medieval-era cliff dwellings in Arizona all employ ventilation concepts pioneered sometime in the first or second millennium B.C.E.

In their use of durable, carved basalt aqueducts, the Olmec showed a mastery of stonemasonry, which they seem to have developed to a fine point by 1000 B.C.E. Later civilizations in both Mesoamerica and South America, who had little contact with the Olmec civilization, also became well known for their stonemasonry, which suggests that this inventive engineering was developed in several places independently. The Late Pre-Classic Maya (400 B.C.E.–250 C.E.) adapted earlier stonemasonry to their own needs, adding a stone and lime compound that Romans, who were inventing it at roughly the same time, would call concrete. The early Maya also developed a softer mortar, now called stucco, that they carved into beautiful designs on their palaces and temples.

Many hunting tools were invented by early Americans to support a lifestyle that was far from sedentary. Detachable harpoon points from the Northwest Coast North Americans and fluted arrow points from the Clovis culture allowed whalers and hunters to fire at their prey and then get out of the animal's way as it rampaged. The weapons were carefully recovered from the dead animal by the fisherman or hunter. By sea, river, and estuary, ancient Americans also became master fishers in their canoes, kayaks, or reed or skin boats, all invented in ancient times. Combining efficient weapons and watercraft with woven fishing nets and waterproof garments, ancient Americans invented an almost modern ensemble of fishing apparatuses.

American agriculture was apparently in progress by the seventh millennium B.C.E. By the second millennium B.C.E. a full range of farming techniques existed in the Americas, from terraced fields to desert, swamp, and jungle plantations. Some scientists believe ancient Americans may have loosely tailored certain North and South American forests to increase the density of food sources, modifying established forests. The ancient Americans exhibited some of the world's

most creative methods of agriculture. Their development from around 8000 to 7000 B.C.E. of milpa, or slash-and-burn agriculture, was probably influenced by the observation of nature's own replenishing forest fires. Raised-bed agriculture, by contrast, seems to have been invented without the inspiration of a natural process.

Around the second millennium B.C.E. raised-bed agriculture was separately invented in Mesoamerica by the Maya and by several peoples in the Andes. In this process, mounds of earth (and sometimes composted, biodegradable debris) were built up in artificially drained or flooded swamps. Thus, farmers could make islands of food grow in otherwise dry areas (like the Andes) or vary an ecological system to include drier-climate plants, such as corn, in a swampy area (like some parts of the Maya territory). Guano, a fertilizer derived from bird droppings collected along the Pacific coast of Peru, had been used in the Andes since around 3000 B.C.E. to boost crop production.

Perhaps the most influential of ancient American inventions is biological. Selective breeding by Native Americans, perhaps over a period of centuries, has produced the plant we know as maize. Maize, or corn, is a plant that has no apparent wild relative, except perhaps a grass called teosinte that produces a very small grain. Maize cannot grow by itself. Hidden inside a protective husk, kernels of corn cannot germinate unless they are removed and tended by a farmer. Between 7000 B.C.E. and 2500 B.C.E. Mesoamerican farmers seemed to have biologically engineered corn from a wild variety, probably teosinte, into a high-yielding, starchy grain. Thus, Mesoamericans did far more than domesticate a preexisting species; they created a new one. This engineered food source is now a staple in Africa, Europe, and Asia, having been adopted by almost every society that can grow it.

CONTRIBUTORS

Saheed Aderinto is a Ph.D. student at the Department of History, University of Texas at Austin. Some of his most recent publications include “Prostitution and Urban Social Relations” and “Policing Urban Prostitution: Prostitutes, Crime, Law and Reformers in Colonial Nigeria” in *Nigeria’s Urban History: Past and Present* (2006) and “Discrimination in an Urban Setting: The Experience of Ijebu Settlers in Colonial Ibadan, 1893–1960” in *Inter-group Relations in Nigeria during the 19th & 20th Centuries* (2006). His writings have also appeared in *IFRA Special Research Issue*, *Ethnic and Third World Review of Books*, *African and Asian Studies Journal*, and *The Encyclopedia of Prostitution and Sex Work* (2006).

Olutayo Charles Adesina, Ph.D., teaches at the Department of History, University of Ibadan, Nigeria. He is the author of “The Underground Foreign Exchange Market in Ibadan during Devaluation” in *Money Struggles and City Life: Devaluation in Ibadan and Other Urban Centres in Southern Nigeria, 1986–96* (2002) and “Teaching History in Twentieth Century Nigeria: The Challenges of Change” in *History in Africa: A Journal of Method*, vol. 33 (2006).

David Otieno Akombo, Ph.D., teaches music education and world music at Wabash College of Indiana. He is the author of *Music and Healing across Cultures* (2006).

Francis Allard, Ph.D., teaches in the Department of Anthropology at Indiana University of Pennsylvania. His research interests include the archaeology of early China and Mongolia. He has contributed articles to *Archaeology of Asia* (2005) and *Beyond the Steppe and the Sown: Proceedings of the 2002 University of Chicago Conference on Eurasian Archaeology* (2006).

Miguel Arisa is finishing his doctoral studies in art history at the Graduate Center, City University of New York. He teaches at Technical Career Institutes and is a regular lecturer at the

Cloisters and a docent at the Metropolitan Museum of Art, New York.

Mariam F. Ayad, Ph.D., teaches graduate-level classes on Egyptian language and literature at the University of Memphis, where she is the assistant director of its Institute of Egyptian Art and Archaeology. Her main research interests focus on the role of women in ancient Egyptian temple ritual and the selection and transmission of funerary texts in post-New Kingdom Egypt. Her book on the God's Wife of Amun is under contract with Routledge.

Heather D. Baker, D.Phil., is a researcher at the University of Vienna, Austria, specializing in Babylonian history, society, and culture. She has published widely on Babylonian and Assyrian history and is writing a book to be titled *The Urban Landscape of First Millennium BC Babylonia*.

Robin Barrow, Ph.D., FRSC, is professor of philosophy of education at Simon Fraser University, Canada. His most recent books include *Plato* (2007) and *An Introduction to Moral Philosophy and Moral Education* (2007). He is the author of *Athenian Democracy* (2001) and *Greek and Roman Education* (1996).

László Bartosiewicz, Ph.D., D.sc., teaches archaeozoology at the Loránd Eötvös University in Budapest (Hungary) and the University of Edinburgh (United Kingdom). He is the author of *Animals in the Urban Landscape in the Wake of the Middle Ages* (1995) and principal author of *Draught Cattle: Their Osteological Identification and History* (1997) and has published more than 200 scholarly articles.

Kirk H. Beetz, Ph.D., emeritus, has published over two dozen books and more than 900 articles. His books span topics from endangered mammal species to children's literature, including *Exploring C. S. Lewis' "The Chronicles of Narnia"* (2000). His recent writings have focused on the history and culture of ancient Japan.

Craig G. R. Benjamin, Ph.D., teaches world and ancient Eurasian history at Grand Valley State University. He is the coeditor of vols. 2 (1998), 4 (2000), and 6 (2002) in the Brepols Silk Roads Studies series and the author of *The Yuezhi: Origin, Migration and the Conquest of Northern Bactria* (2007).

Uffe Bergeton, Ph.D., is in the Ph.D. program in the Department of Asian Languages and Cultures at the University of Michigan. He is the author of *The Independence of Binding and Intensification* (Ph.D. dissertation, University of Southern California) and various articles on theoretical phonology and syntax.

Amy Hackney Blackwell has degrees in history from Duke University and Vanderbilt University and a J.D. from the Uni-

versity of Virginia. Her books include *Mythology for Dummies* (2002), *LSAT for Dummies* (2004), *The Everything Irish History and Heritage Book* (2004), and *Essential Dictionary of Law* (2004). She has contributed to the *Encyclopedia of World Nations and Cultures* (2006), *Alternative Energy* (2006), and *Chemical Compounds* (2006).

Christopher Blackwell, Ph.D., teaches classics at Furman University. He is the author of *In the Absence of Alexander: Harpalus and the Failure of Macedonian Hegemony* (1999) and various protocols and software applications for building digital libraries, and he serves as technical editor for the Center for Hellenic Studies of Harvard University.

Amy Bogaard, Ph.D., teaches prehistory and archaeobotany at the Department of Archaeology, University of Nottingham, United Kingdom. She is the author of *Neolithic Farming in Central Europe* (2004).

Peter Bogucki, Ph.D., is an archaeologist who is associate dean for undergraduate affairs of the School of Engineering and Applied Science at Princeton University. He has studied prehistoric settlements in Poland and has a particular interest in the spread of farming in Europe. He is the author of *The Origins of Human Society* (1999) and the editor (with Pam J. Crabtree) of *Ancient Europe 8000 B.C.–A.D. 1000: An Encyclopedia of the Barbarian World* (2004).

Larissa Bonfante, Ph.D., professor of classics at New York University, is the author of several books on Etruscan and early Roman culture as well as publications on ancient dress and nudity, including *The World of Roman Costume*, co-edited with Judith Sebesta (1994).

Charlotte Booth is a Ph.D. student at the University of Wales, Swansea, and teaches Egyptology for Birkbeck College and other institutions in the United Kingdom. She is the author of *People of Ancient Egypt* (2007), *The Hyksos Period in Egypt* (2005), and *The Role of Foreigners in Ancient Egypt* (2005).

Lisa R. Brody, Ph.D., teaches Greek and Roman art history at Queens College, City University of New York. Her research interests include Greek iconography and cult, ancient lamps and their decoration, children in antiquity, and representation of ethnicity in Greco-Roman art. She compiled the revised edition of David Sacks's *Encyclopedia of the Ancient Greek World* (2005) and is author of *Aphrodisias III: The Aphrodite of Aphrodisias* (2007).

David Brown, Ph.D., is researching the interactions of the pre-Islamic astral sciences of Mesopotamia, Greece, India, Egypt, Iran, the western Semitic world, and China at the Free University of Berlin. He is the author of *Mesopotamian Planetary Astronomy-Astrology* (2000) and *The Interactions of Ancient Astral Science* (forthcoming).

Deborah N. Carlson, Ph.D., teaches in the Nautical Archaeology Program of the Department of Anthropology at Texas A&M University. She also directs the Institute of Nautical Archaeology's shipwreck excavation of a Roman marble carrier off the Aegean coast of Turkey at Kizilburun and is preparing the final publication of the Classical Greek ship excavated by the Institute of Nautical Archaeology at nearby Tektas Burnu.

Jeffrey S. Carnes is associate professor of classics at Syracuse University. He is the author of *The Uses of Aiakos: Pindar and the Aiginetan Imaginary* (forthcoming) as well as articles on Greek lyric poetry, gender studies, literary theory, and Plato.

Julia Marta Clapp is pursuing her doctorate in art history at the Graduate Center, City University of New York. Her research interests include modern and pre-Columbian Latin American art.

Wendy E. Closterman, Ph.D., teaches ancient history and Greek at Bryn Athyn College. Her research focuses on Athenian burial and funerary ritual. She is the author of "Family Members and Citizens: Athenian Identity and the Peribolos Tomb Setting" in *Antigone's Answer: Essays on Death and Burial, Family and State in Classical Athens*, edited by C. Patterson (forthcoming).

Leah A. J. Cohen is an independent writer and editorial consultant with a master's degree in geography from the University of Florida. She specializes in Africa area studies and food security. She was a senior author for the *Encyclopedia of African History and Culture*, volumes 4 and 5 (2005).

John Collis is professor emeritus in the Department of Archaeology, University of Sheffield, where he taught for over 30 years. He has had a major role in the development of university and professional training in archaeology in Britain, and is secretary of the European Association of Archaeologists' Committee on Training and Education. He is author of several books and excavation monographs, including *Digging Up the Past* (2004) and *The Celts: Origins, Myths and Inventions* (2004).

Constance A. Cook, Ph.D., directs the Asian Studies program and teaches Chinese language and literature courses at Lehigh University. She is the author of *Death in Ancient China: The Tale of One Man's Journey* (2006) and coeditor of *Defining Chu: Image and Reality in Ancient China* (1999).

Susan Cooksey, Ph.D., is the curator of African art, Harn Museum of Art, University of Florida.

Justin Corfield, Ph.D., teaches history and international relations at Geelong Grammar School, Australia. He is the co-author of *Historical Dictionary of Cambodia* (2003) and

has written extensively on Asia, Australia, and European colonial history.

James A. Corrick, Ph.D., is a full-time editor and writer with 25 books to his credit. His most recent titles are *The Early Middle Ages* (2006), *The Byzantine Empire* (2006), and *The Renaissance* (2007).

Arden Decker is a Ph.D. candidate in the history of art at the Graduate Center, City University of New York. Her research interests include Mesoamerican art as well as modern and contemporary art of Mexico.

Leo Depuydt, Ph.D., teaches Egyptology at Brown University and is curious about everything relating to ancient Egypt in its Near Eastern and Mediterranean context, especially the area's languages and history. He wrote *Civil Calendar and Lunar Calendar in Ancient Egypt* (1997) and *The Other Mathematics: Language and Logic in Egyptian and in General* (2007).

Haig Der-Houssikian, Ph.D., is professor emeritus (2003), linguistics, at the University of Florida, Gainesville. His research and publication interests are in morphology, Creolization, and sub-Saharan Africa.

Christine End, M.A., works on the Giza Archives Project at the Museum of Fine Arts, Boston. Her main interests of research are Middle Kingdom funerary iconography, material culture, burial practices, and mummification. As a researcher and illustrator, her work has appeared in Egyptological publications and documentaries.

Linda Evans, Ph.D., specializes in ancient Egyptian art at Macquarie University, Sydney, Australia. She recently completed her doctoral dissertation on the representation of animal behavior in Egyptian tomb paintings and has published several papers on the role and depiction of animals in the ancient world. She has also contributed chapters to *Egyptian Art: Principles and Themes in Wall Scenes* (2000), *The Encyclopedia of Animal Behavior* (2004), *Egypt: The Land and Lives of the Pharaohs Revealed* (2005), and *Historica* (2006).

Stephen M. Fabian, Ph.D., is an anthropologist and currently teaches seminars on religion, myth, and ritual at Princeton University. He is the author of *Space-Time of the Bororo of Brazil* (1992), *Clearing Away Clouds: Nine Lessons for Life from the Martial Arts* (1999), and *Patterns in the Sky: An Introduction to Ethnoastronomy* (2001).

Erin Fairburn is a graduate student in the Department of Egyptology and Western Asian Studies at Brown University. She has contributed to *The City and Urban Life* (forthcoming).

Alessia Frassani is a Ph.D. candidate at the Graduate Center of the City University of New York. Her research interests in-

clude the art and civilizations of ancient Oaxaca and issues surrounding the cultural interaction between the Old and New Worlds.

Markham J. Geller is professor of Semitic languages at University College London, in the Department of Hebrew and Jewish Studies. He has recently published a text edition of cuneiform medical texts, *Renal and Rectal Disease Texts, Babylonisch-assyrische Medizin VII* (2005).

J. J. George is working on his Ph.D. at the Graduate Center, City University of New York. His research area is pre-Columbian art and architecture.

Wolfram Grajetzki, Ph.D., wrote his dissertation at the Humboldt University of Berlin and has taught Egyptology there. He has excavated in Egypt and Pakistan and was principal archaeologist and author for the online learning project Digital Egypt for Universities (University College London). He is preparing the catalogue of Egyptian coffins in the Fitzwilliam Museum, Cambridge. His publications include *Burial Customs in Ancient Egypt* (2003) and *The Middle Kingdom in Ancient Egypt* (2006).

Lyn Green, Ph.D., has taught at several Canadian universities and for the Royal Ontario Museum. She has contributed to several encyclopedias, including *The Oxford Encyclopedia of Ancient Egypt* (2000) and the *Encyclopedia of the Archaeology of Ancient Egypt* (1999) as well as *The Royal Women of Amarna* (1996). Currently she is devoting her time to her duties as president of the Society for the Study of Egyptian Antiquities, which has over 400 members and subscribers internationally, and to writing.

Angela Herren, Ph.D., teaches pre-Columbian art and architecture as an assistant professor in the Department of Art and Latin American Studies at the University of North Carolina at Charlotte. A specialist on painted manuscripts from central Mexico, she completed a 2005 dissertation entitled "Portraying the Mexica Past: A Comparative Study of Accounts of Origin in Codex Azcatitlan, Codex Boturni, and Codex Aubin."

David B. Hollander, Ph.D., teaches ancient history at Iowa State University. He is the author of *Money in the Late Roman Republic* (2007).

Brooke Holmes, Ph.D., is an assistant professor of classics at the University of North Carolina, Chapel Hill. She is at work on a book about the symptom in early Greek medicine and classical Greek literature.

Michael Allen Holmes is a freelance editor and writer who recently contributed to *Shakespeare for Students*, 2nd edition (2007). He has also written an unpublished novel.

John W. Humphrey, Ph.D., is professor of Greek and Roman studies at the University of Calgary. A veteran of many seasons of archaeological excavation in Turkey and Greece, he is the author of *Greek and Roman Technology: A Sourcebook* (1998, with J. P. Oleson and A. N. Sherwood) and *Ancient Technology* (2006).

Keith Jordan, M.Phil., is a Ph.D. candidate in pre-Columbian art history at the Graduate Center of the City University of New York. He is currently finishing his doctoral dissertation, entitled "Stone Trees Transplanted? Central Mexican Stelae of the Epiclassic and Early Postclassic and the Question of Maya 'Influence.'"

Amr Kamel is an Egyptologist in the Rare Books and Special Collections Library at the American University in Cairo, Egypt.

David Kelly is an instructor of English writing and literature at Oakton Community College in Illinois. He has written over 100 published literary analyses and wrote the instructor's manual for the *Exploring Poetry* computer program. His short fiction has been published in *The Rockford Review*, *Grub Street*, and *The Iconoclast*, among other places.

Panagiotis I. M. Kousoulis, Ph.D., is a lecturer in Egyptology at the Department of Mediterranean Studies of the University of the Aegean. He is the author of *Moving across Borders: Foreign Relations, Religion and Cultural Interactions in the Ancient Mediterranean* (2007) and *Ancient Egyptian Demonology: Studies on the Boundaries between the Demonic and the Divine in Egyptian Magic* (2007).

Philippa Lang teaches ancient science and related subjects, with research interests in ancient medicine and philosophy, in the Classics Department of Emory University, Atlanta. She is the editor of *Re-Inventions: Essays on Hellenistic and Early Roman Science*, *Apeiron* special issue vol. 37 (2004).

Russell M. Lawson, Ph.D., is associate professor of history and chair of the Division of General Studies at Bacone College in Oklahoma. He is the author of *Science in the Ancient World* (2004), *The Land between the Rivers: Thomas Nuttall's Ascent of the Arkansas, 1819* (2004), and *Passaconaway's Realm: John Evans and the Exploration of Mount Washington* (2002, 2004).

Anne Mahoney, Ph.D., teaches Greek and Latin linguistics and literature at Tufts University. She is the author of *Plautus: Amphitryo* (2004) and *Roman Sports and Spectacles: A Sourcebook* (2001). She is also the editor of revised editions of *Allen and Greenough's New Latin Grammar* (2001), *Morice's Stories in Attic Greek* (2005), and *Bennett's Essentials* (2007).

Susan Malin-Boyce, Ph.D., serves as deputy director of the Regime Crimes Liaison Office, Mass Graves Investigation

Team, in Baghdad, Iraq. She has contributed to *Ancient Europe 8000 B.C.–A.D. 1000: Encyclopedia of the Barbarian World* (2004) and to publications addressing Early and Late La Tène settlement in Bavaria, Germany.

Renee McGarry is a student in the Ph.D. program in art history at the City University of New York Graduate Center. Her research interests include Aztec sculpture of the natural world and religious manuscripts from the post-Conquest period.

Paul McKechnie, D.Phil., is a senior lecturer in classics and ancient history at the University of Auckland, New Zealand. He is the author of *First Christian Centuries: Perspectives on the Early Church* (2002) and *Outsiders in the Greek Cities in the Fourth Century B.C.* (1989).

John M. McMahon, Ph.D., teaches at Le Moyne College in Syracuse, New York, where he directs the classics program. He is author of *Cave Paralysis: Impotence, Perception and Text in the Satyricon of Petronius* (1998) and numerous articles on the intersection of ancient literature and natural history. His most recent work includes nine entries in the forthcoming *Biographical Encyclopedia of Astronomers* (2006).

Jianjun Mei, Ph.D., teaches the history of science and technology at the University of Science and Technology Beijing. He is the author of *Copper and Bronze Metallurgy in Late Prehistoric Xinjiang: Its Cultural Context and Relationship with Neighbouring Regions* (2000).

James E. Meier, Ph.D., is assistant professor in the Department of Humanities and Social Sciences at Central Florida Community College. He is a contributor to the *Encyclopedia of African History and Culture* (2005).

Francesco Menotti, Ph.D., is a lecturer in European prehistory at the Institute of Prehistory and Archaeological Science, Basel University, Switzerland. He is the author of *Living on the Lake in Prehistoric Europe* (2004).

Melissa Moore Morison is associate professor of classics and classical archaeology at Grand Valley State University. She has extensive experience in archaeological fieldwork in Greece, Turkey, and the United States. Her research interests include Roman provincial archaeology, Greek and Roman pottery, and ceramic technology.

Penny Morrill, Ph.D., teaches pre-Columbian and early colonial Mesoamerican art at Hood College, Frederick, Maryland. She has an essay, "The Queen of Heaven Reigns in New Spain: The Triumph of Eternity in the Casa del Deán Murals," in a Brill anthology, *Woman and Art in Early Modern Latin America* (2006). She has authored several books on modern Mexican silver: *Mexican Silver: 20th Century Hand-*

wrought Silver Jewelry and Metalwork (4th ed., 2007), *Silver Masters of Mexico: Héctor Aguilar and the Taller Borda* (1996), and *Maestros de Plata: William Spratling and the Mexican Silver Renaissance*, a catalog for a traveling exhibit (2002–2004).

Julian M. Murchison, Ph.D., teaches in the Department of Sociology and Anthropology at Millsaps College. His work in cultural anthropology examines the intersections of medicine and religion in East Africa. He recently published a chapter examining stories about a cure for HIV/AIDS in *Borders and Healers* (2005).

Caryn E. Neumann, Ph.D., teaches history in Ohio Wesleyan University's Black World Studies Department. She is a former managing editor of the *Journal of Women's History*.

Emily Jane O'Dell, is a Ph.D. candidate at Brown University and has taught at Brown University in both the Department of Egyptology and Ancient Western Asian Studies and the Department of Literary Arts. She has been the chief epigrapher of the Cairo-Brown University Abu Bakr Epigraphic Survey in the western cemetery of the Great Pyramids in Giza, Egypt, for the past five years.

Simon O'Dwyer is founder and researcher for Prehistoric Music Ireland, author of *Prehistoric Music of Ireland* and prehistoricmusic.com, and contributor to *The Encyclopedia of Music in Ireland* and *The Encyclopedia of Ireland*. He has published four papers for the International Study Group on Music Archaeology.

Penelope Ojeda de Huala is a Ph.D. candidate in art history at the Graduate Center of the City University of New York, where she studies pre-Columbian to contemporary art of Latin America. Her research focus is Guatemala and Peru, particularly the enduring thoughts and practices of indigenous cultures as manifested in art.

Michael J. O'Neal, Ph.D., is a writer who lives in Moscow, Idaho. He is a frequent contributor to reference and educational books, including *Lives and Works: Young Adult Authors* (1999), *The Crusades* (2005), and *America in the 1920s* (2006).

Dianne White Oyler, Ph.D., teaches African history at Fayetteville State University. She is the author of *The History of the N'ko Alphabet and Its Role in Mande Transnational Identity: Words as Weapons* (2005) as well as articles in the refereed journals *Research in African Literature*, *the Mande Studies Journal*, and the *International Journal of African Historical Studies*.

Katie Parla is an art historian and archaeological speleologist working in Rome and Naples as a docent leading didactic seminars of archaeological sites. She consults for the History

Channel and will appear in their 2007 series *Cities of the Underworld* as an expert on underground Rome and Naples.

Marie Passanante is a doctoral candidate in the Department of Egyptology and Ancient Western Asian Studies at Brown University.

William H. Peck teaches at the College for Creative Studies, Detroit, and the University of Michigan, Dearborn. He was for many years the curator of ancient art at the Detroit Institute of Arts and is at present a member of the Brooklyn Museum excavations in Egypt at Karnak. He is the author of *Drawings from Ancient Egypt* (1987) and numerous contributions to reference books and encyclopedias on the ancient world.

David Petechuk is a freelance writer specializing in educational texts focusing on the sciences, literature, and history. The former director of publications for the health sciences at the University of Pittsburgh, he is the author of *The Respiratory System* (2004), *LSD* (2005), and *Health & Medical Issues Today: Organ Transplantation* (2006).

Mark Anthony Phelps is taking a leave after teaching continuously since 1994 (primarily at Drury University, in five different departments) to finish his dissertation at the University of Arkansas entitled "Sewage from the Orontes: Roman Elite Attitudes toward Ecstatic Religion in the 3rd and 4th centuries C.E." This degree in ancient Mediterranean history augments his graduate degrees from Harvard and Johns Hopkins in Hebrew Bible and ancient Near Eastern languages and cultures. His research interests reflected in his writings are widely eclectic, spanning Paleolithic to contemporary society and including the disciplines of archaeology, linguistics, cultural anthropology, physical geography, historical geography, classical history, ancient Near Eastern history, medieval history, modern history, religion, and biblical history.

Jen Piro is a Ph.D. candidate in anthropological archaeology at New York University. Her dissertation research focuses on the development of pastoral economies in Early Bronze Age Transcaucasia.

Karen Radner, Ph.D., is lecturer in ancient Near Eastern history at University College, London. She specializes in the Assyrian Empire and is the author of *Die neuassyrischen Texte aus Tall Seh Hamad* (2002), *Das mittelassyrische Tontafelarchiv von Giricano/Dunnu-sa-Uzibi* (2004) and *Die Macht des Namens: Altorientalische Strategien zur Selbsterhaltung* (2005).

Judith A. Rasson, Ph.D., teaches in the Department of Medieval Studies, Central European University, Budapest (a post-graduate American-accredited university). Her research interests lie in southeastern Europe (especially the countries

of the former Yugoslavia) and focus on Neolithic and historic archaeology and ethnographic material culture.

Kelly-Anne Diamond Reed, Ph.D., teaches ancient Egyptian history and archaeology at Villanova University's Department of History. She is investigating early Egyptian funerary rituals and burial customs.

Duane W. Roller is professor of Greek and Latin at Ohio State University. Trained as an archaeologist, he has over 30 years' experience in field archaeology in numerous Mediterranean countries. He is the author of *The Building Program of Herod the Great* (1998), *The World of Juba II and Kleopatra Selene* (2003), and *Through the Pillars of Herakles* (2006) as well as many other publications in history, classics, and archaeology.

Kelley L. Ross, Ph.D., teaches philosophy at Los Angeles Valley College. He specializes in Kantian epistemology, metaphysics, and ethics, with emphasis on members of the Friesian tradition—Jakob Fries, Leonard Nelson, Rudolf Otto, Sir Karl Popper, and others. Since 1996 he has been the publisher and editor of the online philosophy journal *Proceedings of the Friesian School, Fourth Series*.

Edward M. W. A. Rowlands, M.Phil., has research interests in Mycenaean political geography, trade, and religion.

Lucas G. Rubin, Ph.D., develops master of science programs for Columbia University. He was previously administrator of the university's Center for Archaeology, where he managed multiple excavations and projects. His research and scholarship have focused on fires and firefighters in ancient Rome.

Michael M. Sage, Ph.D., teaches classics and ancient history in the Classics Department at the University of Cincinnati. His main areas of study are historiography and military history. He is the author of *Cyprian: A Biography* (1975) and *Warfare in Ancient Greece: A Sourcebook* (1996).

Rick Schulting, Ph.D., is a lecturer in scientific and prehistoric archaeology at the University of Oxford. His current research interests lie in understanding the Mesolithic-Neolithic transition in western Europe, emphasizing the use of radiometric dating and stable isotope analysis, and in skeletal evidence for interpersonal violence in earlier prehistoric Europe.

David R. Sear, a fellow of the Royal Numismatic Society in London and the American Numismatic Society in New York, has authored an extensive range of numismatic books over the past four decades, aimed at collectors and students of ancient Greek, Roman and Byzantine coinage. He has been a resident of Los Angeles for the past 25 years and operates a research service authenticating ancient coinage. His

numerous publications include *Roman Coins and Their Values* (1964; rev. ed., 2000–2005), *Byzantine Coins and Their Values* (1974, rev. ed., 1987), *Greek Coins and Their Values* (1978–1979), and *The History and Coinage of the Roman Emperors, 49–27 B.C.* (1998).

Robert Shanafelt, Ph.D., teaches courses in anthropology, religion, and Africana studies at Georgia Southern University. He has published a number of articles on different aspects of life in southern Africa, among them, “Crime, Power, and Policing in South Africa” in *Democratic Policing in Transitional and Developing Countries* (2006).

Alison Sheridan, Ph.D., is head of early prehistory in the National Museums Scotland, Edinburgh, specializing in the British and Irish Neolithic and Bronze Age. Exhibition work includes *Heaven and Hell—and Other Worlds of the Dead* (2000), for which she was lead curator and book editor. Other books include *From Sickles to Circles* (with A. M. Gibson, 2004) and *Vessels for the Ancestors* (with N. M. Sharples, 1992).

Spyros Siropoulos is senior lecturer of Greek philology and history at the Department of Mediterranean Studies, University of the Aegean, Greece. He has published various articles in three books: *Unlike a Woman: Gender and the Social Function of the Athenian Tragedy* (2003), *The Goat’s Skin: The Other Side of Alexander the Great’s Power* (2003; in Greek with English summary), and *The Things after Alexander: The Centrifugal Potencies of the Hellenistic Kingdoms* (2005, in Greek).

Bradley Skeen, M.A., has taught at the University of Minnesota, Webster University, and Washington University. He is a specialist in magic, religion, and philosophy in late antiquity and has contributed to research in that field in *Die Zeitschrift für Papyrologie und Epigraphik*, among other journals.

Christopher Smith, D.Phil., is professor of ancient history at the University of Saint Andrews in Scotland. He is the author of *Early Rome and Latium: Economy and Society c 100–500 B.C.* (1996) and *The Roman Clan: From Ancient Ideology to Modern Anthropology* (2006) as well as editor of several collections of essays, including *Trade, Traders and the Ancient City* (with Helen Parkins, 1998); *Sicily from Aeneas to Augustus* (with John Serrati, 2000), and *Religion in Archaic and Republican Rome and Italy: Evidence and Experience* (with Edward Bispham, 2000). He is engaged in work on Roman historiography and oratory.

Nancy Shatzman Steinhardt is professor of East Asian art and curator of Chinese art at the University of Pennsylvania. She is author of *Chinese Traditional Architecture* (1984), *Chinese Imperial City Planning* (1990), *Liao Architecture* (1997), and *Chinese Architecture* (2002) and more than 60 scholarly articles.

Tom Streissguth is a freelance author, editor, and journalist who has published more than 70 nonfiction and reference books. His most recent titles include *Clay v. United States*, *Genghis Khan’s Mongol Empire*, *Library in a Book: Hate Crimes*, *Eyewitness History: The Roaring Twenties*, and the *Greenhaven Encyclopedia of the Middle Ages*.

Ananda Cohen Suarez is a Ph.D. student at the Graduate Center of the City University of New York, specializing in pre-Columbian and colonial Latin American art history. She is particularly interested in cross-cultural encounters, vernacular religious art, and manuscript production in the early colonial Americas.

Frank J. Swetz, D.Ed., is professor emeritus of mathematics and education, Pennsylvania State University. His research interests focus on cultural and societal impact on mathematics learning and teaching. Among his recent books are *Legacy of the Luoshu: The 4000 Year Search for the Meaning of the Magic Square of Order Three* (2002) and *Teaching Mathematics to Children* (2003).

John Thorburn, Ph.D., is associate professor of classics at Baylor University, where he teaches a variety of subjects dealing with the classical world. He has published on Greek tragedy, Greek comedy, Greek and Roman history, and a variety of ancient subjects. He is the author of *The Alcestis of Euripides* (2002) and the *Facts on File Companion to Classical Drama* (2005).

Alain Touwaide, Ph.D., is a historian of sciences in the Department of Botany of the National Museum of Natural History at the Smithsonian Institution (Washington, D.C.). He has extensively published on the history of medicine in the Mediterranean world from antiquity to the Renaissance. Recently, he coedited the volume *Visualizing Medieval Medicine and Natural History, 1200–1550* (2006).

Francesca C. Tronchin, Ph.D., teaches Greek and Roman art and archaeology at Ohio State University. Her primary area of research is Roman domestic decor and issues of eclecticism in ancient sculptural displays.

David K. Underwood, Ph.D., teaches Western humanities, art history, philosophy, and Latin American studies at the University of South Florida in Tampa and at Saint Petersburg College in Clearwater, Florida. He is the author of two books and several articles and essays on Iberian and Latin American art and architecture.

David Vallilee is an independent scholar.

Frans van Koppen, M.A., teaches Akkadian at the School of Oriental and African Studies, London. He contributed to *The*

Ancient Near East: Historical Sources in Translation (2006) and *The Babylonian World* (forthcoming).

Lawrence Waldron, M.F.A., is an associate professor and doctoral candidate at the City University of New York, specializing in non-Western fields of art history and culture. He has presented and published various articles on the art and culture of the pre-Columbian Caribbean and Southeast Asia.

Ezekiel A. Walker, Ph.D., teaches African and world history at the University of Central Florida. His forthcoming book is entitled *Growth, Crisis and Transformation in the Cocoa-Farming Economy of Southwestern Nigeria* (2007).

Peter S. Wells is professor of anthropology at the University of Minnesota. His publications include *The Barbarians Speak: How the Conquered Peoples Shaped Roman Europe* (1999), *Beyond Celts, Germans and Scythians: Archaeology and Identity in Iron Age Europe* (2001), and *The Battle That Stopped Rome: Emperor Augustus, Arminius, and the Slaughter of the Legions in the Teutoburg Forest* (2003).

Jacqui Wood is an archaeologist and authority on prehistoric cooking and the lifestyles of prehistoric Europeans. She runs her own excavation in Cornwall, England.

Ronald Young, Ph.D., teaches in the Social Sciences Department at Canterbury School in Fort Myers, Florida. His teaching and research interests are in the area of Latin American Studies. In addition to numerous reference articles, he is presently working on a general history of Colombia to be published by Greenwood Press.

Katharina Zinn, M.A., is writing her Ph.D. dissertation on ancient Egyptian libraries and archives at the University of Leipzig, Germany. She works in a project on scarabs in the Fitzwilliam Museum, Cambridge (United Kingdom) and a project on Middle Kingdom Reliefs from Lisht in the Princeton University Art Museum. She has published articles on the organization of collective wisdom as well as multilingualism in ancient Egypt.

List of Illustrations

VOLUME I

Glass kohl tube in the form of a palm column, from Egypt	5	Marble statue of the Greek goddess of fertility, Demeter	37
Gold lion, used as a fabric ornament and found at Persepolis, Persia (modern-day Iran)	7	Section of the facade of a Roman aisled, barnlike building on a villa estate in the parish of Meonstoke, Hampshire, England	44
Jade ornament of four discs carved from a single jade pebble, from China	8	Facade of the Great Temple of Abu Simbel, Egypt	59
Toiletry implements from Roman Britain	10	The ruins of Persepolis (in modern-day Iran), the seat of the Achaemenian Empire of Darius I	63
Greek marble head, showing headdress of snail-shell curls	11	Panoramic view of West Lake in Lin'an (modern Hangzhou), China	66
Gold coin of the Roman emperor Marcus Aurelius, set in a gold ring	12	The theater at Epidaurus, Greece	76
Jade pectoral of the Olmec culture (Mexico), showing large holes in the earlobes, where earplugs would be placed	13	Engraving of the Roman Colosseum by Antoine Lafréry	80
View of rice fields in the Malagasy Republic of southern Africa	17	Petroglyph of animals and people at Tassili, Algeria, in North Africa	90
Wooden model of a man plowing with oxen, from Egypt	21	Banquet scene, fragment of wall painting from the tomb of Nebamun, Thebes, Egypt	95
Cuneiform tablet recording barley rations given to workers and their families at the temple of the goddess Bau, from Tello (ancient Girsu), southern Iraq	25	Human-headed winged bull from the palace of King Sargon II at the Assyrian capital Dur-Sharrukin (modern-day Khorsabad, Iraq)	99
Ritual spear blade from Japan	31	Schist head of the fasting Buddha, from Rawalpindi District, Gandhara, Pakistan	101
Iron Age farming tools, from Stantonbury Hill, Somerset, England	35		

Bird bone engraved with animal heads from the cave of Courbet, Penne-Tarn, France	106	Terra-cotta statuette of a lady in a swing, from Agia Triada, Herakleion	182
Hermes with the Infant Dionysus, by the Greek sculptor Praxiteles	111	Amphora from Pompeii, Italy	184
Roman terra-cotta relief showing an Egyptian scene set on the Nile	117	Feline-head ceramic bottle from Peru	185
Inner coffin of the priest Hornedjitef, Thebes, Egypt	125	Boys kept in seclusion in an initiation camp in Angola, southern Africa	188
Cuneiform tablet with observations of Venus, Nineveh, northern Iraq	126	Game of Senet from Egypt	190
Chinese covered jar	128	Terra-cotta figurine of a woman with a child, Cyprus	191
The Semna dispatches, administrative documents from an Egyptian outpost, from Thebes, Egypt	141	Profile of a Greek boy	195
Babylonian boundary marker, Sippar, southern Iraq	143	Roman rag doll made of linen, rags, and papyrus	196
Dedication by Alexander the Great to Athena Polias, from Priene, Asia Minor	146	Olmec figure of a baby (ceramic, cinnabar, and red ochre), Mexico	197
Wattle framework being filled with red mud, a construction technique used in ancient times, from Zambia	151	Ancient Egyptian city of Sesebi	206
Clay foundation peg from Bad-tibira, southern Iraq	154	Panels with striding lions, Neo-Babylonian, during the reign of Nebuchadnezzar II	211
Dolphin fresco in the queen's megaron (reception hall) at Knossos, the capital of Minoan Crete	159	Jade ritual reaping knife, from Henan, northern China	215
Iron window grill, Roman Britain	160	Roman silver coins depicting the founding twins of the city of Rome, Romulus and Remus	227
View of the royal tombs at Meroë, ancient city of northeastern Africa in present-day Sudan	164	Pottery vessel of the storm god, Teotihuacán, Mexico	232
Fragment of a basalt water clock, from Tell el-Yahudiya, Egypt	166	Grass, sand, and volcanic formation in the Sahara, southern Algeria	236
Kerma ware pottery beaker, from Kerma, Sudan	175	The Great Temple at Abu Simbel on the banks of the Nile	243
Painted pottery group of cattle, from el-Amra, Egypt	177	Ax made from reindeer antler found at Earls Barton, Northamptonshire, England	254
Ceramic bowl with abstract decoration, from Tall-i-Bakun in modern-day Iran	178	Petroglyph of a human figure wearing a loincloth, from the Sahara Desert at Tassili, Algeria, North Africa	273
Pottery jar with dragon handles, from China	180	Pair of child's leather sandals from Thebes, Egypt	275
Buccero ware water jug, from Chiusi, Tuscany, Italy	181	Two Assyrian court officials from the reign of Sargon II	276
		Caryatids from the Porch of the Maidens at Erechtheion, a temple on the north side of the Acropolis at Athens	280

Pottery figures of a drummer and a woman and child, Tala-Tonalá style, Jalisco, Mexico	283	Roman gold bars with assayers' stamps	368
Group of bronze tools for woodworking from Thebes, Egypt	287	Granite statue of Senmut holding Princess Neferure, the temple of Amun, Karnak, Thebes, Egypt	378
Stone bowl from Khafajeh, Iraq	288	Cuneiform tablet with schoolwork, probably from southern Iraq	379
Bird head made of stone, Papua, New Guinea	290	Yue ware water dropper in the shape of a frog drinking from a cup, from Zhejiang, southern China	381
Steatite vase from Greece	293	Fragments of painted plaster, Roman Britain, from Otford, Kent, England	385
Papyrus with part of the "Tale of the Eloquent Peasant" from Egypt	298	Colossi of Egyptian pharaoh Ramses II and his wife at entrance to Karnak Temple	395
Drawing by Michelangelo of the Crucifixion of Christ and two thieves	304	Portion of a relief in the tomb of Darius I, king of Persia, showing his throne bearers	400
VOLUME II			
Pyramid of a king, thought to be Adikhalamani Tabirqa, in Meroë, Sudan	312	Cowrie shells, the earliest form of money in China	429
A reconstructed Egyptian grave pit	314	Roman marble relief of Jason, the physician and patient	433
Jade eye plaques from China	316	Stucco head of a monk, said to be from Hadda, Gandhara	440
Iron Age pottery cinerary urn shaped like a hut, from Italy	318	<i>The Dream of Scipio</i> , by Raphael	444
Stele of Aristion, a philosopher of Athens	319	Papyrus marriage contract between the priest Pagosh and Teteimhotep, from Assiut, Egypt	449
Gold diadem, found in the Camaná valley, Peru	321	Scarab stamp seal and impressions, in lapis lazuli, depicting Ishtar, the Assyrian and Babylonian goddess of love, fertility, marriage, and childbirth	451
Bronze figure of Isis and Horus, from North Saqqara, Egypt	329	Fragment of an archaic Greek stele, with the heads of a mother and child	455
Babylonian lapis lazuli cylinder seal of Sin-ishmeanni	331	Ethiopian Orthodox priests at festival of Timkat	463
A 19th-century Indian painting depicting the climax of the epic the Ramayana	332	Roman hand of Sabazius, found at Tournai, Belgium	469
The figure of Silenus, the mentor of Dionysus, Greek god of plays	334	Pottery dog, from Colima, Mexico	471
Marble relief with two Roman theater masks	337	Fineware cup decorated with frogs and lotus flowers painted in black, from Faras, Sudan	473
The Great Harris Papyrus, from Thebes, probably Deir el-Medina, Egypt	347		
Mesopotamian stone vase depicting animals of the first city dwellers of Mesopotamia	351		
Indian bronze cast coin	355		
Mesolithic perforated part skull and antlers of red deer, from Star Carr, Vale of Pickering, North Yorkshire, England	359		

“Empress” pepper pot, from the Hoxne hoard in Suffolk, Roman Britain	478	Stone weight carved in the form of the head of an aquatic bird and thought to have been used in fishing, from Orange County, Florida	582
Terra-cotta utensil with six receptacles, thought to be an egg dish or cup holder	480	A bronze lamp found at the palace of Persepolis, Persia	586
Detail of an Ethiopian tribute bearer, from a relief in stairway of the palace at Persepolis, Persia (modern-day Iran)	486	Broken limestone lamp from the cave of Courbet, Penne-Tarn, France	589
Greek terra-cotta statuettes: woman holding pancake and woman kneading dough	500	Roman lamp showing a chariot race	591
Spout and bridge vessel in the shape of a woman, holding what is thought to be a spindle wrapped in cloth, from the Nasca culture of Peru	503	Paleolithic stone hand ax from Olduvai Gorge, Tanzania	593
Olmec jade perforator, from Mexico	536	Papyrus from the Book of the Dead of Nakht with agricultural scenes, from Thebes, Egypt	595
Coffin with skeleton of a child, from Speos Artemidos, Egypt	547	An administrative text in cuneiform (the world’s earliest form of writing), recording food supplies, probably from southern Iraq	597
Terra-cotta votive womb, Italy	551	Pair of fragments of silk, from Cave 17, Mogao, near Dunhuang, China	599
Hellenistic ivory figure of a hunchback thought to show signs of Pott’s disease	553	Roman aqueduct in Tunis	602
Altar from Roman Britain dedicated to the goddess Fortuna, the healing god Aesculapius, and Salus, goddess of health	554		
Paleolithic stone chopping tools from Olduvai Gorge, Tanzania	562	VOLUME III	
A folding wooden headrest, from Akhmin, Egypt	563	Sandstone offering table with Meroitic cursive inscription around the edges, from Faras, Sudan	610
Stone bowl and pitcher from Greece	567	Clay tablet with Elamite inscription found in the treasury of the palace at Persepolis, Persia (modern-day Iran)	613
Roman jug, two-handled cup (the handles now missing), strainer, ladle, and stirrer, from Arcisate, near Como, northern Italy	569	Jade disc inscribed with a poem by the Qianlong emperor, from China	614
Archery case painted with a hunting scene, from Thebes, Egypt	574	Linear A tablets, from Agia Triada, Heraklion	617
Impressions of cylinder seals on clay, depicting hunting scenes and found in the treasury of the palace at Persepolis	575	The Rosetta Stone, from Fort St. Julien, el-Rashid (Rosetta), Egypt	623
Harpoon tips made of antler from the cave of Courbet, Penne-Tarn, France	578	Jade cicada, China	626
Fragments of a fresco from Tiryns, Greece, showing hunter and dog	579	Page from the Book of the Dead of Hunefer, Thebes, Egypt	644
		Sculpted panel depicting Vishnu Trivikrama, eastern India	650
		Frieze of three Greek muses	657

Copper vessel with silver wire, from Ur, southern Iraq	680	Whistling vessel in the form of a macaw, Peru, Moche culture	773
Gold cup of the Bronze Age, beaten out of a single lump of gold and found in Rillaton, Cornwall, England	683	Rock inscription at Seheil, Egypt, recording a seven-year famine	777
Gold mask from Mycenae	684	Roman wall painting showing a coastal landscape, from Boscoreale, Campania, Italy	782
Hammered gold standing figure, Colombia or Ecuador	687	Petroglyph showing herders and cows, from Sahara Desert at Tassili, Algeria, North Africa	787
Granite statue of Senwosret III, from Deir el-Bahari, Thebes, Egypt	694	The Rhind Mathematical Papyrus, showing mathematical problems and solutions, from Thebes, Egypt	799
Albert Bierstadt, The Rocky Mountains, Lander's Peak	719	Painted Greek stele with metrical inscription	804
Detail of a Persian soldier from the stairway of the palace of Darius, king of Persia, at Persepolis (modern-day Iran)	728	Granite statue of Ankhwa, the shipbuilder, possibly from Saqqara, Egypt	810
The fortifications of Eleutherae, a city in the northern part of Attica, bordering the country of Boeotia	733	Spinning and weaving tools from Iron Age England	814
Roman marble statue of a youth on horseback and wearing a military cloak	735	Frieze of <i>hydriaphoroi</i> (water carriers) from the Greek Parthenon	815
Linen bag of salt for mummification, from Deir el-Bahari, Egypt, New Kingdom	743	Traditional healer in anti-smallpox costume, Nigeria, West Africa	820
Stone panel from the palace of Sennacherib, Nineveh, northern Iraq	744	Mesopotamian terra-cotta figure of an animal thought to be a dog	822
Lead pig (ingot), Roman Britain, from Hints Common, Staffordshire	749	Greek marble block from the frieze of the Temple of Apollo Epikourio (Apollo, the Helper), Bassae, Arcadia	826
The el-Amarna Hoard, from el-Amarna, Egypt	754	Limestone stela with images of the goddess Tanit, from Carthage (modern-day Tunisia)	834
Silver coins of various cultures found at Persepolis, Persia (modern-day Iran)	756	Limestone relief panel depicting the departure of Prince Siddhartha from his palace, to start on the spiritual journey that brings him to Buddhahood	846
Fragments of a stone mould and bronze knife money, from northeastern China	757	Iron Age horned helmet, from the River Thames at Waterloo Bridge, London, England	851
Cast ingots of bronze used as money in Rome before the invention of silver coinage	761	Frieze of the gods Greek gods Poseidon and Apollo and the goddess Artemis from the Parthenon	854
Babylonian relief plaque of harpist	766		
Red sandstone railing pillar in the form of a flute player, Mathura, northern India	767		
The Greek god Apollo with kithara, a stringed instrument similar to a lyre	770		

Jade votive ax of a figure combining human and animal traits and thought to represent a supernatural being, Olmec, from Mexico	863	Painted wooden model of a boat, from Meir, Egypt	977
Head of the Greek philosopher Socrates	878	Terra-cotta model of a merchant ship, Amathus, Cyprus	978
Ivory panel commemorating Quintus Aurelius Symmachus, an orator and figure in Roman government and a prominent pagan	881	Wall painting of Ulysses and the Sirens, Roman, from Pompeii	983
Section of the Neolithic Sweet Track, the oldest prehistoric timber trackway in Britain, from Somerset, England	888	A Scythian slave and the satyr Marsyas	992
Iron hipposandal, Roman Britain, found in London	891	Image of Psyche on a lead coffin lid, Roman, made in Lebanon	994
VOLUME IV			
Deep gorge in the Atlas Mountains of Africa	898	Sarcophagus of Nectanebo II, the last native ruler of Egypt, from Alexandria	1001
Limestone stela of Heqaib, from Abydos, Egypt	900	Basalt relief of a gazelle, Neo-Hittite, from Carchemish, southeastern Anatolia (modern Turkey)	1002
Iron Age Lindow Man, found in Lindow Moss, Cheshire, England	903	A Neolithic burial jade carved with faces, from southern China, Liangzhu culture	1004
View of Mount Olympus, in Attica	905	Coins from the Hoxne hoard, Roman Britain, found in Hoxne, Suffolk	1007
Gold ring bought by a pilgrim and showing the Roman Temple of Aphrodite at Palaepaphos	906	Servants carrying food for the king's tables, palace of Xerxes, Persepolis, Persia (modern-day Iran)	1019
Neo-Assyrian stone panel from the palace of Sennacherib, Nineveh, northern Iraq	912	Pottery, Japan	1026
Base-silver radiate of Carausius, with the emperors Diocletian and Maximian, Roman Britain	914	Double spout and bridge vessel with pelican and fish, Nasca culture of Peru	1041
Unwrapped mummy of a woman, perhaps from Thebes, Egypt, Late Period	926	Game of 58 Holes, made of ivory inlaid with gold and blue paste, from Megiddo, Palestine	1050
Bust of Pseudo-Seneca by Peter Paul Rubens	942	Ceramic Liubo players, from China	1052
Altar to the sea god Neptune, an offering from the Roman admiral of the British fleet, from Lympne, Kent, England	959	Bronze group of a bull and acrobat, Minoan, from Crete	1053
Aerial view of the Niger River and surrounding savanna during the rainy season	963	Hockey game, found in the Themistoclean wall, Athens	1054
Relief fragment showing Assyrian soldiers towing a boat through shallow water	967	Roman terra-cotta sculpture of two gladiators fighting	1056
		Stone <i>hacha</i> (ax), Veracruz, Mexico	1057
		Painted wooden model of a granary, from Aswan, Egypt	1063
		Amphora, a ceramic vessel used for storing and carrying oil and wine and other commodities, from Athens	1068
		Ugandan woman wearing a bark cloth dress	1074

Tapestry made of multicolored wool on linen showing Artemis and Actaeon, Egypt	1076	Bust of a Greek warrior known as Leonidas	1145
Wool textile fragment from Persepolis, Persia (modern-day Iran)	1078	Bronze statuette of the Mars, Roman god of war, Earith, Cambridgeshire, England	1151
Bone needles from the cave of Courbet, Penne-Tarn, France	1081	Stone ball found in Olduvai Gorge, Tanzania	1162
Greek utensil used for unwinding balls of wool, called Ariadne's clew box	1081	Short sword of steel, bronze, and gold from eastern Central Asia	1165
Mantle border fragment made of cotton and camelid hair, Peru	1084	Spear thrower carved in the shape of a mammoth, from the rock shelter of Montastruc, Tarn-et-Garonne, France	1167
Site of ancient walled town, Cameroon, Central Africa	1087	Vase from Mycenae portraying warriors in battle gear	1168
Gold bracelet or diadem, from the Phoenician trading center of Tharros, Sardinia	1099	Sixteenth-century shield depicting Roman battle scene	1170
Steatite seals from the Indus Valley	1100	Bronze duck weight, found in the treasury at Persepolis, Persia (modern-day Iran)	1175
Iron Age luxury imports from Italy, Rome, and the Near East, found at Hertfordshire, England	1102	Bronze steelyard with lead weights from Roman Britain	1178
The Crawford Cup, Roman, found on the border between Syria and Turkey	1105	Red porphyry one talent weight, from Knossos	1179
Petroglyph of camel and horse, from the Sahara Desert at Tassili, Algeria, North Africa	1111	Roman cup or bowl depicting a man carving the number 7 on a nilometer, a device used to measure the water level of the Nile's annual flood	1181
Achaemenid Persian gold model chariot from the region of Takht-i Kuwad, Tadjikistan	1114	Abu Simbel—hymn in praise of the Egyptian pharaoh Ramses II	1185
Horse harness fittings from Iron Age Britain	1116	Clay tablet with Babylonian inscription, found in the treasury of Persepolis, Persia (modern-day Iran)	1186
Chariot with horse and rider, from a sarcophagus at Heraklion	1119	Pillar edict of the emperor Asoka from Uttar Pradesh, India	1188
Frieze in the temple of the Egyptian pharaoh Ramses II, showing a listing of captured cities in Nubia	1127	Painted pebbles from cave of Mas d'Azil, Ariège, France	1188
Clay prism of King Sennacherib	1132	Bilingual milestone marker	1190
Stone figure of the war god Skanda, from eastern India	1139	Pottery inkwell from Roman Britain, inscribed with its owner's name, Iucundus	1191

► language

INTRODUCTION

Most paleontologists believe that modern humans, called *Homo sapiens*, as well as their language originated in Africa. The language spoken by the San (commonly called Bushmen) is believed to be related to the first languages spoken in Africa. In ancient times the San populated most of sub-Saharan Africa, only to be pushed aside by the Bantu-speaking peoples who now populate most of Africa. Their language includes clicking sounds that are unique, and these clicks are thought to have been part of Africa's first languages. Over thousands of years some Africans lost the clicking sound from their speech; these people were the ancestors of the people who spread out from Africa to populate the rest of the world. This is why the clicks of the San are not found elsewhere in the world.

Linguists have struggled hard to trace the development of languages after people migrated out of Africa, but developments during and before the last great ice age, which ended about 9000 B.C.E., may be impossible to fully trace. Complicating the history of language is a side branch of human development, the Neanderthals, who may have been a subgroup of *Homo sapiens* or a different human species that evolved in Europe or the Near East rather than in Africa. Some paleontologists believe the Neanderthals could speak languages, but others think that the shape of the palate and throat of Neanderthals would have limited them to a small number of grunts.

Perhaps the earliest of ancient languages outside Africa were those of the Elamo-Dravidian group. Elamo refers to the Elamites who lived in the Near East and Dravidian refers to the peoples who migrated along the southern coast of Asia

and across islands to Australia. In ancient times their descendants populated such places as the Indus River valley, most of India, and almost all of Southeast Asia, including South Vietnam and Indonesia. Other early language groups are harder to trace. According to technology that traces changes in human genes that have been passed on over time, the descendants of a group of people who settled in central Asia populated all the rest of the world, including the Americas. This could have happened more than 100,000 years ago, though paleontologists disagree vigorously with each other about the date.

Linguists can begin tracing most of the world's languages in about 9000 B.C.E. By then Indo-European had developed somewhere in eastern Europe or central Asia and was spreading west, east, and south. The languages of the ancestors of the Chinese and other east Asians were developing. The peoples who migrated to the Americas brought a root language from central Asia, a language that may have remained among the Ainu ethnic group of Japan, who during the last great ice age probably populated all of eastern Asia north of the Dravidians. Research into Native American languages is complicated by the problem of repeated migrations from the Old World into the Americas, perhaps as many as seven major migrations over thousands of years. Whether the Native American languages have only one root language or more is not yet known.

AFRICA

BY HAIG DER-HOUSSIKIAN

Languages on the African continent are divided into four distinct groupings: Afro-Asiatic, Niger-Congo, Nilo-Saharan,

Sandstone offering table with Meroitic cursive inscription around the edges, from Faras, Sudan (first to second centuries C.E.) (© The Trustees of the British Museum)

and Khoisan. Until several hundred years ago most African languages lacked a written tradition or archaeological support that would indicate time; nevertheless, it has been assumed that they have been present in Africa since ancient times. The exceptions to this assumption are the Semitic languages of the Afro-Asiatic group and Nubian, the only language in the Nilo-Saharan group with an ancient script derived from Coptic. These languages fit into the time frame of antiquity by evidence of their written traditions. The Semitic languages in question are ancient Egyptian (the language of hieroglyphs), Coptic, Amharic, and Tigrinya. Arabic is an uncertain member of this group. It made its presence with written documentation during the seventh and eighth centuries C.E. with the Muslim conquest of North Africa. It is assumed that the language may have been spoken in North Africa prior to Islamization.

Afro-Asiatic covers Somalia, Eritrea, Djibouti, Ethiopia, northern Nigeria, Niger, and the North African countries of Egypt, Libya, Tunisia, Algeria, and Morocco. Tunisia, Algeria, and Morocco are collectively called Maghreb, meaning “west” in Arabic. Some of the major languages in this division include Somali in Somalia, Amharic in Ethiopia, Tigrinya in Ethiopia and Eritrea, Hausa in northern Nigeria, Arabic in North Africa, and Berber in the Maghreb. The largest grouping within Afro-Asiatic is the Semitic subgroup that extends beyond Africa into the Middle East and the Arabian Peninsula where Arabic and Hebrew have remained current since antiquity. Semitic includes ancient Egyptian, of which Coptic is the most recent evolution, now used only in parts of the Coptic Orthodox Church mass. The word *Copt*, “*qubt*” in Arabic, is etymologically the root of the word *Egypt*. Thus, one can appreciate the term *Afro-Asiatic* for the entire group of languages under this rubric.

Niger-Congo covers the countries collectively referred to as sub-Saharan Africa. Interestingly, the next three divisions are geographically embedded within this vast area. The term Niger-Congo was first coined and the subgroupings within it were explicitly established by Joseph H. Greenberg in a series of articles and books from 1949 to 1966. There were others, of course, both before and after Greenberg who contributed to what has emerged as the widely accepted distinct division called Niger-Congo. A look at a map of sub-Saharan Africa will show that the Niger River with its diverse tributaries covers much of sub-Saharan western Africa. Similarly, the Congo River is the most extensive in subequatorial Africa; hence the name Niger-Congo.

The Niger-Congo group is itself divided into six subgroups: West Atlantic, Mande, Gur (also called Voltaic because of the Volta River), Kwa, Benue-Congo, and Adamawa-Ubangi. The most common languages under these subgroups are Wolof, Fula (also known as Fulani, Fulfulde, Pular, and Pulaar), Mandinka (also known as Mandingo, Manding, Maninka, and Madinka) under West Atlantic; Bambara (also known as Bamanankan) under Mande; Moore and Kabyle under Gur; Akan, Ewe, Yoruba, and Ibo (also spelled Igbo) under Kwa; and Efik under Benue-Congo.

The Benue-Congo subgroup is especially significant because it is through this subgroup that sub-Saharan western African and subequatorial African languages have been shown to be typologically and, to a certain extent, lexically related. The subequatorial languages within this subgroup are collectively known as Bantu. The word *Bantu* means “people,” and the root *-ntu* is the most commonly, if not universally, shared lexical item in the Bantu grouping.

Efik in southeastern Nigeria is notable. Historically the languages generally spoken in the adjacent areas between southeastern Nigeria and southwestern Cameroon have been called Bantoid or semi-Bantu because of typological and lexical similarities with both Bantu and sub-Saharan western African languages. The Bantu languages, despite their sub-subgroup status, cover the largest amount of territory and probably have the largest number of speakers. The most commonly recognized languages in the Bantu grouping are Swahili in East Africa and central Africa, Kikuyu (also spelled as Gikuyu) in Kenya, Shona in Zimbabwe and central Mozambique, Zulu and Xhosa in South Africa, and Tswana (also spelled Setswana) in Botswana.

Nilo-Saharan covers southern Sudan, northern Uganda, the western side of Lake Victoria, and the central border areas of Kenya and Tanzania. Commonly known speakers within this division are the Dinka of southern Sudan, the Acholi of northern Uganda, the Luo of Kenya, and the Massai on the border of Kenya and Tanzania. Historically, the most prominent speakers of a Nilo-Saharan language are Nubians in southern Egypt and northern Sudan.

The Khoisan are spread over a large territorial space covering parts of Namibia and South Africa. They are known in popular literature as the “Bushmen.” Statistics on the num-

ber of people who belong to this division are not reliable. A common number often cited is 200,000. Two small pockets of speakers from this speech community are found in central Tanzania. The presence of these two isolated pockets, known as Hata and Sandawe, has led many linguists and anthropologists to hypothesize that much of southern Africa was once populated in much larger numbers by the Khoisan. The same theory claims that migrations southward by speakers of Bantu languages absorbed the vast majority of this population, in other words, migrations Bantuized and otherwise marginalized them geographically.

It is popularly held that there are “thousands” of African languages; however, this widely held impression is exaggerated. Early and diverse missionaries gave the languages they came across different names. Colonial administrators repeated the diverse naming practice. The native speakers of the languages themselves had their own names for their languages. Often the differences were due to legitimate community or clan territorial imperatives. Consider the two examples given earlier: Fula, Fulani, Pular, Pulaar, and Fulfulde, on the one hand, and, on the other, Mandinka, Manding, Mandingo, Madinka, and Maninka. Five names are cited for one and the same language in each case, creating a 5 to 1 ratio. If we were to take a popularly exaggerated figure of 3,000 African languages and apply an admittedly unscientific ratio of 5 to 1, the result would be 600. This may well be at the low end of possible numbers; nevertheless, it is a more rational number.

EGYPT

BY LEO DEPUYDT

The language of ancient Egypt was Egyptian. That language has died out, and modern Egyptians speak Arabic. Along with related languages in western Asia and northern Africa, Egyptian forms the family of Afroasiatic languages. Other branches of this family are Semitic and Berber. Among the members of the Semitic branch are Akkadian, Arabic, and Hebrew, but Egyptian is the only language in its branch.

Egyptian was both written and spoken for over 4,000 years, from about 3000 B.C.E. to about 1500 C.E. That makes Egyptian the oldest known written language. During these four millennia Egyptian changed greatly, just as any language does. The five stages usually distinguished in Egyptian, along with approximate dates for the time periods from which written sources exist, are Old Egyptian (2500–2100 B.C.E.), Middle Egyptian (2100–1500 B.C.E.), Late Egyptian (1500–1000 B.C.E.), Demotic (650 B.C.E.–500 C.E.), and Coptic (300–1000 C.E.). The word *Coptic* (*CCpt*) is another form of the word *Egyptian* (*gCpt*). Literacy was probably always the privilege of a small group of people. Only about 1 percent (but probably less) of the Egyptian population had some degree of literacy at any given time in Egyptian history.

Egyptian evolved by countless infinitesimally small leaps. At certain intervals the language would be fixed in writ-

ing while the spoken language gradually changed. As time passed, the gap between the written language and the ever-evolving spoken language grew. After some centuries the gap was so large that the current written language was abandoned and the language spoken at the time was committed to writing. This process repeated itself more than once. In principle, there are no “stages” of Egyptian. The stages identified by historians amount to a sort of deception caused by the surviving evidence: written testimonies providing frozen snapshots of the evolving spoken language at certain moments in time. In reality, language change is a continuous process.

One typically begins a study of Egyptian by focusing on one stage. The stage traditionally chosen is Middle Egyptian, which is also called Classical Egyptian, for two main reasons. First, it is the first stage of Egyptian in which great works of literature were written. Second, when Middle Egyptian ceased being spoken, it remained in use as a literary and liturgical language by scribes in temples and schools. As a dead stage of the language, Middle Egyptian coexisted with later spoken stages. This written or artificial Middle Egyptian differs from the original spoken Middle Egyptian in that the later spoken stages influenced the written form, and Egyptians in later years lacked sufficient knowledge of Middle Egyptian to keep the written form static.

The three main types of hieroglyphic writing are hieroglyphic proper, hieratic, and Demotic. Just as handwritten English differs from printed English, hieroglyphs written with a pen on papyrus differ from those carved or painted on tomb walls. Carved or painted hieroglyphs are hieroglyphic proper. *Hieroglyph* is, in fact, Greek for “holy (*hiero*) carved character (*glyph*).” Hieroglyphs written in pen are called hieratic. In hieratic, the pictorial character of many hieroglyphs has become unrecognizable. *Hieratic* is Greek for “(script) of the priests.” Saint Clement of Alexandria (ca. 150–ca. 211 C.E.) gave it this name around 200 C.E. because hieratic was used at the time for religious purposes only. Demotic, which evolved from hieratic, is evident from about 650 B.C.E. onward. *Demotic* is Greek for “(script) of the people (*demos*).” Demotic evolved from hieratic. This form is even more cursive than hieratic and is used to write the fourth stage of the language, which is also called Demotic. Demotic is therefore both a script and a stage of the language.

Hieroglyphic proper and hieratic script remained in use alongside the Demotic script, mainly for ceremonial and religious purposes. In sum, Old and Middle Egyptian were written in hieroglyphic proper and in hieratic. Late Egyptian was written mainly in hieratic. The Demotic language was written almost exclusively in the Demotic script. Finally, modern Egyptologists write hieroglyphic proper with a pen. That is something Egyptian scribes rarely did, since hieroglyphic proper was carved with a chisel or painted with a brush. To write hieratic, however, scribes typically used pens.

The last specimens of hieroglyphic writing date to about 450 C.E. The hieroglyphic tradition had been in strong decline since about 150 C.E. Between 200 and 300 C.E. the Greek

alphabet was adopted to write Coptic, the final stage of Egyptian. The last person who could read hieroglyphic writing probably lived in the sixth or seventh century C.E. Long after, in 1822, the French Egyptologist Jean-François Champollion (1790–1832) began to decipher the hieroglyphic script.

The rise of Christianity had been the principal cause of the demise of the hieroglyphic tradition. In the fourth century C.E. Christianity became the official religion of Egypt. Hieroglyphics remained exclusively linked with the native pagan religion; there is no such thing as Christian hieroglyphic writings. The end of hieroglyphic writing, therefore, coincided with the end of the worship of the ancient Egyptian gods. The end came soon after 550 C.E., a century or so after the latest dated hieroglyphic inscription and about a century before the Muslim conquest of Egypt. Around 550 C.E. the Byzantine emperor Justinian (r. 527–565) ordered the last native Egyptian religious compound at Philae in the deep south of Egypt to be closed down.

After hieroglyphic writing died out, the Egyptian language lived on in its latest stage, Coptic. Around 640 C.E. Islam came to Egypt. From then on, the Coptic language was gradually replaced by Arabic as the spoken language of Egypt. Probably sometime between 1000 and 1500 C.E. Coptic ceased to be spoken. The knowledge of the Coptic language and of Coptic writing, however, did not vanish. Coptic manuscripts continued to be read, copied, and understood for liturgical purposes. Thus, while the knowledge of hieroglyphic writing became extinct, the language itself never did. Egyptian lived on in an evolved stage, as the liturgical Coptic used in the Coptic Christian church. The term *Coptic* therefore has two meanings. It denotes the last stage of the Egyptian language, and it is also a synonym for Christian Egyptian. Today, Christian Egyptians, or Copts, are a minority in Egypt.

If not for the surviving liturgical Coptic, ancient Egyptian might have remained undeciphered. It had long been assumed that hieroglyphic Egyptian was a form of early Coptic, which gave linguists some sense of the language they were trying to decipher from the hieroglyphic script.

THE MIDDLE EAST

BY JUSTIN CORFIELD

Many languages were spoken in the Near East during ancient times. The earliest to have survived in transcribed form is Sumerian. It is known only through inscribed texts, mainly on clay tablets, that show a simple pictograph system known as Archaic Sumerian. The oldest tablets date to about 3300 B.C.E. and were found at the city of Uruk. On them a pictograph represents an object or idea. Around 3000 B.C.E. the pictographs changed to become a more coherent script in which the inscription came to represent a sound. This allowed for a greater variety of new words and ideas to be expressed.

The language of Sumerian rapidly seems to have developed into Akkadian, a Semitic language to which Hebrew and Arabic both are related. Akkadian first arose in south-

ern Mesopotamia and gradually started supplanting Sumerian. Surviving texts in Akkadian date to about 2400 B.C.E.; the language, an inflected one, in which words take different forms to reflect grammatical information, remained in use until about 75 C.E. From 1800 until 1200 B.C.E. Akkadian was clearly the major written language in western Asia for trade and diplomacy. Subsequently, it was overtaken by two variants or dialects, Babylonian and Assyrian. Babylonian, starting in southern Mesopotamia, by the ninth century B.C.E. quickly became the lingua franca, or common language, of the region. It varied from Akkadian, but Akkadian was still used by the Babylonians. At Susa, King Hammurabi (d. ca. 1750 B.C.E.) erected a stela (a monumental stone slab) on which he wrote his laws for the whole of the Babylonian Empire. The inscription was in Akkadian, with many Sumerian terms incorporated into it. Akkadian would have gained some loanwords from Hebrew when the Jews were held in exile in Babylon from 587 to 538 B.C.E. The Assyrian dialect arose in northern Mesopotamia and is often called Assyrian Neo-Aramaic.

Gradually the cuneiform script, a wedge-shaped form of writing used by the Babylonians and the Assyrians, came to be the basis of other languages of the ancient Near East, such as Eblaite, Elamite, Hittite, and Hurrian. This common descent allowed Akkadian cuneiform, in all its variations, to remain the major script used for administration and also for diplomatic correspondence and regional trade until the emergence of the use of Greek in the region in the late seventh century B.C.E.

The Achaemenid Persian Empire (538–331 B.C.E.) was polyglot, speaking different languages. Three languages were used for the administration of the empire, and surviving stelae show inscriptions in Old Persian, Elamite, and Akkadian. Persian represented the major language of the government, with a new writing system used for official proclamations. It was always the first language for any official inscriptions, followed by Elamite, showing the Persian support for the former “underclass” in Assyria. The oldest surviving inscriptions in Elamite come from 2200 B.C.E. and were found in modern-day Khūzestān and Fārs in Iran. Elamite rulers exerted significant control over much of Mesopotamia until the Babylonians and Assyrians insisted on the sole use of their own languages on stelae. By 600 B.C.E. Elamite had developed very differently from Babylonian and Assyrian. The language of the Elamites gradually fell into disuse during Assyrian rule but was revived by the Persians to harness goodwill from the surviving Elamites as well as to demonstrate that the empire extended far beyond the borders of modern-day Persia. Similarly, the Persians also used Akkadian, though only on official Achaemenian inscriptions in the empire; Akkadian was used only rarely by ordinary people outside Mesopotamia.

The Phoenician alphabet, with 22 letters, was introduced in about the 11th century B.C.E., with the oldest inscription being the epitaph at the tomb of King Ahiiram at Byblos (Jubayl in modern-day Lebanon). The 22-letter alphabet gradually

came to be more important than the cuneiform script. With the rise of Carthage in the sixth century B.C.E. the Phoenician language developed into what is known as Punic, the official language of Carthage. A number of Greek, Latin, and Hebrew words have Phoenician origins. In turn, the Phoenician alphabet came to be adapted by various groups to form the basis of the alphabets of Hebrew, Aramaic, and then Greek. The influence of these languages and their alphabets gradually eroded the use of cuneiform, which dwindled to recording religious ceremonies and some scientific discoveries. Cuneiform continued to be used in southern Mesopotamia until the second century C.E.

Aramaic is believed to have been spoken from about 2000 B.C.E. and was probably a written language from 950 B.C.E. It was used throughout the Persian Empire for business and in provincial administration. Only one royal inscription in Aramaic survives, on the side of a cliff at Bisitūn, in Media, showing that its use was accepted by the Persian court. It continued to be spoken in Palestine and was the language used by Jesus. At the time of Christ, Aramaic was developing into Western Aramaic and Eastern Aramaic, the latter being influenced by the related languages of Syriac, Mandaean, and Eastern Neo-Assyrian. Aramaic was also the basis of the Nabataean alphabet, which was used in the kingdom of Petra. It remained widely spoken until 650 C.E. when it was supplanted by Arabic, and it is still spoken in the town of Maaloula in modern-day Syria. Another language in that region was Moabite, closely related to Hebrew, and using an early Semitic alphabet.

Two other languages that came to be spoken in the Near East were Greek and Latin. Greek was widely spoken and indeed was effectively the lingua franca of the Near East from well before the time of Alexander the Great (r. 336–323 B.C.E.). It was the principal language that grew from the spread of Greek influence, or Hellenization, across the Near East. Over

many centuries Greek merchants had settled in ports along the coast of Anatolia and the Eastern Mediterranean. There was also a large Greek presence in the Achaemenid Persian Empire, with many Greeks serving in the Persian army.

During the brief rule of Alexander the Great, Greek became the language of administration of his empire, which incorporated the Persian Empire, and continued as such in many of the successor states. Certainly during the wars of the Diadochi (323–281 B.C.E.), the rival successors to Alexander, it is clear that Greek was extensively spoken, and the Seleucid Empire (311–ca. 140 B.C.E.), the Hellenistic successor state to Alexander's empire, also used Greek for administrative purposes, with inscriptions surviving on votive tablets of the period. Greek was also used as far east as the Kushan Empire, which covered parts of modern-day Afghanistan, northern India, Pakistan, and Tajikistan during the first through the third centuries of the Common Era. Although Latin was the language of government of the Roman Empire that covered much of the Near East, it never gained the acceptance accorded to Greek; for this reason on some official notices, such as the *titulus crucis* (the headboard above the cross upon which a person was crucified), it did not appear first. For example, the inscription on the headboard of Jesus was in Aramaic, then Latin, and Greek.

ASIA AND THE PACIFIC

BY KELLEY L. ROSS

Southern India has a language family, the Dravidian languages, that probably included the original languages on the subcontinent. One Dravidian outlier (a language that is related but geographically detached), Brahui, survives in the north of India. Linguists speculate that the Dravidian languages originally were dispersed throughout India and that the language of the ancient Indus Valley civilization (ca. 3000–1600 B.C.E.) was a Dravidian language. There is no direct evidence of this, as the Indus Valley script remains undeciphered. There are indeed no bilingual texts and most remaining inscriptions, on seals, are no more than five characters long. This is a poverty of evidence compared with what was used for the decipherment of other ancient scripts, such as Egyptian hieroglyphics or Mesopotamian cuneiform.

The other languages of the north of India are descendants of Vedic Sanskrit, the language of the ancient sacred scriptures of Hinduism, the Vedas, which date to about 1500 B.C.E. These scriptures could be committed to writing starting around 800 B.C.E., when an alphabet writing system was borrowed from the Middle East. A later script, the Karoshthi, still reflects components of an Aramaic original. Out of Vedic Sanskrit were derived Classical Sanskrit and a group of spoken languages, the Prakrits. Classical Sanskrit (from a word meaning “prepared, purified, corrected”) was in part created by grammarians trying to fix the Vedic language and preserve it from phonetic and grammatical changes that were becoming evident in the Prakrits. Sanskrit then remained the

Clay tablet with Elamite inscription found in the treasury of the palace at Persepolis, Persia (modern-day Iran) (Courtesy of the Oriental Institute of the University of Chicago)

principal language of religion, literature, and philosophy in India for many centuries.

Possibly the most important Prakrit language was Pali, the language of the earliest version of the Buddhist scriptures. These scriptures were first preserved in the region of modern-day Sri Lanka, where Buddhism was established by missionaries of the emperor Ashoka (r. ca. 269–232 B.C.E.). Other Prakrits, like Magadhi, are found in subsequent ancient Indian history, down to the dynasty of the Guptas (ca. 240–550 C.E.). From the early Brahmi writing system Sanskrit grammarians created the Devanagari syllabary (a list of characters representing syllables), which thenceforth was used to write Sanskrit and is still used to write modern languages such as Hindi. It is the basis of the development of many later writing systems in India and Southeast Asia.

Because of the similarities of Sanskrit to classical Greek and Latin, in 1786 the British linguist Sir William Jones proposed that the three languages had arisen from a common source. These languages are now viewed as members of the Indo-European family of languages. Jones's proposal was the beginning of what in the 19th century was called philology and is now historical linguistics, the study of the history and development of languages.

The Indo-European languages of India were closely related to ancient Persian and Avestan in Iran, and the group of Indian and Iranian languages is called "Indo-Aryan." Iranian languages also extended far into central Asia by way of the highway of grassland that stretches from Hungary to Mongolia, the Steppes. Indeed, both Iranian and Indo-Aryan languages appear to have arisen in the Steppes, perhaps earlier than 2000 B.C.E. Recent finds of well-preserved mummies in central Asia may belong to these peoples. In the Ukraine at the western end of the Steppes the Scythians spoke an Iranian language, though we know about it only from words preserved by Greek writers. At the eastern end of the Steppes lived an earlier Indo-European speaking group, called the Yuezhi by the Chinese. This was apparently the group that later left Buddhist texts in Xinjiang, whose language is now called "Tocharian." This group appears to be the one known as the Kushans, who invaded India and ruled in the north of the country from about 20 B.C.E. to the fourth century C.E.

In central Asia we find speakers of Altaic languages, but the earliest evidence of an Altaic language is Turkish from the fifth or sixth centuries C.E. Prior to that we have the conflict of the Chinese of the former Han Dynasty (202 B.C.E.–220 C.E.) with a people they called the Xiongnu. There is considerable uncertainty about the language or languages of the Xiongnu. There is at least the presumption that they were principally or entirely Altaic speakers, along with some proto-Turkish or proto-Mongolian language, but this is largely speculative. Equally speculative is whether the Xiongnu were actually the Huns who later turned up in India and Europe. Still, there is little evidence even about the language of the Huns in Europe, where their most famous leader, Attila ("Little Father"), carried a name from Gothic, a Germanic language. There is also

Jade disc of ancient times, later inscribed with a poem by the Qianlong emperor, from China (ca. 1500–1050 B.C.E.) © The Trustees of the British Museum

ground for skepticism about the identification of the Xiongnu with the Huns, since many centuries elapsed between Chinese accounts of the former and accounts from Rome or India about the latter. Either way, we are faced mostly with a mystery about these ancient peoples from central Asia.

Some linguists question whether the Altaic languages even constitute a proper family. Others not only accept the kinship of the Altaic languages but also include Korean and Japanese in the family. Otherwise, it is not obvious whether Korean and Japanese are related to any other language or even to each other. In ancient history there is no evidence of the Japanese language. The Korean states of Silla, Paekche, and Koguryo began under the cultural influence of the Chinese in the period of the Han Dynasty, but in the early days Koreans mainly wrote Chinese rather than their own language, and the use of Chinese characters tended to conceal the nature of the Korean language even when it was being written. The languages of Korea and Vietnam in the ancient period (and later Japanese) were strongly influenced by Chinese, borrowing the system of Chinese characters and much of the vocabulary that went with the characters. Phonetic systems to write those languages, as with the hangul system for Korean, would not come until long after the ancient period.

It is generally but not universally agreed that Chinese belongs to the Sino-Tibetan family of languages. The Tibeto-Burman subgroup is relatively distinct from the Sinitic, or Chinese, subgroup. Although there appears to be much common vocabulary across the family, there are otherwise few affinities that linguists normally like to see uniting language families. In this family, evidence is found only of Chinese in ancient times. We know it mainly as the written language, from the Shang Dynasty (1500–1045 B.C.E.) forward. Chinese literature (history, philosophy, and so on) reached its full flowering during the Spring and Autumn Period (722–481 B.C.E.).

Chinese characters provide only indirect evidence of pronunciation, and even today the characters in the ancient and classical language are read with the phonetic values of the modern languages. Chinese characters have been described as originally “pictographic,” writing characterized by pictorial signs and symbols of objects; as “ideographic,” writing that depicts concepts or ideas but not sounds; or as “logographic,” writing that stands for words of the spoken language. Although the latter description is now preferred in linguistics, there is no doubt that most characters began as representative depictions, and sometimes characters take on a conceptual life of their own, independent of the spoken language. Thus, all the descriptions of the characters are appropriate in varying degrees. Ancient Chinese as a spoken language, however, is a matter of reconstruction, inference, and speculation, calling on the full skills of modern linguistic science, with the help of some ancient testimony by the Chinese themselves. The results involve great measures of uncertainty and are the subject of dispute. Thus the study of the ancient language can focus with greatest certainty on the grammar of the language and on the development of the system of writing.

In Southeast Asia there was only one literate culture in ancient times, and that was in Vietnam. Vietnamese is a member of the Austroasiatic family of languages, which is divided into the Mon-Khmer branch, whose principal representative is Cambodian, and the Vietnamese languages. Evidence of Mon-Khmer languages dates to the Middle Ages. Written Vietnamese, however, originally was expressed by writing Chinese (as was Korean) or by using Chinese characters to represent the Vietnamese language. The word *Vietnam* itself is simply the Vietnamese pronunciation of the name that would be *Yuenan* in modern Mandarin or *Yütnam* in modern Cantonese. The earliest Vietnamese state, Annam, was contemporaneous with the Chinese Qin Dynasty (221–207 B.C.E.), but by 111 B.C.E. it had been absorbed by Han China. Annam was not independent again until 544 C.E. A phonetic system, as in Korea or Japan, was never developed to write Vietnamese. The modern language is written in a form of the Latin alphabet.

There is no evidence from ancient times of the other major language family of Southeast Asia, the Thai-Lao, Kadai, or Daic languages. This family seems to have originated in southwestern China, where some members, such as Zhuang and Dai, still exist, and then moved down through Burma (where today the Shan people live) into Southeast Asia. But this dispersal did not happen until as late as the 13th century C.E.

Before European exploration the most extensively distributed language family in the world was the Austronesian family, which spread southeast from Asia and across the Pacific. None of the languages of this family was a written language in ancient times, and none would ever be written until writing systems from India, Islam, or the West were introduced in the Middle Ages or later.

EUROPE

BY AMY HACKNEY BLACKWELL

Almost all ancient European languages were part of the Indo-European language family that includes English, German and Germanic languages, Celtic languages, Greek, Latin and the Romance languages, Armenian, Iranian, and the Slavic tongues. Scholars believe that these languages all evolved from a single ancient tongue called Proto-Indo-European, which originated between 6500 and 4500 B.C.E., either in the region between the Black Sea and the Caspian Sea or in Anatolia. Proto-Indo-European gradually traveled east through India and west through Europe and evolved into distinct tongues.

The people who lived in ancient Europe north and west of Greece and Rome spoke languages from two Indo-European branches, Celtic and Germanic. People in eastern Europe spoke Thracian languages. Scholars do not know much about the languages that these ancient people actually spoke. Most ancient Europeans could not write, and so they did not record their own history or write grammars or dictionaries of their own languages. Written evidence of ancient European tongues comes from a small number of inscriptions that survive on stone, ceramics, and coins. Modern linguists have reconstructed parts of ancient European languages by comparing words that appear in many languages and by applying linguistic rules to more recent forms of a language to restore the older forms of the same language.

The Celtic languages evolved from a common Indo-European ancestor called Proto-Celtic, or Common Celtic. Proto-Celtic was closely related to Italic, which evolved into Latin. Proto-Celtic emerged in Europe around 1000 B.C.E. and seems to have been centered in central Europe in the area of the Alps. By 400 B.C.E. most people in northwest Europe and the British Isles spoke Celtic languages. As Proto-Celtic spread across Europe, it split into several subfamilies, including Gaulish, Brythonic, Goidelic, and Celtiberian. Gaulish, named by scholars for the people of Roman Gaul, was spoken from France and Belgium to Italy and as far east as Turkey. Historians have reconstructed Gaulish from inscriptions on stone and pots found throughout Roman Gaul. The earliest inscriptions date to the sixth century B.C.E. Gaulish inscription writers used both Italic and Greek letters. People were still speaking Gaulish in the area that is now France as late as the 500s C.E. Gaulish was related to the languages called Lepontic and Galatian. Speakers of Galatian settled in Asia Minor around the third century B.C.E. but gradually stopped using their Celtic language in favor of Greek. Lepontic, which was spoken in what is modern-day northern Italy, seems to have died out around 400 B.C.E.

Brythonic languages, which include Breton, Welsh, Cornish, and possibly Pictish, were spoken in Brittany, Wales, and Cornwall, and they developed in Britain around the sixth and fifth centuries B.C.E. Brythonic languages adopted numerous Latin words during the Roman occupation of Britain in the

first four centuries C.E. The Brythonic language known as Breton arrived in Brittany (France) around the fifth century C.E. as British people moved to the Continent fleeing Germanic warriors who were invading Britain. Scholars believe that the residents of Scotland spoke Brythonic languages before Goidelic-speaking Irish people displaced them in the first or second century B.C.E. and brought Goidelic languages to Scotland.

People in Ireland, Scotland, and the Isle of Man spoke Goidelic languages, which include the Gaelic tongues of Irish, Scottish, and Manx. The name *Goidelic* comes from the Irish Celts' name for themselves, *Goídil*. Goidelic is not closely related to Brythonic, but it seems to be linked linguistically to the Celtic languages of Spain; this has led scholars to believe that the ancestors of the Irish Celts traveled from Spain, probably arriving in Ireland around 350 B.C.E. These people moved from Ireland north into Scotland and the Isle of Man in the early centuries C.E., bringing Goidelic languages with them. The Romans called the Irish people Scotti and named the territory north of Britain Scotia after its Irish settlers. Scotia eventually became Scotland.

People on the Iberian Peninsula, modern-day Spain and Portugal, spoke Celtiberian. Historians have found little information to help them reconstruct Celtiberian, but they know that locals were speaking it during the Roman Republic and Roman Empire. A few Celtiberian inscriptions survive; Celtiberian writers used a unique script that appears to have been a hybrid of Greek and Phoenician writing systems.

Proto-Germanic is the ancestor of the Germanic languages, which include German, English, and the Scandinavian languages. People probably began speaking Proto-Germanic around 500 B.C.E. in northern Germany and southern Scandinavia. The earliest firm evidence of Germanic languages comes from a single inscription on a helmet dated to the second century B.C.E., but besides that almost nothing is known about Germanic languages before the first century C.E. During the first five centuries C.E. Germanic tongues split into three groups: North, East, and West Germanic. Between 300 and 700 C.E. Germanic peoples migrated widely throughout Europe, spreading Germanic dialects that were probably mutually unintelligible. The earliest well-known Germanic language was Gothic, the language of the Visigoths. The best source of information on Gothic grammar and syntax is a fourth century C.E. Gothic translation of the Bible.

People north of Greece in the territory that includes modern-day Bulgaria, Serbia, Romania, Ukraine, Hungary, and Slovakia spoke Thracian languages. What little is known about Thracian languages comes from inscriptions written in Greek characters and reconstruction from modern Bulgarian and Romanian. Greeks and Romans colonized most of this territory, and the inhabitants gradually adopted Greek and Latin as their primary languages. Thracian languages had completely disappeared by about 400 C.E. Greek and Latin were the most important languages of the Classical Period (480–323 B.C.E.), and many Europeans learned one or both of

RECONSTRUCTING ANCIENT LANGUAGES

In the late 1700s scholars noticed that the languages they knew shared certain similarities. Take the word for *father*: *father* is *pater* in Greek, *pater* in Latin, *fadar* in Gothic (an early form of German), and *pita* in Sanskrit (the language of ancient India). The word for man was *wir* in Latin, *wair* in Gothic, *were* in Old English, and *virah* in Sanskrit. Clever scholars deduced that these languages must have all come from a common root. They called this root a *protolanguage* and envisioned languages taking the shape of a family tree with a protolanguage splitting into sublanguages that could become protolanguages themselves; for example, Proto-Indo-European could split into Proto-Celtic and Proto-Germanic, each of which split into several new languages.

This discovery led to the invention of a new field of study called linguistics. Linguists look for rules that show how languages evolve. They find the oldest examples they can of known languages and trace the language forward in time, analyzing the way words and grammar change. Languages change in predictable ways. For example, the *d* sound often turns into a *t* sound. A short *e* can become a short *a*. Linguists apply these rules to available information to reconstruct old languages. Jacob Grimm, better known (along with his brother, Wilhelm) for his *Grimm's Fairy Tales*, was one of the first linguists to reconstruct a language; in the early 1800s he compiled a comprehensive study of the development of German dialects from a common Germanic source.

Linguistic information allows historians to trace the paths of different peoples who moved around Europe in ancient times. Scholars of Celtic believe that Gaulish and Brythonic are more closely related to each other than are Goidelic and Celtiberian because of a sound difference. They classify Gaulish and Brythonic as P-Celtic and Goidelic and Celtiberian as Q-Celtic because sounds that are pronounced *p* in Gaulish and Brythonic languages are pronounced *q* in Goidelic and Celtiberian. This is why many scholars believe that the Celts who colonized Ireland came from Spain, not nearby Britain.

them. During the Roman Empire the use of Latin in particular became widespread throughout Gaul, Spain, and Britain. Greek was more common in eastern Europe.

A few European languages did not come from the Indo-European family. Before Celts arrived in Spain, people on the Mediterranean coast spoke non-Indo-European languages

known as Iberian; these languages died out by the first century C.E. and were replaced by Latin. People in the Pyrenees spoke a language that became the ancestor of Basque; these people were isolated enough to keep their language into modern times. The Finno-Ugric languages, ancestors of modern Finnish and Hungarian, came from western Asia and may have arrived in the area between the Baltic Sea and the Ural Mountains as early as 4000 B.C.E.

GREECE

BY JEFFREY S. CARNES

Ancient Greek is one of the branches of the Indo-European language family; that is, it is one of the several dozen descendants of Proto-Indo-European, a language spoken at least 4,500 years ago in Central Asia and whose “daughter languages” (descendants) include English and almost all modern European languages. Proto-Indo-European left no written records, but its existence and much information about its vocabulary and structure have been reconstructed by historical linguists based on similarities among its daughter languages, including obvious similarities in vocabulary. We find Greek *mētēr* cognate with, or similar to, Latin *mater*, Sanskrit *mat*, Russian *mat’*, German *Mutter*, and English *mother*. Related Indo-European languages form subgroups (Germanic, Italic, and Balto-Slavic); Greek is the only surviving member of the subgroup to which it may have belonged. (Although Greek has obvious structural similarities to Latin, and there was much borrowing of vocabulary between the two, the idea that the languages belonged to the same Indo-European subgroup has been discredited.)

Greek is a heavily inflected language; that is, one in which the relation between words in a sentence is conveyed by changes in the form of the word, typically by the addition of suffixes. Greek nouns and adjectives can be inflected to form five different cases (nominative, accusative, genitive, dative, and vocative), which have different functions in syntax, or the grammatical arrangement of words in a sentence. The nominative, for instance, is used for the subject of a sentence and the accusative for the direct object of a finite verb. A practical consequence of this is that Greek word order is freer than that in English: *anthrōpos tima theon* (“a man honors a god”) could equally well be written with its three elements (subject, object, and verb) in any other order (*theon tima anthrōpos* or *tima theon anthrōpos*) with almost no difference in meaning. In English, where word order determines meaning, this would be impossible. The Greek case system is inherited from Indo-European and shows the tendency of languages to simplify case systems; thus, older cases like the ablative (still found in Latin) have been lost in Greek, their functions taken over by the genitive (which expresses possession) and the dative (expressive of the indirect object of a verb). The vocative indicates the speaker’s direct address to another person.

Greek nouns and adjectives exhibited gender and number. Number included not only the expected singular and plural but also a form called the dual, sometimes used for beings or items in pairs, as in a team of oxen or a pair of shoes. Grammatical gender, another Indo-European inheritance whose original function is obscure, divides nouns into three classes: masculine, feminine, and neuter. Nouns representing male humans and animals typically belonged to the

Linear A tablets, from Agia Triada, Heraklion (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

“masculine” group and females to the “feminine.” Inanimate objects, however, could belong to any category, and the fact that a table is feminine or a foot masculine ultimately says little about the Greek (or Indo-European) worldview.

Verbs in Greek were also heavily inflected, with suffixes (and occasionally prefixes) used to express differences in person, number, mood, voice, and tense. (Most of these are expressed in English with auxiliary verbs: I free; I will free; I will be freed, in contrast to the Greek equivalents *luō*, *lusō*, *luthēsomai*.) Moods include not only the indicative (for statements of fact) and subjunctive (for possibilities) but also the optative (similar in use to the subjunctive, expressing a doubt or wish, and eventually abandoned in favor of it). The Greek voices were active, passive, and middle; this last category was used to emphasize the subject’s participation or involvement in the action described. Tenses included not only the time of an action but also its aspect—in other words, its status as complete or incomplete. Aoristic aspect viewed an action as happening once (“Socrates spoke in the agora” on one particular occasion); imperfective aspect showed incomplete or repeated action (“Socrates was speaking/kept speaking/used to speak in the agora”). A typical Greek verb had three different stems (to be used with different tenses) and might have well over three hundred distinct forms.

The large number of verb forms made it easy for the language to create a complex syntax: For example, conditional sentences used different moods to express differing degrees of probability. A speaker wishing to say “If it snows tomorrow” would use the subjunctive to indicate there was some distinct possibility this might happen; the optative would indicate that it was far less likely (from the speaker’s perspective). Syntactic constructions tended to be simpler in poetry (especially in the Homeric poems, which were composed orally), but historical, oratorical, and philosophical prose works display a great variety of subordinate clauses and long, periodic sentences.

The pronunciation of Greek is understood surprisingly well for an ancient language, thanks to the data provided by historical linguistics. Most Greek dialects had five short vowels and seven long, plus a small number of diphthongs (a double vowel sound forming one sound forming one syllable); most of these have at least rough equivalents in English. Among consonants the most surprising feature is the treatment of aspirated consonants (pronounced while breathing out) such as *phi* and *theta*. While English derivatives of Greek words containing these letters (for example, philosophy and theater) treat them as fricatives (the consonant sound in speech made by forcing breath through a narrow opening), they were in fact voiced stops—that is, the equivalent of the initial sounds of “top” and “pot.” The Greek letters *pi* and *tau* represented an unvoiced version, closer to the final sounds of “top” and “pot,” a distinction that is extremely difficult for native speakers of English to hear. The least understood feature of Greek pronunciation is pitch accent: the vast majority of words bore an accent that indicated not stress but instead a change in pitch, rising (acute), falling (grave), or rising-falling

(circumflex). By sometime in late antiquity the pitch accent was abandoned in favor of a stress accent (which continues in Greek to this day), and scholars do not agree on precisely what Greek pitch accent sounded like. Modern tonal languages such as Chinese are thought to provide an imperfect analogy for the sound of Greek.

Our earliest historical records show that Greek was already widespread throughout the eastern Mediterranean: It was the language of the Greek mainland, the coastal areas of Asia Minor, and the islands that lay between. In addition, the language spread along with the great colonization movements of the Archaic Period—mostly to southern Italy and Sicily but also to North Africa, southern France, and the shores of the Black Sea. Different cities and regions had distinct dialects, which spread along with the settlers (colonies spoke the dialect of their mother city); despite differences in spelling and pronunciation, all Greek dialects seem to have been mutually intelligible. The Greeks themselves roughly classified their numerous local dialects into two main groups, Doric and Ionic, a classification that came to possess cultural and political significance. This was particularly true in the fifth century B.C.E. when the Athenians, who spoke Attic (a variant of Ionic), were opposed to the Spartans and their allies, who spoke Doric. In literature dialects reflected not only the author’s place of origin but also the demands of the particular genre: The epics of Homer were composed in a mixed dialect with Doric features; the comedies of Aristophanes use a particularly colloquial version of Attic; and the choral odes of Athenian tragedy were written in a semi-Doric style. Eventually a form of Attic became the dominant dialect of the Greek-speaking world. Called the koine, or common dialect, it became the language of the Eastern Roman Empire, and it is from koine that Byzantine and Modern Greek are descended.

ROME

BY JUSTIN CORFIELD

The Latin language is officially classified by linguists as being one of the Italic group of Indo-European languages. It was originally spoken by small numbers of people who lived on the Latium plain near the Tiber River in central Italy. It was related to Greek, Germanic, Celtic, and many other languages in Europe at the time. As the language of the city of Rome, its importance resulted from the rise of Rome and its domination first of Italy and then of the Mediterranean region, central and southern Europe, and much of the Near East.

At the foundation of Rome, according to tradition in 753 B.C.E., several related dialects were used in central Italy. Umbrian, Samnite (or Oscan), Volscian, and Marsian, for which inscriptions survive, all appear to differ from Latin slightly in inflections and pronominal roots, that is, the roots of pronouns. There are also many loan words from Etruscan, mainly technical and religious terms, as well as a large number of personal names, such as Sulla and Casca.

The oldest surviving example of Latin is a brief inscription of four words on a cloak pin in Greek characters. This shows that the full vowels were used in unstressed syllables, a system that changed gradually as the Latin language developed. The other early surviving Latin scripts show a stress accent on the first syllable of any word, whereas by the late republic the accent fell on the second or second-from-last syllable. Indeed, one of the striking features of Latin is the importance placed on accentuation.

As the Romans expanded their rule, with Latin as the language of administration, the use of the language became common throughout the empire. Roman citizens and many others became fluent in Latin. Through the Roman system of education many Roman boys and also people all over the empire learned Latin grammar. Cato the Censor (234–149 B.C.E.) told everybody that he had taught his son to read and write, and the Roman scholar Pliny (23–79 C.E.) also believed that children should be taught by their parents. Many tutors, sometimes slaves, were employed to teach children Latin, and secondary schools taught boys both grammar and rhetoric (the study of methods of speaking and writing effectively and persuasively). When the Edict of Caracalla (212 C.E.) extended Roman citizenship to all freeborn men throughout the Roman Empire, the desire to learn Latin increased further.

Although they were certainly not the first texts, the earliest surviving extensive works in Latin were the comedies of Titus Maccius Plautus (ca. 254–184 B.C.E.) and Terence (ca. 185–159 B.C.E.). The latter was a slave born in Carthage and freed by his Roman master, a senator. There was also the poetry of Quintus Ennius (239–169 B.C.E.) and Gaius Lucilius (ca. 180–ca. 102 B.C.E.). Literature from the middle of the first century B.C.E. is dominated by the works of Marcus Tullius Cicero (106–43 B.C.E.), and this period is often known as the Age of Cicero. It was also the era of Lucretius (ca. 100–ca. 55 B.C.E.), Gaius Sallustius Crispus (86–34 B.C.E.), and the military victories of Julius Caesar (100–44 B.C.E.). The works of the latter, *The Conquest of Gaul* and *The Civil War*, are the oldest surviving accounts of a military campaign by one of its leaders. Caesar himself established the first state library in Rome, which was completed by Asinius Pollio (76 B.C.E.–4 C.E.). This had works in Greek as well as Latin, but eventually works in Latin began to overtake those in Greek. Gradually many cities throughout the Roman Empire established their own libraries, a process that coincided with the rise in *bibliopola*e (publishers). These used scribes (professional copyists) to produce copies of books and made many works available throughout the empire, indicating that there was an extensive market for books.

During the Augustan Age (27 B.C.E.–14 C.E.) writers such as Horace (65–8 B.C.E.), Virgil (70–19 B.C.E.), Ovid (43 B.C.E.–17 C.E.), and Livy (59 B.C.E.–17 C.E.) wrote what are regarded as some of the major Latin texts. Virgil's *Aeneid*, describing the arrival in Italy of Aeneas, a Trojan prince, was one of the longest Latin epics of its period. Livy's massive *Ab urbe condita libri* (Books from the Foundation of the City) comprised

142 books, but only 35 survive. The detail in the surviving books demonstrates an extensive literary tradition wherein Livy was able to base his work on previous historians. Horace, Virgil, Ovid, and Livy were followed by Seneca the Elder (ca. 55 B.C.E.–ca. 39 C.E.), Seneca the Younger (ca. 4 B.C.E.–65 C.E.), Tacitus (ca. 56–ca. 120 C.E.), and Petronius (d. 66 C.E.), the first writer of fiction. Suetonius (ca. 69–ca. 140 C.E.) and Juvenal (ca. 55–ca. 127 C.E.) represented the climax of the Roman Silver Age.

Literary works from the Age of Cicero showed that there were at least three different types of Latin used by the Romans. Cicero wrote in what has become known as classical oratorical Latin. This was used for oratory, senatorial and other records, legal texts, and an old form of poetry called Saturnian verse. Some other writers used classical written Latin, and evidence from references in texts and also from inscriptions and votive tablets (a tablet used for sacred or religious purposes) show that the colloquial Latin used by many citizens of the Roman Empire was quite different and also changed extensively over time, diverging from the other two and becoming known as Vulgar Latin. There are also references to these differences by Roman grammarians. By the third century C.E. books were written in this colloquial form. Both Saint Jerome and Saint Augustine, writing in the fourth and fifth centuries, continued to write in classical Latin.

In terms of grammar Latin had six cases (forms of a noun or pronoun indicating its role in a sentence) for the declensions (changes in form to designate grammatical function) of nouns and adjectives, and some nouns also had a locative case (indicating place or direction). Some of these cases survived in languages derived from Latin. In the early Christian Church, Latin played a crucial part in recording information. It was the language of the city of Rome, which became the center of western Christendom, of the Vulgate (the Roman Catholic Bible), and of administration throughout the empire. The language's extensive reach ensured that it would survive within the Christian Church and remain the language of learning and diplomacy for many centuries.

THE AMERICAS

BY MICHAEL J. O'NEAL

Unraveling the history of language development and dispersion in the ancient Americas is a daunting task for historians, linguists, and archaeologists. The first problem is the sheer number and diversity of languages. Linguists have identified some 200 distinct language families in the Americas, many with subfamilies and sub-subfamilies, but even that number is in dispute. (A language family is a group of languages that have important similarities, suggesting that they developed from a common older language. These languages can be grouped into a family "tree.") Efforts to compare languages that, in most cases, are long extinct or nearly extinct require gathering and analyzing immense amounts of information, and linguists have barely begun the process.

Further, historians dispute the origins of these languages. If the first Americans arrived in North America by crossing a land bridge between Siberia and Alaska—a theory that is not universally accepted—and then over millennia migrated and settled throughout North, Central, and South America, this would suggest that American languages originated in Asia. Comparing even one of the many Native American languages with an ancient Asian language, however, is a process fraught with difficulties. Nonetheless, some language historians have claimed to find similarities between the structure of Pacific Asian languages and that of one or more ancient American languages, particularly those of northwestern North America. Meanwhile, many historians remain convinced that the earliest people who settled in the modern-day southeastern United States were of European origin, meaning that they imported an entirely different family of languages to the Americas.

A third difficulty is assigning a language to a particular geographic locale. When archaeologists do find evidence of an ancient language, the natural tendency is to conclude that the language in question had been spoken in the place where the evidence surfaced. However, such a conclusion is not always defensible. Over time, as people moved about in the ancient Americas, they took their languages with them. The result was the blending of languages or, in the case of military conquest, the replacement of languages. Upon encountering each other through trade, people often borrowed words from one another. There is no way to “carbon-date” a language in the same way that physical objects can be dated. The ongoing swirl of peoples and languages over thousands of years makes it nearly impossible to peg a particular language to a particular place.

The final difficulty is the near-complete absence of written records. Few of the languages of the Americas had a written form until after Europeans arrived many centuries later. Archaeologists have found glyphs, or written symbols, at sites throughout the Americas, but attempting to reconstruct an extinct language from this scant evidence is nearly impossible. In many cases the best linguists can do is to make inferences on the basis of what they know about languages that survived well past ancient times and perhaps into the modern world.

It is highly likely that language families developed in the Americas by much the same process that occurred in other parts of the world. Over time communities of speakers dispersed throughout the Americas from the far northern reaches of arctic North America to the woodlands of the eastern United States, the deserts of Central America and Mexico, and eventually the southern tip of South America. These communities remained isolated from one another primarily because of natural barriers such as mountain ranges, rivers, and uninhabitable deserts. Communities themselves often fractured as competition for food and other resources increased, causing part of a community to break off and travel in search of a new home. Thus, languages can be grouped into families because at some time in the distant past, the speakers' ancestors spoke a common tongue, and many of these

commonalities were preserved over time. But over hundreds of years and many generations, the language of each new community evolved and changed, creating a new language with roots in the more ancient tongue. That language would have “cousins” that developed within other breakaway groups from the common ancestral tongue.

A simple list of ancient American languages, often referred to as AmerInd languages (from *American Indian*), is extensive. In the eastern half of the United States, for example, was the Algonquian family of languages, consisting of 33 or more languages, including those of the Arapaho, Blackfoot, Ojibwe, and Shawnee. Another major family of North American languages is referred to as either the Athabaskan or the Na-Dene languages, spoken from northwestern Canada down to the Rio Grande. This family includes various languages spoken by the Inuit as well as those spoken by tribes in the Pacific Northwest, along the coast of California, and in portions of the American Southwest.

Farther south the Hokan languages were spoken by communities along the southwestern coast of the United States and into northwestern Mexico. This family included some 28 distinct languages. The ancient Aztecs gave rise to two branches of their language, northern and southern, with a total of about 31 languages. The northern group included the languages spoken by the Hopi, the Paiute, the Shoshone, and the Comanche.

The Mayan languages of Central America have attracted the particular interest of scholars, largely because Mayan continues to be spoken by some six million people, primarily in Mexico and Belize but also because of the existence of a Mayan hieroglyphic script that dates back to the first millennium B.C.E. The spoken language descended from a language referred to as Proto-Mayan, first spoken about 5,000 years ago. The language appears to have originated in the highlands of Guatemala, and it began to spread in roughly 2200 B.C.E. The family tree that descended from Proto-Mayan is complex, consisting of four main branches, some of which in turn gave rise to other branches that developed into separate tongues. Scholars know of at least 31 and perhaps 33 distinct Mayan languages.

In Central and South America at least 15 additional distinct language families have been identified. Linguists have identified at least 17 additional South American languages that they have not been able to classify. Making matters more complicated is the fact that numerous languages from the interior of South America are known to have existed and perhaps survived but have not yet been named or identified. Some of these languages, not only in South America but also in Central and North America, are known as isolates because they have no known connection with other languages and may have developed independently.

► laws and legal codes

INTRODUCTION

Laws and legal codes among ancient hunter-gatherers were probably primitive and administered by force. A person would have looked to a tribal leader for redress if another member of the tribe had wronged him, and justice would have been administered swiftly and according to custom and tradition rather than by reference to any formal legal code. As people settled into fixed communities after the development of agriculture, and as those fixed communities evolved into more populous towns and cities, legal obligations became more complex, and more formal legal codes were developed

to define the obligations between private citizens and between citizens and the state. Thus, ancient legal systems dealt with many of the same matters that modern-day legal systems do: criminal matters, such as murder, assault, and robbery, and civil matters, such as taxes, inheritance, and land ownership.

Many codes and laws were transmitted orally and continued to be based on custom and tradition, but others were written down. Ancient Mesopotamia was home to the world's first written legal code, the Code of Hammurabi, named after the Babylonian king who formulated it. Historians continue to take an interest in the Code of Hammurabi not only for its specific laws but also for its philosophical discussion about justice and how it should be administered. In particular, the Code of Hammurabi created the legal principle often known as "an eye for an eye." This principle was not a call for revenge. It introduced the concept of equivalent retaliation, the idea that punishment should be proportional to the offense.

Many ancient legal codes were structured according to social classes. It was common for these codes to identify classes of nobles and aristocrats, property owners, free people, and slaves and peasants. Very often, the severity of an offense was determined in part by the social class of the victim. For a free landowner to assault a peasant or steal that peasant's bull, for example, was considered a much less severe offense than if the victim had been a noble, and the punishment would have been correspondingly less severe. Physical punishment in the ancient world was common, and so, too, were fines for various offenses. Physical punishment, including death, was often administered only if the offender was unable to pay the fine. With a few exceptions, there were no prisons; people considered dangerous were often simply exiled to other lands.

Just as laws and legal codes evolved to reflect the increasing complexity of society, so, too, did the administration of these laws. In early civilizations it was common for the king to act as judge in all legal disputes, rendering judgments and determining penalties. Later, civilizations such as the Roman and Chinese empires developed classes of magistrates and civil servants who were educated and trained in the law. In some civilizations, including that of ancient India, police forces existed to enforce the law. In others, the enforcement of the law was more of a private matter, requiring parties who believed that they had been wronged to lodge complaints, find witnesses, and bring cases to court.

AFRICA

BY SAHEED ADERINTO

Legal codes such as those we have today did not exist in ancient Africa. Codification of African customary laws is therefore a 20th-century development—a product of colonial rule. Laws are part of the custom and tradition of every community. Law forms an integral part of oral literature, which is transmitted from one generation to another. By and large, it is often difficult to differentiate between laws and tradition and custom. Basic aspects of the laws of a society are intertwined with the

customs and values of that society. When laws are respected, custom and tradition are also respected.

The origin of law in Africa is closely connected to the origin of communities. Founders of each community laid down rules and regulations for people to follow and respect. As time unfolded in the history of states and empire building, new forms of social, political, and economic developments had far-reaching consequences on the nature of law and how society was governed and structured. In other words, as African society underwent the natural process of transformation, the need to maintain the status quo and move ahead led to the establishment of regulations and orders.

Since rulers played significant roles in determining the tranquility of each community, the law of succession seems to have been one of the most significant laws. In traditional Africa laws needed for the peaceful running of society could work only if the right person was allowed to rule. The gods and goddesses might be infuriated by any attempt at doctoring the law of succession—a situation that could lead to the collapse of the state. Each community laid down principles on how rulers were to be selected. In most cases rulers were selected from the clan or family of the founder of the community. The idea of rulers as “naturally ordained” suggested that a ruler was sanctioned by the gods and goddesses. Rulers were naturally selected if the law of the society stipulated that the first child of the reigning ruler should rule. Such was always the case in societies with one ruling house. Selection might be done rotationally if there was more than one ruling house. In these two instances, the gods would have been consulted before rulers were allowed to rule.

By and large the authority of a ruler was derived from his or her role as the intermediary between gods and goddesses and human beings. A significant part of the coronation ceremony involved initiation into several secret societies and the transformation of the ruler from an “ordinary” human being to a “supernatural” being who communed with ancestors and other apparitional entities. The perception of the king among the Yoruba of modern southwestern Nigeria was *Kabi o osi, Oba alase ekeji orisa* (“someone who cannot be questioned, king, ruler, and deputy of the gods”). This appellation indicated that the king could not be questioned or reprimanded for his or her actions and that he or she was the deputy of the gods. Kings represented the gods on earth, and their command was therefore that of the gods. Since the gods and the ancestors were considered the founders of the community who also laid down the foundation of its custom and convention, a person who disobeyed the king automatically incurred the wrath of the gods.

Laws are needed to ensure the smooth running of a society. A very old proverb among the Yoruba indicates the role of law in their society: *Ilu ti ko si ofin, ese kosi ni be*, or “There is no offense in a place where there is no law.” This proverb suggests that the prime purpose of making and enforcing law is the need to avoid a breakdown of order. Moreover, every community has its own laws that must be obeyed. A Yoruba

poem that sheds a considerable amount of light on the significance of law and order is as follows:

The king whose reign is peaceful
Will have his name remembered for life.
The king whose reign is marred with tribulations
Will have his name remembered for life.

Ancient African rulers were aware of the implications of the breakdown of law and order. They were capable of incurring the wrath of the gods. Their ruling house and succeeding generations might be prevented from having access to the throne in the future. It was therefore not unusual for rulers to commit suicide to avoid the humiliation associated with an inability to make or enforce laws.

The operation and scope of laws and their enforcement varied from one part of the continent to another. Centralized societies developed a larger instrument of law enforcement compared with their noncentralized counterparts. Enforcement of laws seemed to be diffused in societies that were governed by more than one administrative body. It was typical, for instance, for secret societies to have their own courts where members were tried. Secret societies were groups that drew their members from the class of priests, elders, and people whose age, position, or status was important in the day-to-day running of the community. Laws of secret societies tended to have direct impact on the larger society in part because most of their members were political elites. There seems to have been no sharp dichotomy between people who made laws and those who enforced them. Rulers had the power to enforce laws through their agents, including lesser chiefs as well as heads of lineage, clans, compounds, and servants. Associations, such as the age grades (a social category based on age) among the Igbo of modern southeastern Nigeria, also performed some law-enforcement roles.

Laws could also be enforced through sorcery and by religio-magical means. Ancestral worship, offerings, and sacrifices could be employed in enforcing laws. People naturally abided by laws to avoid incurring the wrath of the gods and goddesses. Some deities were associated with the enforcement of laws. Because they were associated with spirituality, taboos and superstitions had a strong impact on people's attitudes about laws. For instance, people naturally abided by a law ordering that no one should hunt in a sacred forest if spirits or gods lived there. Game animals from a forest where the gods resided were thought to be possessed by spirits that could kill human beings or were considered food that the gods were not expected to share with human beings.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

In contrast to the codified legal theory and practices of the people in the ancient Near East (Sumerians, Assyrians, Hittites, and Babylonians), Greece, or Rome, the ancient Egyptians did not compose or possess an organized and strictly

specified law. No formal Egyptian legal codes have been preserved, at least not until the seventh century B.C.E., when the demotic language (a simplified form of Egyptian hieroglyphic writing) developed and Egyptians began using written legal documents and contracts instead of the traditional oral agreements of the Pharaonic Period (third to first millennium B.C.E.).

That is not to say that the writing down of laws was unimportant at earlier dates in Egypt. Specific enactments were issued, published, and consulted as laws. The surviving evidence of documents, however, is scanty, preserved in a fragmentary form on stelae (monumental stone slabs), in archives on papyrus, or in funerary texts. Important information about crimes and punishment derives mainly from official records rather than private documents. Those include decrees on behalf of temples or funerary cults that describe the means by which a decree was to be enforced, records of the Great Prison from the late Middle Kingdom (2040–1640 B.C.E.), and papyri documenting actual criminal investigations of the late New Kingdom (1550–1070 B.C.E.).

Quite common in the vocabulary of these enactments is the term *hep*—like the English term *law*—which refers to the specific enactment but also to the normative custom and to the law as an abstract moral order. *Hep* belonged to *maat*. It existed from the very beginning of time as the embodiment of the order given to the organized world by the creator god. The tight relationship between these two concepts of cosmic and political order and justice was best exemplified by the appearance of the *maat* goddess symbol as an amulet (charm) motif around a judge's neck, as described by the ancient Greek historians Herodotus and Diodorus.

The ultimate authority in the settlement of disputes was the pharaoh, whose decrees were supreme. Law in Egypt, especially during the New Kingdom, was specifically “what Pharaoh had said.” The king referred to himself as a “fixer of laws.” The Great Edict of Horemheb (r. ca. 1319–1307 B.C.E.) and the Nauri Decree of the Seti I (r. 1306–1290 B.C.E.) provide idealized literary expressions of royal control of judging and administering, presented in the form of specific instructions to limit the independence of authority. For example, in his edict, Horemheb proclaims that he is “the one who fixes laws for the king and gives regulations to the courtiers.” Because of the complex nature of legal administration, the pharaoh delegated powers to provincial governors and other officials. Most prominent among them was the vizier, who could appoint magistrates as part of his legal duties.

In modern legal systems there is a clear distinction between public or official law and private cases. Public law includes basic penal law, administrative law, and relationships between individuals and functionaries. Private law deals with relationships between individuals. In ancient Egypt, however, no basic distinction existed between administrative and judicial authority or function. “Courts,” or “courts of auditors,” were formed, with officers who held administrative as well as judicial duties and sat “as a court constituted to judge”

(according to the Great Edict of Horemheb). All local courts were controlled by the “great court” of Thebes and the court of Heliopolis; both consisted of the most prominent civil or military officers of Upper and Lower Egypt under the vizier's command. Important lawsuits, such as those involving land or influential people, were brought directly to the great court after a written complaint had been laid before the vizier. Lesser cases were left to local courts. Specialized courts and judges sitting in permanent rooms developed only after the Twenty-sixth Dynasty (664–525 B.C.E.).

The court was responsible for keeping legal records and documents, such as depositions, and dealt with litigation and punishment. The members of the court were responsible for the preliminary investigations of a case—questioning witnesses and suspects, examining the validity and truth of their statements, hearing the depositions of litigants, and examining the written evidence. In New Kingdom texts from Thebes (southern Egypt), those agents who were responsible

The Rosetta Stone, from Fort St. Julien, el-Rashid (Rosetta), Egypt (Ptolemaic Period, 196 B.C.E.); the inscription is a decree passed by a council of priests, one of a series that affirm the control of the royal cult of the 13-year-old Ptolemy V on the first anniversary of his coronation. (© The Trustees of the British Museum)

for investigating an accusation were sometimes identified as “officials of the Place of Examination.” The only criminal hearings that are described in detail are the Great Tomb Robbery investigations of the late Twentieth Dynasty (ca. 1196–1070 B.C.E.). The robberies were a series of assaults by various gangs of thieves on the tombs and temples of western Thebes. The vizier seems personally to have been involved in most criminal investigations and probably in all cases involving individuals of the official class.

In a legal proceeding the plaintiff was required to bring suit. The tribunal then ordered the defendant to appear in court if a point of law seemed to be involved in the dispute. Usually the judge ruled on the grounds of the documents and the testimony of each party. Egyptian officials asserted that they always acted according to “what His Majesty loves” or to “what the king favors.” According to an Egyptian inscription, an ideal judge is “a man of justice before the Two Lands . . . who causes two men to go out content with the utterance of his mouth.”

According to the *Teachings of Ptahhotep*, an instructional text from the Old Kingdom (2575–2134 B.C.E.), whoever transgressed the laws was punished. Reporting crime and criminal behavior was every official’s duty. Failure to do so was itself a crime and was punished almost as heavily as the original offense. Punishments included property restrictions, imprisonment, beatings, tortures, and even mutilation. Incarceration with hard labor is well documented, most notably in the Middle Kingdom records of the Great Prison at Thebes. This and other prisons were not only places of confinement but also workhouses or labor camps. Moreover, they served as places of detention for criminals awaiting harsher penalties.

For state officials the most serious punishments were loss of property, office, status, and even political and social identity, whereby an esteemed official was reduced to the status of a laborer in the fields. The death penalty or severe mutilation of the face, nose, and ears was reserved for crimes against political or religious authorities. Such capital offenses and rebellions lay outside the formal executive competence even of the vizier and required referral to the king himself.

THE MIDDLE EAST

BY JAMES A. CORRICK

The ancient Near East produced the first known written laws, in the form of decrees handed down by kings. Typically, they were first read to the populace and then inscribed on clay tablets. Later, all the royal edicts of a particular ruler would be engraved on a stone pillar, called a stela. The laws carved on the stelae were often organized in no particular order, with criminal and civil laws, covering a variety of legal issues, being mixed indiscriminately. Crimes such as murder, thievery, and assault were addressed, as were civil issues, including inheritance, land ownership, and divorce. Some codes also specified wages and prices and regulated the sale and treat-

ment of slaves. Each king’s legal code often superseded the laws of his predecessors. This practice did not mean, however, that older laws were necessarily discarded. Instead, laws from earlier codes were frequently brought forward and copied word for word by the new king.

In addition to these written legal codes, a large body of unwritten laws may also have existed. These unwritten laws would have been passed down orally through the centuries. Some would eventually have been incorporated into the written legal record. It is remarkable that in the thousands of legal texts—records of judgments in cases of divorce, land sales, slave sales, and so on—the law code of Hammurabi is never referred to.

From the beginning much of ancient Near Eastern law was what would later be called *lex talionis*, or the law of equivalent retaliation. Often described as a “tooth for a tooth” or an “eye for any eye,” *lex talionis* required the punishment to mirror the crime. Thus a man who broke another’s arm had his own arm broken. If he caused the death of someone else’s child, he had to give up the life of one of his own children. However, it was not unusual for a fine to be substituted for the punishment. Ancient Near Eastern law did not apply equally to all. Aristocrats normally paid higher fines than commoners, while commoners were more likely to receive harsh punishment, such as flogging, or to be executed for capital crimes.

The earliest known legal code was that of the Mesopotamian king Urukagina (or Uruinimgina), who ruled the Sumerian city of Lagash beginning in 2351 B.C.E. Concerned with rectifying social injustice, Urukagina forbade several practices in the collection of taxes. Thus, for example, a priest or palace official could not take wood or fruit in tax payments from a poverty-stricken widow. Law codes also survive from the early second millennium B.C.E., such as the laws of Eshnunna (modern-day Tell Asmar, Iraq) and the law code of the Mesopotamian ruler Lipit-Ishtar (r. ca. 1934–ca. 1924 B.C.E.).

The most famous code from the ancient Near East was that of Hammurabi (r. 1792–1750 B.C.E.). At capital of Babylon, Hammurabi erected a polished black stela that stood 8 feet tall. In the 12th century B.C.E., Shutruk-Nahhunte, king of Elam, took the stela as booty back to his capital Susa, in southwestern Iran. On one side of the stela was a relief showing the king conferring with Shamash, the god of justice; on the other was the code. As was traditional with such legal codes, the divine inspiration of Hammurabi’s laws was made clear by a prologue in which the king explained how the gods of his city required justice and order and that the laws set down below were an attempt to meet these divine needs. Like Urukagina, the Babylonian king set himself up as a protector of the weak. Thus he sought justice by preventing the exploitation and victimization of the powerless and the destruction of the lawbreaker.

The prologue was followed by the laws themselves. In 51 columns of cuneiform characters containing 282 laws, Hammurabi covered commercial and real estate dealings; personal

property disputes; injuries, both accidental and intentional; and labor matters. After the body of laws came the epilogue, which urged those seeking justice to read and heed the laws of Hammurabi. Additionally, the Babylonian ruler called on all later kings to follow the laws carved on the stela. Hammurabi's appeal to future kings revealed that his code was not so much a set of laws describing what was and was not illegal as it was a model for how justice should be dispensed. Indeed, on the stela Hammurabi's legal statements were termed *decisions* rather than *laws*. In other words, the code was a list of decisions, each of which was probably based on a number of cases but not on any specific case, and each of which was meant to serve as a guide in rendering future judgments.

To what extent Hammurabi's code was used in actual judicial proceedings is unknown. Still, stelae, some with additional commentary expanding on the meaning of Hammurabi's laws, were erected throughout the ancient Near East as late as the fourth century B.C.E. The Assyrians appear to have accepted Hammurabi's code, though they imposed considerably harsher penalties than did the Babylonians for the same crimes. There were no police to enforce the laws of the ancient Near East. In general when one person accused another of wrongdoing, the accuser, along with relatives, friends, and neighbors, would see that the accused appeared at the trial. In cases of treason or other crimes against the king, soldiers would bring the suspect to trial.

Most trials were local affairs, at which the accuser would lay out his complaint before a council of elders who acted as judges. Serious crimes, such as murder, would be heard by a judge appointed by the king. Verdicts from local councils could also be appealed to these royal judges as well as to the king. For most of the ancient Near Eastern period, there were no lawyers; the accuser prosecuted, and the accused defended. In the Persian Empire, however, a group called *speakers of the law* specialized in explaining legal matters to those involved in court cases as well as helping them present their cases. At a trial witnesses would be called, some of whom had to make long journeys to be present. Documents would be produced and examined. If all else failed in reaching a verdict, the judges would order the accused to undergo a "river ordeal," in which he or she was thrown into a river. Those who survived were declared innocent, while those who drowned were deemed guilty.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Only the ancient Indians and Chinese left extensive written legal codes; therefore, the laws of other cultures are mostly lost. The history of laws in Asia suggests that laws were regarded as a defense of civilization against barbarism. For example, by the Han Dynasty (202 B.C.E.–220 C.E.) the rulers of China regarded human sacrifice as evil, and laws were made to outlaw it, giving regional legal authorities the backing of the government in stamping out the practice.

In India the first laws were Vedic laws, which were derived from the religious epics of the Aryan invaders who migrated through most of northern and central India from 1500 to 500 B.C.E. As the Vedic peoples adapted to their environment and mixed with the original populations, much of the religious law became too vague and unrealistic for practical use; from about 500 to 200 B.C.E. the laws were revised. The laws were written down as *sastras* and sutras. The *sastras* were books of rules written in verse, and the sutras were books of prose combined with verse. The book most often cited by historians is the Code of Manu, a *sastra* dating to between 200 B.C.E. and 100 C.E.

The Code of Manu and other codes made kings ultimately responsible for justice in their kingdoms. Kings were expected to hear complaints from petitioners, to make sure that justice was served, and to prosecute cases when there were no plaintiffs. Kings delegated much of their legal authority to magistrates who were expected to know thousands of laws and were supposed to be of irreproachably high moral character. Three magistrates were responsible for 10 villages. They had scribes and police to serve them. The tradespeople of Indian society frequently belonged to guilds devoted to their professions. Sometimes entire villages were devoted to just one trade. In such cases the guild was responsible for maintaining the law in the city and could punish people convicted of crimes, usually by fining them.

In the case of some crimes, punishment was swift. If the police caught someone burglarizing a home or other property, he or she could be taken to the center of town and executed, but in most cases people accused of crimes would be tried in court. A defendant was given three days to write a defense, with the aid of a legal scribe. Up to three witnesses could speak for the defendant in court. Brahmans, criminals, women, and certain other people could not be called as witnesses. Witnesses who were caught lying could be tortured as punishment. In cases when guilt was likely but not certain, the defendant could be tortured until he or she confessed or until an appeal was granted. Each defendant was allowed to appeal to higher authorities until reaching the king, who had the final word.

Not much is known of China's laws during the Shang Dynasty (1500–1045 B.C.E.) and the Zhou Dynasty (1045–256 B.C.E.), but the laws tended to favor emperors and aristocrats. During the Warring States Period (453–221 B.C.E.) of the Zhou Dynasty, several legal philosophies arose. One of these was legalism. This philosophy was law taken to the extreme. Every action was supposed to have a law governing it, and everyone, except the king, was subject to the law. Every profession had its designated responsibilities and its social rank. Even nobles were ranked in importance. Each person was allowed a certain amount of land and a certain number of servants according to his or her status. Punishments for breaking the law were severe, to dissuade people from committing crimes; actions considered beneficial to society, such as valor in battle, were rewarded. People who did not report a crime that they knew about were executed.

Jade cicada, China (second to first century B.C.E.); jade cicadas were placed as protection on the tongue of the dead, but full burial suits of jade were restricted by sumptuary laws to royalty. (© The Trustees of the British Museum)

In the 300s B.C.E. the province of Qin adopted legalism. There its chief advocate was Shang Yang (d. 338 B.C.E.). He saw to it that even the crown prince of Qin was punished for a crime. He was known for his cruelty and political treachery. When the crown prince became king of Qin, Shang Yang had to flee the province. When Zheng of Qin reunified China and renamed himself Qin Shi Huangdi, he imposed legalism on the empire. He tried to regulate all of the business of the nation. Some of his efforts had practical value. For example, a law that standardized the width for all axles on carts meant that ruts in roads could be standardized, allowing for greater speed in transporting goods to market and putting an end to the tipping over of carts because one wheel was in a rut while the other was not. Other laws made tax collecting easier. However, the criminal laws were unbearable. It seemed that no one could go a day without violating a few laws, and the punishments for breaking those laws were cruel. Qin Shi Huangdi took advantage of people's tendency accidentally to break laws, amassing a huge force of convicted laborers who worked on building projects, such as the Great Wall. Legalism was so loathed by the Chinese that they exterminated Qin Shi Huangdi's entire family in 210 B.C.E., ensuring that the Qin Dynasty and legalism would not rise again.

The founder of the Han Dynasty, Liu Bang, instituted Confucianism as the philosophy of his government. The law retained some of the doctrines of legalism, such as those enforcing taxation and obedience to the emperor, but Confucianism replaced most of the harsh laws of legalism with the principle of compassion. It took until about 100 B.C.E. for Confucianist magistrates fully to supplant legalist magistrates.

In 145 B.C.E. Governor Wen Weng of the province of Shu, not satisfied with the number of educated people available for employment in his government, began schools that taught Confucianism to boys of all social classes. His idea was adopted by the empire as a whole, and the schools produced the magistrates and the law enforcement officers of China. A

magistrate was expected to be impartial, with his court being the one place in the empire where a poor person could challenge a rich one. People could appeal to higher authorities in government if they lost their cases. The emperor was expected to right wrongly decided cases in order to maintain his divine right to rule, which the gods could take away from him if he were unjust, but by 1 C.E. a census showed that there were nearly 60 million people in China, making it impossible for the emperor to hear every appeal. The emperor's magistrates were expected to memorize the laws they enforced and to prove themselves knowledgeable before being appointed to office. These magistrates helped maintain a sense of a single nation with one legal code through the centuries of upheaval after the Han Dynasty ended, even though there were often three or more governments vying to rule the empire.

A lack of written records for ancient laws makes identifying any laws outside China and India very difficult. Many Pacific islands were not yet settled, and those that were settled were only beginning to form societies governed by laws. The islands of Java and Borneo seem to have begun forming kingdoms late in the ancient era, perhaps in the 200s or 300s C.E., but the possible existence of these kingdoms is mostly inferred from scant Chinese records of trade in southeastern Asia during the medieval era. The formation of legal systems on these islands may not have begun before the medieval era.

The major nation in Southeast Asia from the 100s to 500s C.E. was Funan, which controlled territory from the Mekong Delta into what is now Cambodia. It left behind Hindu temples, the existence of which suggests to archaeologists that Funan's laws probably resembled those of ancient India. Direct evidence of Funan's laws is scant. Korea was influenced by China, which established trade cities on the Korean peninsula during the Han Dynasty. In about 384 C.E., when the royal family of the Korean kingdom of Paekche converted to Buddhism, Chinese forms of government and Chinese laws began to be adopted by Paekche, and the Chinese legal system moved through the Korean peninsula over the next 200 years. Ancient Korea is believed by most historians to have had a strong influence on ancient Japan; through Korea, Chinese culture came to Japan. The laws of ancient Japan are not known, but sometime in the 100s or 200s C.E., the Japanese on the island Kyushu, and probably the island Honshu as well, began adopting Chinese customs. During the 300s and 400s C.E., governments on these islands began modeling themselves on Chinese governments, and they probably adapted Chinese legal practices to their own needs. Early Japanese written records from the medieval era suggest that the laws mostly applied to the upper classes of Japan and that traditional Japanese tribal customs prevailed among the rest of the Japanese.

EUROPE

BY AMY HACKNEY BLACKWELL

The people of ancient Europe did not record their laws in writing. Historians have reconstructed ancient European

laws from the descriptions of Roman observers and from laws that were written slightly after the ancient period. The best evidence of Celtic legal codes comes from Ireland's Brehon laws, which were first written down in the 600s C.E. but are presumed to have come from ancient Celtic laws. Historians think that these laws may have developed among Celtic peoples in Europe during the Bronze Age, between 2300 and 900 B.C.E. Legal experts memorized the laws and transmitted them orally over the years. After many years of study, these experts became skilled at interpreting the law, advising rulers, and arbitrating disputes. (The name *Brehon* is an Anglicization of the Irish word for "judge.")

Celtic law divided people into five social classes. At the top were kings, followed by nobles. Free people who owned property formed a third class and free people without property a fourth. The fifth class consisted of slaves and other nonfree people. These ranks indicated how people had to behave with respect to other members of society. Kings and nobles owned their own property and paid no rent to anyone. Men of the third class, freemen with property, did not own land but did own cattle and other movable goods, which allowed them to function as the lowest level of chiefs. The vast majority of people fell into the bottom two classes. The fourth class rented land from nobles, to whom they owed allegiance in war. Some members of the fifth class were slaves, many of them captured from other tribes; others were not slaves but did not hold all the rights of full members of the tribe.

In addition to defining social classes, Celtic laws organized people into groups that served as the basis for distributing land. The family was the smallest group. The clan was a larger group of relatives descended from a common ancestor. A tribe consisted of several clans likewise descended from a common ancestor. Each tribe and clan was governed by its own chief, who in turn owed allegiance to higher rulers. Allegiance took the form of yearly payments of property and military assistance.

Celtic laws did away with the ancient practice of retaliation for crimes and replaced them with a scheme of compensation designed to end disputes peacefully. If a person harmed another, the victim or the victim's family would bring the case before a chief and a legal expert. The legal expert would listen to the facts and decide the appropriate punishment. Every crime merited a specific compensation; cutting off someone's hand earned a smaller fine than murdering someone would. There were several levels of court; petty disputes went to the courts of local chiefs, while major disputes might go all the way to a king. A party who brought a case to court had to bring at least two witnesses to testify on her behalf. Social rank was important in courts; a person of lower rank could not always testify against someone of higher class.

One notable aspect of ancient Celtic law is its near absence of capital punishment for crimes. The only time Celtic laws recommended death was when a murderer failed to pay the full amount of the specified fine. Celtic kings and chiefs

did execute criminals, but this practice was done outside the legal setting. Methods of execution included hanging and drowning.

Germanic tribes did not begin to compile formal legal codes until the very end of the Roman Empire in the 400s. For almost all of the ancient period they governed themselves according to custom, passed orally from generation to generation. These laws specified the treatment of criminals and the settlement of disputes.

German tribes assembled periodically to hold a festival that in medieval times was called the *Thing*, which was an occasion to trade, exchange spouses, and settle disputes. People who believed they had been wronged would wait until a major gathering and then bring their grievance before the king, who acted as a judge. Both parties were allowed to speak and bring witnesses to back them. The king would then issue a judgment. If all went well, both parties would abide by the agreement, and the dispute would be ended. Sometimes people settled disputes themselves by force, but there was community pressure to follow the king's judgment and settle matters peacefully. If the king summoned a person to appear at the *Thing* and he failed to come, he would be fined. Any party who summoned another person to appear because of a dispute and then himself failed to appear would have to pay a fine to the person he had summoned.

German laws covered many different types of crime. Stealing cattle was a serious offense, and penalties varied depending on the value of the cattle stolen; a bull owned by the king merited a higher fine than a bull that serviced only the cows of a single herd owned by an ordinary man. Stealing an object that lay outside a house was not as serious as breaking into a house to steal something. Merely breaking into a house without stealing anything was also a crime, especially if the thief broke a lock to get in. Rape, assault, insult, and murder were all criminal offenses punishable by fines. Tribes set fines according to the value of the victim. Killing a pregnant woman merited a higher fine than killing a woman past her childbearing years. If a murderer concealed his victim in an attempt to hide his crime, the punishment was greater than if he did not. A murderer who did not have enough money to pay the fine was expected to ask his relatives and friends for help. If he still could not raise enough money, he might be executed. Germanic inheritance law favored male heirs. If a father died and left sons, they would inherit his property. If he had no sons, then his property would go to his parents, his siblings, or his relatives on his father's side. In most cases, the inheritance could not go to a woman.

During the 400s C.E., Germanic groups began compiling codes of laws. The Visigothic leaders Theodoric I, Thorismund, and Theodoric II all created bodies of law that they used to govern their people, but they did not write these laws down. The Visigothic king Euric (d. 484 C.E.) made the first compilation of Visigothic law in 471, gathering the laws of his predecessors and arranging them in a single volume. His laws regulated only disputes involving Goths or Goths and

Romans. Even after the fall of Rome, Roman law continued to apply to disputes with only Roman parties.

GREECE

BY JEFFREY S. CARNES

The earliest views of Greek legal systems come from the poems of Homer (ninth or eighth century B.C.E.) and Hesiod (ca. 800 B.C.E.). In Homer's *Iliad* a relief on the shield of Achilles displays vignettes from daily life, including a legal case involving a dispute over a homicide. Two men argue about the payment of a blood price to atone for the murder, and the case is settled by elders and arbitrators, with a prize going to the one who "speaks the straightest opinion." Similarly, Hesiod's *Theogony* praises kings primarily for their role in administering justice. Both poems reflect a world in which justice was administered on a somewhat improvised basis by social elites and in which law was a matter of custom rather than something created by a legislative body or an individual lawgiver. More important, they show the origins of legal practice in private matters: in the settling of disputes between individuals, presenting a socially agreed-upon alternative to retribution and vengeance.

By the seventh century B.C.E. the various city-states began to develop legal codes and permanent legislative bodies. These early developments were typically assigned to individual lawgivers, such as Lycurgus (ninth century B.C.E.) in Sparta or Draco (seventh century B.C.E.) and Solon (ca. 630–ca. 560 B.C.E.) in Athens; many cities held that their oldest laws had been established by their lawgivers and handed down unchanged, though this was rarely historically accurate. In fact, lawgiver traditions reflect the social realities of the Age of Tyrants (sixth century B.C.E.), in which strong individuals brought about changes to break the monopoly on legal power held by the aristocracies of their cities.

Writing is typically associated with these reforms as a way to ensure the fairness and transparency of the judicial system. Lawgivers such as Draco and Zaleucus of Locri Epizephyrii (ca. 660 B.C.E.) are said to have ensured that the laws would be written down and publicly accessible so that all citizens could read them and see that they were being applied fairly. This development implies a certain degree of literacy throughout the Greek world; there must have been enough literate citizens to make public postings of laws worthwhile.

In Athens the laws were originally written down on wooden blocks called *axones*, which seem to have been attached to wooden pillars and mounted in such a way that readers could turn them, thus allowing more laws to be displayed in a limited amount of space. By the late fifth century B.C.E. the Athenian laws were written in stone, as was the case in numerous other Greek cities. Much of the current information about Greek law codes, especially during the Archaic Era (600–480 B.C.E.), comes from inscriptions. Of particular value is the inscription from Gortyn in Crete, dating to about 450 B.C.E. but thought to reflect the laws of a somewhat ear-

lier era. The inscription, one of the longest to survive from antiquity, deals with a wide variety of matters both civil and criminal, including rape, inheritance, gifts, mortgages, and the status of slaves.

With the exception of Gortyn, however, Athens is the only city for which we have a detailed picture of the legal system, with sources including inscriptions, speeches from law courts, theoretical treatises such as the *Constitution of the Athenians* by Aristotle (384–322 B.C.E.), and even the comedies of Aristophanes (ca. 450–ca. 388 B.C.E.), in which the Athenians' litigious nature is frequently parodied. The Athenians held that their first code of laws was given to them by Draco in 621 B.C.E.; these laws were famous for their severity (thus the English word *draconian*, meaning "cruel" or "severe"), with the death penalty prescribed for even minor offenses. The laws ascribed to Draco, with the exception of the one concerning homicide, were replaced by those of Solon in 594 B.C.E. Publicly displayed on the *axones*, the law code of Solon formed the basis of Athenian law for more than 250 years, supplemented by the numerous laws passed by other legislative bodies during Athens' era of democratic rule (508–322 B.C.E.). The laws were of two sorts: *nomoi*, laws that established a permanent rule, and *psephismata*, decrees that were designed to apply to a particular instance. Legal reforms in the late fifth century ensured that *psephismata* could not override *nomoi* and that different legislative bodies were responsible for the two types of law.

The Athenian legal system (and probably other Greek systems) retained strong vestiges of the Greek law's origins in the settling of private disputes. Until the time of Solon, all actions at law were essentially private; only the injured parties or their families could bring a case to court, even in criminal matters. After Solon, Athenian law permitted *dikai demosiai* (public actions) for offenses that were regarded as affecting the community as a whole. Categories of offense subject to *dikai demosiai* included matters related to public administration (such as bribery or misconduct while in office) and to civic life generally (including accusations of impiety, as religion was considered a state matter). There were, however, no public prosecutors: actions could be brought by magistrates holding other offices or by *ho boulomenos* ("the one who wishes"); that is, by any free adult male, usually including noncitizens. The line between public and private matters was drawn differently from the way it is in most modern legal systems: Most crimes, including murder, remained a matter for private actions, and it was up to the victim or the victim's relatives to prosecute.

Participation in the legal system was encouraged by popular sentiment. The Athenian statesman Pericles (ca. 495–429 B.C.E.), in his Funeral Oration, expressed disdain for those who take no part in government. It also was encouraged by financial incentives. Monetary fines were the most common punishments for guilty defendants, and in a private suit the money went to the prosecutor, who was either the injured party or a member of his family. In some public suits there

was a monetary reward for successful prosecution; this led to a class of professional prosecutors known as *sykophantes*. Measures were taken to reduce the number of frivolous or opportunistic prosecutions: A prosecutor who failed to secure 20 percent of the votes of the jurors was liable to a hefty fine and was prohibited from bringing similar actions in the future.

Participation in jury service was also encouraged with financial incentives starting in the mid-fifth century B.C.E. As a result, law courts were extremely democratic; the poorest citizens could participate as jurors, and courtroom procedure in many ways resembled that of the popular Assembly, a meeting of the citizens to discuss affairs of state. Juries were extremely large—typically several hundred people, and in some cases as high as 6,000. As in the Assembly, decisions were reached after listening to speeches. There were no professional lawyers, and both prosecutor and defendant pleaded their own cases. Professional speechwriters, such as Demosthenes (384–322 B.C.E.), sometimes wrote speeches for their clients to deliver.

There were few rules of evidence; hearsay, popular opinion (what Pericles referred to as “unwritten law”), and appeals to the emotions of the jurors were commonly brought to court. The authority of the spoken word was still strong in the legal system. Witnesses were given precedence over written testimony at least until the mid-fourth century, and although they could be questioned by the side that called them, they could not be cross-examined. As in the Assembly, a simple majority was necessary to decide conviction or acquittal, and voting was carried out by dropping pebbles or tokens into urns. If the vote was for conviction and the offense carried no fixed penalty, a separate penalty phase of the trial would be carried out, with each side proposing a punishment; the jury then would choose one or the other but could not compromise between them.

ROME

BY JAMES A. CORRICK

The earliest Roman legal writings were the Twelve Tables. Completed in 450 B.C.E. and modeled on the Athenian legal code, the Twelve Tables, though not a comprehensive listing of Roman law, covered such matters as debt, inheritance, property questions, liability, perjury, and bribery. The tables mostly addressed what the Romans called *ius privatum*, or private law, as opposed to *ius publicum*, or public law. Public law, which included criminal law, was the body of ordinances that regulated the relationship between citizens and the Roman state. Conversely, private law dealt with legal relations between citizens, such as contracts and suits.

For much of the Roman Republic (509–27 B.C.E.) private law covered some acts that later were deemed criminal. For example, robbery began as a private affair in which the victim sought redress through a lawsuit against the thief. By the late republic, however, theft was a crime with a state-imposed penalty. Public law initially was restricted to very serious

threats against the state. Therefore, treason was a matter for public law. By the end of the republic and continuing into the empire, *ius publicum* grew to include such crimes as extortion, embezzlement, murder, and forgery.

Roman law was also divided into *ius scriptum* and *ius non scriptum*. Although these terms literally mean “written law” and “unwritten law,” respectively, both were in fact written down. *Ius scriptum* referred to statute laws, those passed by legislative or other official action, while *ius non scriptum* referred to laws that by tradition and custom were accepted as binding, very similar to later English and American common law.

Roman private law was controlled by male Romans. Rome never had a staff of prosecutors, and it was therefore up to each individual citizen to prosecute his own case. The first of the Twelve Tables gave each citizen the right to summon any who wronged him before a magistrate, before whom the plaintiff and the defendant would argue their sides of the case. The table also gave the plaintiff the right to use force to bring the defendant before the magistrate if he would not come voluntarily.

The body of magistrates originally included only officers known as consuls. The office carried a certain status known as imperium, which gave the bearer, among other rights, the right to interpret and execute the law, including imposing the death penalty. In 366 B.C.E. a new office, praetor, took over many of the consuls’ judicial duties, particularly those involving private law. Like the consuls, the praetor’s office carried imperium. Dictators also had imperium, as did the emperors of imperial times; they, too, were considered magistrates.

As Rome brought first Italy and then much of the rest of the Mediterranean region under its control, it found a need for a *praetor urbanis*, who dealt solely with legal matters involving Roman citizens, and a *praetor peregrinus*, whose responsibility was suits between citizens and foreigners. The law of the former was called the *ius civile* (“citizen law”), while that of the latter was *ius gentium* (“law of nations”). Eventually six more praetors were added to help the *praetor urbanis*. Praetors continued to act as magistrates through the first centuries of the empire. By late imperial times, however, the judicial duties of praetors were taken over by officials appointed by the emperor.

When assuming his duties, a praetor would issue an edict explaining the legal principles under which he would operate. These edicts often expanded upon or clarified existing law, and they accordingly became known as praetorian law. Along with laws passed by the plebian assemblies under the republic or issued by emperors under the empire, praetorian edicts became part of the Roman legal code. *Ius privatum* proceedings were handled solely by a praetor for as long as the office existed. Under the republic a praetor did not act as a judge. Rather, his role was to review each case brought before him, determine its legal merits, issue a formula that explained the legal points under which the case would be tried, and then appoint a judge to hear the case. For an important case a five-

judge tribunal was authorized to try the case. Judges were prominent private citizens, though they were rarely trained in the law. Under the empire this procedure was modified. Private citizens no longer were asked to act as judges. Instead, a single magistrate both reviewed and tried each case.

In *ius publicum* cases any magistrate who had imperium could preside over a trial. Under the republic *ius publicum* cases were initially tried before the centuriate assembly and then, beginning in the second century B.C.E., before *quaestiones perpetuae* (“standing jury courts”), composed of juries of 50 to 75 members. Eventually, under the empire, the *quaestiones* were replaced by trials conducted solely before a single magistrate.

Since praetorian-appointed judges, as well as plaintiffs and defendants, generally had little legal knowledge, they often depended upon legal advice. Beginning in the third century B.C.E. a group of professional jurists, or lawyers, appeared. These jurists offered their services as advisers and sometimes advocates at trials and in the drafting of praetorian edicts and other legal legislation. For these services they were not paid, though they often accepted gifts in exchange for their help. Around 304 B.C.E. one of the earliest of these jurists, Gnaeus Flavius, published the rules by which trials were conducted as well as a calendar of the days that legal business could be conducted. Prior to Flavius, only the patrician-controlled priesthood had such knowledge, whose possession now allowed plebians to have greater access to the Roman legal system.

Rome’s jurists also produced a large body of legal writing, much of which was detailed analysis of specific cases, often from each jurist’s own career. Jurist writing began with Appius Claudius Caecus, who lived in the fourth and third centuries B.C.E. and wrote a treatise on property. One of the most notable legal writers was Quintus Mucius Scaevola (d. 82 B.C.E.), who produced the first standard Roman law work. In 18 volumes Scaevola collected together Roman law and organized it by category. To what extent Scaevola’s work was a complete collection of Roman law is unknown, since it did not survive the centuries. Even if complete, however, the work would not have been a legal code because it was not an official state-produced document. Indeed, apart from the Twelve Tables, republican Rome made no attempt to codify its laws.

In imperial times the occasional effort was made to create at least a partial legal code. The emperor Hadrian (r. 117–38 C.E.) had the edicts of the praetors edited during the final years of his reign. Diocletian, who ruled from 284 to 305 C.E., issued an incomplete legal code. At the end of the fourth century C.E. the emperor Theodosius I (r. 379–95 C.E.) issued what was probably to that date the most complete code, which included the laws passed since the reign of Constantine I (r. 306–37 C.E.) as well as Diocletian’s work. It was not until after the fall of the western empire that a comprehensive code was issued by the eastern emperor Justinian I (r. 527–65 C.E.) in 529 C.E. The *Codex Justinianus* was based on the study of some 2,000 texts of Roman law.

THE AMERICAS

BY KIRK H. BEETZ

Little is known of the legal codes and the practices of law in the ancient Americas. For North America north of Mexico, anthropologists rely on comparisons of ancient American cultures to similar cultures about which more is known. For ancient South American cultures, almost nothing of their laws is known; either they are little studied, or scant evidence is left for archaeologists to find. Of the great ancient civilizations of Mexico and Central America more is known, though little is known about the Olmec and other predecessors of the Maya.

Ancient North Americans formed a variety of cultures, from hunter-gatherers to city dwellers. The legal needs of those who lived in small hunter-gatherer groups and those of people who lived in large settled communities would have been very different. Legal authority usually rested with a senior member of a small group, a shaman, or a group of elders. For the large communities of eastern North America and of the Mississippi River region, laws governing social conduct almost certainly existed. For small hunter-gatherer groups, theft was probably not a problem because almost everything was owned by everyone in the community. In villages and towns, laws governing theft probably existed.

Although the ancient Maya were a literate culture who left much for archaeologists to discover, little is known about their laws. The laws of modern Mayans are of little help in understanding ancient laws because modern Mayans have long been scattered in communities that often have communicated little with others, giving rise to many different laws that may have little to do with ancient practices. Records of ancient Mayan laws are rare. Therefore, historians often draw information about ancient laws from the myths of the Mayans, a somewhat unreliable approach because the laws of the supernatural world could vary from those of actual Mayan practice. Some aspects of Mayan law are known, but only in fragments. Thus a law about marketplaces might survive from one Mayan city, another about marriage from another city, and another about theft from another city. The ancient Mayans lived in many different communities, each with its own laws and legal code. The legal codes may have varied from one place to another and from one time to another, but it is not known by how much. If one pieces all the hints at laws together, a general picture of Mayan legal life emerges that may be altered as new discoveries are made.

Ancient Mayan kings ruled over city-states. They were responsible not only for making laws but also for leading the military and their city’s religious life. In legal cases the king was the last court of appeal; whatever he decided was final. Every village and town as well as the main city within a king’s territory had its own courts. Small villages might have had only one judge, and for most minor problems that judge’s decision would not be appealed. When a decision was appealed, the case would be taken to a judge in a large town or city.

Beyond that, a case had to be taken to the capital, where it would be heard by a higher judge. The appeal after that was to the king himself. A king probably devoted part of every day to hearing legal appeals.

A person on trial probably was not compelled to testify. Neither the accused person nor any witnesses would be tortured in order to force testimony. Everyone was subject to the law, including judges and nobility. A difference in punishment between a noble and a commoner may have been that a noble was punished in private while a commoner was publicly humiliated. Convicted thieves were required to repay their victims or became slaves to their victims. Slavery was dangerous. In some cities slaves could be freed after fulfilling their obligations to their victims or for virtuous behavior, but the Maya practiced human sacrifice, and slaves were usually the first to be sacrificed.

The marketplace was an essential part of the economic and social life of Mayan villages, towns, and cities. Crimes committed in marketplaces were taken seriously. Apparently, some Mayan cities had police forces that patrolled marketplaces, and anyone could complain to them about someone dishonestly weighing or measuring their goods, about someone selling stolen goods, or about shoplifters. Judges were available to hear such complaints almost immediately, and it was possible for a case to be tried and resolved before the day was over.

People could file lawsuits, and there may have been lawyers to help them. Adultery, criminal business dealings, and breach of contract could draw lawsuits. The same judges who heard criminal cases would hear civil cases. The loser of a lawsuit could be fined, in which case his or her family would be summoned to make payment. If the family could not make payment, the defendant and some of his or her family could be forced to become slaves.

Judges worked long hours, probably beginning to hear cases within moments after sunrise. They were expected to be examples of virtue to other people, and if they were caught committing crimes, they could be put to death. If

they were found to be taking bribes or showing prejudice by favoring nobles over commoners or the reverse, they probably were executed. Being drunk while at work also brought penalties. Even the highest judge below the king was subject to punishment.

Laws may have been written down, but at present it appears that the laws of the Maya may have been transmitted verbally, perhaps by experts who memorized the laws. Scribes held a high place in Mayan society, and some of them may have been assigned to record court proceedings, especially testimony by witnesses. The highest courts in a city almost certainly had scribes. Mayan laws may have derived in part from those of previous civilizations, especially the Olmec, and their laws certainly influenced cultures even as late as the Aztecs. How far they influenced communities north or south of Mayan lands is not really known, but some archaeologist speculate that Mayan laws influenced cultures in what is now the southwestern United States.

The laws of the cultures south of the Maya are mostly unknown. Archaeologists are only just discovering some of the civilizations that existed in South America, in part because the earliest ones seem to have built their structures mostly of dirt, which has left mounds only recently recognized as remnants of structures, and in part because they existed in places in the mountains that are hard to reach and very dangerous. Given the sophistication of the arts and crafts of some of these ancient cultures as well as their evidently vigorous trade, they probably had laws governing social conduct and the means to enforce those laws. It is known that most Andeans were expected to treat strangers well and that their punishments were severe.

Egypt

~ The Precepts of the Vizier Ptah-hotep, ca. 2350 B.C.E. ~

Precepts of the prefect, the lord Ptah-hotep, under the Majesty of the King of the South and North, Assa, living eternally forever.

The prefect, the feudal lord Ptah-hotep, says: . . . Who will cause me to have authority to speak, that I may declare to him the words of those who have heard the counsels of former days? And the counsels heard of the

gods, who will give me authority to declare them? Cause that it be so and that evil be removed from those that are enlightened; send the double . . . The majesty of this god says: Instruct him in the sayings of former days. It is this which constitutes the merit of the children of the great. All that which makes the soul equal penetrates him who hears it, and that which it says produces no satiety.

(continued)

(continues)

Beginning of the arrangement of the good sayings, spoken by the noble lord, the divine father, beloved of Ptah, the son of the king, the first-born of his race, the prefect and feudal lord Ptah-hotep, so as to instruct the ignorant in the knowledge of the arguments of the good sayings. It is profitable for him who hears them, it is a loss to him who shall transgress them. He says to his son:

... Inspire not men with fear, else Ptah will fight against you in the same manner. If any one asserts that he lives by such means, Ptah will take away the bread from his mouth; if any one asserts that he enriches himself thereby, Ptah says: I may take those riches to myself. If any one asserts that he beats others, Ptah will end by reducing him to impotence. Let no one inspire men with fear; this is the will of Ptah. Let one provide sustenance for them in the lap of peace; it will then be that they will freely give what has been torn from them by terror. . . .

If you are one of those who bring the messages of one great man to another, conform yourself exactly to that wherewith he has charged you; perform for him the commission as he has enjoined you. Beware of altering in speaking the offensive words which one great person addresses to another; he who perverts the trustfulness of his way, in order to repeat only what produces pleasure in the words of every man, great or small, is a detestable person.

If you are a farmer, gather the crops in the field which the great Ptah has given you, do not boast in the house of your neighbors; it is better to make oneself dreaded by one's deeds. As for him who, master of his own way of acting, being all-powerful, seizes the goods of others like a crocodile in the midst even of watchment, his children are an object of malediction, of scorn, and of hatred on account of it, while his father is grievously distressed, and as for the mother who has borne him, happy is another rather than herself. But a man becomes a god when he is chief of a tribe which has confidence in following him. . . .

Do not repeat any extravagance of language; do not listen to it; it is a thing which has escaped from a hasty mouth. If it is repeated, look, without hearing it, toward the earth; say nothing in regard to it. Cause him who speaks to you to know what is just, even him who provokes to injustice; cause that which is just to be done, cause it to triumph. As for that which is hateful according to the law, condemn it by unveiling it. . . .

If you are a son of the guardians deputed to watch over the public tranquility, execute your commission without knowing its meaning, and speak with firmness. Substitute not for that which the instructor has said what you believe to be his intention; the great use words as it suits them. Your part is to transmit rather than to comment upon. . . .

Do not plunder the house of your neighbors, seize not by force the goods which are beside you. Exclaim not then against that which you hear, and do not feel humiliated. It is necessary to reflect when one is hindered by it that the pressure of authority is felt also by one's neighbor. . . .

If you hear those things which I have said to you, your wisdom will be fully advanced. Although they are the means which are suitable for arriving at the *maat*, and it is that which makes them precious, their memory would recede from the mouth of men. But thanks to the beauty of their arrangement in rhythm all their words will now be carried without alteration over this earth eternally. That will create a canvass to be embellished, whereof the great will speak, in order to instruct men in its sayings. After having listened to them the pupil will become a master, even he who shall have properly listened to the sayings because he shall have heard them. Let him win success by placing himself in the first rank; that is for him a position perfect and durable, and he has nothing further to desire forever. By knowledge his path is assured, and he is made happy by it on the earth. The wise man is satiated by knowledge; he is a great man through his own merits. His tongue is in accord with his mind; just are his lips when he speaks, his eyes when he gazes, his ears when he hears. The advantage of his son is to do that which is just without deceiving himself.

To attend therefore profits the son of him who has attended. To attend is the result of the fact that one has attended. A teachable auditor is formed, because I have attended. Good when he has attended, good when he speaks, he who has attended has profited, and it is profitable to attend to him who has attended. To attend is worth more than anything else, for it produces love, the good thing that is twice good. The son who accepts the instruction of his father will grow old on that account. What Ptah loves is that one should attend; if one attends not, it is abhorrent to Ptah. The heart makes itself its own master when it attends and when it does not attend; but if it attends, then his heart is a beneficent master to a man. In attending to instruction, a man loves what he attends to, and to do that which is prescribed is pleasant. When a son attends to his father, it is a twofold joy for both; when wise things

are prescribed to him, the son is gentle toward his master. Attending to him who has attended when such things have been prescribed to him, he engraves upon his heart that which is approved by his father; and the recollection of it is preserved in the mouth of the living who exist upon this earth. . . .

A son who attends is like a follower of Horus; he is happy after having attended. He becomes great, he arrives at dignity, he gives the same lesson to his children. Let none innovate upon the precepts of his father; let the same precepts form his lessons to his children. "Verily," will his children say to him, "to accomplish what you say works marvels." Cause therefore that to flourish which is just, in order to nourish your children with it. If the teachers allow themselves to be led toward evil principles, verily the people who understand them not will speak accordingly, and that being said to those who are docile they will act accordingly. Then all the world considers them as masters and they inspire confidence in the public; but their glory endures not so long as would please them. Take not away then a word from the ancient teaching, and add not one; put not one thing in place of another; beware of uncovering the rebellious ideas which arise in you; but teach according to the words of the wise. Attend if you wish to dwell in the mouth of those who

shall attend to your words, when you have entered upon the office of master, that your words may be upon our lips . . . and that there may be a chair from which to deliver your arguments. . . .

Do that which your master bids you. Twice good is the precept of his father, from whom he has issued, from his flesh. What he tells us, let it be fixed in our heart; to satisfy him greatly let us do for him more than he has prescribed. Verily a good son is one of the gifts of Ptah, a son who does even better than he has been told to do. For his master he does what is satisfactory, putting himself with all his heart on the part of right. So I shall bring it about that your body shall be healthful, that the Pharaoh shall be satisfied with you in all circumstances and that you shall obtain years of life without default. It has caused me on earth to obtain one hundred and ten years of life, along with the gift of the favor of the Pharaoh among the first of those whom their works have ennobled, satisfying the Pharaoh in a place of dignity.

It is finished, from its beginning to its end, according to that which is found in writing.

The Middle East

≈ *The Code of Hammurabi, ca. 1780 B.C.E.* ≈

CODE OF LAWS

2. If anyone bring an accusation against a man, and the accused go to the river and leap into the river, if he sink in the river his accuser shall take possession of his house. But if the river prove that the accused is not guilty, and he escape unhurt, then he who had brought the accusation shall be put to death, while he who leaped into the river shall take possession of the house that had belonged to his accuser.
3. If anyone bring an accusation of any crime before the elders and does not prove what he has charged, he shall, if it be a capital offense charged, be put to death. . . .
6. If anyone steal the property of a temple or of the court, he shall be put to death, and also the one who receives the stolen thing from him shall be put to death.

7. If anyone buy from the son or the slave of another man, without witnesses or a contract, silver or gold, a male or female slave, an ox or a sheep, an ass or anything, or if he take it in charge, he is considered a thief and shall be put to death.
8. If anyone steal cattle or sheep, or an ass, or a pig or a goat, if it belong to a god or to the court, the thief shall pay thirtyfold therefor; if they belonged to a freed man of the king he shall pay tenfold; if the thief has nothing with which to pay he shall be put to death. . . .
14. If anyone steal the minor son of another, he shall be put to death. . . .
16. If any one receive into his house a runaway male or female slave of the court, or of a freedman, and does not bring it out at the public proclamation of the

(continued)

(continues)

major domus, the master of the house shall be put to death.

17. If any one find runaway male or female slaves in the open country and bring them to their masters, the master of the slaves shall pay him two shekels of silver.

18. If the slave will not give the name of the master, the finder shall bring him to the palace; a further investigation must follow, and the slave shall be returned to his master. . . .

21. If any one break a hole into a house (break in to steal), he shall be put to death before that hole and be buried.

22. If any one is committing a robbery and is caught, then he shall be put to death.

23. If the robber is not caught, then shall he who was robbed claim under oath the amount of his loss; then shall the community, and . . . on whose ground and territory and in whose domain it was compensate him for the goods stolen. . . .

25. If fire break out in a house, and some one who comes to put it out cast his eye upon the property of the owner of the house, and take the property of the master of the house, he shall be thrown into that self-same fire. . . .

44. If any one take over a waste-lying field to make it arable, but is lazy, and does not make it arable, he shall plow the fallow field in the fourth year, harrow it and till it, and give it back to its owner, and for each ten gan [a measure of area] ten gur of grain shall be paid.

45. If a man rent his field for tillage for a fixed rental, and receive the rent of his field, but bad weather come and destroy the harvest, the injury falls upon the tiller of the soil.

48. If any one owe a debt for a loan, and a storm prostrates the grain, or the harvest fail, or the grain does not grow for lack of water; in that year he need not give his creditor any grain, he washes his debt-tablet in water and pays no rent for this year. . . .

125. If any one place his property with another for safe keeping, and there, either through thieves or robbers, his property and the property of the other man be lost, the owner of the house, through whose neglect the loss took place, shall compensate the owner for all that was given to him in charge. But the owner of the house shall

try to follow up and recover his property, and take it away from the thief. . . .

129. If a man's wife be surprised (in flagrante delicto) with another man, both shall be tied and thrown into the water, but the husband may pardon his wife and the king his slaves. . . .

135. If a man be taken prisoner in war and there be no sustenance in his house and his wife go to another house and bear children; and if later her husband return and come to his home: then this wife shall return to her husband, but the children follow their father.

136. If any one leave his house, run away, and then his wife go to another house, if then he return, and wishes to take his wife back: because he fled from his home and ran away, the wife of this runaway shall not return to her husband. . . .

138. If a man wishes to separate from his wife who has borne him no children, he shall give her the amount of her purchase money and the dowry which she brought from her father's house, and let her go. . . .

141. If a man's wife, who lives in his house, wishes to leave it, plunges into debt, tries to ruin her house, neglects her husband, and is judicially convicted: if her husband offer her release, she may go on her way, and he gives her nothing as a gift of release. If her husband does not wish to release her, and if he take another wife, she shall remain as servant in her husband's house. . . .

LAWS of justice which Hammurabi, the wise king, established. A righteous law, and pious statute did he teach the land. Hammurabi, the protecting king am I. I have not withdrawn myself from the men, whom Bel gave to me, the rule over whom Marduk gave to me, I was not negligent, but I made them a peaceful abiding-place. I expounded all great difficulties; I made the light shine upon them. With the mighty weapons which Zamama and Ishtar entrusted to me, with the keen vision with which Ea endowed me, with the wisdom that Marduk gave me, I have uprooted the enemy above and below (in north and south), subdued the earth, brought prosperity to the land, guaranteed security to the inhabitants in their homes; a disturber was not permitted. The great gods have called me, I am the salvation-bearing shepherd, whose staff is straight, the good shadow that is spread over my city; on my breast I cherish the inhabitants of the land of Sumer and Akkad; in my shelter I have let them repose in peace; in my deep wisdom have I enclosed them. That the strong might not injure the weak, in order to protect the widows and

orphans, I have in Babylon the city where Anu and Bel raise high their head, in E-Sagil, the Temple, whose foundations stand firm as heaven and earth, in order to bespeak justice in the land, to settle all disputes, and heal all injuries, set up these my precious words, written

upon my memorial stone, before the image of me, as king of righteousness.

Greece

~ The Law Code of Gortyn (Crete), ca. 450 B.C.E. ~

I. Whoever intends to bring suit in relation to a free man or slave shall not take action by seizure before trial; but if he do seize him, let the judge fine him ten *staters* for the free man, five for the slave, and let him release him within three days. But if he do not release him, let the judge sentence him to a *stater* for a free man, a *drachma* for a slave, each day until he has released him. But if he deny that he made the seizure, the judge shall decide with oath, unless a witness testify. If one party contend that he is a free man, the other that he is a slave, those who testify that he is free shall be preferred. But if they testify either for both parties or for neither of the two, the judge shall render his decision by oath. But if the slave on account of whom the defendant was defeated take refuge in a temple, the defendant, summoning the plaintiff in the presence of two witnesses of age and free, shall point out the slave at the temple; but if he do not issue the summons or do not point him out, he shall pay what is written. And if he do not return him, even within the year, he shall pay in addition to the sums stated onefold. But if he die while the suit is progressing, he shall pay his value onefold.

II. If one commit rape on a free man or woman, he shall pay 100 *staters*, and if on the son or daughter of an *apetairos* ten, and if a slave on a free man or woman, he shall pay double, and if a free man on a male or female serf five *drachmas*, and if a serf on a male or female serf, five *staters*. If one debauch a female house slave by force, he shall pay two *staters*, but if one already debauched, in the daytime, an *obol*, but if at night, two *obols*. If one tries to seduce a free woman, he shall pay ten *staters*, if a witness testify. . . .

III. If one be taken in adultery with a free woman in her father's, brother's, or husband's house, he shall pay 100 *staters*, but if in another's house, fifty; and with the wife

of an *apetairos*, ten. But if a slave with a free woman, he shall pay double, but if a slave with a slave's wife, five. . . .

IV. If a husband and wife be divorced, she shall have her own property that she came with to her husband, and the half of the income if it be from her own property, and whatever she has woven, the half, whatever it may be, and five *staters*, if her husband be the cause of her dismissal; but if the husband deny that he was the cause, the judge shall decide. . . .

V. If a man die, leaving children, if his wife wish, she may marry, taking her own property and whatever her husband may have given her, according to what is written, in the presence of three witnesses of age and free. But if she carry away anything belonging to her children she shall be answerable. And if he leaves her childless, she shall have her own property and whatever she has woven, the half, and of the produce on hand in possession of the heirs, a portion, and whatever her husband has given her as is written. If a wife shall die childless, the husband shall return to her heirs her property, and whatever she has woven the half, and of the produce, if it be from her own property, the half. If a female serf be separated from a male serf while alive or in case of his death, she shall have her own property, but if she carry away anything else she shall be answerable.

VI. If a woman bear a child while living apart from her husband after divorce, she shall have it conveyed to the husband at his house, in the presence of three witnesses; if he do not receive the child, it shall be in the power of the mother to bring up or expose. . . .

VII. The father shall have power over his children and the division of the property, and the mother over her property. As long as they live, it shall not be necessary to make a division. But if a father die, the houses in the

(continued)

(continues)

city and whatever there is in the houses in which a serf residing in the country does not live, and the sheep and the larger animals which do not belong to the serf, shall belong to the sons; but all the rest of the property shall be divided fairly, and the sons, howsoever many there be, shall receive two parts each, and the daughters one part each. The mother's property also shall be divided, in case she dies, as is written for the father's. And if there should be no property but a house, the daughters shall receive their share as is written. And if a father while living may wish to give to his married daughter, let him give according to what is written, but not more. . .

X. As long as a father lives, no one shall purchase any of his property from a son, or take it on mortgage; but whatever the son himself may have acquired or inherited, he may sell if he will; nor shall the father sell or pledge the property of his children, whatever they have themselves acquired or succeeded to, nor the husband that of his wife, nor the son that of the mother. . . . If a mother die leaving children, the father shall be trustee of the mother's property, but he shall not sell or mortgage unless the children assent, being of age; and if anyone shall otherwise purchase or take on pledge the property, it shall still belong to the children; and to the purchaser or pledgor the seller or pledgee shall pay twofold the value in damages. But if he wed another, the children shall have control of the mother's property.

XI. If a slave going to a free woman shall wed her, the children shall be free; but if the free woman to a slave, the children shall be slaves; and if from the same mother free and slave children be born, if the mother die and there be property, the free children shall have it; otherwise her free relatives shall succeed to it.

XIV. The heiress shall marry the brother of the father, the eldest of those living; and if there be more heiresses

and brothers of the father, they shall marry the eldest in succession. . . . But if he do not wish to marry the heiress, the relatives of the heiress shall charge him and the judge shall order him to marry her within two months; and if he do not marry, she shall marry the next eldest. If she do not wish to marry, the heiress shall have the house and whatever is in the house, but sharing the half of the remainder, she may marry another of her tribe, and the other half shall go to the eldest. . . .

XVI. A son may give to a mother or a husband to a wife 100 *staters* or less, but not more; if he should give more, the relatives shall have the property. If anyone owing money, or under obligation for damages, or during the progress of a suit, should give away anything, unless the rest of his property be equal to the obligation, the gift shall be null and void. One shall not buy a man while mortgaged until the mortgagor release him. . . .

XVII. Adoption may take place whence one will; and the declaration shall be made in the market-place when the citizens are gathered. If there be no legitimate children, the adopted shall receive all the property as for legitimates. If there be legitimate children, the adopted son shall receive with the males the adopted son shall have an equal share. If the adopted son shall die without legitimate children, the property shall return to the pertinent relatives of the adopter. A woman shall not adopt, nor a person under puberty.

XVIII. Whatever is written for the judge to decide according to witnesses or by oath of denial, he shall decide as is written, but touching other matters shall decide under oath according to matters in controversy. If a son have given property to his mother, or a husband to his wife, as was written before these writings, it shall not be illegal; but hereafter gifts shall be made as here written.

Rome

~ The Twelve Tables, ca. 450 B.C.E. ~

TABLE I.

1. If anyone summons a man before the magistrate, he must go. If the man summoned does not go, let the one summoning him call the bystanders to witness and then take him by force.

2. If he shirks or runs away, let the summoner lay hands on him.

3. If illness or old age is the hindrance, let the summoner provide a team. He need not provide a covered carriage with a pallet unless he chooses.

4. Let the protector of a landholder be a landholder; for one of the proletariat, let anyone that cares be protector.

6-9. When the litigants settle their case by compromise, let the magistrate announce it. If they do not compromise, let them state each his own side of the case, in the *comitium* of the forum before noon. Afterwards let them talk it out together, while both are present. After noon, in case either party has failed to appear, let the magistrate pronounce judgment in favor of the one who is present. If both are present the trial may last until sunset but no later.

TABLE II.

2. He whose witness has failed to appear may summon him by loud calls before his house every third day.

TABLE III.

1. One who has confessed a debt, or against whom judgment has been pronounced, shall have thirty days to pay it in. After that forcible seizure of his person is allowed. The creditor shall bring him before the magistrate. Unless he pays the amount of the judgment or some one in the presence of the magistrate interferes in his behalf as protector the creditor so shall take him home and fasten him in stocks or fetters. He shall fasten him with not less than fifteen pounds of weight or, if he choose, with more. If the prisoner choose, he may furnish his own food. If he does not, the creditor must give him a pound of meal daily; if he choose he may give him more.

2. On the third market day let them divide his body among them. If they cut more or less than each one's share it shall be no crime.

3. Against a foreigner the right in property shall be valid forever.

TABLE IV.

1. A dreadfully deformed child shall be quickly killed.

2. If a father sell his son three times, the son shall be free from his father.

3. As a man has provided in his will in regard to his money and the care of his property, so let it be binding. If he has no heir and dies intestate, let the nearest agnate have the inheritance. If there is no agnate, let the members of his gens have the inheritance.

4. If one is mad but has no guardian, the power over him and his money shall belong to his agnates and the members of his gens.

5. A child born after ten months since the father's death will not be admitted into a legal inheritance.

TABLE V.

1. Females should remain in guardianship even when they have attained their majority.

TABLE VI.

1. When one makes a bond and a conveyance of property, as he has made formal declaration so let it be binding.

3. A beam that is built into a house or a vineyard trellis one may not take from its place.

5. Usucapio of movable things requires one year's possession for its completion but usucapio of an estate and buildings two years.

6. Any woman who does not wish to be subjected in this manner to the hand of her husband should be absent three nights in succession every year, and so interrupt the usucapio of each year.

TABLE VII.

1. Let them keep the road in order. If they have not paved it, a man may drive his team where he likes.

9. Should a tree on a neighbor's farm be bent crooked by the wind and lean over your farm, you may take legal action for removal of that tree.

10. A man might gather up fruit that was falling down onto another man's farm.

TABLE VIII.

2. If one has maimed a limb and does not compromise with the injured person, let there be retaliation. If one has broken a bone of a freeman with his hand or with a cudgel, let him pay a penalty of three hundred coins. If he has broken the bone of a slave, let him have one hundred and fifty coins. If one is guilty of insult, the penalty shall be twenty-five coins.

3. If one is slain while committing theft by night, he is rightly slain.

4. If a patron shall have devised any deceit against his client, let him be accursed.

(continued)

(continues)

5. If one shall permit himself to be summoned as a witness, or has been a weigher, if he does not give his testimony, let him be noted as dishonest and incapable of acting again as witness.

10. Any person who destroys by burning any building or heap of corn deposited alongside a house shall be bound, scourged, and put to death by burning at the stake, provided that he has committed the said misdeed with malice aforethought; but if he shall have committed it by accident, that is, by negligence, it is ordained that he repair the damage or, if he be too poor to be competent for such punishment, he shall receive a lighter punishment.

12. If the theft has been done by night, if the owner kills the thief, the thief shall be held to be lawfully killed.

13. It is unlawful for a thief to be killed by day . . . unless he defends himself with a weapon; even though he has come with a weapon, unless he shall use the weapon and fight back, you shall not kill him. And even if he resists, first call out so that someone may hear and come up.

23. A person who had been found guilty of giving false witness shall be hurled down from the Tarpeian Rock.

26. No person shall hold meetings by night in the city.

TABLE IX.

4. The penalty shall be capital for a judge or arbiter legally appointed who has been found guilty of receiving a bribe for giving a decision.

5. Treason: He who shall have roused up a public enemy or handed over a citizen to a public enemy must suffer capital punishment.

6. Putting to death of any man, whosoever he might be unconvicted is forbidden.

TABLE X.

1. None is to bury or burn a corpse in the city.

3. The women shall not tear their faces nor wail on account of the funeral.

5. If one obtains a crown himself, or if his chattel does so because of his honor and valor, if it is placed on his head, or the head of his parents, it shall be no crime.

TABLE XI.

1. Marriages should not take place between plebeians and patricians.

TABLE XII.

2. If a slave shall have committed theft or done damage with his master's knowledge, the action for damages is in the slave's name.

5. Whatever the people had last ordained should be held as binding by law.

► literature

INTRODUCTION

Even people who have studied literature most of their lives are often unsure how to define what literature is and what it is not. Perhaps everything that has ever been written is literature. Some people would exclude such writings as laundry lists and legal documents, yet a historian might be able to see a world of information about an ancient culture in its laundry lists and legal documents. This fuzziness in definition can be maddening when one wishes to be precise, but part of the attraction of the study of literature is its tendency to transcend boundaries, changing its shape to suit the needs of a particular author or culture.

In general, literature can be divided into four categories: poetry, fiction, drama, and prose nonfiction. Poetry is expressed in verse, using rhythms and associations of sounds, as in the case of rhyme. Fiction tells a story and usually has a plot and characters whose actions make up the plot. Drama also tells a story but through actors depicting the characters of the story. Nonfiction prose is harder to define. Prose is writing that is not in verse, and nonfiction prose is a factual accounting of the subject under consideration, often taking real events and people as its starting point. Some literary scholars insist that prose is more than that; they assert that writing should be artful and graceful in order to be considered prose, meaning that laundry lists do not count. These four categories are commonly used to discuss literature because they are convenient. When looked at closely, however, they are not as well defined as they may seem, because they sometimes overlap.

Take the matter of poetry. Poetry is the oldest-known literary form, owing to its oral tradition. Long before people created written languages, they learned to tell stories. These stories were passed down orally from one generation to the next; hence the term *oral tradition*. In illiterate societies or in societies in which literacy was limited to a minority of people, the oral tradition was a way to preserve religious stories, tales of heroes, wisdom acquired through experience, and stories that were just plain fun to hear. In almost every known society certain people became professional storytellers.

Storytelling was a way for a traveler to earn food and lodging for a night. A good storyteller could barter the telling of a story for goods or exchange it for money. A professional storyteller would be expected to know certain tales, long and short, that audiences wanted to hear over and over again. This required storytellers to memorize lengthy historical and religious tales as well as numerous small stories. That ancient people were illiterate did not mean they also were stupid; an audience would often know the most important stories by heart and would know when a storyteller got something wrong. This is how poetry became important, because poetry has rhythm, and rhythm makes remembering words easier. Thus, many ancient religious works were first written down in verse, because they were originally part of the oral tradition.

If one looks at pictures of ancient storytellers such as Homer, one may notice that the storytellers often hold a stringed instrument or are accompanied by a musician. The rhythmic strumming of the instrument would help the storyteller keep his or her rhythm when reciting a tale, which would assist the storyteller in remembering the words. Long epics such as Homer's *Iliad* were composed in verse and memorized and recited in verse. In fact, in the *Iliad* itself Homer refers to storytellers as singers. One can see immediately the fuzziness in the four categories of literature, because the ancient epics were both poetry and stories. The people who first heard them probably appreciated them for both their poetic use of language and their plots and characters. When studying drama, one is likely to see the same sort of blending. Many ancient dramas were written in verse, and audiences admired the poetic language as well as the plots.

Dramas may have been the next step in the development of literature. Most of what is known about ancient dramas comes from plays that were composed by writers who were self-consciously creating literary works, which means that they are imperfect representations of the dramas that preceded them, before people could write. Most anthropologists believe that drama developed out of religious rites. In dramas people portrayed religious figures, perhaps singing or dancing to show the spiritual nature of the figures. The earliest such dramas seem to have been presented during celebrations of the coming of spring. In many parts of the world, these festivities included the ritual killing of one or more of the actors, usually youngsters, whose deaths were meant to renew the fertility of the soil for the upcoming planting of crops.

Once a culture became literate, it was difficult to stamp out this practice. Even after a government managed to end the practice of sacrificing actors, a playwright might be ritually killed if his play did not satisfy his audience. This seriousness is sometimes a help to people studying ancient societies, because various literary works were intended to express the hopes, fears, dreams, and nightmares of the authors and audiences. For example, the Epic of Gilgamesh from ancient Mesopotamia reveals a concern for defining what is good and what is evil, a concern about loneliness, an interest in what makes someone a friend, bewilderment at why people suffer, and a longing for immortality. The very fact that ancient peoples wrote down this epic and preserved it for centuries shows that it touched on matters of importance to them; by reading the epic, a person can learn about them. Further, a great literary work touches on our common humanity, and Gilgamesh speaks of issues that still interest people today, allowing modern audiences to see how another group of people in circumstances different from our own viewed issues that still matter.

AFRICA

BY DIANNE WHITE OYLER

Literature in ancient Africa represents the creative thought of indigenous people in both oral and written forms of

communication. In the ancient world these forms of communication most likely transmitted knowledge in the language spoken by the community. As the community expanded into kingdoms and empires, people were exposed to other languages through trade and conquest. Ancient African written literature may have used a writing system invented by the indigenous people of the region. However, this writing system probably recorded literature in the language of the upper class rather than the vernacular language spoken by the peasants. Written literature may have also used a writing system from a nearby community or trading partner that was adopted or adapted to the needs of the community.

For most of the continent literature was in an oral form that today is called *orature*. This oral literature preserved indigenous thought by committing it to memory and passing it down from one generation to the next. In many cases certain members of society were charged with the responsibility of remembering the oral literature and maintaining its accuracy. This literature included such forms as oral tradition, religious poems and songs, and myths and legends of past heroes whose actions should be emulated. Individual families also passed down similar stories that specifically involved their family members and told these stories from their own point of view. These families transmitted the accepted morals and practices of the community in stories, poems, riddles, proverbs, and songs to the children, who would become the next generation of leaders. It was the responsibility of each of the family members to communicate this type of literature.

The earliest-known written literature appeared as early as 3000 B.C.E. when Egypt began recording governmental, religious, and business documents as well as creative thought. They were transcribing indigenous thought from the canon of oral literature of the upper class into the indigenous writing system, hieroglyphics. Having an intimate relationship with Egypt, Nubia and the kingdoms of Kush and Meroë (present-day Sudan) on the upper Nile River borrowed Egypt's hieroglyphics, adopting the writing system. Later, however, it changed the hieroglyphic writing system by adapting it and thus creating the Meroitic script. Spanning the Red Sea, early Axum (present-day Ethiopia) developed its own writing system, called Ge'ez, based on the Sabeian alphabet from southern Arabia. In addition to these three indigenous writing systems, the Greek language and alphabet became a dominant writing system after the conquest by Alexander the Great, and cultural diffusion brought literature from southern Europe and western Asia as the continent became more engaged in the larger Mediterranean world.

Ancient African literature can be found written on papyrus, the paper of the day used by many societies, and recorded on the walls of palaces, temples, tombs, and monuments such as obelisks and stelae, both forms of monolithic pillars. However, in these literate societies, only a small segment of each community could actually read and write. It was the duty of the scribe to keep official records and write literature. Nevertheless, all segments of the community participated in and

enjoyed both oral and written literature. And while literacy remained in the northern and eastern part of the continent until the arrival of Islam, each community had its own canon of oral literature.

ORAL LITERATURE

Oral literature is creative thought delivered by word of mouth. Other than the manipulation of language to communicate in prose or verse, oral literature used performance techniques, including music, repetition, song, and phrasing. Oral literature included various genres: historical tales, folktales, legends, epics, myths, divination prose and verse, hunter's tales, as well as poetry such as praise poetry, songs, proverbs, and riddles. This literature was passed down from generation to generation until it was fixed in the written record. The storytelling activity was a form of local entertainment that could be found within the extended family compound, among the clans, or in the larger village or town setting. As the family gathered in the evening to share the events of the day, storytelling provided entertainment and an education that enabled children to participate in the intellectual life of the community. African literature was unique in that audience participation was required in all genres. Children were not passive in the storytelling process, and their inclusion began the process of the memorization that preserved this type of knowledge. However, the family's oral literature could change from one generation to the next despite efforts to preserve its accuracy. These stories continued in this way until they were written down, which fixed them so that they could no longer change.

Folktales presented scenarios of questionable human behavior. The action of the story centered on a human or animal that portrayed dubious human characteristics such as greed or jealousy. Using an animal to portray negative human characteristics allowed society to correct inappropriate behaviors without accusing any one individual, especially an individual who was highly placed in society. Regardless of the central actor in the folktale, the story had a twofold purpose; it entertained while either teaching or reinforcing an intrinsic message as to the family or community's standards of appropriate behavior. There were two types of folktales. The trickster folktale was usually about an animal that was smart but mischievous and lacked a sense of what is right and wrong. The dilemma tale posed a problem that could be solved many different ways. Those who engaged in the trickster folktales saw what could happen to someone who used poor judgment, and those who engaged in the dilemma tale participated in an open-ended discussion that provided practice in honing oral arguments and choosing appropriate solutions to problems faced by the community each day.

The historical tale included stories of genealogy and those of the community's heroic and historic past. The genealogy traced the ancestors of the family lineage who first settled in the area from whom the first community leader was chosen. The historical tale could also share the exploits of a

larger-than-life person from the past. The legend was a tale of ancestors or events from the heroic historic past that the community considered memorable and instructive to be retold. It could also be a historical tale.

The myth often described a tale of the origins of the community's ancestors. These often included the environment, culture, gods, and authoritative ancestors. These myths could also be legends. In South Africa around 2000 B.C.E. two groups inhabited the region. The Khoikhoi who lived in present-day Botswana had a creation myth concerning Tsui Goab, who was a great powerful chief. Tsui Goab was the first Khoikhoi from whom all the Khoikhoi clans took their origin. At the same time, the neighbors of the Khoikhoi during this period, the Khoisan of present-day South Africa, Namibia, and Botswana, had a creation myth about Cagn, the first being, who created the world. In eastern Africa around 1000 B.C.E. the founding myth of the kingdom of Axum relates the origins of the kingdom through the birth of Menelik I, son of Axum's Queen of Sa'aba (Sheba) and King Solomon of Israel.

The divination tale came from a large body of community wisdom collected and incorporated in the decision-making process. The Yoruba of West Africa (present-day Nigeria and Benin) date back to 350 B.C.E., and they developed divination texts that were a large corpus of Yoruba wisdom reflecting the group's history, culture, moral values, and views on specific issues. The diviner was the repository of this type of specialized knowledge, which was passed down from one generation to the next. This knowledge was related in verse, "the sixteen cowries," which was recited as required by the events.

The hunter's tale was a story from the hunt of bygone days where the community's hunters regaled one another and their families with stories. They also told tales of their ancestor hunters, who were remembered and who became larger than life as their exploits were recounted.

Poetry is thought communicated in verse and an important genre found in most communities of the continent, where the people enjoyed rhyming and rhythmic composition. For many, poetry was synonymous with language, and it was an integral part of daily life. Members communicated about serious issues, such as local politics, or recreational topics, such as romantic love. Poetry included epic poems, songs, praise poetry, proverbs, and riddles. Oral poetry was composed according to a predetermined formula. It may have been composed, remembered, and performed, or it may have been composed as it was performed.

The epic poem was a historical tale told in verse form in which the accomplishments of a larger-than-life family or community figure from the heroic historic past was further embellished. Epic poems were either part of oral tradition or stand-alone stories. In any case the poem was accompanied by music and or dance and used varying performance techniques.

The song was an important form of communication used by all communities on the continent. As an example of the concept of African oral literature being participatory, songs

used the call-and-response method. Work songs were call-and-response because they were sung in a specific rhythmic pattern to pace the work, where the group leader called out the lyric and the group answered.

The praise poem could be found in most communities on the continent. This elaborate poetry detailed the important qualities and accomplishments of historic family or clan members that were singled out for praise. Praise poetry was composed and sung by professional artists who performed them at public functions. While different singers could perform a praise poem, the content remained the same, as the poems were improvised by applying the techniques of suggestion and insinuation from language and imagery in the portrayal of the person or event. Praise songs were incorporated into the performance of the epic poem. Praise songs praised the gods, the deeds of the hunter or warrior, the family of a bride or groom at a wedding ceremony, or ancestors who were important for the family to remember. However, praise poetry used to extol the virtues of the community members who might be considered leaders of the group was composed for actions that were more than just praiseworthy; these acts had to be remarkable, even for them.

The proverb used language and imagery to bring into focus daily lessons for living. They were succinct and could be in prose or verse. In many communities the knowledge of proverbs demonstrated wisdom and was used to prove a point or to correct behavior. For some of these communities knowledge of proverbs was important or even required to participate in effective conversation. The riddle was much like the proverb in that the focus was on analogy; however, the riddle was a question that asked for the identification of common qualities between different objects and situations. The riddle was part of evening storytelling, and it, too, had an educational dimension as it helped to develop perception.

The oral tradition is another form of literature passed down from one generation to the next. For many societies this form of oral literature was a kind of specialized knowledge controlled by a specific group identified as such by the community. For example, many of the Mande speakers of West Africa had a socially constructed cultural caste of storytellers known as the *djelw*, who possessed this specialized knowledge. Many other groups also had this specialized job, called by the French term *griot*. Identified by families, these storytellers or local historians were charged with the responsibility of maintaining the accuracy of the tradition as it was passed down from generation to generation. Some families kept this knowledge for the king, the royal *griot*, while others kept knowledge for the local community. Each family or community had its own cultural historians with its own version of the facts that amplified its own contribution to the tale.

Nevertheless, while the emphasis of the story may have shifted from community to community or performer to performer, the facts of the story were accurately remembered and presented. The audience judged the purveyor of the oral tradition based on their own memories of these stories that had

been told to them in the family setting. They also judged the performance based on their perception of how well the storytellers portrayed the contribution made by their ancestors to the events in the story. Oral tradition is performance art in which the storyteller or historian used prose, verse, song, dance, and accompaniment by instruments such as drums, harps, or xylophones. While the oral historian's performance had to be compelling, it also had to maintain a delicate balance between the facts and the portrayal of the contributions by the ancestors of the local audience. The audience or the performer may have changed, but the factual content remained the same.

WRITTEN LITERATURE

Written literature existed in the ancient African world since the founding of the state of Egypt by King Menes around 2920 B.C.E. In fact, more is known about ancient Egyptian civilization than any other because of the extensive writings on papyri preserved in the library at Alexandria built in 283 B.C.E. by Ptolemy II Philadelphus (r. 285–246 B.C.E.). Following this invention, most written literature in indigenous writing systems occurred in the upper Nile kingdom of Kush and in the Red Sea kingdom of Axum. Other written literature was brought to the North African Maghreb by Christians using Greek written in the Greek alphabet and Latin written in the Roman alphabet to teach and copy the Bible and write important doctrines for the Christian world.

Written literature in prose along the upper Nile and the kingdoms of Kush and Meroë included literature that used adopted Egyptian hieroglyphics. This writing system was adapted from the eighth to the fourth centuries B.C.E., the Napatan period, using a form of hieroglyphic writing for texts. After Kush under the rule of Kashta and later Piye conquered Egypt, the Nubians ruled as the pharaohs of Egypt's Twenty-fifth Dynasty. Piye ruled from 750 to 712 B.C.E. "The Stele of Victory," the Piye stela, is the longest and most detailed text about ancient Egypt. Written in Egyptian hieroglyphics, the text is inscribed on a stele of pink granite with 159 lines describing Piye's military prowess and his deliberations as king. The Nubian pharaoh Shabaka, who ruled Egypt from 712 to 698 B.C.E., inscribed theological issues shared by the Egyptians and the Nubians on a black stele known as the "Memphite Theology." The tomb of Queen Shanakdakhete (r. 170–160 B.C.E.), the first female ruler of Kush's Meroitic period, is inscribed with the oldest known Meroitic hieroglyphs. Adapted from Egypt hieroglyphics, these hieroglyphs were changed to meet Nubian needs. While the writing has been deciphered, the Meroitic language has not, so understanding this document is difficult. In addition there are more than 800 funerary texts that cannot be deciphered. Under King Taniydamani (first to second century B.C.E.) two stelae of funerary texts provide the first long Meroitic texts. In the sixth century C.E. the Nubian kingdoms converted to Christianity, and written records of their Christian religion include fragments of scripture, liturgical texts, and lives of saints.

Written literature in prose from Axum includes Ge'ez inscriptions from the feudal empire as early as the fifth century B.C.E., though some of these inscriptions are also in verse similar to folk poetry. While many of these inscriptions were religious, some provided detailed accounts of battles fought and won, like those fought by King Ezana in defeating the failing kingdom of Kush at Meroë. A body of literature does not begin until King Ezana accepted Christianity and made it the state religion in the fourth century C.E. Biblical scripture and religious texts were translated into Ge'ez from the Greek language and alphabet, preserving texts that date to before the schism in the Christian Church that created Western Roman Christianity and Eastern Roman Christianity. These translations preserved entire books of biblical text, such as the book of Enoch, the book of Jubilees, and the Ascension of Isaiah. Monasteries were the repositories for the Ge'ez manuscripts and also acted as schools that educated those who became Axumite writers. Secular literature existed in the form of history and the recording of the founding myths of the kingdom.

Written literature in poetry was important in the religious world of Axum. Hymns provide the bulk of Ge'ez poetic literature, and a large book of Ge'ez hymns, *Diggua*, is a collection of songs that rhyme. The compilation of this book is credited to the sixth-century priest from Axum who later became Saint Yared. As a part of the liturgy, ceremonial singers participated by singing these religious hymns. Ge'ez hymn poetry includes *qine* hymns that were a form of praise poetry. Different from the ceremonial singers, the composer of the *qine* hymn observed rules concerning length and number of rhyming lines and the rhythm of the grammar. The composer also chose effective figures of speech to create a powerful statement. The *qine* hymns eulogized political and religious leaders or admonished them for their mistakes. The *qine* hymn was verse that could be used only once at a particular church for one particular event.

Written literature in prose in the North African Maghreb concerned Christian religious texts. In the area previously known as Carthage, Latin written in the Roman alphabet was established as the language of the Western Roman Christian Church. In the second century C.E. Quintus Septimius Florens Tertullianus (born ca. 155–160) played an important role in the development of early Christianity. He composed works defending Christianity against corrupting beliefs, including "Against Valentinus," "Against Marcion," and "Against Hermogenes." Aurelius Augustinus of Hippo (354–430 C.E.) became Saint Augustine, the Western Christian bishop of Hippo (Algeria). Saint Augustine was an important contributor to the institutionalization of the Western Roman Christian Church. He was instrumental in clearly articulating the relationship between the concepts of predestination and free will and grace and good works. After his conversion to Christianity he wrote a spiritual biography, the *Confessions* (397 C.E.), which is a prose poem. His work *The City of God* (410–426 C.E.) is an epic that vindicates Christianity against those

who claimed that it was the reason for the fall of the Western Roman Empire to the Visigoths.

Literature in ancient Africa represents oral and written indigenous creative thought. Although many documents appear to have been written during this time, few people could read them because they were either not literate or the language of the text was foreign to them, like the new Christian religious texts that began to permeate society. Pre-literate and literate members of society could appreciate indigenous written literature as it was read in an oral performance. They also were exposed to the reading of and the chanting performance of liturgical literature written in foreign languages. However, all members of society could enjoy and appreciate the many forms of oral literature that eventually were later transcribed into text or incorporated into other written texts.

EGYPT

BY KELLY-ANNE DIAMOND REED

The ancient Egyptians produced many types of written texts, such as religious works (funerary texts and autobiographies, hymns, and litanies, or collections of prayers), administrative documents (inventories and payrolls), legal documents, medical texts, historical texts, letters, manuals, *onomastica* (catalogues of things arranged by kind), spells, narratives, love poems, teachings, dialogues, and lamentations. The texts are diverse, so the question arises as to which of them can be categorized as literature in the Western sense of the word. This question is difficult to answer, and not all scholars agree.

Unfortunately, there is no Egyptian word to define the different types of writings. The blanket term *writings* was used by the ancient Egyptians to describe most of their textual material. Alternatively, the terms *command* and *teaching* were also sometimes applied. Modern scholars tend to categorize the documents based on their context, content, physical form, date, or script. The majority of what was written down was written to communicate or record information. However, there are several texts that seem to conform to modern ideas of literature.

OLD KINGDOM

In the beginning writing was used to label items, such as a person, a place, or a belonging and sometimes even an event. The art of writing was said to be derived from the gods, and there was a certain mystique that went along with the written word. The first time that writing emerges on a large scale is in the Offering List that appears in the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) private tombs. These tombs belonged to the wealthy nobles who generally invested everything they had in their tomb construction. This sort of list enumerates such items as materials, ointments, and food products. These were the items that the deceased wished to receive. The Offering List was a significant step toward the development of literature, and this occurred in the private realm.

Eventually the list increased in size and warranted re-organization. The Egyptians then decided to substitute for the list a “Prayer for Offerings.” This prayer became the focal point for all tomb decoration. Simultaneously, with the addition of narrative, the long lists of the deceased’s titles evolved into an autobiography. It was during the Fifth Dynasty (ca. 2465–ca. 2323 B.C.E.) that both the prayer and the autobiography were standard features in tomb decoration. However, the “Prayer for Offerings” had certain limitations in that it was tightly bound to the cult of the dead; the autobiography, on the other hand, became quite elaborate in the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) and remained in use for the next two millennia.

The autobiography focused on the positive characteristics of the deceased, or the idealized characteristics created by society. Nothing negative or derogatory was ever included in these inscriptions. The purpose of the autobiography was to preserve the name of the deceased for all eternity. The deceased himself would be reborn in the hereafter, and his name would live forever on earth. An example of a Sixth Dynasty tomb autobiography is that of Weni, which consists of 51 vertical columns of hieroglyphs. It is from Abydos. A short excerpt reads as follows: “While I was senior warden of Nekhen, his majesty made me a sole companion and overseer of the royal tenants. I replaced four overseers of royal tenants who were there. I acted for his majesty’s praise in guarding, escorting the king, and attending. I acted throughout so that his majesty praised me for it exceedingly.” Often the tomb autobiography seems very self-laudatory to the modern reader. One of the most well-known Old Kingdom tomb autobiographies is that of Harkhuf, which also dates to the Sixth Dynasty and is found at Aswān.

Accompanying the autobiography was the more formulaic catalogue of virtues. This set of moral standards mirrors the ethical code illustrated in the second type of literature that emerged in the Old Kingdom: wisdom literature. Wisdom literature can be broken down further under the headings teachings (instructions), laments, and dialogues. Short maxims were created and then consolidated to form the instruction. The teachings, or didactic texts, take the form of instructions given by a father to his son. In some examples the characters involved are officials or royalty from the past.

The earliest surviving instruction is that of Hardjedef. This text has been compiled from nine ostraca (pieces of pottery with inscribed writing) of New Kingdom date (ca. 1550–ca. 1070 B.C.E.) and a wooden tablet of the Late Period (ca. 712–ca. 332 B.C.E.). However, it is thought that the text dates to the Fifth Dynasty; it opens, “Beginning of the Instruction made by the Hereditary Prince, Count, King’s Son, Hardjedef, for his son, his nursling, whose name is Au-ib-re.” One of the preserved instructions advises that one should found a household, take a wife, and have a son.

The “Instruction Addressed to Kagemni” and the “Teaching of the Vizier Ptah-hotep” also date to the Old Kingdom. The former text is preserved in the Papyrus Prisse, but

Page from the Book of the Dead of Hunefer, Thebes, Egypt (ca. 1300 B.C.E.) (© The Trustees of the British Museum)

its beginning is lost. It is followed on the papyrus by the only complete copy of the latter text. The “Teaching of the Vizier Ptah-hotep” is also preserved on two additional papyri and a wooden tablet. This work is a very long instruction and consists of 37 maxims, a prologue, and an epilogue. The main themes of this work are self-control, moderation, kindness, generosity, justice, and truthfulness. Both of these two texts are thought to date to the Sixth Dynasty. At this time the evolution of the written word had come into its own and exhibited many similarities with the work of the succeeding period, the Classical Period of Egyptian literature.

The instructions are some of the few texts that identify an author. It is generally thought that the people to whom the texts are attributed are genuine people, for example, Prince Hardjedef, the son of King Khufu of the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.), and the vizier Ptahhotep, who lived under King Isesi of the Fifth Dynasty. Some scholars, however, suggest that the names are pseudepigraphic, meaning that these were false names. These attributions do not correspond

to other dating criteria, namely, the language in which the text was written. The “Instruction of Hardjedef” contains certain archaic phrases that may indicate a Fifth Dynasty date, but its structure makes a Fourth Dynasty date seem unlikely. The “Instructions Addressed to Kagemni” and the “Teaching of the Vizier Ptahhotep” are written in Middle Egyptian; therefore, they could not date to the early Old Kingdom, at least not in the form in which they are preserved. This situation in turn presents a whole new set of problems for dating because there is no parallel for an Old Egyptian text being translated into Middle Egyptian. Likewise, the mention of King Huni, the last king of the Third Dynasty (ca. 2649–ca. 2575 B.C.E.), and Snefru, the first king of the Fourth Dynasty, at the end of the “Instruction Addressed to Kagemni” confuses the matter further, in that the art form is more evolved in this text than in that of Hardjedef. These Old Kingdom examples inspired scribes to continue this genre, and it became very popular.

The situation was slightly different in the royal sphere in the Old Kingdom. Kings had no tomb inscriptions. Some

scholars suggest that the lack of royal autobiographies is due to the sanctity of kingship, because a king's persona was stylized and idealized. The royalty of the Old Kingdom created three types of monumental inscriptions: the decree, the annals, and the recording of one event, none of which qualifies as literature. However, the royal religious compositions did include literary notions. The Pyramid Texts offer myriad literary devices that were written to ensure the successful transfiguration of the king's spirit into the afterlife. These texts were inscribed on the inside walls of the pyramids of some of the late Old Kingdom kings and queens. Various scholars have categorized them as poetry. As an example, Pyramid Texts "Utterance 337" reads as follows:

Heaven shouts, earth trembles
 In dread of you, Osiris, at your coming!
 O you milch-cows here, O you nursing cows here,
 Turn about him, lament him, mourn him, bewail him,
 As he comes forth and goes to heaven
 Among his brothers, the gods!

FIRST INTERMEDIATE PERIOD

In the following period, the First Intermediate Period (ca. 2134–ca. 2040 B.C.E.), the tomb autobiography appeared on stelae, monumental slabs of stone or sometimes wood. The autobiography was accompanied by the offering prayer and a scene. The stela was the focal point of the private funerary cult. Since most of the tombs dating to the First Intermediate Period have been destroyed, these stelae function as an all-in-one funerary memorial. At the time, they were also handy because they were easy to transport to Abydos, the cult place of Osiris, so that the deceased could be near him.

The second type of literature that the First Intermediate Period produced was the royal instruction. This genre follows the idea of the Old Kingdom instruction, but instead the departing king educates his son and successor. Most likely such a work as the "Teaching for Merikare" was not composed by the father of Merikare but was commissioned by the reigning king. The "Teaching for Merikare" is an ambitious literary work and surpasses all previous instruction compositions. It is a treatise on kingship, and the historical context is assumed to be accurate. This type of literary genre was further developed in Hellenistic times and in the Islamic world; however, there is no direct correlation between its appearance in ancient Egypt and its later popularity. The work is preserved on three New Kingdom papyri. The topics presented in this composition consist of ways in which to defeat rebellion, deal with subjects (both rich and poor), acquire troops for battles, perform required religious duties, and be a good king.

MIDDLE KINGDOM

The works that were created up to this time were, for the most part, experimental. The Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) was known as the Classical Period for both its use of

language and its literary output. Vast numbers of works were composed at this time, and many new genres of literature appeared. The autobiographies of the Old Kingdom continued to be used and were now much more elaborate than before. They contain additional elements, such as hymns to deities and exultations of the king. The "Teaching of Amenemhet I" develops the themes first presented in the royal "Teaching for Merikare," in which the king cautions against fully trusting one's subjects. The themes of wisdom literature expanded in the Middle Kingdom, and two more types developed: laments and dialogues. The laments discuss the absence of truth and justice in a chaotic world. It has been postulated that the emergence of this type of literature at this time has to do with the poor state of affairs in Egypt during the First Intermediate Period. The prosperity that Egypt had previously enjoyed no longer existed. Others think that "pessimistic" literature was only a literary theme and had very little to do with the actual state of affairs when the pieces were composed.

Two examples of this type of wisdom text are the "Prophecy of Neferti" and the "Admonitions of Ipuwer." The "Prophecy of Neferti" was probably created as a form of propaganda to legitimize the rule of the reigning king Amenemhet I (r. ca. 1991–ca. 1962 B.C.E.), the same Amenemhet mentioned earlier. The "lament" takes the form of artificial despair that pervades the prophecy of the sage Neferti, who foretells the civil war and destruction that are to come. Amenemhet is the savior who will rescue Egypt from ruin. The idea of "national distress" was a societal issue that became a literary theme. This composition is preserved on Papyrus Leningrad, which dates to the Eighteenth Dynasty (ca. 1550–ca. 1295 B.C.E.), and on various ostraca that date to about 1295–1069 B.C.E.

The "Admonitions of Ipuwer" is another work that is thought to be centered on the notions of order versus chaos and social disorder—themes that did not carry over to New Kingdom literature. In this text the sage Ipuwer recounts the anarchy occurring within Egypt while he is speaking with a divinity, possibly the creator god:

Lo, hearts are violent, storm sweeps the land,
 There's blood everywhere, no shortage of dead,
 The shroud calls out before one comes near it.
 Lo, many dead are buried in the river,
 The stream is the grave, the tomb became a stream.
 Lo, nobles lament, the poor rejoice,
 Every town says, "Let us expel our rulers."
 This text could also be categorized as a dialogue.

The third category of instruction literature is the dialogue. Dialogues present contemplative discussions on various themes. The composition modernly entitled "Dispute between a Man and His Soul" is one example of a dialogue, or discourse. This text is very intriguing, and there is a variety of interpretations as to its exact significance. In general, the work explores the idea of death, its dreadfulness and its sacredness. One of the mainstream interpretations sees a man

who is not enjoying life and is longing for death. His soul, on the other hand, wishes that he would stop complaining and enjoy life. The man is tired of living and repeatedly says so; his soul is angry at the man's complaints and threatens to leave him. According to ancient Egyptian religious belief, one cannot resurrect in the hereafter without one's soul (*ba*). This threat scares the man, and he tries to convince his soul of his opinion. In the end they rectify their differences and stay together.

"The Tale of the Eloquent Peasant" is another example of a dialogue, or discourse, of which there are four Middle Kingdom copies. In this narrative a peasant is robbed by a nobleman and appeals to the king's high steward for help. The peasant returns to the high steward nine times, each time providing the opportunity for a poetic speech, before his goods are returned. As it turns out, the high steward fervently enjoys the man's eloquence and therefore makes the man continue his speech until he can do so no longer. In this tale it is eloquent speech that is used to defend justice. In essence, this work is a serious discourse on social justice that humorously expounds the virtues of fine speech.

The second major category of Middle Kingdom literature is the fictional narrative. Examples of the fictional narrative include "The Shipwrecked Sailor," "The Tale of Sinuhe," "The Tale of King Neferkare and General Saset," and *Three Tales of Wonder*. These stories would be most familiar to the Western reader as examples of literature. Some suggest that these tales are derived from the educated class and were the products of the court. Thus, it would not appear that these written works evolved from oral folklore because of their content and the style in which they were written. Others believe that these narratives appear for the first time fully formed, perhaps suggesting that these same stories did exist in the oral tradition. Those pieces that belong to the late Middle Kingdom are less elaborate than those that date earlier; likewise, those appearing from the Twelfth Dynasty (ca. 1991–ca. 1783 B.C.E.) onward are written in a more colloquial language. These texts were privately owned. The Middle Kingdom stories were regarded as classics and have been discovered in private libraries from later periods. Some date to the Middle Kingdom, while a larger number of them date to the New Kingdom; examples are preserved from later periods. In the New Kingdom this corpus of texts was organized and used to instruct scribes on the classical language of Middle Egyptian.

The "Shipwrecked Sailor" survives in only one manuscript whose provenance is unknown. The story is about an official who is returning home from an unsuccessful venture and is worried about reporting to the court. He is accompanied by a subordinate who attempts to cheer him up. The subordinate tells him a wondrous tale about his own ship having once capsized, thus causing him to land on a desert island inhabited by an enormous snake. This tale is one of the simpler stories as far as Egyptian grammar is concerned and is actually a story within a story.

The "Story of Sinuhe" is considered the most advanced piece of Middle Kingdom literature. Numerous fragmentary copies of this work have been preserved, confirming its prominence within the literary sphere. This composition is a fictional autobiography of an official who takes flight from Egypt when he hears of the king's death. He lives abroad, marries a local chieftain's daughter, has a family, and achieves success. When he reaches old age, he wishes to return to Egypt. One of the major themes of this piece is the contrast between the ordered state of Egypt and the impulsive way of life abroad.

NEW KINGDOM

The New Kingdom brought with it a continuation of all the old genres of literature. The autobiography is still represented in the "Autobiography of Ahmose, Son of Abana." Annal-style historical writing flourished in this new international age, as evidenced by the "Annals of Thutmose III" (r. 1479–1425 B.C.E.), the "Poetical Stela of Thutmose III," and the "Sphinx Stela of Amenhotep II" (r. 1427–1401 B.C.E.). Hymns to the gods were very popular in the New Kingdom, and the works from this period elaborate on those from the previous period. Two of the more significant hymns are the "Great Hymn to Osiris," recorded on the stela of Amenmose, and the "Great Hymn to the Aten," from the site of Amarna. In the realm of funerary literature the Book of the Dead continues the ideas of the Coffin Texts, which comprise a set of spells that were inscribed on coffins in the Middle Kingdom. These texts evolved from the Old Kingdom Pyramid Texts. Likewise, new books of the underworld emerged. There was also continuity from the Middle Kingdom in the narrative fiction.

Two new genres of literature appear in the New Kingdom—love poetry and the epic poem. Some suggest that the love poems are immature and simple; however, the appearance of new and rare words within this group of compositions reflects the precision with which these works were created. "The Poem" in the "Kadesh Battle Inscription" and the "Poetical Stela of Merneptah" are two examples of the latter genre. These works represent the first time that poetry had a narrative purpose. There were many relations between nations at this time, and many new ideas and concepts arrived in Egypt from its neighbors. Another interesting development was the emergence of school texts. A school text may consist of a variety of texts put together to make a "schoolbook," these texts having no relation to one another.

LATE PERIOD

In the Late Period narratives and instructions flourished. The tales at this time became longer and more complex. In the Ptolemaic Period (304–330 B.C.E.), Greek themes mingle with Egyptian themes, and animal fables appear for the first time. So far, no school texts or love poems have come to light from this period. Many ancient Egyptian texts cannot be categorized under just one heading. For example, "The Tale of the Eloquent Peasant" is both a literary narrative about a man

who petitions to get his goods back through dialogue and a lament that has a somewhat didactic undertone.

Most of Egyptian literature was anonymous. The emphasis was not placed on the author, and the texts were identified by their protagonists. The narratives also lacked titles; only the wisdom texts had titles. Specifically in the New Kingdom, there existed a series of literary texts that praised the scribal profession. The Egyptians held the idea that the tomb could crumble, but writing was imperishable. This idea was probably reinforced in society by the fact that ancient wisdom was clearly admired and wisdom literature was cherished. Certain preserved texts patently declare that the idea of being a scribe was a virtuous occupation. One such text states, "As for those scribes and sages from the time which came after the gods—those who would foresee what was to come, which happened—their names endure for eternity, although they are gone, although they completed their lifetimes and all their people are forgotten. . . . Be a scribe! Put it in your heart, that your name shall exist like theirs!" This text is a eulogy to dead scribes from Papyrus Chester Beatty IV. The ancient Egyptian scribes imagined writing as a means to immortality.

Ancient Egyptian literature was written in either hieroglyphic or hieratic (cursive) script. There was also an intermediary stage of cursive hieroglyphs. If hieroglyphic script corresponds to our modern printing, then hieratic script corresponds to our writing. Hieroglyphs were inscribed on stone, plaster, or wood and could be written from left to right, right to left, or top to bottom. Cursive hieroglyphs usually appear on wood or papyrus, and hieratic script usually appears on papyrus or writing boards. The Egyptians used papyrus as their main writing surface. This material came from the papyrus plant, which was grown in the marshy delta region in the north. Strips were cut from the plant and made into sheets. The papyrus rolls were used over and over again. Some papyri have various documents on them while others had the original text erased and then were reused. These are called "palimpsests." Scribes used both red and black ink. The red was used for titles and headings, corrections, insertions, and highlighting.

THE MIDDLE EAST

BY KIRK H. BEETZ

Among the world's earliest civilizations were those of the Near East, particularly those that arose in and around the modern-day countries of Iran and Iraq. The people who forged these civilizations thousands of years ago, including the Sumerians, Akkadians, Assyrians, and Babylonians, developed advanced and sophisticated cultures, with cities, libraries, scientific inquiry, legal codes, mathematical systems, trade and commerce, and religious institutions. They also gave the world some of its earliest written literature. For this reason, the ancient Near East, stretching from the eastern shore of the Mediterranean Sea to the easternmost border of modern-day Iran, has often been called the "Cradle of Civilization."

The most common literary form that survives from ancient Mesopotamia is the epic. An epic is a long narrative poem that chronicles the adventures of a heroic individual. This individual was often thought of as partly human and partly divine, so he was able to serve as a kind of mediator or link between gods and humankind. Typically, an epic has many of the characteristics of an adventure story. Historians as well as literary critics are interested in epics because they record myths and legends that are important to the culture from which they arose because of their legendary, religious, and historical significance.

Like many epics, the epics that emerged from ancient Mesopotamia were not strictly speaking "written" by one author as authorship is understood in modern life. Rather, these epics were compilations of stories and legends that had been transmitted orally for hundreds of years. Accordingly, while we sometimes have a colophon, in effect, the name of the scribe who copied a particular text and sometimes a date, at the end of a text, such names are only those of the learned scribes involved in the transmission of a given work, not its original composition. Mesopotamian literature was widely transmitted in written form wherever the tradition of cuneiform writing (a wedge-shaped script) was found. Thus, copies of well-known works also have been found at archaeological sites in Turkey, Syria, Iran, and Lebanon.

THE EPIC OF GILGAMESH

One of the world's great epic poems is the Epic of Gilgamesh, which was written sometime around 2000 B.C.E. The Epic of Gilgamesh is one of the oldest surviving works of literature, and its author, Shin-eqi-unninni, is the oldest writer of literature whose name is known. To call Shin-eqi-unninni the text's "author," though, is a little misleading, for stories and legends had been told about Gilgamesh for hundreds of years, and while the epic is the main Gilgamesh text, other poems and stories claim to record his deeds. Shin-eqi-unninni was therefore as much a compiler as he was an author, for he did not make up the stories and legends. However, he gave them a form that remains memorable, and the Epic of Gilgamesh has been translated into virtually all the world's major languages. It is also a common text read in literature courses, especially those that deal with ancient literature or the development of the epic form. Its topic is a historical king named Gilgamesh, who ruled the city of Uruk in southern Mesopotamia and is credited with building its city wall, probably around 2700 B.C.E.

The Epic of Gilgamesh was written on 12 clay tablets in Sumerian. This language has no resemblance to any other language in the world. The version of the epic that survives, though, is written in Akkadian, a Semitic language that was related to Arabic and to Hebrew. Akkadian was the language spoken by the Akkadians, Assyrians, and Babylonians. The first exemplar of the Epic of Gilgamesh known to Western scholars was found at Nineveh, near the modern-day Iraqi city of Mosul, in the ruins of a library amassed by Ashurbanipal, king of Assyria from 669 to 633 B.C.E.

The story of the Epic of Gilgamesh is a timeless one of adventure, seduction, rivalry, peril, battles, twists of fate, and floods. It influenced later epics, such as those written by the Greek poet Homer, as well as later epics written in the medieval period. The first tablet, or book, introduces Gilgamesh, the king of Uruk. He is one-third human and two-thirds god, and he is the strongest, most heroic person every created. At the opening of the epic he has become somewhat saddened and uncertain of his role as king. His subjects, however, believe his rule is too harsh; when they complain, Aruru, the goddess of creation, creates Enkidu to serve as Gilgamesh's rival, thinking that a rival will both perk up Gilgamesh and keep him in line. Enkidu is described as a wild man, but he is seduced by a priestess, Shamhat, who tames him and makes him a fitter companion for and rival to the king.

In the second book Enkidu challenges Gilgamesh. The two engage in a mighty battle, but Gilgamesh breaks off the fighting and proposes that the two adventure to the Cedar Forest to kill a demon. Cedar was a highly valuable wood in the region, for its oils make it resistant to rot from moisture; for this reason, cedar would have held great cultural significance as a symbol of some permanence in a world that could abruptly change from flooding. The third book details their preparations for the journey, and readers learn that they have gained the support of Shamash, the sun god. The fourth book narrates the events of their journey to the Cedar Forest, and then, in the fifth book, Gilgamesh and Enkidu, with help from Shamhat, kill Humbaba, a demon who guards the forest. They then fell the trees, turn them into a huge raft, and float them back to Uruk.

In the sixth book Gilgamesh is tempted by Ishtar, a goddess who is the daughter of Anu. Ishtar grows angry because Gilgamesh rejects her sexual advances, so she asks her father to send the Bull of Heaven to avenge her, but Gilgamesh and Enkidu kill the bull. Now the gods are angry, and in the seventh book they want to exact punishment on someone for killing the bull. The gods condemn Enkidu to death, but in the meantime he becomes ill. As he is dying, he describes the Netherworld, or underworld, to Gilgamesh. The eighth book consists of Gilgamesh's lament for the death of the man who has become his friend and companion.

Gilgamesh, having seen his friend die, wants to avoid death, so in the ninth book he makes a journey filled with perils to consult with Ut-napishtim and his wife. These two were the only humans to have survived the Great Flood, and the gods granted them immortality. Gilgamesh hopes that they can share with him the secret of immortality. While he is on the journey, he encounters Siduri, an alewife who tries to turn him from his quest.

In the 10th book Gilgamesh crosses the Waters of Death in the company of a ferryman, Urshanabi. In the epic's climactic 11th book Gilgamesh meets up with Ut-napishtim, who recounts for him the events surrounding the Great Flood—again, a common motif in a region susceptible to flooding. With reluctance, he agrees to offer Gilgamesh a

chance at immortality by telling him that if he can remain awake for six days and seven nights, he will achieve immortality. Gilgamesh, however, has been fatigued by his travels and adventures and falls asleep. Ut-napishtim believes that Gilgamesh will deny that he has slept, so he has his wife bake one loaf of bread for each day Gilgamesh sleeps. The loaves of bread would be proof of Gilgamesh's failure.

When Gilgamesh awakens, Ut-napishtim offers his king another chance at immortality by telling him about a plant that will make him young again if he eats it, but only if he can retrieve the plant from the bottom of the sea. Gilgamesh succeeds in obtaining the plant, but he does not eat it, for he wants share it with others in Uruk. He decides to bathe, so he places the plant on the shore, where a snake steals it. Gilgamesh has lost both of his opportunities to achieve immortality. When he returns to Uruk and sees its imposing walls, he realizes that mortals can achieve a kind of immortality by building lasting cultures and civilizations. While the epic nominally consists of 12 books, the last book was written later and added to the first 11. In that book Enkidu is still alive, so the book is out of sequence. Most literary historians regard the 12th book as a separate work.

THE ATRAHASIS EPIC

In a region of the world that flooded every year, it comes as no surprise that floods and their consequences would play a major role in the fate of characters. Flooding, too, occurs in cycles, and it was this cycle of death and rebirth that people wanted to understand and, if possible, escape. In the Epic of Gilgamesh, one of the central events narrated is the Great Flood, but as noted, the epic is in a sense a compilation of stories and myths. One of these myths is the Atrahasis epic, which provides more detail about a great flood. Scholars believe that the Atrahasis epic formed the basis of the flood story in Gilgamesh and that, in fact, the Atrahasis epic was incorporated into Gilgamesh. It is also worth noting that historians and theologians believe that the Babylonian flood stories formed the basis for the story of the biblical Flood and Noah's ark in the book of Genesis. For this reason the Atrahasis epic is sometimes referred to as the "Babylonian Genesis."

Historians date the oldest copy of the Atrahasis epic to sometimes around 1646 to 1626 B.C.E., during the reign of Ammisaduqa, the great-grandson of the great Babylonian lawgiver, Hammurabi. For hundreds of years scribes continued to copy and transmit the epic, which was originally written in Akkadian. The epic outlines the cosmology of the ancient Babylonians—that is, their view of the world and or creation—who saw the heavens as ruled by the god Anu, the earth ruled by Enlil, and the oceans by Enki. The epic opens with Enlil ordering the lesser gods to work the land as farmers and to control the waters with irrigation ditches, but when the lesser gods refuse to continue work after a period of 3,600 years, Enki proposes that humans be created to do the work. Thus, a goddess named Mami creates humans out

of clay mixed with spit and the blood of the god Aw-ilu, who dies in the process.

Enki, who regards humans as his creation because he proposed creating them, warns Atrahasis, whose name means “extremely wise,” to tear down his reed house and build a boat to escape a great flood that Enlil is planning to send to destroy humankind—after already having sent a plague, a drought, and a famine. Throughout, Enki acts as a savior to humankind, filling the river with fish, for example, to feed the people during the famine. Atrahasis complies, builds an elaborate boat similar to Noah’s ark, and boards the boat with his family and animals.

The flood rages for seven days. When it ends, Atrahasis offers sacrifices to the gods, who realize that by destroying humans, they also have destroyed their labor force and the source of food offerings to them. Enlil, who had been upset by the noise of the cities that disturbed his sleep, is angry, for he had planned to eliminate humans, but Enki stands up to him; eventually the two reach an agreement about how they will control the human population in the future. At this point the story breaks off, and readers never learn the fate of Atrahasis.

The Atrahasis epic closely parallels the story of the Great Flood narrated in the 11th book of the Epic of Gilgamesh. In comparing the two versions, scholars note many similarities in language and detail, but they also see differences that show the hand of an editor, who changed details. In particular, the Atrahasis epic depicts the gods as having human characteristics, such as the ability to experience hunger, thirst, and fear. In the Epic of Gilgamesh, these particulars are changed or omitted, thereby giving the gods more divine, all-powerful qualities.

THE *ENÛMA ELISH*

So far, the focus has been on myths of destruction, with flooding as an important motif. The ancient Sumerians also had a creation myth, one that, like the flood story, has many parallels with the biblical account of Creation in the book of Genesis. This creation myth, called *Enûma Elish* from its first words, meaning “when on high,” dates probably to around the eighth century B.C.E. It was written in Akkadian and, like the Gilgamesh epic, was found in fragmentary form at the ruined library of Ashurbanipal. It consists of about 1,000 lines on seven tablets. While most of the fifth tablet is lost, most of the rest of the text is relatively complete. Historians have concluded that the text was used in religious ceremonies and probably was read aloud to mark the beginning of the new year.

The *Enûma Elish* focuses on Marduk, the greatest of the gods. His greatness is attested to by the sixth and seventh tablets, which record the 50 names by which he was known. The origins of the world, at a time before the sky and the earth were separated, are described in the first tablet. Again, biblical historians note the similarity between this myth and the account in Genesis, when “the earth was without form and

void, and darkness was upon the face of the deep.” At that time, there were two gods, a male god named Apsu and a female goddess named Tiamat. Apsu is the god of freshwater and Tiamat the goddess of the salt ocean waters, and it was as bodies of water that these two gods existed.

These two give birth to Lahmu and Lahamu, who are depicted as snakes and represent the life-giving silt of the rivers, in much the same way that God in Genesis ordered “the dry land appear” and separated the land from the water. They give birth to Anshar and Kishar, who in turn give birth to a son named Anu, who gives birth to Ea. Although each new generation of gods has more power than the previous generation, the younger gods become unruly and ill behaved. They refuse to listen to their father, Apsu, while the matriarch, Tiamat, does nothing to restrain them.

In disgust, Apsu decides to dispose of his progeny, but Ea learns of his plans, casts a spell on him, and kills him while he sleeps. Ea then builds a temple on the body of Apsu, where he lives with his consort Damkina, who gives birth to a son, Marduk, destined to be a hero-king. For Marduk’s amusement, Anu creates the four winds, which continuously disturb Tiamat, the ocean, and finally goad her into action, with the backing of the other gods. She decides to declare war on Marduk, so she gathers an army of monsters and gods to fight Marduk. This army was led by Kingu, variously described as her son and lover.

At this point, portions of the text are missing, so scholars can only infer details, but when the story resumes, Marduk has agreed to fight Tiamat, but only if his backers name him the supreme god if he emerges victorious from the battle. Armed with a bow, one arrow, a mace, lightning, a net, and seven hurricanes and with his body filled with fire, Marduk goes off to do battle in his chariot. With his hurricanes churning up the ocean, he challenges Tiamat to a battle and then throws the net over her and her army. When she tries to swallow him, he uses the hurricanes to split open her jaw and a single arrow to rend her body. Now the supreme god, he sets about creating the world, including humankind, doomed to physical labor so that the gods can live in leisure.

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

Literature in the Asia and Pacific regions of the ancient world was well advanced, and many works survive from the period either in original form or, more often, in later copies. During the late 19th century and the early 20th centuries many of these works were translated into European languages, mainly English, and provide historians with an understanding of society in the respective areas at the time.

INDIA

Although some writing survives from the period of the Indus Valley civilizations from between 2500 and 1800 B.C.E., it comes from seals and short inscriptions and cannot really

be regarded as literature. Indian literature traces its origins to the Vedas, the main Hindu sacred writings, which were written in Sanskrit. To these have been added later prose commentaries called the Brahmanas and the Upanishads. The Vedas have been regularly updated; although some parts date to 1400 B.C.E., most come from the first to seventh centuries C.E., with other sections being added as late as 1200 C.E.

The Vedas, written in archaic Sanskrit, represent the religious thinking of the Indo-Aryan peoples who settled India in the period 1400–1200 B.C.E. Forming the basis of Hindu beliefs, the Vedas refer to the cosmic forces, such as fire, the sun, war, storms, rain, and creation. In them various gods, such as Indra and Vishnu, appear to explain these concepts. Initially these ideas were remembered orally, possibly with the help of brief manuscripts, but later were written down. As a result, there are several different versions of the work. The Upanishads build on some of the ideas in the Vedas and take their name from the term that means “sitting at the feet of a teacher.” In all there are 108 surviving Upanishads, and they have a special philosophical concern with developing the idea of a supreme being and directing knowledge at a reunion between mortals and that being.

The other great epics of Sanskrit literature are the Mahabharata and Ramayana. The former is a heroic epic based on a battle for supremacy between two families of cousins, the Kauravas and the Pandavas. The story evolved considerably during the period 400 B.C.E.–200 C.E. and runs to about 100,000 couplets (or about 1.8 million words), making it the longest surviving epic of this period; it is about seven times as long as the *Iliad* and the *Odyssey* combined, making it also the longest surviving epic poem in the world. The date for its setting is said to be 1302 B.C.E., and according to legend, its authorship is attributed to the sage Vyasa. It begins with a prince who is blind and is passed over for succession to the throne by his father, the king. Rivalry starts between the prince’s descendants and those of his younger brother, who takes the throne. This rivalry leads to a series of great battles that shows the balance between good and evil and, like the *Iliad* and the *Odyssey*, serves to teach people about the problems people face in life, including romance, greed, valor, and human frailties. The story does not end with the “great” battle but continues with details of bickering following the battle, further infighting among members of the successful faction, and continued troubles. It ends with the life of Krishna. There are numerous subplots, with many characters from the contending families and also gods and demons. One aim of the poem is to elucidate the four main goals in human existence: *kama* (“pleasure”), *artha* (“wealth”), *dharma* (“duty”), and *moksha* (“liberation”).

The Ramayana dates to 300 B.C.E., though a few historians believe that some parts are possibly 200 years older. Altogether it consists of 24,000 couplets. It tells of the romance of Prince (later King) Rama in Ajodhya (modern-day Oudh), from his royal birth through to his falling in love with Sita. Rama manages to bend the great bow of Siva in a test of

strength (showing some similarities to the end of the *Odyssey*). Rama is then banished to the forests with his new wife and also his brother. There Sita is seized by Ravana, the 10-headed king of the demons, and taken to Lanka (modern-day Sri Lanka).

Rama then allies himself with Hanuman, the monkey god, and a war ensues, with Rama seeking to rescue Sita and Ravana and calling on a collection of demons to protect him. The monkeys attack Lanka, eventually taking the island. Ravana is killed, and Sita is rescued. Although the story revolves around Rama, the loyalty of his brother, Laksamana, and the cunning of Hanuman are both major factors in the story. In addition to these main characters, numerous other Indian gods make brief appearances, and the Ramayana serves to introduce them to the reader. However, because many people of ancient times were unable to read, the literary tradition quickly lent itself to theater, with the Ramayana being relatively easy to perform and the ex-

Sculpted panel depicting Vishnu Trivikrama, eastern India (10th century C.E.); the myth of Vishnu Trivikrama appears in the earliest of Indian texts, the *Rig-Veda*. (© The Trustees of the British Museum)

aggerated nature of many of the characters leading to their easy recognition by the audience.

While Sanskrit was the language used for Hindu scriptures, Buddhist literary works tended to be written in Pali, and those of the Jains in Ardhamagadhi. All three, especially the first two, were to have a major influence on Indian culture and also on the Indian diaspora. Tamil, in southern India, gradually established a literature of its own, though it has incorporated some Sanskrit stories. Pali would also become important in Buddhist areas of Southeast Asia, such as modern-day Cambodia and Indonesia. Indeed, the Buddhist literary tradition also served to explain many problems of the world as experienced through the life of Lord Buddha and his subsequent teachings.

SOUTHEAST ASIA

In Indian-influenced Southeast Asia the Mahabharata and especially the Ramayana became an important part of literature in modern-day Cambodia and Indonesia. In the former some early local legends survive from the ancient period, mainly involving the *nagas*—many-headed snakes—and also the founding of the Funan Empire in about 200 C.E. by Kaudinya, an Indian prince who married the daughter of a local naga.

Early literature in Indonesia also involved the Ramayana, albeit a slightly different version, adapted for Sumatran or Javanese circumstances. As in Cambodia, the story was acted rather than written down, and gradually the plot was adapted to allow for local traditions to be incorporated. Although it was still acted out as in Cambodia, in Indonesia the central part of the story was often told within the context of a *wayang kulit* performance, with shadow puppets and necessarily few characters.

CHINA

Unlike the oral literary traditions of Southeast Asia, China has the longest continuous written literary tradition in the world, dating back to at least the 14th century B.C.E. Although there have been many changes in the Chinese language, and the characters have changed since the early scripts of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.)—and pronunciation has changed dramatically—the tradition is certainly a continuous one. Curiously, invaders often adopted the Chinese script rather than compelling the Chinese to use their own, and the Chinese script was also used in Vietnam until the French romanized the script in the 19th century. It was also used in Korea in ancient and early medieval times.

The earliest examples of Chinese script are carved on bones and tortoiseshells from the Shang Dynasty. These are often called “oracle bones” because there was a tradition by which questions were carved on the shoulder blades of oxen or on tortoiseshells, which were then heated, with the cracks that appeared determining the answer to a question posed. In 1899 a scholar, Wang Yirong, started to transcribe some of the inscriptions, and many of the early surviving ones that

have been deciphered describe royal and religious activities. In all there are some 20,000 pieces in the Academia Sinica, now in Taiwan. Those on late Shang bronze vessels and also brief surviving genealogies are too brief to be regarded as literature by some scholars. However, they do show the use of 3,400 characters (of which two-thirds have been deciphered), indicating a wide vocabulary.

It was during the Zhou Dynasty (1045–256 B.C.E.) that many great works of literature were compiled. These detailed myths about the creation of the world and the founding of China seek to explain many natural and historical events. Unfortunately, the vast majority have not survived in their original form, largely because the first emperor of China, from the Qin Dynasty (221–207 B.C.E.), Qin Shi Huang, ordered the “burning of the books” in 213 B.C.E. Although he did allow some exceptions, notably medical works and some works praising him, his order resulted in the destruction of many early works of Chinese literature. The great Confucian works, however, survived the burning of the books. These works consist of the *Lun yü* (Conversations), and the *Analects*, which are collected teachings of Confucius (551–479 B.C.E.). Confucius taught extensively about philosophy and morality. His request for filial piety and for people to respect the emperor ensured that his works survived when those of many other sages were undoubtedly destroyed. In addition to having many works destroyed, Qin Shi Huang also had a large number of scholars executed. According to one account, 460 scholars were buried alive. According to Wei Hong, a second-century scholar, 1,160 scholars were buried alive. The “burial of the scholars,” as the incident came to be known, ensured, at least in the short-term, that Qin Shi Huang’s view of history survived.

After Qin Shi Huang’s reign there were attempts by scholars to reconstruct the texts that had been lost. During the Han Dynasty (202 B.C.E.–220 C.E.) scholars tried to write down many of the old stories. Some were clearly later literary works, but many incorporated pieces of literature that may have survived or may have been remembered by people. On occasion Han historians quite clearly added new material or in some cases tried to clarify ambiguities in previous works.

Apart from the works of Confucius, another survivor from before the reign of Qin Shi Huang was the *Dao de jing* (Classic of the Way of Power) of Lao-tzu. It is the principle work of Daoism, a Chinese philosophy that venerates the “feminine” qualities that promote longevity as well as equanimity and unity with nature. There was also the book of Meng-tzu, or Mencius (ca. 371–ca.289 B.C.E.), the collected thoughts of the sage put together by his students. The other major work to survive is a series of five books from the Zhou Dynasty known as the *Wu ching* (Five Classics). These consist of the *I ching* (Classic of Changes), the *Shu ching* (History Classics), the *Shih ching* (Poetry Classics), the *Li chi* (Record of Rites), and the *Ch’un-ch’iu* (Spring and Autumn Annals).

The *I ching* describes cosmology, and the *Shu ching* is a collection of official documents. The *Shih ching* is an

anthology of poetry from the time of Confucius and includes some 305 separate poems. Four of the longer ones, about 400 lines each, go over historical events. None of the poems is very long, suggesting that there was no epic poetry tradition as there was in India and elsewhere in the ancient world. The *Li chi* covers many court rites, along with anecdotes, and the last book, the *Ch'un-ch'iu*, is a history of the feudal kingdom of Lu, which included the town where Confucius was born.

During the Qin Dynasty, Qin Shi Huang ensured that his own accomplishments were recorded in detail. By this time printing was being used in a limited way; the earliest fully printed book was not produced until 868 B.C.E. Printing obviously made it easier to produce many copies of works. As the Chinese language did not suit movable type, books were produced from a carved wooden block of an entire page. Printing methods became more effective during the Han Dynasty, and the *Huai-nan-tzu* (The Master of Huai-nan) was written in about 140 B.C.E.

The next major work was the first detailed history of China. Written from about 85 B.C.E., the *Shih-chi* (Historical Records) took 18 years to complete and ran to 520,000 words, in 130 chapters, covering the 2,000 years of Chinese history. In some ways it is similar to the *Histories* of the Greek writer Herodotus (ca. 484–between 430 and 420 B.C.E.), who sought to write down everything he knew about history. However, the *Shih-chi* is a far more serious work, lacking the idiosyncrasies of Herodotus's text, though it is lively and does tell anecdotes about some of the characters. The work seems to have inspired the poet and historian Pan Piao, who put together the *Han shu* (Han Documents), which relate in 800,000 words the history of the Han Dynasty. The aim of the book is to draw from previous texts, and the *Shih-chi* includes a “catalogue” of works consulted. A large number of the texts listed in this bibliography have not survived.

In 26 B.C.E. one of the emperors of the Han Dynasty, Cheng Di (r. 32–7 B.C.E.), tried to undo some of the damage done during the destruction of the books by Qin Shi Huang, ordering that copies of all literary works be assembled in his capital, with a view to copying them and augmenting the imperial collection. He was also keen on ensuring that the “correct” manuscripts were being kept. The works were all copied onto silken scrolls, helping to preserve many works that might otherwise have been lost.

The poetry of the Qin Dynasty and especially that of the Han Dynasty often led to long poems reflecting the glory of the Chinese Empire, its wealth, and its structure, and also starting to include information about everyday life. The Yüeh Fu (Music Bureau) was reestablished in 125 B.C.E., and it started to gather earlier songs and music that were collected together centrally, possibly for the first time on an organized scale. The ballads collected include some early poems, such as *Lo-fu hsing* or *Mo-shang sang* (The Song of Lo-fu or Roadside Mulberry Tree), in which a government commissioner gives a ride in his carriage to a young lady he meets in his travels.

The collapse of the Han Dynasty and the subsequent wars resulted in the period known as the Six Dynasties (220–589 C.E.). In northern China warlike tribes invaded and gradually came to adopt Chinese ways, including literary traditions. In the south Chinese culture prevailed, with poems with a romantic theme being more popular than the military epics of the north. These differences became accentuated for several centuries, though the unity of the later Sui Dynasty and Tang Dynasty did result in a fusion of the two concepts. The relative peace of the Tang Dynasty also allowed for more literary works from earlier periods to be written down and reinterpreted.

VIETNAM AND KOREA

In Vietnam, occupied by China for more than a thousand years, from 111 B.C.E. to 939 C.E., the Chinese literary tradition took over from the previous folk ballads, and the Vietnamese came to adopt the Chinese script. Classical Chinese was used for official proclamations as well as for inscriptions on a number of early Vietnamese stelae that survive from this period. The variations in language tended to come from the recording of legends and Vietnamese mythical heroes as well as from stories that sought to portray Vietnamese as different from Chinese, such as the early accounts of the Trung sisters, who led the Vietnamese against the Chinese for three years (39–42 C.E.). Although the main account of their lives was from a chronicle written in 1272 C.E., the amount of detail in it shows that it must have come from an ancient text.

At the same time, Chinese merchants came to settle in other parts of Asia and proved to be a major influence on early literature in Korea, which also used Chinese characters before adopting its own national alphabet. Ancient Korean poems tend to follow Chinese themes and styles, using a system known as Hyangga poetry, in which Korean and Chinese words are used, with some characters taken from one language and other concepts expressed in characters from the other. This system continued until medieval times, with the first changes coming about in the seventh century C.E. Many of these Korean poems survive, as do other early literary works that include texts on Confucian ideas, Buddhism, and also Daoism.

JAPAN

Japanese literature also traces its origins from Chinese literary styles, and the Japanese originally used the Chinese script to record their thoughts. The oldest-known Japanese inscription, on a sword from 440 C.E., clearly shows the use of Chinese characters to cover Japanese names and expressions. Gradually the Japanese came to use their own characters, but not until the eighth century C.E. Indeed, the term “ancient” Japanese literature often refers to the works of the eighth century C.E.

POLYNESIA

Although there is no written literature from the Pacific during this period, there are legends and stories that may have originated from ancient times. Many of them concern great

sea epics and journeys of early Polynesian sailors, many entwined with legends of the gods and deities, often reflecting some degree of violence and cruelty. The strong oral traditions in Polynesia were noted during the 19th century by many of the early European anthropologists, who were able to compare the oral literary traditions of various islands and detail the common themes, some of which appear to date back to the original settlement of the Pacific islands by the Polynesian seafarers. There is also some linguistic evidence of seafarers from mainland Asia having arrived in some of the Pacific islands by 2500 B.C.E. If scholars are correct about this date, then some early Chinese literary traditions also survive in the Pacific. If one rejects the concept of Mu, the “submerged sea kingdom” of the Pacific, as most scholars do, the similarity in concepts around the Pacific islands can be explained only by regular contact between the various islands.

AUSTRALIA

Although there was no written literature of the Aboriginal peoples of Australia, they have maintained a very strong oral tradition, with stories that seek to explain the creation of the world, the formation of land and sea, and the origins of rivers and other land features. From the oldest continuous civilization in the world, in the areas where it still flourishes, Aboriginal oral tradition has been shown to reflect stories going back thousands of years. Some early drawings illustrate many of these stories, known as the “Dreamtime,” and anthropologists have worked hard to record these epics. Differences in the stories reflect the many Aboriginal tribes that exist in Australia and provide a far more philosophical outlook than many of the other stories of the Asia and Pacific region during ancient times.

EUROPE

BY RUSSELL M. LAWSON

The literature of ancient Europe includes some of the finest examples of oral and written expression in epic verse and poetry by the illiterate and literate peoples of the British Isles and western, central, and eastern Europe. Like the early poetry that the Greeks created, the Germans, Gauls, Celts, Saxons, and Norse of ancient Europe (before 500 C.E.) composed stories and poems about great heroes, past events, the divine and supernatural, nature, and human feelings. Whereas the Greeks after 700 B.C.E. put into written words their oral compositions—for example, Homer’s *Iliad* and *Odyssey* and Hesiod’s *Theogony* and *Works and Days*—northern Europeans of antiquity maintained their exclusive reliance on the spoken word.

Illiterate bards made their living traveling, composing, and reciting great epics and poems. Verse allowed for ease of recollection. The basic structure of the story was tailored specifically to the circumstances of each telling. Bards relied on memory as well as the creative impulse present at each performance. Repetitions in poems and stories were techniques

that helped bards get their poetic bearings and helped the audience not to lose track of the story. Eventually, a literate bard recorded in writing the poem or story in its final rendering. Indeed, much of the ancient literature of Europe is known only through medieval (after 500 C.E.) versions.

GERMANS AND GAULS

Since ancient northern European cultures were oral and illiterate, evidence of their eloquence and verse comes from external sources, especially those of the Romans and Greeks, who had much contact with the Gauls, Germans, and Celts. The Roman Cato approved of the eloquence of the Gauls, as did the first century B.C.E. Greek writer Diodorus Siculus. The Roman historian Cornelius Tacitus, who wrote *De origine et situ Germanorum*, commonly known as *Germania*, in Latin in the early second century C.E., described the oral culture of the ancient German tribes. The Germans, according to Tacitus, sang of the deeds and travels of heroes of the past and of the gods of the woodlands and streams. “In the traditional songs which form their only record of the past,” he wrote in *Germania*, “the Germans celebrate an earth-born god called Tuisto. His son Mannus is supposed to be the fountain-head of their race and himself to have begotten three sons who gave their names to three groups of tribes—the Ingaevones, nearest the sea; the Herminones, in the interior; and the Istaevones, who comprise all the rest.” Tacitus also recorded that the Germans lauded Hercules and sang songs in his honor.

That the Germans and Gauls worshipped Hercules, whom the ancient world pictured as a human of supernatural strength, as the god of eloquence, reveals that they considered eloquence to be as important as physical strength. The Gauls were specialists in the panegyric, a formal writing of praise for a person that was often used in the Roman Empire in the third and fourth centuries C.E. Indeed, Gauls were frequently hired as tutors to Roman students seeking to learn eloquence. The Roman orator Symmachus of the fourth century C.E. was trained in the art of rhetoric by a Gallic orator.

The northern European bards, like their counterparts in the ancient Mediterranean and Near East, were possessed of a singular, mystical gift, blessed by the gods, it was believed, above all others with the ability to perceive and sing the truth. Lords and kings retained bards at their great halls during feasts, to entertain the dinner guests with songs of old. One lord, named Lovernius, a Celt who lived in the first century B.C.E., loved his feasts and entertainments. “When at length he fixed a day for the ending of the feast,” wrote the Greek observer Posidonius (ca. 135–ca. 51 B.C.E.), “a Celtic poet who arrived too late met Lovernius and composed a song magnifying his greatness and lamenting his own late arrival. Lovernius was very pleased and asked for a bag of gold and threw it to the poet who ran besides his chariot. The poet picked it up and sang another song.” A century later the Roman satirist Juvenal (ca. 55 or 60–ca. 127 C.E.) joked that “eloquent Gaul has taught the Britons to plead a case.”

The ancient Gauls were Celtic peoples. During the several centuries before and after the birth of Christ, the free and independent Celts who resisted conquest and incorporation into the Roman Empire became isolated in the British Isles. Julius Caesar (100–44 B.C.E.), the Roman conqueror of Gaul (France) and first Roman invader of England, wrote an account of his military conquests in the *Commentarii de bello Gallico*. Caesar's book focused mostly on military affairs, though he also provided scattered accounts of the culture of the Gauls. The ancient Celts, he wrote, held the Druids in the highest esteem. The Druids were religious leaders whose authority extended to education, criminal proceedings, and government. As the intellectual and cultural leaders of the Celts, they attracted many students. "It is said," Caesar wrote, "that these pupils have to memorize a great number of verses—so many, that some of them spend twenty years at their studies. The druids believe that their religion forbids them to commit their teachings to writing," as they do "not want their doctrine to become public property, and in order to prevent their pupils from relying on the written word and neglecting to train their memories."

With the power of the spoken word at their disposal, the Druids taught their disciples about the great mysteries of life, such as the idea of reincarnation. During his attempted conquest of Britain in 55–54 B.C.E., Caesar discovered the commonalities of the Celtic culture of Gaul and Britain, that Druidism was important in both places, that the Gauls considered Britain as the source of Druidism, and that the British people had a long oral tradition of being the original inhabitants of the island.

THE CELTS OF THE BRITISH ISLES

The Celtic peoples of Britain initially repulsed the Roman invasion under Caesar, but finally succumbed to the larger, more organized attack of the emperor Claudius in 43 C.E. Under the Roman occupation of almost four centuries, the Celts resisted political and cultural Romanization, and varied Celtic kingdoms retained some independence in what is today Scotland and Wales; the Romans never attacked Ireland, which remained a Celtic stronghold. As Roman control lessened in the late fourth and early fifth centuries C.E., the Celts were forced to contend with a new invasion by the Saxons of Europe. The Celtic defense sparked heroic legends told for centuries. One story involved a Celtic king, Arthur, identified by the later Celtic historian Gildas (d. 570 C.E.) as Aurelius Ambrosianus, who made a heroic defense against the Saxons on the Welsh border. Celtic Wales was dominated by oral rather than literary tradition, and professional bards, the *cyfarwyddiaid*, passed along prose stories based on ancient tales into the European Middle Ages.

Celtic oral traditions in poetry and prose found a home in ancient and medieval Ireland. The Irish bards, the *filid*, told stories and poems with a strong emphasis on nature and the supernatural, on heroic warriors and great battles. Bards were attached to the court of a king or lord and nightly entertained

the feasting revelers at the lord's hearth. Like the heroic literature of other cultures, such as the ancient Mediterranean, Irish Celtic heroic verse and prose focused on kings and warriors of extraordinary strength and courage whose martial abilities relied on a high degree of hubris and extreme individualism in the pursuit of honor and glory. Warriors bragged of their prowess on the field of battle before taking to arms. Warfare was a human's highest calling, hence only members of the aristocracy were warriors. Duration of life was less important than whether or not one acted according to a code of valor. Gods who took human form (anthropomorphic gods), spirits of nature, were capricious and jealous, and played an often-disruptive role in human affairs.

Early Irish heroic sagas include the *Táin Bó Cualnge*, which is the account of warfare among Irish nobles over a prize bull. Another, the *Fled Bricrenn*, is the story of warriors at a feast fighting over the best portions of the meat. Diodorus Siculus described such a competition among Gauls of the first century B.C.E.: "When they dine, . . . they have hearths with big fires and cauldrons, and spits loaded with big joints of meat. . . . Some of the company often fall into an altercation and challenge one another to single combat—they make nothing of death." An early Irish epic love story is the *Longas mac n-Usnig*, the tragic story of lost love, in which Deirdre, raised to marry Lord Conchobar, falls in love instead with Naisi, a warrior serving under the lord. The two lovers flee north but eventually come back under promise of safety. On returning, however, Naisi and his men are attacked and killed, and Deirdre kills herself in despair.

Irish bards composed beautiful verse about nature and the mysteries of the divine. One of the earliest examples is *The Mystery*, composed (perhaps) before the Common Era by the Druid Amergin. *The Mystery* is one of a series of poems from *Lebor Gabála, The Book of Invasions*, which describes the settlement of Ireland as a series of military invasions by various groups of warriors. The theme of *The Mystery* is that all of nature—its beauty, power, glory—can be summarized by the "I," the poet himself. "I am the wind which breathes upon the sea, / I am the wave of the ocean, / I am the murmur of the billows."

Irish verse about the natural world is brief, descriptive, and powerful in evoking the grandeur and wonder of nature. Poetry about the supernatural involves heroic people, usually princes and princesses, who fall in and out of love, and repeatedly suffer a range of emotions—sickness, despair, longing, fulfillment. The divine is shadowy and inexact in these poems, often making its appearance by means of magic and supernatural phenomena.

ANGLO-SAXONS

By the end of the sixth century C.E. the Celts of Britain had scattered to remote locations (Wales and Ireland) in the face of the onslaught of Germanic invaders from Europe—the Angles, Saxons, and Jutes. The Anglo-Saxons who ruled Britain during the subsequent four centuries brought their Germanic

customs, heritage, and language, including reliance upon ancient stories and songs to recall past heroes and heroic deeds. The Anglo-Saxon bards were called *scops*, and the poems they recited were *lays*. As in other cultures relying heavily upon oral tradition, the scop performed before warriors, lords, and ladies banqueting in great halls. The performance took place nightly for successive days, as the scop sang songs of the past, changing and adapting them as warranted by circumstances and the audience. The theme of the lay was the heroic code of valor and brave deeds. An example is *Widsith*, which in its current literary form dates from the seventh century, but which is mentioned here because it includes structure and verse that dates from an earlier ancient time. The poem is an account of the journey of the poet Widsith and a recollection of all the places he has visited and all the kings and warriors he has known from earlier times in Europe, before the Anglo-Saxon invasion of England.

Another example of a lay recited by a scop is *Beowulf*, the eighth-century literary version of which, like *Widsith*, was based on earlier oral traditions and stories. Indeed *Beowulf*, like Homer's *Iliad* and *Odyssey*, was meant to be sung by a bard rather than read. The story is based on a heroic code of the Germanic past, where the worth of a person is based on great deeds and courage. Beowulf, a king of the Geats, is a hero who fights monsters such as Grendel without flinching, emerging victorious in the end. Even when he dies of wounds suffered from fighting the Dragon that threatens his kingdom and people, it is an honorable death, made memorable by his courage, the stuff of which bards will sing for years to come.

RUNES

The Germanic tribes of Europe and their descendants, the Saxons and the Norse, devised a script that was native to their lands and peoples and not significantly influenced by Latin or Greek. The runic script, called the *futhark*, developed during the third century C.E., was based on 24 characters. The runic script was a simple form of inscribing a single word or short phrase of identification or indication, which was done by cutting letters into wood or stone with a blade or chisel. Runic letters were composed of single-stroke lines that were vertical or diagonal but never circular or horizontal. A straight vertical line | was the letter *i*. The symbol < was the letter *k*. The symbol ↑ was the letter *t*. The symbol ◊ was the letter *n*, pronounced as an *ng* sound.

The Germanic peoples developed and used the runes at the close of the ancient world to identify personal ownership of property or to indicate the name of the rune master who carved the letters. Some ancient Germans believed that the runic letters and words themselves were magical. Runes were carved into battle implements, such as shields or swords, as a means of magic for protection or to help wage battle. The owner of a sword that had been named *Márr* inscribed on it the magic words: "May Márr spare nobody." The ancient runic script was not a literary device, though some of the earliest Anglo-Saxon poems used runes as abbreviations for phrases.

GREECE

BY DAVID K. UNDERWOOD AND MICHAEL J. O'NEAL

The literature of the ancient Greek world spans more than a thousand years, from the epic poetry of Homer in the late eighth century B.C.E. to the first century of the Common Era. Turning their oral traditions and legends into written form, the Greeks created the first great body of Western literature: a vast corpus of poetry, prose, dramatic art, philosophy, history, biography, and criticism, which, through its availability to a large literate public, preserved and passed down a tradition of canonical works that defined the identity of their civilization, its ideals, and its standards. The earliest works of Greek literature reflect the impact and creativity of the roving bards, who retold the heroic stories, myths, and legends of the world of ancient Mycenae and the Heroic Age.

THE ILIAD AND THE ODYSSEY

Foremost among these heroic tales is the story of the Greek expedition that conquered the wealthy trading city of Troy, also known as Ilium, on the Ionian or western coast of Asia Minor, in modern-day Turkey. The oral tradition recounting this episode of Greek history served as the raw material from which a great poet, whom the Greeks called Homer, composed the two epic masterpieces in hexameter verse (consisting of six metrical feet) that became the classic texts of Greek literature: the *Iliad* and the *Odyssey*. Dating to the end of the eighth century B.C.E., Homer's works were probably among the first to make use of a new alphabetic script that developed in the Greek world at that time. These two texts were more than literature: They represented the ethical standards by which Greek men and women were to lead their lives in relation to each other and to the gods. Like the Bible, Homer's works set a standard and established a foundational tradition for subsequent Western literature.

The *Iliad* deals with the Trojan War, the wrath of the proud Greek hero Achilles, and the eventual demise of his Trojan enemy, Hector; the *Odyssey* concentrates on the character Odysseus, king of Ithaca, and his long and arduous voyage home after the end of the war. A major theme of the *Iliad*, announced in the very first line, is the destructive effects of the anger of Achilles, which is brought on initially by the loss of his slave girl to a fellow Greek and then by the death of his friend Patroclus. Achilles' prideful anger further intensifies when he temporarily withdraws from the battle against Troy, brooding in resentment because the Greeks believe they can succeed militarily without him. Restored to the battlefield, Achilles slays Hector and drags his body in front of the city gates for all to see. This brash violation of the body and honor of a great hero foreshadows the demise of Achilles himself. Homer's point seems clear: Uncontrolled rage and unbridled hubris can have only one result—the death of the hero.

The opening lines of the *Iliad* announce a second major theme, one that is explored in the *Odyssey* as well: that this "sovereign doom" of human war and strife is the will of the

gods, a will that no mortal man can hope to oppose. The war, however, ends with a spark of willful human improvisation—the defeat of the Trojans by the cunning device of the Trojan horse, the brainchild of Odysseus himself. Homer continues to offer moral lessons by relating the character and motivations of his hero to their eventual outcomes. The patience and mental cunning of Odysseus eventually enable him to return home and reclaim his throne in the face of adversity from both men and gods. But in the end it could be argued that this homecoming would not have been possible without the intervention of the goddess Athena, his protectress, and Poseidon, god of the sea, who for years throws Odysseus's ship off course until his own anger at the hero finally subsides.

The *Odyssey* explores all the major elements of what the anthropologist Joseph Campbell calls the “hero’s journey.” Homer’s poem begins with the search for Odysseus by his son Telemachus, who refuses to believe that his father has been killed in the war. The background is important. Odysseus’s departure for Troy on the day his son is born is motivated by the Greek sense of honor, the oath of loyalty sworn between fellow Greek kings. Helen, the wife of the Greek king Menelaus, has been carried off by the Trojan prince Paris. Torn by the conflict between the code of honor and an equally strong Greek love for his family, Odysseus sets sail with his comrades to conquer Troy and reclaim Menelaus’s wife, or so the story goes. In fact, the Greeks had imperial ambitions toward the rich trading city of Troy and longed to control its trade routes and resources. In the story, however, Athena, goddess of war and wisdom, visits Odysseus on board ship and tells him that she “wants him to go” for the glory of the ages. The war rages for 10 long years, as described in the *Iliad*. In the *Odyssey*, the episode of the Trojan horse is recounted as a distant memory, but this episode brings an end to the war and enables Odysseus to begin his journey home.

The hero’s journey back to Ithaca is plagued with difficulties because of Poseidon’s anger at Odysseus. Soon after leaving Troy, Odysseus’s ship washes ashore on the island of the Cyclops Polyphemus, Poseidon’s son. Odysseus endures many more dangers and confrontations with death in his attempt to get back home. Washed ashore on an island ruled by the witch Circe, he discovers that during their shore leave she has turned his men into pigs, and he is forced to submit to her terms (to have sex with her) in order to get his men back and find his way home. Later, Odysseus and his crew encounter the Scylla, a multiheaded, cave-dwelling monster who kills several of Odysseus’s men as they try to navigate through her cave, at the far end of which lurks the Charybdis, a deadly whirlpool that sucks all save Odysseus himself down to their deaths. Left to his own devices, Odysseus is again blown off course and comes upon the island of Calypso, a sea nymph who seduces him and keeps him on her island for seven years, until Hermes, the winged messenger of the gods, interceding on behalf of Athena, arrives and insists that he be released.

After further adventures, the dramatic denouement of the story comes when the anger of Poseidon finally subsides

enough to allow Odysseus, war torn and beaten, to wash ashore near Ithaca. He has an emotional reunion with his son and a faithful slave of many years. They tell him of the intruders and their plans to take over his palace, but rather than impulsively falling on the enemy, Odysseus characteristically reflects on his situation and contemplates his strategy. Impressed with his patience and wisdom, Athena appears to him and transforms him into an old beggar so that he may move about his palace unrecognized, until such time as he can safely resume his throne without being killed by the intruding suitors. The suitors have devised a plot to provoke Telemachus into a fight so that one of them can kill him, thereby removing any lingering bloodline to the throne. Odysseus advises his son to be patient, saying that “to be angry is easy.” Meanwhile Penelope, unaware that Odysseus is alive and back, has prepared a test, under the advisement of the slave who knows of Odysseus’s plan. The suitor who can string the bow of Odysseus and shoot an arrow clean through a series of rings will take his place as her new husband and rightful king. When none of the suitors is able to accomplish the task, the old beggar steps up, strings the bow, and fires the arrow straight through the rings, at which moment he is transformed, before the eyes of all, back into the true king of Ithaca.

Loyalty, bravery, courage, and honor; the heroic journey; the love of family and comrades; persistence and the virtue of patience; the ability to control one’s anger; the importance of timing and rational contemplation; humility toward the gods; the equation of happiness and a man’s world with his home, his wife, and his family—these are some of the major themes of Western literature established in their most complete and powerful form in the works of Homer.

HESIOD: WORKS AND DAYS AND THEOGONY

Homer’s near contemporary Hesiod (active ca. 700 B.C.E.), another great Greek poet who wrote in hexameter verse, is considered to be the father of Greek didactic poetry (as opposed to the epic poetry of Homer). Didactic poetry was so called because it was intended to teach moral lessons or offer important instruction or factual information. The *Theogony*, for example, gives an account of the emergence of the universe from chaos and a detailed genealogy of the gods, carrying strong moral implications for humankind. *Works and Days*, Hesiod’s other major work, however, is the more interesting of the two, in part because it deals with a subject—farming—that had not been given any attention by Homer and in part because it contains what little information we have on Hesiod’s life. He was the son of an impoverished farmer who went to sea to make a better living. Hesiod spent most of his life farming in Boeotia, living in resentment of his brother, who had apparently cheated him out of his share of the family property. Hesiod’s personal experience would thus appear to be a valuable background for understanding *Works and Days*, which consists of a series of moral maxims and precepts on farming.

Frieze of three Muses; the Muses typically are invoked at or near the beginning of a Greek epic poem. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

The poem glorifies the solid, earthbound values of hard-working agricultural people, who at that time constituted the majority of humankind, and their never-ending, backbreaking work of plowing, sowing, reaping, threshing, and grinding. These were the peasants whose hard labor made possible the privileged lifestyles of the warrior-kings and princes of Homeric legend.

Works and Days deals first with the questions of why humans have to work so hard. Hesiod's answer places the blame on the demigod Prometheus, who defied Zeus, king of the gods, by giving humanity the forbidden gift of fire, forging thereby the arts and crafts of civilization. Enraged by this defiance, Zeus punished both Prometheus and humanity by sending down a woman, Pandora, who unleashed on the world all manner of evils—work, disease, hatred, envy, old age, and every other problem that continues to plague the human race.

As a follow-up to this troubling scenario, Hesiod describes his “Myth of the Five Ages,” which is a further attempt to characterize the wretched state of humanity in his day. Before the defiance of Prometheus and the wrath

of Pandora, humanity lived in a golden age, free of toil and trouble. But this idyllic situation was followed by three successive stages—the Silver Age, the Bronze Age, and the Iron Age—each one regressively worse than the last. Hesiod's sequence also makes room for a nonmetallic “Heroic Age,” which drew from the collective Greek memory of the glories of the Mycenaean civilization. Such heroic memories served only to intensify the sense of human wretchedness in Hesiod's own time, the Iron Age.

ARCHAIC LYRIC AND IAMBUS: ARCHILOCHUS OF PAROS

Archaic lyric refers to the earliest Greek poetry that expresses subjective thoughts and feelings, often in a songlike style or form. The poets who wrote after Hesiod explore a variety of poetic forms and rhythms, including the elegiac couplet (a combination of the epic hexameter and a shorter line), the pentameter (five metrical units rather than six), and iambic rhythms (metrical units consisting of an unstressed syllable followed by a stressed syllable, or a short syllable followed by

a long syllable, as in the word *betray*). The earliest lyric poet, Archilochus of Paros (mid-seventh century B.C.E.), explores a wide variety of forms but never allows them to overwhelm his directness of expression and emotion.

The dithyramb is a frenzied, impassioned choric hymn and dance of ancient Greece, performed in honor of Dionysus, god of the harvest and wine. It also refers to an irregular poetic expression or an enthusiastic piece of writing, like that of Archilochus, that is suggestive of the original dithyramb. Such impassioned forms and style seem appropriate given the controversial nature of Archilochus's life. The poets Critias and Pindar considered him a scoundrel because some of his poetry speaks directly of a life of scandalous episodes and attitudes, especially toward women and family. But Archilochus also wrote passionately of military battles and heroic struggles with the enemy, in terms that offer moral guidance and urge men to overcome the whining hubris of Achilles.

TYRTAEUS AND "THE SPARTAN CREED"

Not all poetic characterizations of the glory of battle are sensitive to the emotional aspect of war. The poet Tyrtaeus (seventh century B.C.E.) was the official voice of the stern military ethic that made his native city, Sparta, famous. The Spartans are remembered today for their rigorous discipline and fighting skills, the products of a long and arduous training that created an intense spirit of community belonging and an efficiency admired by Plato and the Athenians of the Classical Age. Inspired by Homer's *Iliad*, "The Spartan Creed" of Tyrtaeus uses elegiac verse to celebrate, in even-tempered terms, the noble values of Spartan warrior-chiefs and their city: "For no man ever proves himself a good man in war / unless he can endure to face the blood and the slaughter, / go close against the enemy and fight with his hands."

SAPPHO AND THE WORLD OF LESBOS

There could hardly be a world more different from the harsh Spartan society than that of the Island of Lesbos, with its rich farmland, olive groves, wide pastures, orchards, vineyards, gardens, and, above all, atmosphere of wealth and leisure. This world was the setting for the idyllic and passionate lyric poetry of Sappho (ca. 610–ca. 580 B.C.E.). Uninterested in political matters, Sappho wrote about themes of intense concern to the young female devotees who surrounded her and together celebrated the cult and festivals of Aphrodite, goddess of love. Especially poignant is her exploration of the love of these young women for one another and the inevitable separation they would experience as they moved from girlhood to wedlock. Often nostalgic and sentimental, Sappho composed some of the most moving poetry ever written. Sappho's muse, Aphrodite, is frequently invoked as the powerful source of the emotions explored in her poetry.

XENOPHANES AND THE CRITIQUE OF THE GODS

Not every Greek poet of the late sixth century and early fifth century B.C.E. gave himself or herself over to the adoration of

the Greek gods so wholeheartedly as did Sappho. An exception to the rule and the first Greek writer seriously to question the idea and power of the anthropomorphic gods of Mount Olympus was Xenophanes of Colophon. His logic, leading toward a kind of monotheism, was that the obvious imperfections of the gods were based on all-too-human characteristics; therefore, humans must have created the gods in their own image and not vice versa. Xenophanes' poetry anticipates the skeptical humanism of the Classical age of Athens.

PINDAR AND THE OLYMPIAN ODE

Some of Xenophanes' humanistic sentiments are found as well in the odes of Pindar of Thebes (ca. 522–ca. 438 B.C.E.), a prolific poet who addresses many different themes in various genres—hymns to the gods, dithyrambs to Dionysus, funeral dirges, heroic eulogies, and four books of odes, dedicated mostly to the winners of Olympic competitions throughout Greece. A particularly moving piece is his "Third Pythian Ode (for Hiero of Syracuse)," written to comfort and console a man who was mortally ill. Its ending recalls the thought of Xenophanes—the idea of a humble human thinker, a self, who confronts the power and glory of one god: "I will be small in small things, great among great. / I will work out the divinity that is busy within my mind / and tend the means that are mine."

HERODOTUS, THUCYDIDES, AND THE BIRTH OF HISTORY

Greek literature encompasses not only a rich variety of poetry but also historical, political, biographical, and philosophical writing. Historical writing as a serious enterprise and fine art began with Herodotus (ca. 484–between 430 and 420 B.C.E.), and was further developed by Thucydides (d. ca. 401 B.C.E.). First called the father of history by the Roman writer Cicero, Herodotus was the first writer to conduct research into the events of the past and the history of foreign lands and to attempt to treat them in a rational rather than a mythical manner. Although he was often forced to rely on spurious sources, usually oral accounts that were frequently secondhand, his narratives are informative, vivid, and extensive in their treatment; his history of the Persian invasions of Greece up to 479 B.C.E. takes up nine books. Thucydides was an exiled Athenian general who wrote a remarkably objective account of the Peloponnesian war between Sparta and Athens. His account stresses painstaking reporting and a descriptive analysis of contemporary events that reveal considerable appreciation for cause and effect. The most famous passages are those dealing with Pericles' funeral oration and the plague at Athens.

THE BIRTH OF WESTERN DRAMA

In the history of dramatic literature five names from ancient Greece stand out. Three dramatists—Aeschylus, Sophocles, and Euripides—were tragedians. Additionally, Aristophanes wrote comic plays that are still part of the theater repertoire around the world, and Menander was a major figure in Greek comedy.

Aeschylus (525/524–456/455 B.C.E.), probably the world's first writer of tragic drama, expanded the possibilities of stage drama. He wrote about 90 plays, 80 of which are known by name but only seven of which have survived in their entirety: *Persians*, *Seven against Thebes*, *Suppliants*, *Prometheus Bound*, and the three plays of the *Oresteia* trilogy—*Agamemnon*, *The Libation-Bearers*, and *The Furies*. Until Aeschylus, drama was largely a static affair, recited by a chorus and a single main actor. Aeschylus added a second actor, expanding the possibilities for dialogue and incorporating action into the play. Sophocles (ca. 496–406 B.C.E.) was a prolific writer, author of at least 123 plays, though only seven survive in their entirety: *Ajax*, *Antigone*, *Trachinian Women*, *Oedipus the King*, *Electra*, *Philoctetes*, and *Oedipus at Colonus*. It is known that at least 24 of his plays won major dramatic competitions and that he never came in lower than second place. Two of his plays, *Antigone* and *Oedipus the King*, remain perennial favorites on the stage and are widely read by students for their tragic vision of the interaction of flawed judgment and cruel fate, leading to disaster. Euripides (ca. 484–406 B.C.E.), the author of some 92 plays, 19 of which survive, wrote darker, more frenzied tragedies in which the disaster that befalls the central characters is more a result of their personal flaws and irrationality than a cruel fate. His most famous plays include *Medea*, *Hippolytus*, *Electra*, *Trojan Women*, *Ion*, *Iphigenia at Aulis*, and *Bacchae*. In most of his plays he used legendary and historical figures as his main characters, turning them into ordinary, contemporary people.

Among comic dramatists, two names stand out. The first is Aristophanes (ca. 450–c. 388 B.C.E.), who wrote about 40 plays, only 11 of which survive intact: *Archarnians*, *Clouds*, *Wasps*, *Peace*, *Birds*, *Lysistrata*, *Women at the Thesmophoria*, *Frogs*, *Knights*, *Women at the Ecclesia*, and *Wealth*. Among these plays, perhaps *Lysistrata* is the most famous and widely performed because of its contemporary theme: The women of Athens, led by Lysistrata, seize the Athenian Acropolis and the city's treasury and declare a ban on sexual relations with their husbands until they put an end to the 20-year-old Peloponnesian War. Overall, Aristophanes' plays continued to be admired for their wit, their biting political satire, and their overall good humor.

Later, Menander (ca. 342–ca. 292 B.C.E.) wrote more refined plays in a sophisticated literary language that became a model for educated Greeks. While earlier Greek comedies, such as those of Aristophanes, were devoted largely to politics and public affairs, the comedies of Menander seem more modern in their depiction of the manners and foibles of ordinary people and their wider range of character types: the stern father, the wily slave, the misanthrope (one who dislikes other people), pairs of young lovers, and the like. Menander is known to have written about 70 plays, but, unfortunately, the complete text of only one survives. Large portions of other plays have been found, and Menander survives largely because Roman writers adapted many of his plays.

HELLENISTIC LITERATURE: THEOPHRASTUS, CALLIMACHUS, AND APOLLONIUS OF RHODES

Cultural diversity and innovation characterized the Hellenistic Age that was ushered in by Alexander the Great, king of Macedonia (r. 336–323 B.C.E.), conqueror of Asia Minor, Syria, Egypt, Babylonia, and Persia. In literary terms, the new sense of variety and experimentation is reflected in the works of Theophrastus (ca. 372–ca. 287 B.C.E.), Callimachus of Cyrene (ca. 305–ca. 240 B.C.E.), and Apollonius of Rhodes (ca. 295–ca. 215 B.C.E.). Theophrastus, Aristotle's successor as the head of the School of Philosophy in Athens, wrote many scientific and philosophical studies, but his most colorful work is a book called *Characters*, which consists of a series of lively sketches of different human types: the Chatterer, the Talker, the Eager to Please, the Skinflint or Stingy Man, the Tiresome Man, the Boaster, and the Authoritarian. These multifarious types suggest a veritable gallery of Hellenistic diversity, noteworthy for their observant detail and humorous characterizations.

The fundamentally modern feeling of Theophrastus's *Characters* reflects a trend toward novelty that would give rise to the major intellectual debate of later Greek literature: tradition versus innovation. The traditional position was upheld by Apollonius of Rhodes, head librarian at the library at Alexandria and author of an epic poem in the Homeric tradition, the *Argonautica*. The search for new forms for Greek writing is promoted by the poet and scholar Callimachus, the dominant intellectual figure at Alexandria under the kings Ptolemy II (r. 285–246 B.C.E.) and Ptolemy III (r. 246–221 B.C.E.).

Callimachus criticizes Greek poets for continuing to use the lengthy form of the Homeric epic, whose day, he believes, has passed. He claims that “a big book is a big evil.” His proposed alternative includes the elaboration of the epigram—a short, witty poem expressing a single thought or observation—and the *Pinakes*, a series of biographical and bibliographical tablets documenting “those who were outstanding in every phase of culture, and their writings,” a sort of *Who's Who* of Greek literature and culture. Callimachus was thus the “father of bibliography,” the first person known to have catalogued and classified an extensive collection of literature, according to such major categories as philosophy, poetry, oratory, history, law, medicine, and miscellany. Callimachus thus consolidates for the future the vast legacy of Greek literature. This catalogue of literature was not his only contribution, however. In the prologue to one of his major works, *Aitia* (The Causes), he closes out the ancient Greek literary tradition by creating a new one—that of the critic of the literary critic. He calls them “malignant gnomes and “tone-deaf ignoramus” in their critiques of his work, ending by saying, “So evaporate, Green-Eyed Monsters, / or learn to judge poems by the critic's art . . . / and don't snoop around here for a poem that rumbles: / not I but Zeus owns the thunder.”

PHILOSOPHY

No discussion of ancient Greek literature would be complete without mentioning some of the major Greek philosophers. While the works of numerous of these philosophers survive, those of three in particular stand out and continue to be read and studied: Socrates, Plato, and Aristotle.

Socrates (ca. 470–399 B.C.E.) is often regarded as the founder of Western philosophy. Most of what is known about him comes from later sources, including Plato. Because most of his work survives through Plato, it is difficult to distinguish the philosophical views of the two. Socrates is perhaps best remembered not for his unorthodox life as a wandering gadfly but for his death. He was executed by being forced to drink hemlock, a poison, for being perceived as a threat to the Athenian state. Whether Plato (428/427–348/347 B.C.E.) was a student of Socrates is unclear. Much of Plato's philosophy was written in the form of dialogues, the so-called Socratic dialogue, featuring Socrates as the "teacher" and various other contemporary figures as his "students," who have to explain and defend their positions through a seemingly endless series of questions, but Plato never explicitly says that he ever took part in dialogues with Socrates. Either way, it would be difficult to overstate the influence of Plato on Western thought.

Among modern philosophers, a common expression is that all Western philosophy is a "footnote to Plato," meaning that modern philosophy is an attempt to refine and explain philosophical views outlined by Plato over two millennia ago. Perhaps the best-known and most widely read of Plato's dialogues is the *Republic*, a wide-ranging discussion of the nature of justice, courage, wisdom, morals, and virtues as they pertain both to individuals and to society as a whole. Perhaps the most famous portion of the *Republic* is referred to as the Allegory of the Cave. In this passage people are imagined confined in a cave where the only reality they know is shadows cast on the wall. When they are released from the cave, they see reality as it really is.

Finally, Aristotle (384–322 B.C.E.) was one of Plato's students. He began his career as a scientist and physician, and throughout his work he explored a wide range of subjects, including science, poetry, biology, zoology, logic, ethics, politics, government, and rhetoric. It is almost impossible to give a thumbnail sketch of Aristotle's philosophical views, but he remains important for his efforts to understand the nature of the real and the universal, to categorize and systematize knowledge, and to apply reason and logic to philosophical problems. In connection with literature, his *Ars poetica* (Poetics) was an effort to define the essential nature of such literary genres as tragedy, comedy, and the epic. While Plato tended to focus on the moral qualities of literature, Aristotle was more interested in the formal structure and internal logic of such works.

AESOP AND PLUTARCH

The works of two additional writers survive, though neither fits into any of the categories outlined. The first, Aesop, is probably a legendary figure. His name is connected with some

200 "Aesop's fables" that continue to be read for their moral lessons, usually taught through the behavior of animals. Most of these stories were traditional, and their written versions were probably the production of numerous authors. Some of these fables have become woven into the fabric of modern life. Schoolchildren are familiar, for example, with the tale of the hare and the tortoise; the swift hare should beat the slow tortoise in a race, but he keeps getting distracted while the tortoise focuses his attention on what he is doing and wins. The fable of the fox and the grapes is the source of the expression *sour grapes*, referring to the claim that a person did not really want something that he or she was unable to attain, just as the fox claims that he does not really want the grapes he is unable to reach.

Finally, Plutarch (ca. 46–ca. 119 C.E.) is best known for history, essays, and biography. Plutarch wrote an immense number of philosophical essays about a wide range of topics, but many do not survive. His most famous work is generally referred to simply as *Lives*, but more formally the English translation of the title is *Parallel Lives*. In this collection of essays, which has not survived in complete form, he paired famous Greeks and Romans, writing biographical sketches of them with emphasis on their moral strengths and failings. For some historical figures of the time, Plutarch is the only source of information or, in some cases, one of few such sources. His work has been criticized for historical inaccuracies and reliance on gossip and legend, but it survives because of his keen insight into human character.

ROME

BY JAMES A. CORRICK

Roman literature prior to the third century B.C.E. was often associated with specific events. Thus, poetry about the deceased was recited or sung at funerals; later, this poetry was replaced by an oration, a formal speech. At harvest festivals, weddings, and other celebrations, humorous poetry—generally racy and vulgar as well as improvised—was popular. Banquets were the occasion for reciting or singing the deeds of heroes. Political debate generated speeches. Although much of this early Roman literature was oral, some—how much is now uncertain—was written down. The names of these early Roman authors of both the oral and the written have been lost.

THE GREEKS AND THE EPIC

Beginning in 272 B.C.E. with the capture of the Spartan colony of Tarentum in southern Italy and the subsequent conquest of other Greek colonies and finally Greece itself, Greek slaves began arriving in Rome by the thousands. Some of these slaves became tutors to Roman youths and passed on to their charges a love and reverence for much of Greek culture, particularly poetry. Indeed, Greek poetic forms would dominate Roman verse until the end of the empire in 476 C.E.

As with the Greeks, Romans considered the noblest poems to be epics. From the Greek *epos* for "word," an epic is a

long narrative poem that, for the ancients, detailed the deeds of a single hero or band of heroes. This heroic story plays out among a large cast of other characters, both human and divine, with the latter often aiding or hindering the hero. It was the heroic nature of the epic that led the Romans and Greeks to hold it in such high regard. The Greek models for the Roman epics were the *Iliad* and *Odyssey* of the poet Homer (fl. ca. ninth century B.C.E.).

The common meter for the epic is dactylic hexameter. Meter is the poem's rhythm, which is determined by the pattern of its lines. Each line of classical poetry is divided into sections known as feet; in each foot a set number of syllables occurs in a specific order. In classical verse some of these syllables are long and some short, the longer taking more time to say than the shorter. Long syllables generally contain a long vowel or a short vowel followed by two consonants, while short syllables have a short vowel. For example, in English the "a" in *day* is long, while that in *hat* is short. A line of dactylic hexameter has six feet; in each foot, known as a dactyl, is a long syllable followed by two short ones. Other types of feet also exist. The iamb, for example, has a short syllable followed by a long one.

OTHER GREEK-INSPIRED ROMAN POETRY

Also borrowed from the Greek is the elegy, a short poem that alternates a line of dactylic hexameter with one of dactylic pentameter, a line of five rather than six feet. A hexameter and pentameter line together form a two-line unit, known as an elegiac couplet, with each couplet presenting a complete thought. The subject of the Roman elegy is mainly love, detailing the passion and trials of a lover.

Lyric poetry also entered Rome from Greece. Generally short, lyric poetry expresses the poet's emotions or state of mind. A lyric poem usually has a single focus: love, sadness, or regret, for instance. Originally meant to be sung, this poetic form derives its name from the lyre, the stringed musical instrument that once accompanied the singer. For the most part, however, Roman lyric poetry was meant to be read rather than sung.

The epigram is another Roman form derived from the Greek. Typically composed of a single elegiac couplet, it presents a witty observation about love, the gods, morality, or human activities. Pastoral poetry, which idealizes country life and often focuses on the loves of shepherds and shepherdesses, is also of Greek origin.

THE ROMAN NATURE OF LATIN POETRY

Although Roman poetry owes much to Greek poetry, it retains features of earlier Roman verse, such as the favorite device of alliteration. In alliteration two or more words in a line have the same initial sound. In English, for instance, the words of the childhood jingle "Peter Piper picked a peck of pickled peppers" are alliterative. More important, the subject matter of Latin verse is Roman. Roman deeds, heroes, history, and values provided the subjects of Roman verse. Roman fail-

ings also became the subject of satire, the only important native Roman form of poetry after the third century B.C.E. Satire criticizes, often both humorously and harshly, the faults of Romans, particularly hypocrisy and bad behavior. In satire the author typically addresses the reader directly; sometimes the writer's tone is mocking, while at other times it is cynical or sneering, and the language can be obscene. Roman epigrams are frequently satiric.

ROMAN PROSE

Although much satire was written in verse, it could also be in prose or a combination of poetry and prose. Roman prose was much less strongly influenced by Greek traditions than was poetry. Out of funeral orations came biographies and, later, imperial autobiographies. From Roman public speeches grew a whole body of political and judicial writing. From a desire to argue persuasively in public debate came a host of works on rhetoric, the study of principles and techniques that aid in the effective presentation and defense of a line of reasoning. Other native Roman prose works included letters, frequently meant for publication, and novels; the latter were considered mainly a low form of entertainment, however.

Despite its generally native roots, Roman prose shows Greek influence, particularly in the writing of histories and philosophy that used Greek models (some history and philosophy appeared as verse). Initially, Roman histories were written in Greek because Latin was thought to lack the vocabulary needed for historical writing. Using Greek also allowed Roman authors to propagandize Rome's right to rule the Greek city-states.

THE NEW LITERATURE

Greek-inspired Roman literature began with Livius Andronicus (ca. 284–ca. 204 B.C.E.), a Greek slave from Tarentum who eventually won his freedom. Although he was mostly a playwright, Livius also translated the *Odyssey* into Latin; his translation would prove to be popular for the next two centuries. Instead of the Greek dactylic hexameter, Livius used a native Roman meter known as Saturnian. Each line of Saturnian verse is divided into just two feet, separated by a caesura, that is, a break denoting a pause. The second foot is either shorter or the same length as the first. Reading Saturnian verse may have depended on a sequence of long and short syllables or on a succession of accented and unaccented syllables, the former being emphasized, or stressed, during pronunciation. Livius probably used Saturnian meter to make his work more accessible to the Romans, who were still mostly unfamiliar with Greek poetry. Gnaeus Naevius (ca. 270–ca. 201 B.C.E.) also used Saturnian meter in his epic poem on the First Punic War, *Bellum Punicum*. After Naevius, Saturnian meter disappeared from Roman poetry.

It was Quintus Ennius (239–169 B.C.E.) who first introduced Greek meter to Roman verse. Born of Greek and Italian parents in southern Italy, in 204 B.C.E. he arrived in Rome, where he became one of the foremost authors of his time. A

versatile writer, Ennius wrote plays, elegies, epigrams, satires, and even a philosophical poem, *Epicharmus*, which describes the physical nature of the universe. His most lasting work was an epic poem, the *Annales*, which is a history of Rome and became the model for future Roman epics. The *Annales* begins with the story of Aeneas, who flees Troy when that city is overrun and destroyed by the Greeks. Aeneas eventually arrives in Italy, where he settles; according to Roman legend, it would be his descendants Romulus and Remus who would found Rome. Ennius's elegies appear to have made the first use of the elegiac couplet in Roman poetry, while his *Annales* first used dactylic hexameter.

The first Latin prose history was begun just before Ennius's death. In 168 B.C.E. Marcus Porcius Cato (234–149 B.C.E.), who was known as the Elder and the Censor and who was an important military and political leader of his time, wrote the *Origines*, a seven-volume history of the founding of Rome. Left unfinished on Cato's death, *Origines* was the first Roman history written in Latin and became the model for subsequent histories. Cato also wrote a treatise on agriculture, *De agri cultura*, and produced many political speeches, which he may have revised for publication and which were studied as models of the effective use of rhetoric by later Roman orators such as Cicero.

Not long after Cato's death, Gaius Lucilius (ca. 180–ca. 102 B.C.E.) wrote the first important Roman satires. Using Greek hexameter, Lucilius wrote some 30 books of verse, much of the verse attacking both the public and private behavior of his fellow citizens, particularly influential people and other writers. He remained popular until the end of the empire. The period from 70 B.C.E. to 17 C.E. is termed the golden age of Roman literature. The golden age saw the appearance of many major Roman writers, more than at any other period in Roman history. Among prose authors were Cicero and Julius Caesar, and among the poets were Virgil, Horace, and Ovid.

CICERO

The first half of the golden age is sometimes called the Ciceronian age after the Roman orator and statesman Marcus Tullius Cicero (106–43 B.C.E.). Cicero's literary reputation rests on some 60 speeches, 800 letters, and numerous books that he wrote during his successful career as lawyer and political leader. Born to a minor aristocratic family in Arpinum, a small town southeast of Rome, Cicero studied philosophy and rhetoric in both Rome and Greece before launching his legal career in 81 B.C.E. by successfully defending a client accused of murdering his father.

Cicero's earliest-known speech was given in 81 B.C.E. and was a plea in a case whose outcome is unknown. His most famous speeches were the four *In Catilinam* (Against Catiline), which he gave in 63 B.C.E. Catiline had organized an unsuccessful takeover of the Roman government. Cicero's speeches argued successfully for the execution of Catiline and his followers.

Cicero's letters covered a wide range of topics, from politics to poetry to idle gossip. His most important other writings are numerous works on rhetoric and political theory. Among his works on rhetoric was *De claris oratoribus* (On Clear Speaking) (ca. 46 B.C.E.), a study of Roman oratory and, in particular, Cicero's own style. Among his political works was *De legibus* (On Laws), which he finished in 45 B.C.E. and which describes the laws of an ideal state. Cicero's prose, particularly his speeches, came to be seen as excellent examples of the use of argumentative language and have been used from classical times to the present to teach the art of persuasion.

JULIUS CAESAR

The other major prose writer of the Ciceronian period was Gaius Julius Caesar (100–44 B.C.E.). Caesar produced several books, including one of jokes and sayings, and a little poetry. He is best remembered for two histories, *De bello Gallico* (On the Gallic War) (ca. 51 B.C.E.) and *De bello civili* (On the Civil War), begun in 49 B.C.E. and left unfinished at his assassination.

Both of Caesar's histories are vivid accounts, told in straightforward prose, of his military career. In *De bello Gallico*, Caesar details his campaign (58–50 B.C.E.) that added much territory to the Roman province of Gaul. In his second history Caesar describes the war between himself and Pompey the Great (106–48 B.C.E.). Both histories were first and foremost propaganda to enhance Caesar's image and to help him fulfill his political ambitions. In addition, however, both accounts are filled with details of Roman military life and tactics. The commentary on the Gallic War also provides a great deal of information on the land and its people. Nevertheless, *De bello Gallico* does not reveal the brutality that often marked Caesar's war against the Gauls.

LUCRETIUS AND CATULLUS

The Ciceronian age also produced many poets, two of the most notable being Titus Lucretius Carus (98–ca. 55 B.C.E.) and Gaius Valerius Catullus (ca. 84–ca. 54 B.C.E.). Little is known about Lucretius except for his single long philosophical poem *De rerum natura* (On the Nature of Things). A follower of the Greek philosopher Epicurus (ca. 340–ca. 270 B.C.E.), Lucretius explains in his poem how being modest in the pursuit of pleasure combined with an understanding of the workings of the physical world leads to tranquility that in turn frees one from the fear of death. The polished hexameter meter of *De rerum natura* was studied by later poets such as Virgil.

As with Lucretius, few details of Catullus's life are known except that he came from a wealthy family. Also like Lucretius, Catullus influenced the poets who came after him and who were impressed with the polish and sophistication of his verse, which ranged in length from a mini-epic to epigrams. Using a variety of Greek meters, Catullus wrote more than 100 poems on erotic love and friendship, with some 25 addressed to a married woman whom he calls Lesbia and with

whom he may have had an affair. His main theme was faithfulness in love and friendship.

VIRGIL

The second part of the golden age is known as the Augustan age, named for the emperor Augustus Caesar, who solidified his sole rule in 31 B.C.E. Much of the literary bloom of this part of Rome's golden age was due to Gaius Cilnius Maecenas (ca. 70–8 B.C.E.), a long-time adviser to Augustus and a patron of the arts. Maecenas supported many young poets, thus allowing them to write full time. Among Maecenas's clients was Publius Vergilius Maro (70–19 B.C.E.), better known as Virgil. Born in Andes, just south of the Alps, Virgil spent his childhood on his father's farm. Beginning at age 12, Virgil was educated first in Cremona, then in Milan, and finally in Rome, where he studied philosophy and rhetoric.

Virgil's first important work was the *Eclogues*, a collection of 10 short pastoral poems written between 42 and 37 B.C.E. The collection's title means "selections from a larger work," though the *Eclogues* is complete in itself. The poems are full of star-crossed lovers who live in an idealized rural setting. However, among the traditional pastoral concerns are more contemporary ones. Eclogues 2 and 9 deal with the policy of land confiscation that Mark Antony and Augustus (still named Octavian at the time of the *Eclogues*) enacted as a way to give land in payment to their soldiers. The desire to see the end of the strife of the decades of civil war also influences the fourth eclogue, which predicts the arrival of a new age of peace.

Virgil met Maecenas soon after the publication of the *Eclogues*. Maecenas urged the poet to take on a new project that would present country life more realistically than the conventional idealized pastoral. Both he and Augustus believed that Romans needed to return to their old traditions, which included farming. Virgil obliged his patron by writing the *Georgics* (On Farming), which he composed between 37 and 29 B.C.E. The poem's four books are filled with practical farming instructions on such matters as the cultivation of crops and the raising of livestock. It also contains many passages about the satisfactions of the farming life as well as the beauty and restfulness of being surrounded by the natural world.

The last 10 years of Virgil's life was consumed in writing his masterpiece, the 12-book *Aeneid*, which alone among Roman epic poems came to stand as an equal to Homer's *Iliad* and *Odyssey*. The hero of Virgil's epic is Aeneas, of whom Ennius wrote in his *Annales* and who gives his name to the poem. Virgil's Aeneas, son of the goddess Venus, is the first Roman and indeed a model one, devoted to duty and resolute in pursuit of his destiny, which is to seek Italy, where his descendants will found Rome.

The first six books of the *Aeneid* are a mini-*Odyssey* as Aeneas sails from Troy to Italy. The highlight of this section is his arrival in Carthage, where he falls in love with its queen, Dido. Tempted to remain, Aeneas is forcefully reminded of

his destiny in Italy by the god Mercury, so he leaves Carthage. In despair at her abandonment by her lover, Dido commits suicide. In the final six books Aeneas becomes involved in a struggle between the early Latin states. In single combat, reminiscent of that between Achilles and Hector in the *Iliad*, Aeneas slays the enemy of his Latin allies and sets the stage for the eventual appearance of Rome.

Maecenas had originally hoped that Virgil would write an epic about Augustus, but the poet believed that he could serve the emperor better with an older story. Still, Virgil did not forget Augustus. Upon arriving in Italy, Aeneas travels to Hades, where the dead go and where he is shown a shield that contains a pictorial record of future Roman history. The last picture on the shield is of a peaceful, unified Rome under the rule of Augustus.

HORACE

It was Virgil who introduced the poet Quintus Horatius Flaccus (65–8 B.C.E.), or Horace, to Maecenas. Although Horace came from a landed family, he had fought on the losing side of a civil war and had had all his property confiscated. Maecenas set Horace up with a small farm whose income allowed the poet to live comfortably. An extremely prolific writer, Horace produced a substantial body of work, beginning around 40 B.C.E. with the writing of the 17 poems that made up the *Epodes*, published in 30 B.C.E. (In verse, an epode is the third part of a three-part lyric ode.) Using a variety of lengths and meters, Horace specialized in lyric poetry and satires that his contemporaries and later generations considered unequalled in quality. He also coined a number of phrases that remain in use to this day, such as "the golden mean" and "seize the day."

The verse in the *Epodes* is minor, and Horace's first major work were the *Sermones* (Conversations), two books of satire, the first being published in 35 B.C.E. and the second in 30 B.C.E. Horace's satires are not vicious and do not attack public figures. Instead, in a colloquial, conversational style, he pokes fun at the foibles of his fellow citizens. For instance, he writes about those who wish to be in the country and, once there, desire to be back in Rome. He even includes himself in these humorous musings, ridiculing his own short temper and indecisiveness.

Next followed the four books of the *Carmina*, or *Odes*, which contain Horace's major lyric poetry. The first three books were published around 23 B.C.E. and the fourth about 13 B.C.E. In 103 poems Horace covers love, the gods, and friendship, among other subjects. Ever mindful of his patron Maecenas's loyalties, Horace takes pains to celebrate Augustus's victory over Antony at Actium in 31 B.C.E. and voices approval of the emperor's campaign to restore traditional Roman virtues. Around 20 B.C.E. Horace published his *Epistles* (Letters). These are letters written in verse that cover many of the topics found in the satires and lyric poetry. The *Ars poetica* (The Art of Poetry) (ca. 18 B.C.E.) is another verse letter that offers detailed advice on writing poetry.

OID

The third of the major Augustan poets was Publius Ovidius Naso (43 B.C.E.–17 C.E.), or Ovid. From an aristocratic family, Ovid studied rhetoric in Rome in preparation for a career in law, but he soon abandoned law in favor of poetry. Much of Ovid's verse is written in elegiac couplets, of which he was considered in his time and later to be the master. Two of his major subjects are seduction and erotic love, neither of which endeared Ovid to Augustus, who was attempting to reform the morals of Romans. Additionally, Ovid often wrote irreverently about the emperor and his policies. One or more of Ovid's indiscretions—exactly which remains a mystery to this day—earned him permanent exile to Tomis on the Black Sea in 8 C.E.

Ovid's first work was the five-book *Amores* (Loves), begun around 20 B.C.E. It describes, mockingly at times, Ovid's affair with a woman he named Corinna. Ovid followed with *Ars amatoria* (The Art of Love) (ca. 1 B.C.E.), a step-by-step guide to seduction, particularly of married women. In the *Heroides* (Heroines) (ca. 2 C.E.), Ovid collected 20 poems that were supposedly love letters from famous women to their husbands or lovers.

Ovid's major work was the *Metamorphoses* (Transformations), a 15-book poem completed by 8 C.E. that Ovid may have considered an epic because he abandoned the elegiac couplet for dactylic hexameter. The *Metamorphoses* describes the creation and history of the world mostly by telling tales in which divinities or humans are transformed. The poem begins with Prometheus, who changes earth into humankind, and ends with the assassinated Julius Caesar changing into a star. Ovid's theme, as usual, is human passion, as seen in the actions of both his divine and human characters. The *Metamorphoses* is told with wit, a mature and elegant style, and a deep knowledge of Greek and Roman literature and myth.

During his exile Ovid continued to write. His collection of elegies *Tristia* (Sorrow), written between 8 and 12 C.E., and *Epistulae ex Ponto* (Letters from Pontus), written between 12 and 16 C.E., were more sober and personal than his previous work and were unsuccessful pleas for an end to his exile. His last work was the *Fasti*, a description in verse of the Roman calendar and religious festivals. It was unfinished at his death.

THE SILVER AGE

The death of Ovid in 17 C.E. marked the end of the Roman literary golden age and the beginning of the silver age, which lasted for a little over a century. Although none of this period's writers would match in stature those of the golden age, the era did produce a number of notable poets and prose writers.

Among these poets were Martial, Juvenal, and Lucan. Marcus Valerius Martialis (ca. 40–ca. 103 C.E.), or Martial,

was from Spain, and wrote mostly epigrams using the elegiac couplet. In his *Epigrams*, consisting of 12 books published between 86 and 101 C.E. and containing more than 1,500 epigrams, Martial satirized the outrageous behavior of his friends; depicted realistically life in Rome, even as he satirized it; and idealized his childhood in Spain. Decimus Junius Juvenalis (ca. 60–ca. 127 C.E.), or Juvenal, was a sharp-tongued satirist who attacked with vigor injustice and vice in Roman society. His 16 *Saturae* (Satires) (110–127 C.E.) are filled with cynicism, pessimism, and venom. In his short life Marcus Annaeus Lucanus (39–65 C.E.), or Lucan, produced a number of poems, the most famous of which was *De bello civili* (On the Civil War), sometimes also known as the *Pharsalia*, an epic about the battle between Julius Caesar and Pompey.

The silver age produced one of the foremost Roman historians, Publius (or Gaius) Cornelius Tacitus (ca. 56–ca. 117 C.E.). Tacitus's most important works were his *Historiae* (Histories) (106–107 C.E.) and *Annales* (Annals; ca. 116 C.E.). The former covers the period between the death of the emperor Nero in 68 C.E. and that of the emperor Domitian in 96 C.E., while the latter covers the time from Augustus's death in 14 C.E. to that of Nero. Complementing Tacitus's histories were the biographies of Gaius Suetonius Tranquillus (ca. 70–ca. 140 C.E.), whose *De vita Caesarum* (*Lives of the Twelve Caesars*, as it appears in English), published sometime after 122 C.E., contains biographical sketches of Julius Caesar and the first 11 emperors. Suetonius also wrote other biographies of famous orators, poets, and historians.

Among other noted prose writers were Pliny the Elder, Pliny the Younger, Seneca the Younger, and Petronius. Despite much public and military service, Pliny the Elder (Gaius Plinius Secundus) (23–79 C.E.) found time to write histories, biographies, and a work on natural history, the 37-volume *Naturalis historia* (Natural History) (77 C.E.). The latter compiled—without any attempt to separate fact from fiction—every report about the world that Pliny could discover. Pliny died while trying to obtain a closer look at the erupting Mount Vesuvius that buried the city of Pompeii. His nephew Pliny the Younger (Gaius Plinius Caecilius Secundus) (ca. 61–ca. 111 C.E.) was a noted orator and prolific letter writer, the latter of which covered many topics, such as his vivid description of the eruption of Mount Vesuvius that killed his uncle.

Seneca the Younger (Lucius Annaeus Seneca) (4 B.C.E.–65 C.E.) wrote extensively on Stoic philosophy, explaining that self-control, moderation, and detachment from pleasure and pain were necessary to find truth. Petronius (often identified as Titus or Gaius Petronius) (ca. 27–66 C.E.) wrote one of the first novels, the *Satyricon*, or more properly *Satyrica* (Tales of the Satyrs; ca. 60 C.E.), which chronicles the misadventures of two young Greeks. The highlight of the novel is a banquet thrown by a wealthy former slave, Trimalchio—an extravagant and vulgar display of the host's wealth.

LATER WRITERS

Competent but minor poets populated Rome in its last centuries. Prose fared somewhat better. The *Meditations* of the emperor Marcus Aurelius (121–180 C.E.), published after Marcus's death, collects the emperor's private musings about life and the gods while pondering the role of Stoicism in public and private life. Marcus's contemporary Lucius Apuleius (ca. 124–ca. 170 C.E.) wrote the novel *Metamorphoses*, also known as the *Aureus asinus* (The Golden Ass), in which the protagonist Lucius's mishandling of magic turns him into an ass. Before returning to human form, Lucius has a series of humorous and lewd adventures.

Beginning in the fourth century, numerous important Christian writers appeared and dominated Roman writing. Aurelius Ambrosius (ca. 340–397 C.E.), later Saint Ambrose, wrote many hymns, sermons, letters, and treatises defending Christianity against paganism. Eusebius Hieronymous (ca. 347–420 C.E.), or Saint Jerome, wrote biblical commentaries and biographies of Christian writers; his translation of the Bible became the standard Latin text. Aurelius Augustinus (54–430 C.E.), or Saint Augustine, was a prolific writer. His most famous work is his *Confessions* (ca. 397–400 C.E.), an examination of his life that contains a vivid and forceful account of his conversion to Christianity.

THE AMERICAS

BY ALESSIA FRASSANI

Writing and recording knowledge in Native America was limited, and no texts have survived from the pre-Columbian period. Archaeologists, historians, and anthropologists who study ancient indigenous cultures agree that Native American literary traditions were essentially oral. In ancient times tools were used to support memorization of different types of texts, from tribute accounts to religious chants. These tools only partly recorded the spoken word and were meant to give clues for recitation, which was largely improvised. Although this may seem unusual to modern readers used to the support of the printed word for preserving and transmitting information, the human mind has the ability to memorize long texts provided they have a rhythmic, repetitive, and redundant formal structure. People can be specially trained from a young age to become proficient in the art of memory. Schools and tutoring provide the necessary intellectual environment to stimulate this activity, which preserves and creates at the same time. It aims at preserving a preexisting body of literature while the performers are free and even expected to elaborate further during the actual performance. All this was the case with Native American poetry, which historians have been forced to study by examining historical and contemporary cultures from the 16th century onward in order to draw inferences about the content and form of earlier literature.

The single most important element of Amerindian poetics is parallelism. Two verses are coupled by a tight repetition of the syntactic structure (that is, the structure of the sentence and its grammar), with only a slight variation in the wording. This gives the verse its basic rhythm, in a way comparable to the rhyme and metric systems of Western literature. The elementary two-verse unit can be either introduced or concluded by a third line with a different structure and wording from the other two verses. This additional feature creates variations in pitch and stress and enables the performers to pause before starting again with a new sequence of parallel verses. A good example can be found in the creation account contained in the ancient Mayan Popol Vuh, which includes the lines: “now it still ripples / now it still murmurs / ripples, it still sighs / it still hums / and it is empty / under the sky.” Performers and the rhythms of their delivery over a fixed narration and story are ultimately the most remarkable features of Amerindian literature.

Archaeological remains that bear traces of what may have been a literary tradition in the Americas in the early period include carvings and paintings meant for public display. The context points to the function of some literary production and performance as a propaganda tool. Archaeologists and anthropologists tend to view the rise of complex mythology in the early ancient Americas as tied to the emergence of social complexity and the establishment of an elite class that employed literature to justify claims to power. Members of the ruling class impersonated literary and legendary figures during ceremonies and were actively involved in creating a perception of rulership's durability and legitimacy based on the mythological quality of the stories narrated. In other cases agricultural cycles and crops were the main theme, expressing an obvious concern for community sustenance and well-being. Paintings decorated rooms and plazas where fertility rituals took place, and the decoration served as a backdrop for ceremonies taking place in them.

In Mesoamerica the period of pre-Columbian history from 400 B.C.E. to 150 C.E. is known as Late Preclassic or Formative. Both terms define an early stage of Mesoamerican history in relation to later, and better-known, sociopolitical developments. Anthropologists believe that during this period states emerged, along with intensive agriculture. From relatively small and simple societies, cities and even empires came to dominate the Mesoamerican political arena. In the Maya area, including modern southern Mexico, Guatemala, Belize, and Honduras, the importance of ritual reenactment and public sacrifice of rulers during ceremonial occasions is well known. The continuation of political rulership, especially at the critical moments of dynastic succession, was metaphorically tied to the constant renewal of the maize-planting cycle. At the base of this ideology was the Popol Vuh, an epic tradition known only from a text written in the 16th century but widely represented in pre-Columbian

pottery and murals. The central part of *Popol Vuh* deals with the myth of the Hero Twins and is considered the most ancient part of the text. Depictions of events from the *Popol Vuh* are, in fact, frequently found on numerous monuments from the Pacific slope region of Mexico and Guatemala, home during the Preclassic Period to the so-called Izapan style (from the archaeological site of Izapa in Chiapas, Mexico).

The creation of maize, conceived as the capture, death, and resurrection of the maize god, is narrated in the *Popol Vuh* through the story of Hun Hunahpu, a demigod who went to the underworld and was kidnapped and killed by Lords of Death. His sons, the Hero Twins, came to his rescue; when they revived him, he sprouted like a young corn plant. He cracked through the surface of the earth, which is represented by either a turtle shell or a serpent. The whole story takes place in the underworld, a primordial place represented as a dark and cold sea. Stelae (vertical stone slabs decorated with low-carved relief) from Izapa depict the maize god resurrection. A man wearing a godly mask is seen emerging from a large pool of water, arms outstretched, while two flanking figures help his ascension by pulling a cord he is grasping. Scholars believe that the masks the characters are wearing signal that they are performers (rulers or priests) impersonating well-known characters from the *Popol Vuh*.

Among the Maya of the Classic Period (150–650 C.E.) the poetic tradition of the *Popol Vuh* continued to flourish, and it is often found depicted on vases, found mostly in tombs, that reveal an important aspect of Maya ceremonial and courtly life. Images and text strictly interact. Although only a few inscriptions have been translated so far, episodes from the ancient epic deeds of the Hero Twins abound, including the resurrection of the maize god. The refined and private setting of the vase images point to a courtly tradition that was not concerned as much with propaganda as it was with sheer entertainment.

Teotihuacán was the most important center in Mesoamerica during the Classic Period, flourishing between 1 and 650 C.E. It was perhaps the largest city in the ancient Americas, and its domination was felt well beyond the borders of the Valley of Mexico, where its ruins can still be visited. Maya cities to the south largely borrowed from Teotihuacán art its symbols and ideology, pointing to close political, economic, and perhaps military ties between central and southern Mesoamerica. Archaeologists have not as yet discovered written historical documents from the metropolis, and it seems most likely that if written records ever existed, they were destroyed in later times. Nevertheless, mural painting, which covers the walls of many residential compounds throughout the city, bear traces of what was probably a well-developed literature, mostly revolving around fertility and agricultural themes.

Depictions include supernatural or animal figures most often depicted in profile and proceeding in procession. Richly dressed, they seem to be actively involved in sacrificial ritual activities, as indicated by the thorns and incense they often carry. Speech scrolls, indicating chanting, are often coming out of their mouth. As in later Aztec art, flowers and green jade decorations attached to the scrolls indicate poetry. The flower and jade metaphor refers to the preciousness of the words uttered during chanting and praying. Maize decorations may further allude to prayers said to spur the growth of crops.

A striking feature of Teotihuacán mural painting is its repetitiveness. Within large borders of elaborate abstract or representational designs unfold series of very similar depictions of animals, plants, or human figures, which create patterns found throughout the rooms of the same compound. Templates may vary in specific iconographic elements (that is, symbolic representation), especially garments, adornments, and colors. Some scholars suggest that the standardization of Teotihuacán representation can be linked to a writing system, one that was perhaps more fully developed in other media such as books. Repetitions and variations in painting may reflect other well-known and similar conventions of Amerindian poetry noted earlier.

Murals from the residential compound of Techinantla, a compound in Teotihuacán, now found in fragments in museums all over the world, offer a striking example. Four feathered serpents, with long, undulating bodies, curl around a rectangular room. The bright yellow, green, and blue of the feather mantle can still be appreciated. The bodies end with elaborate jeweled rattle tails. From the mouths, streams of waters, flowers, and precious stones pour out. Below the serpents, which serve as a border, is a row of trees depicted in repeated series of nine. They all have the same basic shape and exposed roots, while variations occur in the flowers and fruits they bear.

These kinds of visual representations have been seen in relation to known incantations from the later Aztec (1250–1521) period. Plants were used for medicinal purposes, and their curative effect was sometimes translated into special qualities that were invoked during rituals. Nine was a highly significant number among Mesoamerican civilizations, especially related to the underworld. Shaman-curers were often said to enter this world in a state of trance when curing a patient. Finally, trees were important symbols of genealogy and clans. Techinantla murals may depict a lineage song, a common form of poetry that reckoned and celebrated dynastic histories.

Africa

~ *Saint Augustine: Excerpts from The City of God*
(410–426 C.E.) ~

BOOK 14, CHAPTER 28: OF THE NATURE OF THE TWO CITIES, THE EARTHLY AND THE HEAVENLY

Accordingly, two cities have been formed by two loves: the earthly by the love of self, even to the contempt of God; the heavenly by the love of God, even to the contempt of self. The former, in a word, glories in itself, the latter in the Lord. For the one seeks glory from men, but the greatest glory of the other is God, the witness of conscience. The one lifts up its head in its own glory; the other says to its God, “Thou art my glory, and the lifter up of mine head.” In the one, the princes and the nations it subdues are ruled by the love of ruling; in the other, the princes and the subjects serve one another in love, the latter obeying, while the former take thought for all. The one delights in its own strength, represented in the persons of its rulers; the other says to its God, “I will love Thee, O Lord, my strength.” And therefore the wise men of the one city, living according to man, have sought for profit to their own bodies or souls, or both, and those who have known God “glorified Him not as God, neither were thankful, but became vain in their imaginations, and their foolish heart was darkened; professing themselves to be wise,”—that is, glorying in their own wisdom, and being possessed by pride,—“they became fools, and changed the glory of the incorruptible God into an image made like to corruptible man, and to birds, and four-footed beasts, and creeping things.” For they were either leaders or followers of the people in adoring images, “and worshipped and served the creature more than the Creator, who is blessed for ever.” But in the other city there is no human wisdom, but only godliness, which offers due worship to the true God, and looks for its reward in the society of the saints, of holy angels as well as holy men, “that God may be all in all.”

BOOK 15, CHAPTER 4: OF THE CONFLICT AND PEACE OF THE EARTHLY CITY

But the earthly city, which shall not be everlasting (for it will no longer be a city when it has been committed to the extreme penalty), has its good in this world and rejoices in it with such joy as such things can afford. But as this is not a good which can discharge its devotees

of all distresses, this city is often divided against itself by litigations, wars, quarrels, and such victories as are either life-destroying or short-lived. For each part of it that arms against another part of it seeks to triumph over the nations through itself in bondage to vice. If, when it has conquered, it is inflated with pride, its victory is life-destroying; but if it turns its thoughts upon the common casualties of our mortal condition, and is rather anxious concerning the disasters that may befall it than elated with the successes already achieved, this victory, though of a higher kind, is still only short-lived; for it cannot abidingly rule over those whom it has victoriously subjugated. But the things which this city desires cannot justly be said to be evil, for it is itself, in its own kind, better than all other human good. For it desires earthly peace for the sake of enjoying earthly goods, and it makes war in order to attain to this peace; since, if it has conquered, and there remains no one to resist it, it enjoys a peace which it had not while there were opposing parties who contested for the enjoyment of those things which were too small to satisfy both. This peace is purchased by toilsome wars; it is obtained by what they style a glorious victory. Now, when victory remains with the party which had the juster cause, who hesitates to congratulate the victor, and style it a desirable peace? These things, then, are good things, and without doubt the gifts of God. But if they neglect the better things of the heavenly city, which are secured by eternal victory and peace never-ending, and so inordinately covet these present good things that they believe them to be the only desirable things, or love them better than those things which are believed to be better,—if this be so, then it is necessary that misery follow and ever increase.

BOOK 19, CHAPTER 17: WHAT PRODUCES PEACE, AND WHAT DISCORD, BETWEEN THE HEAVENLY AND EARTHLY CITIES

But the families which do not live by faith seek their peace in the earthly advantages of this life; while the families which live by faith look for those eternal blessings which are promised, and use as pilgrims such advantages of time and of earth as do not fascinate and divert them from God, but rather aid them to endure with greater ease, and to keep down the number of

(continued)

(continues)

those burdens of the corruptible body which weigh upon the soul. Thus the things necessary for this mortal life are used by both kinds of men and families alike, but each has its own peculiar and widely different aim in using them. The earthly city, which does not live by faith, seeks an earthly peace, and the end it proposes, in the well-ordered concord of civic obedience and rule, is the combination of men's wills to attain the things which are helpful to this life. The heavenly city, or rather the part of it which sojourns on earth and lives by faith, makes use of this peace only because it must, until this mortal condition which necessitates it shall pass away. Consequently, so long as it lives like a captive and a stranger in the earthly city, though it has already received the promise of redemption, and the gift of the Spirit as the earnest of it, it makes no scruple to obey the laws of the earthly city, whereby the things necessary for the maintenance of this mortal life are administered; and thus, as this life is common to both cities, so there is a harmony between them in regard to what belongs to it. . . . This heavenly city, then, while it sojourns on earth, calls citizens out of

all nations, and gathers together a society of pilgrims of all languages, not scrupling about diversities in the manners, laws, and institutions whereby earthly peace is secured and maintained, but recognizing that, however various these are, they all tend to one and the same end of earthly peace. It therefore is so far from rescinding and abolishing these diversities that it even preserves and adopts them, so long only as no hindrance to the worship of the one supreme and true God is thus introduced. Even the heavenly city, therefore, while in its state of pilgrimage, avails itself of the peace of earth, and, so far as it can without injuring faith and godliness, desires and maintains a common agreement among men regarding the acquisition of the necessities of life, and makes this earthly peace bear upon the peace of heaven. . . . In its pilgrim state the heavenly city possesses this peace by faith; and by this faith it lives righteously when it refers to the attainment of that peace every good action towards God and man; for the life of the city is a social life.

Egypt

~ "The Tale of The Eloquent Peasant," ca. 1800 B.C.E. ~

There was a man, Hunanup by name, a peasant of Sechet-hemat, and he had a wife. . . . Then said this peasant to his wife: "Behold, I am going down to Egypt to bring back bread for my children. Go in and measure the grain that we still have in our storehouse." . . . Then this peasant went down to Egypt after he had loaded his asses with all the good produce of Sechet-hemat.

This peasant set out and journeyed southward to Ehnas. He came to a point opposite Per-fefi, north of Medenit, and found there a man standing on the bank, Dehuti-necht by name, . . .

Then said this Dehuti-necht, when he saw the asses of this peasant which appealed to his covetousness: "Oh that some good god would help me to rob this peasant of his goods!"

The house of Dehuti-necht stood close to the side of the path, which was narrow, not wide. . . . Upon one side of it was the water and upon the other side was growing grain. Then said Dehuti-necht to his servant: "Hasten

and bring me a shawl from the house!" . . . Then he spread this shawl upon the middle of the road, and it extended one edge to the water and the other to the grain.

The peasant came along the path which was the common highway. Then said Dehuti-necht: "Look out, peasant, do not trample on my clothes!" The peasant answered: "I will do as you wish; I will go in the right way!" As he was turning to the upper side, Dehuti-necht said: "Does my grain serve you as a road?" Then said the peasant: "I am going in the right way. The bank is steep and the path lies near the grain and you have stopped up the road ahead with your clothes. Will you, then, not let me go by?" Upon that one of the asses took a mouthful of grain. Then said Dehuti-necht: "See, I will take away your ass because it has eaten my grain."

Then the peasant said: ". . . As one side was made impassable I have led my ass along the other, and will you seize it because it has taken a mouthful of grain? But I know the lord of this property; it belongs to the

chief steward, Meruitensi. It is he who punishes every robber in this whole land. Shall I, then, be robbed in his domain?"

Then said Dehuti-necht: "Is it not a proverb which the people employ: 'The name of the poor is only known on account of his lord?' It is I who speak to you, but the chief steward of whom you think." Then he took a rod from a green tamarisk and beat all his limbs with it, and seized his asses and drove them into his compound.

Thereupon the peasant wept loudly on account of the pain of what had been done to him. . . .

The peasant consumed four days, during which he besought Dehuti-necht, but he did not grant him his rights. Then this peasant went to the south, to Ehnas to implore the chief steward, Meruitensi. He met him as he was coming out of the canal-door of his compound to embark in his boat. Thereupon the peasant said: "Oh let me lay before you this affair. . . ." Then the steward Meruitensi, sent one of his servants to him, and he sent back by him an account of the whole affair. Then the chief steward, Meruitensi, laid the case of Dehuti-necht before his attendant officials, and they said to him:

"Lord, it is presumably a case of one of your peasants who has gone against another peasant near him. Behold, it is customary with peasants to so conduct themselves toward others who are near them. Shall we beat Dehuti-necht for a little natron and a little salt? Command him to restore it and he will restore it."

The chief steward, Meruitensi, remained silent. . . .

The peasant then came to entreat the chief steward Meruitensi, for the first time, and said: "Chief steward, my lord, you are greatest of the great, you are guide of all that which is not and which is. . . . Let me place your name in this land higher than all good laws: you guide

without avarice, you great one free from meanness, who destroys deceit, who creates truthfulness. Throw the evil to the ground. . . . Do justice, O you praised one, whom the praised ones praise. . . ."

This peasant came to implore him for the eighth time, and said: "Chief steward, my lord, . . . Greed is absent from a good merchant. . . . Your heart is greedy, it does not become you. . . . The officers, who are set as a protection against injustice,—a curse to the shameless are these officers, who are set as a bulwark against lies. Fear of you has not deterred me from supplicating you; if you think so, you have not known my heart. . . . Your real estate is in the country, your bread is on your estate, your food is in the storehouse. Your officials give to you and you take it. Are you, then, not a robber? . . . Do the truth for the sake of the Lord of Truth. . . ."

Then . . . the chief steward, Meruitensi . . . caused them to bring, written on a new roll, all the addresses of these days. The chief steward sent them to his majesty, the king of Upper and Lower Egypt, Neb-kau-re, the blessed, and they were more agreeable to the heart of his majesty than all that was in his land. His majesty said, "Pass sentence yourself my beloved son!" Then the chief steward, Meruitensi, caused two servants to go and bring a list of the household of Dehuti-necht from the government office, and his possessions were six persons, with a selection . . . from his barley, from his spelt, from his asses, from his swine.

[The ensuing words cannot be made out, but it appears that the goods of Dehuti-necht were given to the peasant and he was sent home rejoicing.]

The Middle East

~ *Enûma Elish (The Epic of Creation), excerpt*
(eighth century B.C.E.) ~

THE FIRST TABLET

When in the height heaven was not named,
And the earth beneath did not yet bear a name,
And the primeval Apsu, who begat them,
And chaos, Tiamut, the mother of them both
Their waters were mingled together,

And no field was formed, no marsh was to be seen;
When of the gods none had been called into being,
And none bore a name, and no destinies were ordained;
Then were created the gods in the midst of heaven,
Lahmu and Lahamu were called into being. . . .
Ages increased, . . .

(continued)

(continues)

Then Ansar and Kisar were created, . . .
 Long were the days, then there came forth . . .
 Anu, their son, . . .
 Ansar and Anu . . .
 And the god Anu . . .
 Nudimmud, whom his fathers, his begetters . . .
 Abounding in all wisdom. . . .
 He was exceeding strong . . .
 He had no rival—
 Thus were established and were . . . the great gods.
 But Tiamat and Apsu were still in confusion. . . .
 They were troubled and . . .
 In disorder. . . .
 Apru was not diminished in might . . .
 And Tiamat roared. . . .
 She smote. . . .
 Their way was evil. . . .
 Then Apsu, the begetter of the great gods,
 Cried unto Mummu, his minister, and said unto him:
 “O Mummu, thou minister that rejoicest my spirit,
 Come, unto Tiamat let us go!
 So they went and before Tiamat they lay down,
 They consulted on a plan with regard to the gods, their
 sons.
 Apsu opened his mouth and spake,
 And unto Tiamat, the glistening one, he addressed the
 word:
 . . . By day I cannot rest, by night I can not lie down in
 peace.
 But I will destroy their way. . . .
 Let there be lamentation, and let us lie down again in
 peace.”
 When Tiamat heard these words,
 She raged and cried aloud. . . .
 She uttered a curse, and unto Apsu she spake:
 “What then shall we do?
 Let their way be made difficult, and let us lie down again
 in peace.”
 Mummu answered, and gave counsel unto Apsu, . . .
 and hostile to the gods was the counsel Mummu gave:
 Come, their way is strong, but thou shalt destroy it;
 Then by day shalt thou have rest, by night shalt thou lie
 down in peace.”
 Apsu harkened unto him and his countenance grew
 bright,
 Since he (Mummu) planned evil against the gods his
 sons. . . .
 His knees became weak; they gave way beneath him,
 Because of the evil which their first-born had planned. . . .

Then Ea, who knoweth all that is, went up and he beheld
 their muttering. . . .

[The lines become unintelligible.]

. . . he hath conquered and
 . . . he weepeth and sitteth in tribulation.
 . . . we shall not lie down in peace.
 . . . Apsu is laid waste,
 . . . and Mummu, who were taken captive
 . . . let us lie down in peace. . . .
 And Tiamat harkened unto the word of the bright god,
 and said:
 . . . shalt thou entrust! let us wage war!” . . .
 They banded themselves together and at the side of
 Tiamat they advanced;
 They were furious; they devised mischief without
 resting night and day.
 They prepared for battle, fuming and raging;
 They joined their forces and made war,
 Ummu-Hubur [Tiamat] who formed all things,
 Made in addition weapons invincible; she spawned
 monster-serpents,
 Sharp of tooth, and merciless of fang;
 With poison, instead of blood, she filled their bodies.
 Fierce monster-vipers she clothed with terror.
 With splendor she decked them, she made them of lofty
 stature.
 Whoever beheld them, terror overcame him.
 Their bodies reared up, and none could withstand their
 attack.
 She set up vipers and dragons, and the monster
 Lahamu,
 And hurricanes, and raging hounds, and scorpion-men,
 And mighty tempests, and fish-men, and rams;
 They bore cruel weapons, without fear of the fight.
 Her commands were mighty, none could resist them.
 After this fashion, huge of stature, she made eleven
 [kinds of] monsters.
 Among the gods who were her sons, inasmuch as he had
 given her support,
 She exalted Kingu; in their midst she raised him to
 power.
 To march before the forces, to lead the host,
 To give the battle-signal, to advance to the attack,
 To direct the battle, to control the fight,
 Unto him she entrusted; in costly raiment she made him
 sit, saying:
 I have uttered thy spell, in the assembly of the gods I
 have raised thee to power.
 The dominion over all the gods have I entrusted unto
 him.
 Be thou exalted, thou my chosen spouse,

May they magnify thy name over all of them the Anunnaki.”
 She gave him the Tablets of Destiny, on his breast she laid them, saying:
 Thy command shall not be without avail, and the word of thy mouth shall be established.”
 Now Kingu, thus exalted, having received the power of Anu,

Decreed the fate among the gods his sons, saying:
 “Let the opening of your mouth quench the Fire-god; Whoso is exalted in the battle, let him display his might!”

 (ca. 400 B.C.E.) ~

CHAPTER 1

Dhritirashtra:

Ranged thus for battle on the sacred plain On Kurukshetra—say, Sanjaya! say What wrought my people, and the Pandavas?

Sanjaya:

When he beheld the host of Pandavas Raja Duryodhana to Drona drew, And spake these words: “Ah, Guru! see this line, How vast it is of Pandu fighting-men, Embattled by the son of Drupada, Thy scholar in the war! Therein stand ranked Chiefs like Arjuna, like to Bhima chiefs, Benders of bows; Virata, Yuyudhan, Drupada, eminent upon his car, Dhrishtaket, Chekitan, Kasi’s stout lord, Purujit, Kuntibhoj, and Saivya, With Yudhamanyu, and Uttamauj Subhadra’s child; and Drupadi’s;—all famed! All mounted on their shining chariots! On our side, too,—thou best of Brahmans! see Excellent chiefs, commanders of my line, Whose names I joy to count: thyself the first, Then Bhishma, Karna, Kripa fierce in fight, Vikarna, Aswatthaman; next to these Strong Saumadatti, with full many more Valiant and tried, ready this day to die For me their king, each with his weapon grasped, Each skilful in the field. Weakest—meseems Our battle shows where Bhishma holds command, And Bhima, fronting him, something too strong! Have care our captains nigh to Bhishma’s ranks Prepare what help they may! Now, blow my shell!”

Then, at the signal of the aged king, With blare to wake the blood, rolling around Like to a lion’s roar, the trumpeter Blew the great Conch; and, at the

noise of it, Trumpets and drums, cymbals and gongs and horns Burst into sudden clamor; as the blasts Of loosened tempest, such the tumult seemed! Then might be seen, upon their car of gold Yoked with white steeds, blowing their battle-shells, Krishna the God, Arjuna at his side: Krishna, with knotted locks, blew his great conch Carved of the “Giant’s bone;” Arjuna blew Indra’s loud gift; Bhima the terrible Wolf-bellied Bhima—blew a long reed-conch; And Yudhisthira, Kunti’s blameless son, Winded a mighty shell, “Victory’s Voice;” And Nakula blew shrill upon his conch Named the “Sweet-sounding,” Sahadev on his Called “Gem-bedecked,” and Kasi’s Prince on his. Sikhandi on his car, Dhrishtadyumn, Virata, Satyaki the Unsubdued, Drupada, with his sons, (O Lord of Earth!) Long-armed Subhadra’s children, all blew loud, So that the clangor shook their foemen’s hearts, With quaking earth and thundering heav’n. Then ’twas

Beholding Dhritirashtra’s battle set, Weapons unsheathing, bows drawn forth, the war Instant to break—Arjun, whose ensign-badge Was Hanuman the monkey, spake this thing To Krishna the Divine, his charioteer: “Drive, Dauntless One! to yonder open ground Betwixt the armies; I would see more nigh These who will fight with us, those we must slay To-day, in war’s arbitrament; for, sure, On bloodshed all are bent who throng this plain, Obeying Dhritirashtra’s sinful son.”

Thus, by Arjuna prayed (O Bharata!) Between the hosts that heavenly Charioteer Drove the brightfcar, reining its milk-white steeds Where Bhishma led, and Drona, and their Lords. “See!” spake he to Arjuna,

(continued)

(continues)

“where they stand, Thy kindred of the Kurus:” and the Prince Marked on each hand the kinsmen of his house, Grandsires and sires, uncles and brothers and sons, Cousins and sons-in-law and nephews, mixed With friends and honored elders; some this side, Some that side ranged: and, seeing those opposed, Such kith grown enemies—Arjuna’s heart Melted with pity, while he uttered this:

Arjuna:

Krishna! as I behold, come here to shed Their common blood, yon concourse of our kin, My members fail, my tongue dries in my mouth, A shudder thrills my body, and my hair Bristles with horror; from my weak hand slips Gandiv, the goodly bow; a fever burns My skin to parching; hardly may I stand; The life within me seems to swim and faint; Nothing do I foresee save woe and wail! It is not good, O Keshav! nought of good Can spring from mutual slaughter! Lo, I hate Triumph and domination, wealth and ease, Thus sadly won! Aho! what victory Can bring delight, Govinda! what rich spoils Could profit; what rule recompense; what span Of life itself seem sweet, bought with such blood? Seeing that these stand here, ready to die, For whose sake life was fair, and pleasure pleased, And power grew precious:— grandsires, sires, and sons. Brothers, and fathers-in-law, and sons-in-law, Elders and friends! Shall I deal death on these Even though they seek to slay us? Not one

blow, O Madhusudan! will I strike to gain The rule of all Three Worlds; then, how much less To seize an earthly kingdom! Killing these Must breed but anguish, Krishna! If they be Guilty, we shall grow guilty by their deaths; Their sins will light on us, if we shall slay Those sons of Dhritirashtra, and our kin; What peace could come of that, O Madhava? For if indeed, blinded by lust and wrath, These cannot see, or will not see, the sin Of kingly lines o’erthrown and kinsmen slain, How should not we, who see, shun such a crime We who perceive the guilt and feel the shame Oh, thou Delight of Men, Janardana? By overthrow of houses perisheth Their sweet continuous household piety, And - rites neglected, piety extinct Enters impiety upon that home; Its women grow unwomaned, whence there spring Mad passions, and the mingling-up of castes, Sending a Hell-ward road that family, And whoso wrought its doom by wicked wrath. Nay, and the souls of honored ancestors Fall from their place of peace, being bereft Of funeral-cakes and the wan death-water.¹ So teach our holy hymns. Thus, if we slay Kinsfolk and friends for love of earthly power, Ahovat! what an evil fault it were! Better I deem it, if my kinsmen strike, To face them weaponless, and bare my breast To shaft and spear, than answer blow with blow. . . .

So speaking, in the face of those two hosts, Arjuna sank upon his chariot-seat, And let fall bow and arrows, sick at heart.

Greece

~ Plato: *The Allegory of the Cave, from The Republic*,
ca. 360 B.C.E. ~

Compare our nature in respect to education with our condition. Imagine men in an underground cave with an entrance open toward the light which extends through the whole cave. Within the cave are people who from childhood have had chains on their legs and their necks so they could only look forward but not turn their heads. There is burning a fire, above and behind them, and between the fire and the chains is a road above, along which one may see a little wall built along, just as the stages of conjurers are built before the people in whose presence they show their tricks. . . . Imagine then by the side of this little wall men carrying all sorts of machines rising above the wall, and statues of men and other

animals wrought in stone, wood, and other materials, some of bearers probably speaking, others proceeding in silenced. . . . [Do you think] that such as these [chained men] would have seen anything else of themselves or one another except the shadows that fall from the fire on the opposite side of the cave? How can they . . . if indeed they are forced to always keep their heads unmoved? . . . [S]uch persons would believe that truth was nothing else but the shadows of the exhibitions. Let us inquire then, as to their liberation from captivity, and their cure for insanity. . . . [What if one of these chained persons was] let loose and obliged immediately to rise up, and turn round his neck and walk, and look upwards to the light,

and doing all this still feel pained, and be disabled by the dazzling form seeing those things of which he formerly saw the shadows. What would he say if anyone were to tell him that he formerly saw mere empty visions, but now saw more correctly, as being nearer to the real thing, and turned toward what was more real. Then, what if you specially pointing out to him, and made him tell you the nature of what he saw. Do you think that he would be embarrassed? Do you think that he would think now that what he saw before was truer than what he sees now?

Even if a person could force him to look at the light itself, would he not have pain in his eyes and look away? And then, would not he turn to what he really could see [without pain] and think that these are really more clear than what had just been shown to him? But if a person was then to forcibly drag him out of the cave without stopping, until he was in the light of the sun, would he not be pained and indignant? Would not he, while in this light

and having his eyes dazzled with the splendor, be able to see anything that he thought was true? No, he could not, at that moment. He would need to get some degree of practice if he would see things above him. First, he would most easily perceive the shadows, and then the images of men and other animals in the water, and after that the things themselves. And then he would more easily see the things in heaven, and heaven itself, by night, looking to the light of the stars and the moon, than after daylight to the sun and the light of the sun. How else? Finally, he might be able to perceive and contemplate the nature of the sun, not as respects its images in water or any other place, but itself by itself in its own proper place.

Rome

~ Horace: *The Secular Hymn* (ca. 17 B.C.E.) ~

Phoebus! and Dian, you whose sway,
Mountains and woods obey!
Twin glories of the skies, forever worshiped, hear!
Accept our prayer this sacred year
When, as the Sibyl's voice ordained
For ages yet to come,
Pure maids and youths unstained
Invoke the Gods who love the sevenfold hills of Rome.

All bounteous Sun!
Forever changing, and forever one!
Who in your lustrous car bear'st forth light,
And hid'st it, setting, in the arms of Night,
Look down on worlds outspread, yet nothing see
Greater than Rome, and Rome's high sovereignty.
You Ilithyia, too, whatever name,
Goddess, you do approve,
Lucina, Genitalis, still the same
Aid destined mothers with a mother's love;
Prosper the Senate's wise decree,
Fertile of marriage faith and countless progeny!
As centuries progressive wing their flight
For you the grateful hymn shall ever sound;
Thrice by day, and thrice by night
For you the choral dance shall beat the ground.

Fates! whose unfailing word
Spoken from lips Sibylline shall abide,
Ordained, preserved and sanctified
By Destiny's eternal law, accord
To Rome new blessings that shall last
In chain unbroken from the Past.
Mother of fruits and flocks, prolific Earth!
Bind wreaths of spiked corn round Ceres's hair:
And may soft showers and Jove's benignant air
Nurture each infant birth!

Lay down your arrows, God of day!
Smile on your youths elect who singing pray.
You, Crescent Queen, bow down your star-crowned head
And on your youthful choir a kindly influence shed.
If Rome be all your work—if Troy's sad band
Safe sped by you attained the Etruscan strand,
A chosen remnant, vowed
To seek new Lares, and a changed abode—
Remnant for whom thro Ilion's blazing gate
Aeneas, orphan of a ruined State,
Opened a pathway wide and free
To happier homes and liberty:—
Ye Gods! If Rome be yours, to placid Age
Give timely rest: to docile Youth

(continued)

(continues)

Grant the rich heritage
Of morals, modesty, and truth.
On Rome herself bestow a teaming race
Wealth, Empire, Faith, and all befitting Grace.

Vouchsafe to Venus' and Anchises' heir,
Who offers at your shrine
Due sacrifice of milk-white kine,
Justly to rule, to pity and to dare,
To crush insulting hosts, the prostrate foe
man spare

The haughty Mede has learned to fear
The Alban axe, the Latian spear,
And Scythians, suppliant now, await
The conqueror's doom, their coming fate.

Honor and Peace, and Pristine Shame,
And Virtue's oft dishonored name,
Have dared, long exiled, to return,
And with them Plenty lifts her golden horn.

Augur Apollo! Bearer of the bow!
Warrior and prophet! Loved one of the Nine!
Healer in sickness! Comforter in woe!
If still the templed crags of Palatine
And Latium's fruitful plains to you are dear,
Perpetuate for cycles yet to come,
Mightier in each advancing year,
The ever growing might and majesty of Rome.
You, too, Diana, from your Aventine,
And Algidus' deep woods, look down and hear
The voice of those who guard the books Divine,
And to your youthful choir incline a loving ear.

Return we home! We know that Jove
And all the Gods our song approve
To Phoebus and Diana given;
The virgin hymn is heard in Heaven.

Rome

~ Virgil: Excerpt from the Aeneid (30–19 B.C.E.) ~

BOOK 6

[Anchises, in the realms of the dead, is reciting to his son, Aeneas, the future glories of the Roman race.]

Lo! Caesar and all the Julian
Line, predestined to rise to the infinite spaces of heaven.
This, yea, this is the man, so often foretold you in
promise,
Caesar Augustus, descended from God, who again shall
a golden
Age in Latium found, in fields once governed by Saturn
Further than India's hordes, or the Garymantian peoples
He shall extend his reign; there's a land beyond all of
our planets

Yond the far track of the year and the sun, where
sky-bearing Atlas
Turns on his shoulders the firmament studded with
bright constellations;
Yea, even now, at his coming, foreshadowed by omens
from heaven,
Shudder the Caspian realms, and the barbarous
Scythian kingdoms,
While the disquieted harbors of Nile are affrighted!

[Anchises now points out the long line of worthies and conquerors who are to precede Augustus, and adds these lines.]

Others better may fashion the breathing bronze with
more delicate fingers;
Doubtless they also will summon more lifelike features
from marble:
They shall more cunningly plead at the bar; and the
mazes of heaven
Draw to the scale and determine the march of the swift
constellations.

*Yours be the care, O Rome, to subdue the whole world
for your empire!
These be the arts for you—the order of peace to establish,
Them that are vanquished to spare, and them that are
haughty to humble!*

From: William Stearns Davis, ed., *Readings in Ancient History: Illustrative Extracts from the Sources*, Vol. 2, *Rome and the West* (Boston: Allyn and Bacon, 1912–1913), pp. 174–179.

► metallurgy

INTRODUCTION

Historians identify major periods in ancient history by the primary materials people used to make tools. Thus, the Stone Age, the longest period identified this way, extended back some two million years ago. It ended at various times throughout the world, perhaps about 6000 B.C.E. in the Near East and Asia, 4000 B.C.E. in Europe, and 2500 B.C.E. in the Americas. What brought the Stone Age to an end was the widespread adoption of metal rather than stone for making tools and weapons. The first “metal age” was the Copper Age, when tools made of copper began to be used along with those made of stone. While copper was malleable and easy to work and copper tools did not easily break, its usefulness was limited because it was not very hard.

A major advance in human civilization was the development of bronze, an alloy of copper and tin. The combination produced a much harder metal, allowing people to forge tools that were more durable and could do more work. So important was this development that historians refer to the period running from about the fourth or third millennium B.C.E. to roughly 1200 B.C.E. as the Bronze Age. These dates, though, are very approximate and differed widely depending on the region of the world. Bronze did not even reach the Americas, for example, until roughly 900 B.C.E. For this reason, historians often specify a region of the world in referring to the Bronze Age, such as the Nordic Bronze Age or the Central European Bronze Age.

The Bronze Age came to an end with the emergence of iron as the favored metal, primarily because iron ore was more plentiful and iron was cheaper to mine and refine. Accordingly, historians refer to the Iron Age, which followed on the heels of the Bronze Age cultures that preceded it and lasted through the remainder of ancient times. A further refinement of iron was the development of steel, which hardened iron and enabled metalsmiths to make highly durable tools. It is believed that the ancient Africans were the first to form hard carbon steel in the world’s first blast furnaces, which could reach extremely high temperatures.

The discovery of these metals required ancient peoples to develop the science of metallurgy, referring to technologies for extracting metals from ores, purifying them, combining them with other metals to form alloys, and fashioning them into useful objects. To create metal objects, the ancients learned many forms of casting, or the process of pouring molten metal into molds, where it would cool and harden. The mold was removed, often by breaking it, leaving behind the metal object.

Another way of working metal, especially soft metal, was hammering it into shape; annealing was a process to reduce of the brittleness of hammered metal by heating it. Soft metals such as gold and silver were easily worked into primarily decorative objects such as jewelry; they could also be used to decorate objects made of iron and other materials, enhancing their value and aesthetic appeal. Some historians have theorized that ancient cultures discovered primitive batteries that used electric current to deposit thin layers of metals on the surface of other metals in a process called electroplating.

AFRICA

BY KIRK H. BEETZ

Almost guaranteed to set a gathering of African archaeologists to arguing is the subject of metallurgy. Where it started, how it developed, and how it spread has been disputed in many publications. It is possible that the first metal Africans worked was gold, because it often appears as nuggets that can be hammered into shapes. Other metals available to Africans were copper, tin, and iron. Ancient Africans may have found silver, too, but the archaeological evidence suggests that silver was imported from the Mediterranean world, perhaps from the Iberian Peninsula, the land where Portugal and Spain are today.

Most archaeologists and historians agree that the smelting of metals in Africa probably began in Egypt. The technology for making bronze out of copper and tin probably was imported from the Near East into Egypt. When Egypt solidified its control of Nubia, the land south of Egypt, during the reign of Pepy II (r. ca. 2246–ca. 2152 B.C.E.), Africans outside Egypt were still in the Stone Age. It is likely that the Egyptians introduced the copper to the Nubians; the Nubians used copper to make spearheads that looked like long leaves, though most of their spears were still tipped with stone. Nubian copper tools from that era were either imports from Egypt or copies of Egyptian tools.

Nubia was rich in gold, and over the years Nubia's gold mines yielded about 65 pounds of pure gold from about 9,000 tons of ore annually. This gold went to enrich Egypt, helping to make Egypt one of the wealthiest nations of the ancient world. Elsewhere in Africa gold was being made into jewelry. Whether techniques for smelting gold ore were passed from Egypt to Nubians and then to the rest of Africa or Africans figured out these techniques for themselves is unclear. That Africans loved the decorative possibilities of gold is plain. In central and western Africa people learned to sift gold nuggets out of streambeds and even how to mine gold dust from quartz.

In the 1600s B.C.E. the kingdom of Karmah stretched its domain northward over lands to the south of Egypt nearly to the first cataract of the Nile River. The Karmah culture was still in the Stone Age and did metalworking. Between 1504 and 1492 B.C.E. Egypt conquered Karmah and swept south to take control of Nubia. Until Egypt's withdrawal in 1070 B.C.E., Egyptian technology passed to other Africans through Nubia. By that time the secrets of making bronze were known to the peoples of northeastern Africa, but they still worked primarily in copper, perhaps because tin was hard to find locally and had to be imported from the north or from western Africa, where there were tin mines.

The kingdom of Kush arose around 900 B.C.E., encompassing most of the Blue Nile and White Nile rivers. During several military campaigns from about 728 to 702 B.C.E. Kush conquered Egypt. Although ironworking was established in the Near East in the early 1000s B.C.E., Egyptian armies still used bronze weapons, and Kushites used mostly stone weap-

ons. The use of iron for tools and weapons came crashing in on the Kushites in about 671 B.C.E. when Assyria invaded Egypt. Although bronze held its edge better than iron, iron was easier to manufacture in large quantities and had special qualities for armor, including its ability to be case-hardened. The ancient smiths would either pour liquid iron into molds or hammer it into shape by repeatedly heating it until it was soft, beating it, heating it again, and so on. In a bed of carbon, possibly charcoal but more often the ashes of husks of grain, the hot iron would be set to rest. This might be done several times, during which the iron would absorb the carbon and harden on the outside while remaining soft and flexible on the inside. This meant that when it was struck, iron armor flexed rather than broke. Superior tactics and superior armor were the advantages of the Assyrians.

In 593 B.C.E. Kush moved its capital from Napata to Meroë, where iron from mines was plentiful. There, a large iron-making industry developed. Kushite ironworkers built furnaces out of clay. Into these furnaces were inserted clay tubes. Bellows, probably made of animal skins, were attached to the outside of the tubes. When the bellows were pumped, outside air flowed into and through the furnaces, creating the effect of a blast furnace. The superheating caused by the blasts of air allowed the smiths to reach the 2,797 degrees Fahrenheit required to make iron liquid and pourable. The smiths could therefore make almost anything they wished out of iron, and although bronze remained the preference for decoration, iron vaulted Kush out of the Stone Age. Numerous large slag heaps still exist in Meroë.

The long-standing African custom of remelting metal objects, especially gold, to be remade into whatever was currently fashionable has made it hard to trace how metallurgy spread. Sometime between 700 and 500 B.C.E. a major metalworking culture emerged in a valley along the Niger River in western Africa, almost due west of Kush. It is called Nok after the village near the tin mine where the first remnants of the culture were found in 1928. Its exceptionally well-sculpted ceramic figures have caught the imaginations of archaeologists, but little is known about the Nok. One of the greatest puzzles they present is that they were working metals when Kushites were doing so, and they may have begun smelting iron before the Kush.

Archaeologists and historians have proposed various ways this could have happened. One is that traders brought the knowledge with them from the Phoenicians or the Greeks who traded with the Nok. Another is that people fled west from Kush when nomads invaded their kingdom. They would have fled along the Sahel corridor, grassy steppes that stretch west to east along the southern edge of the Sahara. Another possibility is that the knowledge flowed from tribe to tribe along the Sahel corridor. Yet another possibility is that the Nok learned to make bronze and smelt iron on their own. In any case, as early as 500 B.C.E. the Nok were using blast furnaces of clay with ceramic tubes that may have functioned like the Kushite blast furnaces.

During the first 500 years C.E. the knowledge of how to mine, smelt, and work iron may have been spread by the Bantu-speaking peoples of Africa during their great migrations across central Africa. Among them, certain crafts became the specialties of certain clans. An entire village might have been devoted to the manufacture of iron products. People probably processed iron mostly outdoors, but they probably turned iron into tools or other items indoors in huts similar to ones used for homes. Typically, men smithed the iron, but it seems women were more likely to trade iron products to other people. Much of the spread of ironworking to the south of Africa seems traceable to the movements of the Bantu-speaking peoples.

EGYPT

BY MARIE PASSANANTE

Metallurgy is the science that deals with the procedures used in extracting metals from their ores, purifying and alloying metals, and creating useful objects from metals. These procedures include smelting, casting, and annealing. Smelting is the melting of ore to extract metal from it. Unfortunately, there are no references to smelting in Egyptian texts. All the information we have is from archaeological evidence as well as from experimentation based on recovered artifacts.

Smelting, a relatively simple process, had been developed by the Early Dynastic Period (2920–2575 B.C.E.), and it is possible that the process was used as early as 4000 B.C.E. During smelting, crushed ore is mixed with charcoal. This mixture, called the charge, is then placed in a crucible or mud brick-lined furnace and roasted.

This procedure reduces the metal to prills—small pellets—embedded in slag, or waste material. The prills are extracted by crushing the slag and then melted together to form ingots. A simple smelting furnace would consist of a hole in the ground rimmed with a wall of mud bricks. Holes in the wall would accommodate tuyeres, or nozzles through which air is delivered into the furnace. Blowpipes or bellows would introduce air into the tuyeres. Blowpipes are represented in tomb reliefs as early as the Fifth Dynasty (2465–2323 B.C.E.). Pot bellows were probably in use as early as the Middle Kingdom (2040–1640 B.C.E.), but there is no direct evidence of their use before the Eighteenth Dynasty (1550–1307 B.C.E.). Pot bellows consist of a pottery nozzle, a piece of leather covering the wide end. The leather would be squeezed either by hand or by foot, driving air into the connecting tuyere.

Casting is the process by which an object is created by pouring molten metal into a mold. Cast objects have been dated as early as the Predynastic Period (4000–3000 B.C.E.). The process is depicted in the reliefs in the tomb of the Eighteenth Dynasty vizier Rekhmire (ca. 1450 B.C.E.). In these reliefs metalworkers are creating a pair of bronze doors for the shrine of Amun in Karnak. The molten bronze is contained in a crucible (a vessel used to melt or heat metal), which is handled by two men using wooden sticks as tongs. The men

pour the liquid bronze into series of funnels inserted into the mold; the multiple funnels ensure the even distribution of metal. The crucible containing the metal is bowl shaped and has a hole in the side for pouring. A mold could be carved in stone, shaped in pottery, or even formed in sand.

The lost-wax method of casting allowed the craftsman to fashion an object with greater detail, and for this reason it was a favored method for creating figurines and amulets. First the craftsman sculpted in wax a model of the desired object. He then covered the wax model in clay and fired the result. The heat hardened the clay to create the mold and melt the wax, leaving a space into which the molten metal would be poured. After the metal had cooled, the mold was broken to extract the casting. Alternatively, the craftsman could use a modified version of the lost-wax method called hollow casting. Instead of modeling a figure wholly out of wax, he would model the wax around a clay core. This model would be covered in clay and fired just as in the lost-wax method. The core would be held in place by iron struts, which were in use by the Third Intermediate Period (1070–712 B.C.E.), or possibly by pure copper struts. Hollow casting was favored in the production of larger objects because less metal was used and because the process reduced potential shrinkage and distortion in the mold.

In annealing, a piece of worked metal is heated to reduce the hardness and brittleness that result from hammering. The heat rearranges the internal structure of the metal, making it easier to shape. The earliest object showing evidence of annealing is a copper ax head from the Naqada II Period (3500–3000 B.C.E.). There are few textual references to annealing. The captions in the metalworking scenes in two Fifth Dynasty tombs mention heating sheet metal after hammering it. In the tomb of Wepemnofret, the caption states that the reason for heating the metal is to reduce chance of cracking and imperfections, the very definition of annealing.

Copper was made into a wide range of objects, from tools and weapons to statues, both as pure copper and in alloys with arsenic, tin (bronze), and lead. The earliest examples of cast copper date from the Naqada Period (3300–3000 B.C.E.), and lost-wax casting was in use by the Old Kingdom (2575–2134 B.C.E.). Copper statuary is rare before the Middle Kingdom, and production peaks only in the Third Intermediate Period.

Gold is perhaps the easiest metal to work, and it did not need to be smelted. Gold was extracted from the earth by placing gold-bearing sand or crushed rock in a vessel with water and agitating the mixture to separate the particles; gold is heavier and sinks to the bottom, while the sand and crushed rock are discarded with the water. Gold was not refined further until the Late Period (712–332 B.C.E.), despite having been in use since the Predynastic Period. Gold was worked both by casting and by cutting and shaping sheet gold (gold hammered into a thin sheet). However, because casting wasted metal, objects made from sheet gold outnumbered cast objects; most jewelry and amulets were made from sheet gold, and objects that were cast often had components made from sheet gold.

Despite the availability of iron ore, iron objects were extremely rare, mainly because the refining processes are very complex. Iron has to be worked hot, a practice for which the Egyptian handheld hammers were not suitable; hafted hammers were not introduced until the Late Period. Therefore, the few advantages of wrought iron over copper alloys did not compensate for the cost of production.

Most native silver occurred in the form of a natural alloy with gold, and true silver objects are rare before the New Kingdom (1550–1070 B.C.E.), when expanding contact with the silver-producing nations of the Near East increased the availability of silver. Silver objects were fashioned both by hammering and by casting.

THE MIDDLE EAST

BY LYN GREEN

The Near East, especially Mesopotamia, contains some of the oldest examples of metalworking in the world. From 6000 B.C.E. the peoples of the ancient Near East began exploiting a number of different metals: copper, tin, gold, silver, iron, lead, arsenic (in alloys), and to a limited extent antimony. They also used naturally occurring or artificial alloys, such as electrum and copper. Electrum is a mixture of gold and silver that often occurs in nature. Since gold alloyed with silver is much harder than pure gold, ancient metalsmiths often would not have bothered to try to refine the gold further. Silver occurs in almost all gold and also may be found in association with lead. Copper was also found with other metals, including arsenic, creating a sort of natural bronze. The term *bronze*, however, should be applied only to an alloy of copper and tin. Most of the techniques used in metalworking were standard throughout the Near East, though certain regions had advantages in terms not only of the minerals available but also of other substances useful in refining and working metals.

Although no metals can be mined in southern Iraq, where Sumer was located, the Sumerian and Akkadian languages of that area have names for numerous types of metals and metalworking techniques, and many finely worked metal artifacts have been uncovered there. One explanation for these developments may be the presence of petroleum products, such as asphalts, which could have been used in furnaces to produce temperatures high enough to melt many metals. The Dead Sea also produced bitumen. In Roman times the Nabataeans controlled this trade, though bitumen was usually used in industries other than metalworking. Other civilizations were not so fortunate, however.

One of the major difficulties for ancient metalworkers was the purification of the ore. Recent excavations and experiments have clarified how this might have been done. The first stage was smelting. Researchers who studied the production of tin at the 4,500-year-old mine of Goltepe in Turkey concluded that ancient workers first ground the ore into powder with stone grindstones. Then they put the powder between

layers of charcoal in a shallow container and fired it to about 1750 degrees Fahrenheit (much lower than the temperature of over 2370 degrees Fahrenheit used in tin smelting today) so that the tin would crystallize in the melted charcoal. This procedure was repeated a number of times—perhaps with the addition of arsenic—until the tin was separated from the glassy melt.

Impurities in a metal were not always a drawback, however. Arsenic present in copper meant a harder metal, as did silver in gold. In addition, the mixture of metals in an alloy resulted in a much lower melting point than that of a pure metal, in turn making the metals easier to work. Some scholars have suggested that bronze was discovered when ancient miners and metalworkers exhausted the surface deposits of copper, which were comparatively pure, and had to go underground for ores. These underground ores were much more likely to contain a variety of other substances, especially sulfides, that would have changed the properties of the copper in different ways and inspired smiths to try different combinations of ores to get a desired result.

One of the best examples of a coppersmith's workshop dating to the Bronze Age was excavated in Iran at Tepe Ghabristan. The workshop, which seems to have been active

Copper vessel with silver wire, from Ur, southern Iraq (ca. 2600–2400 B.C.E.) (© The Trustees of the British Museum)

about 4500 B.C.E., was full of molds, crucibles, and a tuyere (a pipe or nozzle to force air into a forge or furnace) as well as many chunks of copper ore. In the ancient Near East the primary method of shaping all metals, including gold and silver, was through annealing (in the case of copper, gold, bronze, and silver) or forging (in the case of iron). Gold, silver, and bronze were also hammered into sheets, which could then be decorated with incised or raised relief. Cast iron was not made, though objects of gold, silver, copper, and bronze were occasionally made by the “lost wax” method from about 3000 B.C.E.

The earliest copper objects appeared in the Near East about 4000 B.C.E., and bronze was being worked about 500 years after that, but it was not until more than 2,000 years later that iron mining and ironworking spread throughout the Near East. There were a number of reasons for the slow development of iron metallurgy, but the most important was the difficulty of working the ore and of building furnaces (as opposed to forges) capable of the high temperatures needed to melt iron. Because ancient smiths were working with ore or iron that contained appreciable amounts of impurities, the furnaces did not need to reach 2800 degrees Fahrenheit (the melting point of pure iron), but they had to be significantly hotter than those used to work the metals in use in the Bronze Age. Such furnaces needed to allow air to circulate, to have the quantity and types of fuel necessary to create high temperatures, and to be tall so that the melted iron could drop.

When copper is smelted, the metal and the impurities become liquid and drop to the bottom of the furnace, where the impurities float on top of the pure copper. Iron ore, on the other hand, would remain more or less unmelted at the highest temperatures an ancient furnace could reach. Some of the other elements (impurities) would melt but would be caught in the spongy-textured iron. Smiths could reheat the spongy blob and hammer it until the impurities squirted out, but this process had to be repeated many times before a relatively pure metal was achieved—and that metal was actually more difficult to work. However, if small amounts of carbon were deliberately added to the iron, the result was a harder metal, something discovered by ancient Near Eastern smiths.

Another reason for the slow spread of iron metallurgy was that certain cultures or groups of people seem to have kept the techniques of ironworking a craft secret. For example, in the book of Samuel, it is mentioned that the Israelites had to take their iron tools and weapons to the Philistines for repair. The reasons for such reluctance to share knowledge are obvious. Not only did those who possessed the skills have a monopoly on the market for them, but there also were distinct military and economic advantages in having iron, rather than bronze, weapons and tools. However, smiths of all kinds were respected as skilled artisans, and their services were keenly sought after, no matter whether they worked in common metal, such as iron, or luxury metal, such as gold.

ASIA AND THE PACIFIC

BY JIANJUN MEI

Metallurgy is absent from the Pacific islands in ancient times, owing to a lack of mineral deposits in the region. The first sign of the emergence of metallurgy in southern Asia is the finding of copper beads from graves dated to the fifth millennium B.C.E. at Mehrgarh, in southern Baluchistan. Evidence from the site of Nal in Baluchistan shows the use of lead and silver as early as the fourth millennium B.C.E. Gold came into use in Punjab (modern-day India and Pakistan) slightly later. Arsenical copper was known in the Indus civilization of the third millennium B.C.E. and became prevalent among the “copper hoards” of the Ganges valley, some of which date from the second millennium B.C.E. The examination of early metals from Mohenjo Daro (Pakistan) demonstrates that tin bronze was in use from the late third millennium B.C.E. Iron first appeared in southern Asia in the second half of the second millennium B.C.E. and became more common from the beginning of the first millennium B.C.E.

Metallurgy emerged in eastern Asia and Southeast Asia later than in Mesopotamia and the Near East. The earliest metal object found in eastern Asia is a piece of copper from Banpo in Xi’an (Shaanxi Province) China, which is dated to the fourth millennium B.C.E. This piece of copper has a high zinc content and could be described as being made of brass. Such a compositional feature is distinctly different from the earliest metals known in Mesopotamia and the Near East, which were without exception made of pure copper. Curiously, two other brass objects dating to the fourth to the third millennium B.C.E. were found separately in Shaanxi and Shandong provinces.

The early third millennium B.C.E. witnessed the beginnings of the use of tin bronze in China. A bronze knife from Linjia, Dongxiang (Gansu Province) dating to about 2800 B.C.E. is the earliest bronze object known so far, not just in China but also in eastern Asia. The knife was made of bronze with 6 to 10 percent tin and cast in an open mold. Increasing metallurgical activities came into sight across northwestern and northern China from the middle of the third millennium B.C.E., as demonstrated by archaeological finds such as metals, fragments of crucible (a vessel used to heat and melt), slag, and casting molds from various sites. These finds are mostly ascribed to the Neolithic cultures of Machang, Longshan, Shijiahe, and Hongshan and date to about 2500–2000 B.C.E.

During the first half of the second millennium B.C.E. northwestern China and the central plains of China were the two major areas where remarkable innovations in metallurgy took place. In northwestern China (mainly the Gansu, Qinghai, and Xinjiang regions), new metals such as gold, silver, and arsenical copper appeared and a new range of objects such as socketed axes, spearheads, mirrors, and earrings came into use. In the central plains of China, piece-mold casting emerged and developed into a unique Chinese metallurgical technology. Thousands of magnificent bronze

ritual vessels were then cast by using piece-mold technology during the following Shang and Zhou dynasties (ca. 1500–256 B.C.E.). These vessels were mainly used to hold food and drink in ancestral rites, the way that the Shang kings or elite communicated with their ancestors. The production of bronze ritual objects reached a scale that was unparalleled anywhere else in the world at the time.

Outstanding new developments in bronze metallurgy can be seen in the growth of several regional bronze-working traditions in the border areas of the Shang cultural sphere during the late second millennium B.C.E. Among these regional traditions, the bronzes found at Sanxingdui, Sichuan, Southwest China are most spectacular. With an astonishing emphasis on the human form and adoration for gold, the Sanxingdui tradition shows unique and mysterious characters, which have attracted considerable research interest worldwide. To the north of the Shang cultural sphere stretched the so-called Northern Bronze Complex, which is well known for its weapons and implements decorated in animal style. These bronzes had a close connection with bronze working in the Eurasian steppes or were even imported from the steppes. They played an important role in bridging the transmission of metallurgical technologies between the central plains of China and Eurasia. To the south of the Shang cultural sphere, along the Yangtze River valley, developed a regional tradition of bronze production that may be called “southern.” The southern tradition is characterized by a prominent stress on musical instruments (bells) and vessels in the designs of animal shape. While strong connections with the Shang bronze technology can be observed, the southern tradition preserves a great variety of local tastes and preferences in bronze design and production.

The emergence and development of ironworking was the major technological advance in eastern Asia during the first millennium B.C.E. Although archaeological evidence for the use of meteoritic iron in China can be traced back to the late Shang Dynasty, from about the 13th century B.C.E., it was not until the eighth century B.C.E. that iron made from the ore came into use in the central plains of China. More than a dozen knives or swords made from the smelted iron have been excavated at various sites in Henan, Shanxi, Shaanxi, and Gansu, all dating to the eighth to sixth centuries B.C.E. Some are swords made with two kinds of metals, for example, an iron blade with a gold handle. This may indicate the rarity and high value of iron at the very early stage when it came to be used. Of great importance is the invention of cast iron, which actually defined the track of the development of Chinese iron metallurgy in the following two millennia. To use cast iron on a large scale changed the Chinese society profoundly with the introduction of iron tools in agriculture.

Under the cultural influence of China and the Eurasian steppes, Korea entered the Bronze Age in the beginning of the first millennium B.C.E. Bronze metallurgy appeared in Japan even later, in the Yoyoi Period, probably around the fifth century B.C.E. Iron technology diffused from China into Korea and Japan during the third century B.C.E.

The beginning of bronze metallurgy in Southeast Asia was a hotly debated topic in the 1980s. Some scholars believed that metallurgy began there as early as the early third millennium B.C.E. In other words, Southeast Asia could be an independent center for the beginnings of bronze metallurgy. However, an increasing number of scholars take a conservative view on the dating of early bronzes found in Thailand and Vietnam. The earliest bronzes have been redated to about 1700 B.C.E., making it possible for some scholars to suggest the possible influence from China or India in the emergence of metallurgy in Southeast Asia. Bronze metallurgy in Southeast Asia is widely known now for its small-scale production, which was most likely organized at the village level.

EUROPE

BY KIRK H. BEETZ

Metallurgy is the art of working metals. Metal is first smelted from its ore (though some metals can also be found in a pure form) and then is worked through hammering, casting, alloying, forging, annealing, riveting, and welding to produce finished products. Metalsmiths in the ancient world developed innovative ways to decorate metal products to create objects that even today are astonishing in their beauty.

The first evidence for metallurgy in Europe dates from before 5000 B.C.E. in southeastern Europe, where copper was smelted from ores such as malachite. Copper is a soft metal by itself and must be alloyed, or combined with other metals, to be hardened. The earliest copper was used for relatively simple ornaments such as beads, pendants, and bracelets, but around 4000 B.C.E. it became possible to cast it into tools such as axes. Ötzi, the famous naturally preserved human found in an Alpine glacier, was carrying an ax made from pure copper when he died around 3300 B.C.E. Copper metallurgy spread to other parts of Europe, reaching the Iberian Peninsula around 3000 B.C.E. and the British Isles late in the third millennium B.C.E.

In the Near East arsenic sometimes occurs naturally with copper ore, which may be how ancient smiths learned that copper hardens and holds its edge better when mixed with arsenic. In central Europe the copper occasionally occurs naturally with tin, which may have been how early smiths learned that mixing tin with copper created true bronze, a very durable and tough alloy that holds its edge better than copper or tin alone. The possibility that Europeans may have discovered true bronze on their own has led some archaeologists to speculate that true bronze making occurred in eastern Europe before it occurred in the Near East. In southeastern and central Europe the period known as the Bronze Age began around 2500 B.C.E., and in northern and western Europe it began around 2000 B.C.E.

The ancient smiths had two principal problems to overcome in making true bronze. One was that tin was scarce. In ancient Europe the best sources were in Iberia and Cornwall (southwestern England), far from the best sources of copper

Gold cup of the Bronze Age (ca. 1700–1500 B.C.E.), beaten out of a single lump of gold and found in Rillaton, Cornwall, England (© The Trustees of the British Museum)

in eastern Europe. Another was that mixing the proportions of tin to copper was tricky. The ancient smiths did not have modern scientific techniques for measuring and mixing copper and tin in the best proportions and therefore had to use their firsthand experiences working with the metals to decide what proportions to use. In general, they created a bronze alloy of 90 percent copper and 10 percent tin. At first they mixed copper ores with tin ores and melted the two together. This left impurities in the final product in the form of minerals that had been present in the ores. Around 1500 B.C.E. the smiths began smelting the ores separately and then blending the melted tin and melted copper.

People used molds to make bronze objects. Numerous molds for axes of various sizes and shapes have been found in eastern Europe. The molds usually included dowels that resulted in holes in the finished product for sliding it onto a wooden handle. Between 2000 and 1800 B.C.E. ancient Europeans began making rivets, nails, and pins of gold, copper, or bronze. Rivets could be used to screw an ax blade into place, and pins were used to fix clothing in place and became status symbols.

During the Bronze Age the working of gold also came into prominence in the parts of Europe where it was available. Gold was generally obtained from placer deposits in streams and hammered into sheets, which were then hammered into ornaments and vessels. Some of the most remarkable gold objects were made in Ireland between 1500 and 500 B.C.E.,

including bracelets, arm rings, and especially collars of sheet gold called *lunulae*. Some of these gold objects are decorated with repoussé, in which a design is made by embossing the back of the metal sheet with a hammer or a punch.

In about 1200 B.C.E. iron smelting came to Europe from the Near East. Iron ore was more common than tin, but it posed special problems for the ancient smiths. Iron requires 2,797 degrees Fahrenheit to melt enough to be poured, whereas copper requires only 1,981 degrees Fahrenheit to liquefy. A furnace hot enough to melt iron appeared first in eastern Europe and then in southern Europe. This began what is often called the Iron Age. By about 600 B.C.E. the use of iron had spread throughout Europe, though bronze continued to be used in great quantities, especially for luxury goods.

Ancient smiths usually had great lumps of iron of 55 pounds or so after smelting. These iron lumps were almost inevitably mixed with charcoal, which may be how the smiths learned that mixing carbon with iron could alter the metal's properties. If the proportion of carbon to iron is not exactly right, the resulting product can be too brittle or too soft. This meant that iron tools and weapons were rarely as good as bronze ones. Once the problem of smelting temperature was solved, however, it was easier to manufacture iron objects in larger quantities than bronze ones, because iron ore was more common than copper or tin ore and it did not require the careful mixing of two metals to create an alloy.

Iron was thus very cheap. European agriculture was revolutionized when molten iron was poured into molds for blades that could be fitted on plows in the first century B.C.E., allowing farmers to break deeper into tougher soils than before. The boom in agriculture from this resulted in a population boom that created the mass movements of people that shaped much of European history during the first millennium C.E.

A problem found in a metal object that has been cast in a mold, and especially in iron castings, is a brittleness caused by the uneven alignment of metal molecules. This meant that tools and weapons that looked fine would sometimes break prematurely. A solution to this problem, discovered in the Near East, was annealing—repeated heating and cooling of metal, which results in the alignment of molecules, making a metal object tougher. The smiths in Europe combined annealing with another method they already used: the pounding of metal to create sheets. Copper and gold lent themselves easily to this method, and beaten sheets of those metals were used to cover wooden sculptures or to make masks. Soon after 1000 B.C.E. people in central Europe were pounding sheets of bronze into new shapes, most notably for helmets and other armor. This involved hammering a lump or a casting of metal until it had a desired shape. Annealing allowed the smith to soften hard metal such as bronze or iron so it could be repeatedly beaten and shaped. The results were sharp edges that could be resharpened without breaking as well as workaday objects, such as bits for harnesses and hammers for construction work, that could endure frequent use without breaking.

For warriors, this meant not only durable armor but weapons that were less likely to break under stress.

GREECE

BY JOHN W. HUMPHREY

As early as the second half of the Neolithic Age (ca. 5000–ca. 3000 B.C.E.), people began to work soft native metals such as copper and gold, which they could form into shapes by hammering with traditional stone tools; hence this period is called the Chalcolithic, or Copper Age. But the shapes of these items were so limited and the malleability of the native metals so high that they could not be used as functioning tools or weapons. The discovery of primitive casting techniques produced more functional shapes, but the off-gassing of molten copper restricted the casting to open, one-piece molds of sandstone or clay, so this technique left one flat surface on the tool and used much precious metal.

By the Bronze Age (ca. 2800–700 B.C.E.) kilns designed originally for firing ceramics produced temperatures high enough (about 2000 degrees Fahrenheit) to smelt copper from its carbonate and oxide ores. It seems likely that copper-based pigments used to decorate ceramics were accidentally smelted in pottery kilns, leaving behind beads of pure copper. This copper was then combined with arsenic or tin to produce bronze, a metal superior to copper because of its lower melting point, ease of casting, and hardness. The invention of two-piece molds then allowed symmetrical tools to be cast, and it saved metal because a removable core could be inserted into the mold to create a hollow object. Such metal tools had several advantages over those of stone: They were thinner, sharper, and more durable; they allowed a greater variety of forms; and they could be reworked when dull or broken.

The processing of ore to extract the desired metal generally followed a common procedure, though some stages were omitted for certain metals. What follows is applicable to ores of copper, tin, and lead/silver, but not gold (which was always available naturally in its pure form) or iron.

Because most ores contain sulfur or oxygen, the first requirement is to separate these from the desired metal. This was done in a simple roasting oven, in which the ore was layered with the fuel (usually charcoal), covered with a temporary shell, and burned in a reducing atmosphere; the carbon combined with the sulfur or oxygen and gassed off, leaving the desired metal behind, though still combined with impurities.

The ore was then broken up by crushing it either in mortars with an iron pestle or in mills that resembled the large “hourglass” grain mills familiar from Pompeii and Ostia. The crumbles were then either sieved or, more commonly, washed to remove the unwanted gangue (surrounding rock), which, because it was heavier than the metal, was left behind on the washing table. This process is well known from the surviving washing tables at Laurion, Greece, which ingeniously used recirculated water.

The remaining concentrated ore was then heated in a smelting furnace with sufficient temperature to produce a molten metal that separated from the unwanted slag; the two would generally be tapped off at different heights according to their specific gravities. Three elements were required for this procedure: a furnace, suitable fuel, and a supply of forced air. Open hearths were first used as furnaces, but they proved unsatisfactory because they could not sustain the necessary temperatures. However, in classical shaft furnaces, like those used for firing pottery, the charcoal and ore could be properly layered and the heat concentrated within the restricted space.

The preferred fuel was charcoal, the only material that could generate sufficient and continuous heat for smelting. Other fuels were tried—wood (before the deforestation of the Mediterranean), lignite coal, and even dried dung—but with little success. The Greeks (like their Egyptian predecessors in the Bronze Age) used bellows to provide a constant supply of forced air to maintain the necessary temperature for smelting copper, though pipettes were used for smaller quantities of precious metals. These bellows were generally fabricated from the skins of animals, with flaps of skin serving as inlet and outlet valves and terra-cotta nozzles to protect them from the heat of the fire. These bellows were often used in pairs and operated by foot to produce a constant flow of air.

Once the metal had been tapped off, it was usually allowed to cool and solidify into ingots before being remelted and cast. Only occasionally did the casting of a final product seem to have been done directly from the smelting stage. Before being worked into its desired form, silver was subject to further refining by cupellation: The smelted ore was placed in a porous clay crucible and heated; the residual lead was

Gold mask from Mycenae (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

either absorbed into the clay or transformed by a steady blast of air into lead oxide that evaporated, leaving the purest silver obtainable.

At this stage, precious metals could be tested for their purity, a necessity for the minting of coins, when the state was guaranteeing the quality of the metal. Gold was scraped over touchstones (black siliceous schists like basalt or chert), leaving behind a streak whose color was compared with those of known pure and alloyed gold. The Greek mathematician Archimedes, of the third century B.C.E., famously discovered that his body submerged in a tub displaced not its weight but its volume in water; so by first determining the volume of a complex gold wreath made for his king, then calculating the weight of that volume of pure gold, and finally comparing it to the actual weight of the wreath, he could prove that the object was too light to have been made of unadulterated gold.

The smelting of iron was a quite different procedure, since (unlike the ancient metallurgists of central and eastern Asia) the Greeks and Romans were unable to attain the melting point of iron (over 2,700 degrees Fahrenheit) and so could not produce the pure metal in liquid form. But at the manageable temperature of about 2,000 degrees Fahrenheit, the lighter slag could be separated from the iron and tapped off, leaving at the bottom a spongy mass called the bloom. This, in turn, was repeatedly hammered to drive off the remaining impurities and then worked into usable tools and weapons by cold-forging or, more commonly, by annealing. Alternately heating, hammering, and quenching the iron, which both hardened it and combined it with carbon from the charcoal fire, created a form of steel.

Because of iron's different treatment from other metals, the objects made from it were more limited in design than tools, weapons, and decorative objects cast in bronze. The smith was metallurgist and metalworker, responsible for both smelting and working the iron in a single continuous process. His requisite tools—tongs, hammer, and anvil—were unique to his specialization. His work required considerable upper-body strength, which almost certainly created the common image of an ironworker with weak legs, a barrel chest, and powerful arms, a caricature reflected in the almost comical description of Hephaistos, mythological god of the forge.

Casting, on the other hand, was the principal ancient technique for working bronze, gold, and silver, in the Iron Age as well as earlier. Purified metal was heated to liquid form in crucibles and poured into two-piece molds made of stone, clay, or sand. The cast object could be made hollow by inserting a removable core into the mold. The final product was smoothed, polished, and perhaps further decorated. One significant advantage of this technique was that the molds were generally reusable, so multiple copies of almost identical items could be produced with ease. As an alternative to casting, the Greeks produced sheet metal by hammering out thin plates of metal, from which they would then "raise" cups with a soft hammer of bone, working in a spiral from the center

and gradually thinning the metal by forcing it outward and upward to create the sides of a round vessel.

The ancient Greeks practiced various techniques of fine metalworking that took their creations beyond the functional to the highly decorative. Relief work included chasing (the hammering of a design from the outer surface) and its counterpart, repoussé work (hammering from the inside to create a raised design on the outside). Inlaying had been successfully practiced by their Mycenaean ancestors, who produced elegant ceremonial dagger blades decorated with delicate scenes of wild animals and hunters made of gold, electrum, and silver set in an adhesive bed of black niello (a black enamel-like alloy). Filigree and cloisonné enameling involved the use of thin wires to create settings for precious stones, and granulation was the application of tiny beads of gold to the surface of a vessel.

An advanced form of hollow casting is known as *cire-perdue*, or the "lost wax" process, which produced not just a hollow object but one with remarkably fine details cast on the surface. A rough core of destructible material was first fashioned, slightly smaller than the finished object would be, with one or two protruding "anchors" that kept the core in place when the next layer, the wax, was removed. A layer of liquid wax was applied that, when hardened, was carved to the exact design of the finished object. Over this was smeared a clay shell that was attached to the "anchors" of the core, with an unobtrusive hole giving access to the wax. Once the shell was set, the wax was melted out of the interior, leaving a thin cavity into which the molten bronze or silver was poured, taking on both the thickness and the fine external decoration of the lost wax.

When the metal cooled, the outer shell was broken (there was no reusing of these molds) and the inner core picked apart and removed using thin probes. The result was a hollow object with a detailed surface design that could be touched up using files and polishes. On a large scale this technique was used in the casting (in multiple parts) of large bronze sculptures such as the Zeus/Poseidon statue in Athens's National Archaeological Museum, the Charioteer of Delphi, and the sole surviving bronze equestrian statue from antiquity, the unparalleled Marcus Aurelius on Rome's Capitoline Hill. The achievements of the Greeks and Romans were not reproduced until the Renaissance, when the technique of *cire-perdue* casting was reinvented.

ROME

BY JOHN W. HUMPHREY

The basic facts of Greek metallurgy apply equally to the Romans, who introduced advances in only a few areas. First, they mined the deeper copper sulfides, which were more difficult to smelt than the superficial carbonates and oxides, requiring a preliminary roasting to drive off most of the sulfur and other impurities before they could be smelted; they did, however, increase dramatically the quantities of copper ore

available for working. Second, they perfected the design of shaft furnaces to allow continuous production of the metal by making it possible to add new ore and tap off slag without shutting down the furnace. And third, they developed the technique of amalgamation, by mixing in a crucible ground, unpurified gold with mercury; the two combined to form an amalgam (gold being the only metal attracted to mercury), leaving behind the impurities. The amalgam was then forced through leather to leave the gold behind or was heated to vaporize the mercury (with its lower boiling point), which was then condensed through cooling, the only known ancient application of distilling.

The Romans practiced and sometimes improved on all the Greek techniques of casting, forging, and annealing together with the more delicate metalworking techniques. Advances in enameling and the production of gold leaf were two of their principal contributions in the latter category. According to Pliny in his *Natural History*, Roman metalworkers could beat a single ounce of gold into 750 leaves of foil, each 4 inches square: a remarkable achievement, even if gold is the most malleable of metals. Enameling they appear to have borrowed from the Celts of western Europe, who as early as the fourth century B.C.E. were applying a fine powder of ground glass and metallic oxides mixed with water to the surface of small bronze objects (brooches seem to have been the most common) that were then heated until the enamel fused. Attractive, multicolored designs were achieved by placing dif-

ferent oxide mixtures into separate cells on the surface of the metal object, formed in various shapes either by cutting directly into the metal (called *champlevé*) or by applying a mesh of wires over the surface (*cloisonné*).

For the hollow casting of small metal objects, the Romans used the same *cire-perdue*, “lost-wax,” process as the Greeks. Metalworkers of both cultures were also capable of producing life-sized bronze statues using the same technique but by casting many parts individually and then fastening them together. To ensure that the constituent elements would fit properly, the artist started from a full-sized model of the entire piece in clay or plaster, from which he would take separate two-piece molds of the individual parts. These molds would then be coated on the inside with a layer of melted wax of the same thickness as the final bronze product, and an inner core of clay would be inserted. The two halves of each mold would be reassembled, the wax melted out, and the liquid bronze added. Once all the parts had been cast, they would be welded together by first heating the points of attachment almost to melting and then applying molten metal around the joint, causing the two pieces to bond. Once cooled, the welding on the surface was filed down to the level of the cast pieces, fine details chiseled out of the metal or engraved into it, patches added to camouflage the inevitable casting flaws, and the statue given its final polishing. With this technique, multiple copies could be made of the same original model.

Although there are documentary claims that the Romans were casting large bronze statuary as early as Romulus in the eighth century B.C.E., it seems more likely that it was the Etruscans who first borrowed from the Greeks the *cire-perdue* technique: one of the earliest surviving Italian examples is the famous Capitoline wolf (without the familiar suckling twins Romulus and Remus, who were added in the Renaissance), dated to around 600 B.C.E. But within a few centuries the Romans were producing bronze statues of a size and quality that matched their predecessors’ work, an achievement in the fine casting of metal that was not reproduced until the Renaissance, when the technique of *cire-perdue* casting was reinvented.

THE SURVIVAL OF BRONZE STATUARY

From classical Greece to the Roman Empire statuary of cast bronze was as popular as sculpted stone, though proportionately less survives today because the material demands of postclassical societies made bronze artistic creations vulnerable to recasting into more practical tools. Many of the few large bronze statues that grace Athens’ National Archaeological Museum or the piazza of the Capitoline Museums in Rome owe their survival to a combination of ancient accident and modern luck—the Zeus/Poseidon and Horse with Jockey now in Athens were recovered from a shipwreck off the east coast of Greece in 1928—or to misplaced reverence: in Rome the bronze Marcus Aurelius on horseback escaped medieval recasting because he was misidentified as Constantine, the first Christian emperor in the Church’s view. This is our sole surviving formal equestrian statue from the ancient world, among what must have been the thousands to which Pliny alludes when he tells us in his *Natural History* that the style was almost certainly developed by the Greeks and was very popular among the Romans.

THE AMERICAS

BY PENNY MORRILL

The history of metallurgy in the Americas is based primarily on the archaeological record. Although most sites have been looted over the centuries since the arrival of the Spaniards, several tombs have been opened and excavated in modern times to reveal magnificent works in gold. In the interpretation of these mortuary caches, it is helpful to consider the cautionary note sounded by the historians Paloma Carcedo Muro and Izumi Shimada, that these works may not have been produced exclusively for burial. They have said that gold artifacts were used in public contexts—courts and temples, for example—to propagate symbolic messages. Then, on the

death of a ruler the gold artifacts would have been gathered up and buried.

The earliest-known use of metals in the Americas was in the Central Andes in about 1500 B.C.E. Subsequently, metallurgy spread into southern Peru, Bolivia, and Chile and into the north to Ecuador and Colombia. In South America the mining and extraction of gold and the production of gold objects were closely related to geographical, social, and historical circumstances. The discovery of gold and copper sources led to local production among the people of Chavín de Huántar in northern Peru (900–200 B.C.E.). Such was also true of the peoples of Malagana (300 B.C.E.–300 C.E.), Calima (1000 B.C.E.–1600 C.E.), Tolima (200 B.C.E.–1000 C.E.), and Tumaco–La Tolita (200 B.C.E.–500 C.E.) in southwestern Colombia.

Gold was discovered in rivers and streams. These placer deposits came in the form of nuggets and flakes that were usually not pure gold but were mixed with silver and other metals. South Americans were not insistent on finding pure gold; rather, their metallurgy developed out of what metals were available to them. Fine metalwork appeared when there were agricultural surpluses and a stable social order with a powerful elite group, thus resulting in a demand for gold objects for ritual use and as emblems of status and the need for full-time artisans. Another important factor in providing the setting for the production of gold objects was a complementary ceramic technology. Technological sophistication was required to build refractory furnaces and create crucibles and molds that could withstand the heat of molten metals.

Gold was the metal most worked in South America. It is exceedingly malleable; the ancient Americans could hammer flakes, chunks, or ingots into flat sheets. Gold would not harden with cold hammering, and its ductility (capability of being easily fashioned) made it possible for smaller gold sheets to be hammered together to form a large sheet. Two final characteristics made gold highly valued: Gold has the color and reflective light of the sun, and it is resistant to corrosion.

Copper was used as an alloy with gold. Before the arrival of the Spaniards it was mined horizontally, not in vertical shafts. Veins of copper, usually on mountainsides, would have made their appearance on the surface as copper carbonates, malachite (green) or azurite (blue). The bright colors appealed to the ancient Americans, and the stones were excavated along the vein. The malachite or azurite was pulverized and mixed with granulated charcoal and placed in a crucible over fire. Using blowpipes to increase the intensity of the heat, the ancient Americans burned away the carbonates as gases and were left with the melted copper in the bottom of the crucible.

The Chavín produced gold sheets, and from these sheets they formed crowns, face masks, pectorals, and ornaments that were sewn onto clothing. The Chavín used soldering to create three-dimensional objects, an indication that they were using alloyed metals. The Chavín goldsmiths were remarkably adept at repoussé. This technique required the ap-

Hammered gold standing figure (first century B.C.E. to first century C.E.), Colombia or Ecuador (Copyright the Metropolitan Museum of Art)

plication of the design by hammering on the reverse side of the gold sheet.

From 500 B.C.E. to 500 C.E. the peoples of southwestern Colombia developed a unique gold-working tradition in a region where gold was much more plentiful than copper. Trade among the sites of the area—Malagana, Calima, Tolima, and Tumaco—led to shared metallurgical technology. Colombian goldsmiths used sheet metal to produce cutout human figures, tweezers, face masks, and hanging plaques. They covered shells and ceremonial wooden staffs with gold foil. The goldsmiths were adept at creating three-dimensional, hollow metal figures and lime flasks by soldering together pieces of gold sheets. Goldsmiths used embossing to provide these complex figures and receptacles with distinctive curvilinear and geometric surface designs. Pectorals and masks exhibit extraordinary detail in repoussage.

Unique to Malagana is the grand variety of beads produced in gold, copper and gold alloy, rock crystal, and colored stones. Beyond the simple tubes and spheres are naturalistic and abstract renditions of birds, animals, and insects. Some of the larger beads are hollow spheres with surface decoration, possibly sewn onto clothing. The goldsmith hammered two small sheets of gold over a doming block, enhanced them with embossing, and joined them without solder.

The goldsmiths of southwestern Colombia achieved a high level of excellence with lost-wax casting. They were able to take advantage of a lower melting point with the higher copper content, much better suited for casting. Artisans began by carving a rough semblance of the image in the core, made up of a mix of clay and pulverized charcoal. This core (or several cores or molds) was filled or lined with beeswax. When there were various parts in beeswax, they were joined together with small pegs. The entire assembly was then placed in an outer mold of clay and charcoal, pierced with holes. The gold was melted in a crucible and poured into the holes in the outer mold, melting away the wax. The mold was broken open to reveal the gold object.

There are indications that Colombian goldsmiths were capable of depletion gilding, a technique that produced a seamless surface layer of gold. The object was formed of tumbaga, a gold-copper alloy, with a high (60 percent) copper content. Goldsmiths removed the surface copper by heating the piece in an open hearth until the copper oxidized. The black oxidized copper was dissolved from the surface with a plant-based acid solution, leaving behind a thin layer of almost pure gold that could be burnished to a high finish.

► migration and population movements

INTRODUCTION

In a broad sense, the history of human migrations is the history of two profound desires: the desire to have a place that is home and the desire to live a better life. These desires have manifested themselves in settlements and movements for thousands of years. At present most anthropologists believe that the ancestors of the modern human being developed in eastern Africa, during a period when the land was dry and resources for survival were few. Some of these first human beings migrated south in Africa, others west in Africa, and others remained in eastern Africa.

What motivated human beings to leave eastern Africa is not known, but the hostility of the climate may have had something to do with it. People may have left to find better sources of game and edible plants. Some people moved northward, perhaps following game, and they may have followed game, perhaps migratory animals, out of Africa and into the Near East. They may not have realized that they were doing anything exceptional; they would just have been providing themselves and their families with food from wherever they could find it.

It is worth remembering that the people who migrated throughout the world in ancient times probably had motivations similar to those of modern people, and their reasons

for moving could be every bit as personal as the reasons why modern people sometimes leave their homelands to move somewhere else. There would have been heroes leading their suffering peoples to new lands, great visionaries foreseeing prosperity just beyond the next mountainside, people wanting to give their children better lives than they had, and people who had no clue as to what they were doing. Their motivations both heroic and mundane have been reduced to enigmatic works of art—paintings on rocks and cave walls, carvings of stone and antlers, and clay sculptures. The art only hints at the complex lives of the ancient migrants.

One of the great controversies about human movements is where the Neanderthals came from and how they were related to modern humans. At present, most evidence suggests that the Neanderthals were a different species from modern humans and may have developed in Europe or the Near East, but their origins remain cloudy. Their remains have been found throughout southern and central Europe as well as in parts of western Asia and the Near East. Their spread may have been motivated by their following the migrations of herds of animals.

Modern humans may have brought something new to migration: the desire to explore. Amid the discussions of famines, wars, and other motivations for great movements of ancient people, one may take note that there are people who like to explore, to know what is beyond the horizon. One explorer or a small number of exploring companions could find a new place to live and go home and tell about it, inspiring others to move to that new place.

The ancient world was a vast place, but people seemed to move through it as rapidly as the climate would allow. Glaciers expanded, blocking people, but then retracted, opening new routes for movement. It seems remarkable from the archaeological discoveries of ancient peoples that when an opportunity for movement presented itself, somebody took that opportunity and moved on. One group of ancient peoples moved east along the southern coast of Asia. The lands of southern India would have been very different from those of the southern Near East, yet people migrated into the lands and adapted to their new environment.

A migration almost inevitably requires adaptations to new environments, and the first migrants would have been challenged by new animals and plants and would have had to figure out what was edible and what was not. Resources for tools would have varied, and the first migrants would have had to adapt their tool-making skills to the woods, fibers, and stones that they found. The first people in Southeast Asia would have found themselves in immense bamboo forests populated by wildcats and giant apes twice as tall they were. The first people in the Americas would have encountered animals unlike any they had seen before, such as giant sloths. Even so, people made their moves into new lands and figured out ways to survive in environments for which they had no natural adaptations. It seems likely that

some migrations failed only to be tried again by new groups of people.

By the time written language developed in Sumer, the migrations into new territories were not yet complete. A multitude of islands in the Pacific Ocean were still unpopulated. Much of the interior of Asia was cold, dry, and unwelcoming, and people were only just beginning to find ways to live there. For some cultures, migration had become a way of daily life. For instance, the Lapps had begun following herds of reindeer in ancient prehistory; as the northern glaciers melted, the reindeer changed their routes ever more northward, and the Lapps followed. Some migratory peoples had taken charge of their migrations. These people domesticated horses, sheep, or cattle and drove their herds to summer quarters and then to winter quarters, back and forth, until outsiders forced them out of their traditional ranges or killed them or they chose to settle down.

War was a powerful motivator for migrations. Some peoples developed warrior cultures, and they migrated by invading lands occupied by farmers or pastoral peoples. These peoples sometimes succumbed to the invaders, fought the invaders off, or fled. Prosperous regions could attract migrations and war. The cultures of ancient Mesopotamia had a persistent problem with attempts by nomadic cultures to settle on their lands. Ancient Egypt drew Libyans who wanted Egypt's farmlands. The Western Roman Empire had to cope with Germanic tribes that wanted to move into Gaul and share the benefits of Roman civilization. Ancient history has many cases where entire populations of people abandoned their homes to escape war, only to displace some other group of people who in turn moved on. For example, the Chinese drove the Xiongnu out of central Asia. The Xiongnu were a violent people who had long vexed China with their raiding of Chinese settlements. Many historians believe the Xiongnu were the ancestors of the Huns, who drove ever westward, displacing the people in their way and reshaping the societies of Asia and eventually Europe.

AFRICA

BY AMY HACKNEY BLACKWELL

Ancient Africa was home to many ethnic populations, but scholars know little about their history or movements. What is known is that discrete groups of people gradually spread throughout the continent, so that by the end of the ancient period Africa's regions were home to specific ethnic and language groups. Most peoples are defined by language groups. Historians assume that groups that share similar languages must have come from a common culture. So, for example, the "Bantu" people are defined by the language they speak, a branch of the Niger-Congo language family that is spoken today in much of sub-Saharan Africa. The Berber people of North Africa spoke Afro-Asiatic languages, related to the Semitic languages of the Near East. The Khoisan of southern Africa spoke a unique language that included clicking sounds.

For most of the ancient period, the majority of Africans lived as hunter-gatherers who did not necessarily inhabit permanent homes, instead choosing to move about the countryside in search of food supplies. A major trend in ancient population movement was the displacement of hunter-gatherers by agricultural peoples. Agricultural societies tended to have better technology and larger populations, which allowed them to take land from the less organized hunter-gatherers. For example, one of the most significant population movements of the ancient period was the expansion of the Bantu peoples throughout sub-Saharan Africa between about 3000 B.C.E. and C.E. 500. The Bantu peoples were farmers who gradually claimed almost the entire continent south of the Sahara, displacing local hunter-gathering populations as they went.

Population movement did involve some warfare, and certainly some indigenous peoples were pushed out of their homelands at great personal cost. In many cases, though, the movement of populations was not as violent as it sounds. Historians track the spread of ancient populations partly by the spread of languages and technologies because it is impossible to track the movements of actual ethnic groups. The Bantu expansion and other movements almost certainly included a large amount of intermarriage with local groups, or local peoples' adoption of Bantu language and customs. In North Africa and northeastern Africa there was much blending of populations and cultural exchange as well as some wholesale warfare.

The geography of the African continent prevented the easy movement of peoples and ideas from place to place. Africa is very large and covers a vast range of latitudes. Its territory lies in both the northern and the southern hemispheres as well as on the equator. Africa also contains a variety of terrains, from extremely dry deserts to very wet rain forests. The range of latitudes and climates made it difficult for people to move agricultural plants from north to south, which impeded the movement of agricultural societies.

The main exceptions to the difficulty of free movement were the Nile, the coastal areas of North Africa and northeastern Africa and the Sahara. Traders did not begin regularly traversing the Sahara until the Islamic period, but ancient Africans had some desert trading networks. Towns that lay on the edge of the desert became important centers of cultural exchange. The Mediterranean coast was easily accessible to ancient sailors, and North Africa received many visitors and settlers from Rome, Greece, and the eastern Mediterranean. The Red Sea coast was close to Arabia and Yemen, so there was regular movement between the two areas. The Nile River also allowed free movement between Egypt and parts south, particularly Nubia. In all of these areas population movement happened more frequently than it did in the rest of Africa.

NORTH AFRICA AND EASTERN SAHARA

The Berber people lived in North Africa throughout the ancient period, despite repeated invasions by foreigners who

wanted to settle there. Their population stretched from Egypt to the Atlantic coast of Morocco and gradually moved south into the Sahara. The origin of the name *Berber* is unknown. The ancient Greeks called the Berbers "Libyans," and the Romans called them "Numidians," "Moors," and other names based on the region of North Africa from which they hailed. The Berbers generally had a Semitic appearance, with lighter skin and straighter hair than Bantu and other African peoples.

Language offers some clues about the movements of people in this area. The Berber people, like the peoples of East Africa (Ethiopia and surrounding countries) spoke Afro-Asiatic languages. Afro-Asiatic languages include the Semitic languages of the Middle East. Scholars disagree about the origin of the Afro-Asiatic languages. Some believe that they originated in the Middle East and were brought to Africa by people traveling from Yemen to Ethiopia and Eritrea. Others believe they originated in Ethiopia and spread from there throughout the Middle East and North Africa.

Archaeologists have found evidence that the ancestors of the Berber were living in North Africa as early as 9500 B.C.E. The Berber people were living in North Africa by 3000 B.C.E., when the ancient Egyptians first wrote about them. The Meshwesh Berbers of Libya had extensive contact with Egypt. During the Eighteenth Dynasty (1550–1307 B.C.E.) they traded cattle with the Egyptian rulers. The Meshwesh moved into Egypt from Libya during the 12th century B.C.E. During the Nineteenth and Twentieth Egyptian Dynasties Berber rulers fought constantly with the Egyptian kings. Finally, around 945 B.C.E., the Berbers took control of Egypt and ruled it until native Egyptians reclaimed the throne around 720 B.C.E.

Between 1000 and 600 B.C.E. the Phoenician people sailed from their home in Lebanon and colonized North Africa from Libya to Morocco. They brought Near Eastern crops such as wheat to the region and used the fertile coastal plain to grow grain for export. During the fifth century B.C.E. Carthage in modern Tunisia became a cosmopolitan city with a large Phoenician population. Romans moved into North Africa during the second century B.C.E. They turned North Africa into public land and rented it to absentee landlords who continued to farm grain there. The local population remained largely Berber.

THE SAHARA AND NORTHWESTERN AFRICA

Several groups of people lived in northwest Africa in ancient times. Berbers had begun moving into the Sahara long before the time of the Greek historian Herodotus, who wrote of a desert people called the Garamantes. The Garamantes lived in the Libyan Sahara between 500 B.C.E. and C.E. 500. Historians believe that the ancestors of the Garamantes probably moved into the Fezzan area of the Sahara around 1000 B.C.E. Herodotus wrote that the Garamantes herded cattle and drove chariots. They often fought with the Ethiopian people who lived in caves, and they were also known to raid Roman towns on the Libyan coast. They grew wheat to trade with

the Romans, digging tunnels to retrieve underground water. Another desert center was the city of Aoudaghost, which appeared in southeast Mauritania around the fifth century B.C.E. It sat at the edge of the Sahara and became a terminus for one of the trans-Saharan trade routes.

Around 1 C.E. the Berbers of the Sahara adopted camels from Arabia. These beasts allowed them to establish trade routes across the desert. Berber traders began traveling across the desert in this period, which allowed for some exchange of peoples and goods. The major Saharan trade routes did not develop, however, until the seventh and eighth centuries C.E.

The region known as Chad was inhabited long before the ancient period. Many humans settled there during the seventh millennium B.C.E., at a time when the Sahara was quite wet. Archaeologists have found rock art dating to that period that shows people hunting and engaging in other activities indicating a fertile climate. Historians believe that most of Africa's sub-Saharan languages originated in this region and must have spread from there during the ancient period, though the details of this spread are unknown.

The Bafour people lived in modern Mauretania in the first millennium B.C.E. The Sahara of this period was wetter than it became, which made it possible for the Bafour to hunt, raise livestock, and fish. As the Sahara grew, the Berber people from North Africa moved into the Bafour region during the third and fourth centuries C.E. Some Bafour became Berber slaves. Others moved south into southern Mauretania and eventually into Ghana.

The people of western Africa spoke languages from the Mande group of the Niger-Congo language family. The Soninke people were Mande language speakers who formed the Ghana kingdom in the early first millennium C.E. This kingdom included the states of Mali, Mema, and Wagadou, in modern Mali, Senegal, and Ghana.

The major form of population migration in this region occurred through trade, which brought people of diverse cultures in contact with one another. The Soninke people traded with people from both north and south, receiving goods from Berber traders crossing the Sahara and salt and gold from the Senegal River. The Soninke also began trading in slaves, capturing local Africans and selling them to merchants who took them to other parts of Africa and abroad, which resulted in a certain amount of inadvertent population migration on the part of the slaves. The town of Djenné in Mali lay on the inland delta of the Niger River. It was built by the Bozo people. It was large town by the third century B.C.E., and by the fifth century C.E. it had become a major trading center. Traders could sail up the Niger River with their goods. Traders also came through the forests or the desert to the north.

NUBIA

Ancient Nubia encompassed northern Sudan and southern Egypt along the Nile. People lived in the area during the early ancient period, but the first distinct culture to leave behind archaeological evidence arose around 3800 B.C.E. This culture

was similar to that of Egypt of the same period. Around 3300 B.C.E. the Nubian people organized themselves into a kingdom, which may have helped create the earliest Egyptian dynasties. The Egyptians took over Nubia around 3000 B.C.E.

Nubia was best known during the Egyptian Dynastic Period as a trade corridor between Egypt and southwestern Africa. Traders began traveling this route starting in the fourth millennium B.C.E. Egyptian craftsmen of this period used materials such as ebony wood and ivory, which must have come from tropical African trees and animals. Egyptians and Africans would have encountered one another and local Nubians as they traveled north and south carrying goods. During the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) Egyptian and African traders passed through Nubia to exchange an increasing variety of goods, including incense, gold, and wild animals. This trade made Nubia a prosperous region. A small kingdom arose there between 2240 and 2150 B.C.E. Historians are not sure whether this kingdom was inhabited by descendants of the earliest cultures in Nubia or by people who had moved there from elsewhere. It is possible that this kingdom was founded by invaders from the Sahara, who moved into Sudan as the desert became too dry for them to live there.

Between 2040 and 1640 B.C.E., Egyptians moved south into Nubia. They took control of the Nubian trade routes and built forts along the Nile to solidify their power, but they appear to have allowed the local people to live unmolested. The people of southern Nubia founded a kingdom of their own during this period, the kingdom of Kerma, which flourished from 2500 to 1520 B.C.E. Kerma was a major trading center, and archaeologists have found artifacts from southern Africa and Egypt as well as Nubian goods. During the period from 1620 to 1550 B.C.E., a period of Egyptian disarray, Egyptians moved back north from Nubia, and Kerma took control of northern Nubia as well. Egyptians returned to the area under Thutmose I (1504–1492 B.C.E.) and conquered Kerma, annexing Nubia as Egyptian territory.

During the 11th century B.C.E. Egypt suffered another period of governmental disarray and abandoned Nubia after locals rebelled. Local Nubians created a new kingdom based at the city of Napata, near modern Khartoum. This kingdom developed into the Kushite kingdom, founded around 708 B.C.E. The Kushites moved north into Egypt and conquered all of Egypt's territory under King Piye (750–712 B.C.E.). Around 690 B.C.E. Assyrians from the Near East moved southwest into Egypt, conquering the northern part of the Egyptian empire and forcing the Kushites back into Nubia. The Kushites lost control of Egypt in 656 B.C.E. when Psamtik I reunited Egypt. In 591 B.C.E. the Egyptians invaded Kush and destroyed Napata.

The Kushites moved south and built a new capital city called Meroë on the banks of the Nile. This city was an important center of government and commerce until about 350 C.E., when it was conquered by the Axumites of East Africa. The Kushite kingdom was strong during the Roman era. Kushites occasionally attacked Roman settlements in Egypt,

but the kingdom also engaged in a great deal of trade with Rome and other Mediterranean powers.

EAST AFRICA

Although eastern Africa around the Horn of Africa (including Ethiopia, Eritrea, Djibouti, and southern Sudan) has been inhabited by humans for millennia, the first historical mention of human beings dates to about 2400 B.C.E. The Nilotic languages were spoken in northeast Africa, originating around the southern part of the Nile. People who spoke Nilotic languages lived in Sudan from at least 3000 B.C.E. The Nilotic people were tall and slender. They appear to have been genetically related to the ancient Khoisan of southern Africa.

The ancient Egyptians called the region Punt, or “God’s Land.” Punt appears to have encompassed coastal Sudan and Eritrea and perhaps some of Ethiopia and Somalia. It definitely had a coastline on the Red Sea and was south of the region known as Nubia. Egyptian pharaohs sent several expeditions to Punt during the second millennium B.C.E. The people of Punt sold exotic goods such as ebony, ivory, wild animals, and incense.

East Africa is very close to the Middle East, and Middle Eastern people have been traveling to Africa for several thousand years. Some historians believe that Semitic peoples from Yemen and Arabia began settling in Ethiopia around 2000 B.C.E. During the first millennium B.C.E. Ethiopia and Eritrea were inhabited by a Semitic people called the Sabaeans. The Sabaeans came to Africa from Yemen. During this period they dominated the Red Sea region. The Sabaeans did not, however, rule all of East Africa. In the eighth century B.C.E. an indigenous African kingdom called D’mt arose in northern Ethiopia and Eritrea. This kingdom thrived until the fifth century B.C.E. Historians are not sure about D’mt’s cultural composition. Some believe that D’mt was entirely African, whereas others argue that it was heavily influenced by the Semitic Sabaeans.

In the fourth century B.C.E. the Axumite kingdom appeared in northeast Africa. This kingdom encompassed the Red Sea coast of Sudan, southern Egypt, Ethiopia, Yemen, Djibouti, and part of Saudi Arabia. Historians believe the Axumites were indigenous Africans, not Semitic Sabaeans from Yemen; the current theory is that they were a mix of Semitic and Kushitic peoples. Axum was a major power by the first century C.E. For the rest of the ancient period it engaged in international trade with Arabia, Persia, Rome, India, and China. It also controlled the government of Saudi Arabia during the third century. In 350 C.E. Axumites conquered the kingdom of Kush, just to the north of Axum. Because of Axum’s international contacts, the Axumite people spread through the region and people from other places came to Axum as emissaries or slaves. Foreign visitors and inhabitants included Indians, Arabs, Jews, Romans, Egyptians, and Sudanese people, as well as people who had traveled there from southern and western Africa.

SUB-SAHARAN AFRICA AND THE BANTU EXPANSION

Between 40,000 and 8000 B.C.E., southern Africa was occupied by people known as Sangoan. By the beginning of the ancient period these people had developed into the culture known as Khoisan, or Bushmen. They spoke a distinctive language that included many clicking sounds. Archaeologists believe that the Khoisan were one of the oldest distinct groups of humans. Studies of modern Khoisan genes show that the Khoisan people were isolated from other genetic groups up to 100,000 years ago. The Khoisan people had a distinctive appearance, with copper-colored skin, high cheekbones, long legs, and an overall short stature. Their eyes had distinctive folds of skin, similar to those of Asian peoples. Khoisan women had a tendency to accumulate fat in their buttocks, possibly an adaptation to life in a harsh climate with an unpredictable food supply. The Khoisan lived throughout the southern half of the continent, in modern-day Angola, Namibia, Botswana, and South Africa. They were adapted to life in dry desert conditions and lived as hunter-gatherers, hunting wild animals and gathering wild plant foods.

During most of the ancient period the jungles of central Africa in the modern Congo nations—Cameroon, Central African Republic, and Gabon—were home to groups of small-statured people most commonly known as today as Pygmies, though this term is considered derogatory. Pygmies also lived further east. For example, the Twa people were the earliest inhabitants of Rwanda. Adult males were less than five feet tall, and many adults were smaller than that. The Pygmies had muscular bodies, short legs, long arms, and large heads. They lived as hunter-gatherers. Historians do not know when Pygmy groups appeared in the jungles. The earliest references to them are in ancient Egyptian writings dating to about 2500 B.C.E. The Greek historian Herodotus also wrote about the small jungle people. The Pygmies did not develop cities or large governments. They instead roamed through the forests, erecting temporary homes and moving when an area’s food supply ran out.

Much of the rest of sub-Saharan Africa was inhabited by small groups of hunter-gatherers. Very little is known about these people. The ones living in East Africa had some contact with traders from Nubia and surrounding regions, but for the most part they were isolated for centuries. This gradually changed during the Bantu expansion. The Bantu people originated in the region that is now Cameroon, Nigeria, and Niger, particularly in the Benue-Cross river region of Nigeria. Sometime during the third, second, and first millennia B.C.E. the Bantu people spread throughout central, eastern, and southern Africa. This spread is known as the “Bantu migration.” The Bantu languages, part of the Niger-Congo language family, are identified by a shared word for “person,” which is *ntu*. The Bantu people had dark skin and curly black hair.

Modern scholars do not agree about the details of this migration. Historians once thought that the Bantu people in

Nigeria developed both agriculture and ironworking during the first millennium B.C.E. The Nigerian Bantu were believed to have somehow learned ironwork in the Middle East and brought it back to Nigeria with them; Nigeria's Nok people were believed to be some of the first expert metal workers. According to this scenario, by about 500 B.C.E. the Bantu were skilled enough at working metal that they were able to quickly conquer the hunter-gatherers of southern Africa.

Historians today believe that the Bantu migration happened over a much longer period of time and was probably a process of gradual cultural transmission instead of a sudden burst of ethnic conquerors. According to the present interpretation of the data, starting around 3000 B.C.E. the Bantu people of Cameroon, Nigeria, and Niger started moving slowly south and east. The reasons for this move are unknown. The Sahara became very dry during the second millennium B.C.E., and Berber inhabitants of the desert may have pushed the Bantu south as they moved into wetter regions. This would have forced the Bantu into the rainforests of central Africa.

The Bantu migration was not necessarily a journey of conquest. As the Bantu moved south and east, local peoples adopted Bantu languages and intermarried with the migrants. Over the generations the Bantu language slowly spread southward, and Bantu physical traits appeared in populations where intermarriage occurred. Modern historians also believe that the Bantu-speaking peoples did not bring ironworking to Nigeria from the Middle East but instead discovered it when they arrived in eastern Africa. The non-Bantu people of Tanzania and Rwanda may have started working with iron around 800 B.C.E., without any influence from the Middle East or Europe, and the Bantu may have learned the craft from them.

However the Bantu learned to work with iron, by the fourth century C.E. they were quite skilled at it and could make good metal farming tools. These tools made it much easier for Bantu farmers to cut grain from tough sorghum and millet stalks, which gave them an advantage over peoples who did not have metal tools. Even if they did not kill native peoples to take their land, the Bantu were much better equipped to raise food, which helped them become the dominant culture. However it happened, the Bantu languages spread down the coast of east Africa by 400 C.E.

The Pygmy groups came into early contact with the Bantu, who lived near them. Pygmy hunters traded with Bantu farmers, exchanging meat and hides for vegetables, pottery, baskets, and metal items. In areas where the Bantu population grew rapidly, the Pygmies were sometimes forced to move, and this could have resulted in decreased Pygmy populations. For example, the Twa of Rwanda gradually disappeared when the Bantu Hutu arrived in the second half of the first millennium C.E.

Around 1000 B.C.E. the Bantu moved into the southern Africa, bringing agriculture and herding techniques with them. Their progress was slow; Africa's terrain does not allow for rapid transmission of crops and livestock, and dis-

eases spread by tsetse flies killed large numbers of people and animals. As the Bantu population grew in Khoisan territory, the Khoisan Bushmen split into two groups. The Khoisan remained hunter-gatherers, but they moved into more marginal habitats, such as the Kalahari Desert. The Khoi, or Khoikhoi, became pastoralists. They acquired livestock, brought to their region by the Bantu, and lived by herding. The Khoi lived throughout the pastureland of South Africa. As the Bantu spread through the region, they adopted some Khoisan practices. The southern Bantu language, for example, acquired some click sounds and Khoisan words.

Around 1 C.E. Bantu culture had moved into Uganda, bringing along agriculture and metalworking. Nilotic peoples also moved into Uganda from the north during the first century C.E. These people included the Luo and Ateker groups. They herded cattle and practiced subsistence farming. Although there were some conflicts, the Luo soon intermarried with the Bantu and adopted Bantu customs. Some Luo continued moving south into Tanzania and Kenya. The Bantu arrived in northern South Africa around 450 C.E. This event corresponds with a period in which local animals such as wildebeest and white rhino began to disappear from the area, presumably displaced by Bantu cattle.

The Bantu included many groups that emerged as separate tribes during the ancient and subsequent periods. The Nguni people spoke the Nguni group of Bantu languages. They lived throughout southeast Africa, inching their way south over the centuries. The Nguni included peoples that developed into the Zulu, Swati, Phithi, and Ndbele. The Xhosa were Nguni people who appear to have arrived in South Africa sometime in the fifth century C.E.

EGYPT

BY KATHARINA ZINN AND MICHAEL J. O'NEAL

One way to know of migration (both emigration and exile) is to study the archaeological evidence of prehistoric societies. The material culture found in excavations tells the story of the links between different cultures. Thus, for example, archaeologists have found tombs that contain luxury goods that were clearly manufactured elsewhere, using processes and materials that were not available at the time in the area of the tomb. It is often difficult to decide whether these links developed from intensive trade exchanges, invasions, or migration movements. Concerning ancient Egypt, another important source used to explain migration movements—and sometimes the only fruitful one—is Egyptian texts, along with the artwork in tombs. While surviving texts do not provide a complete, continuous record, those that do survive give hints about the movement of people throughout ancient Egypt.

Egyptians sometimes migrated to other countries. Such migration movements were recorded in ancient texts, but the number of people who went to other countries was not high, and many wanted to return to Egypt to have an Egyptian burial with all the attendant funerary rituals. Further,

Egypt fostered a mind-set of superiority to other cultures and nations. Put simply, Egyptians looked down their noses at other countries and their people, so few had any real incentive to intermingle with them on their own territory. With the exception of a small number of texts, only a few hints help identify Egyptians outside Egypt. During the Nineteenth and early Twentieth Dynasties (1307–1070 B.C.E.), Egyptian and Egyptian-styled pottery is to be found in Canaan (Palestine) and shows cross-cultural relations between Egypt and its northwestern neighbors. At the same time, fortified towns in Nubia had a fairly uniform design, for example, Amara West and Sesebi. It can be assumed that Egyptians were living in such settlements.

Ancient Egypt was very much a crossroads. Positioned as it was in the northeast sector of the African continent, it became a central hub, engaging in trade relations with the Near East, countries surrounding the Mediterranean Sea, and nations to the south. Egypt became a beehive of activity, with builders, traders, farmers, diplomats, nomads, travelers, and others passing across its borders and moving about within the country. Archaeological evidence suggests that late in the Predynastic Period (ca. 3000 B.C.E.) many of these people came from such regions as Mesopotamia, bringing their science, literature, art, mathematics, and other cultural attributes with them. Many of these people from other lands became the earliest Egyptians; later arrivals chose to remain in Egypt, primarily because it was the most advanced civilization of its time, providing opportunities for wealth, education, and social relationships. In general, Egypt tended to welcome people from other lands, thinking of them as Egyptian as long as they made a point of acting like Egyptians. The result was a swirl of population movement within Egypt, though this population movement was, in general, not organized, nor did it occur among masses of people.

COLONIZATION

At all periods of Egyptian history transplantations of population, or inner colonization, apparently occurred. The central government divided the Egyptian countryside into organized agricultural parts centered on larger settlements, the beginning of the organized nomes, or provinces, of later periods. Some of these settlements were in sparsely populated regions. The land was cultivated by peasants recruited from more populous regions. During the Fourth Dynasty (ca. 2575–2465 B.C.E.) a kind of colony program existed. King Snefru, the first king of the Fourth Dynasty, brought captives from different campaigns in Nubia and possibly Libya to Egypt and settled them in newly founded manors in the eastern delta and in Upper Egypt. In this period administration increased, and the great pyramid-building projects required a large number of new cultivated agricultural areas as economic support.

King Sesotris III (r. 1878–1841? B.C.E.), the fifth king of the Twelfth Dynasty of the Middle Kingdom, constructed a full-scale model town called Wah-sut in connection with a cenotaph and the cult of the death god Osiris near Abydos

Granite statue of Sesotris III, from Deir el-Bahri, Thebes, Egypt (ca. 1850 B.C.E.); Sesotris constructed a town in northern Upper Egypt for the purpose of internal colonization. (© The Trustees of the British Museum)

in northern Upper Egypt. Earlier model towns that suggest internal colonization included the modern Tell el-Dab'a in the eastern part of the Nile delta, known as Auaris at the beginning of the Twelfth Dynasty, and Kahun in the vicinity of modern El-Lahun from the reign of Sesotris II (r. 1897–1878 B.C.E.).

Inner colonization also took the form of resettlement projects during the creation of new capitals like Akhetaten (present-day Tell el-'Amarna) by Akhenaton (r. 1353–1335 B.C.E.) in the Eighteenth Dynasty or Pi-Ramesses by Ramses II (r. 1290–1224 B.C.E.) during the Nineteenth Dynasty. Often foreigners were involved in this effort. A land register from the fourth regnal year of Ramses V (r. 1156–1151 B.C.E.) lists Sherden men who were cultivating farmland that they probably obtained under

lease, turning them from enemies into loyal peaceful foreigners. Other examples of colonization are to be found outside Egypt. In Nubia forts with citadels were built, including Buhen or Semna, and Egyptians were settled there, mainly during the Middle Kingdom (2040–1640 B.C.E.).

The ancient Egyptians were able administrators. While Egypt's power and wealth declined during certain periods, in general Egypt's pharaohs recruited a capable bureaucracy for administering the affairs of the nation, including tax collection, land surveying, construction supervision, water management, and the like. These activities required small armies of trained and educated functionaries to move about the country, establishing settlements, organizing the administrative affairs of the nomes, overseeing activities in village and settlements, importing labor forces (including slaves), and similar activities.

MIGRATION IN THE PREDYNASTIC PERIOD

The development of Egypt cannot be adequately comprehended without a view to its changing position within several existing networks, especially communication and trade with large areas of the ancient world, including northeast Africa, southwest Asia, and the eastern Mediterranean. At all times—especially during periods when Egypt's power was at its height and the state was highly organized, Egypt acted like a magnet on its neighbors. The direction of this effect varied, but the pull was strong.

Contacts with other areas began in the fifth millennium B.C.E. At that time Egypt was not unified into the states of Upper and Lower Egypt. Upper Egypt toward Middle Egypt formed a unit around modern-day Khartoum, while Lower Egypt had a different social and cultural structure. The distinction between the Nile Valley and Lower Egypt was more salient than that between the Nile Valley and Sudan. Whether there were large-scale migrations between the Nile Valley and the eastern and western desert is not certain, but large amounts of products and resources from the desert areas found in the valley suggest regular networks of exchange, possibly combined with migration movements.

Such intensive contacts through trade and cultural exchange provided advantages to nomads, who continued to populate the region. The clearest evidence for these contacts derives from Neolithic burials rather than settlements. Such findings provided the earliest clear images of art that can be dated as well as ritual treatments of human and animal bodies. Around 3500 B.C.E. close trade contacts existed between South Canaan and the Lower Egyptian culture of Maadi-Buto, followed by settlements of these people in each other's cultural area. Locally produced Egyptian pottery has been found in South Canaan, while Canaan houses have been found in Egypt.

With the start of the age of pyramid building beginning with Djoser in the Third Dynasty (2630–2611 B.C.E.), the number of men recruited to build visible signs of dramatically improved knowledge, better organization, and cen-

tralization of the state increased enormously. The influx of more and more foreigners after the end of the Third Dynasty brought cheap manpower. Settlements of Nubians during the Fourth Dynasty can be demonstrated. There is less information available for the Old Kingdom (2575–2134 B.C.E.) than for later periods.

Climate change played a marked role in the movement of ancient Egyptian peoples. For the past 5,000 years the Sahara has been a harsh, forbidding desert, unsuitable for farming and supporting only a very small population of nomads and herders. Running through this desert is the Nile River, a thin but fertile lifeline. The Sahara, though, has not always been this way. Until about 3000 B.C.E. large portions of the Sahara were savanna grassland. This grassland supported a relatively large population of herders and farmers. As the land became dryer, perhaps in part the result of overgrazing and too much cultivation, the desert began to expand. Large numbers of people could no longer make a living in the relentlessly expanding desert. While many of these people moved south or relocated to the northern coast of Africa, many others moved into the Nile River valley, which provided them with fertile alluvial soil that supported agriculture. In this way, the population of ancient Egypt became more concentrated in a narrow strip of land bordering the river.

This early movement of peoples raises a larger question: Who, really, could claim to be "Egyptian" at that time? Being Egyptian was not a matter of race. The people who inhabited the Nile Valley during the Dynastic Period were for the most part not indigenous people who had lived in the area from time immemorial. Rather, ancient Egypt was a melting pot of peoples from around the larger region: nomadic herders and traders from the desert, people from the countries of the Near East and Mesopotamia, and Africans from other parts of the continent.

EGYPT AND NUBIA

Any discussion of population movements of Egyptians has to include Egypt's relations with Nubia to Egypt's south. While the Nubians technically were not Egyptian, the close contact that developed over time "Egyptianized" the Nubians to the extent that it would have been difficult to distinguish a Nubian from an Egyptian. During one portion of its history, Egypt was ruled by pharaohs from Nubia, and many of Nubia's cultural institutions, including government, art, pyramids, and funerary practices, were virtually indistinguishable from those of Egypt. In time, the cultural contacts between Egypt and Nubia became so extensive that Nubia and Egypt became essentially one. That process, though, took time.

Throughout much of its early history Egypt existed in relative isolation from its neighbors. The Nile Valley was bordered on the north by the Mediterranean Sea, and marshland imposed an obstacle to access to the sea. On the east and west the fertile valley was bordered by desert. The only direction in which Egyptians showed any inclination to move was to the south, into the interior of the African continent.

The region to the south of ancient Egypt is still referred to as Nubia. This region was home to people the later Greek historians would refer to as *Aethiopians* (or Ethiopians), a word that means “burnt faces.” This was the name the Greeks gave to all black Africans. The Egyptians themselves referred to the Nubian people as the Kush—usually prefacing the word with a descriptor such as “miserable.” As the Egyptian empire grew in power, wealth, and sophistication, Egyptians looked on the “miserable Kush” to the south with disdain. They had little desire to explore the area, but that lack of desire may have had as much to do with geographical factors as anything else.

Along the Nile River are a series of numbered cataracts, or rapids, where the river falls dramatically and passage by boat is difficult. Near the modern-day Aswān Dam was the first cataract, which formed a natural barrier between Egypt and the kingdom of the Kush. To the north, Egyptians were content to remain in their wide, fertile valley, which provided them with the land they needed to support a thriving agricultural industry. But to the south of the first cataract, the landscape changed dramatically. Because the Egyptians were stretched out along the river, they did most of their travel by boat; they could get to nearly everywhere they wanted to go by river or canals that connected with the river, and there was little incentive to follow overland routes through the desert. But above the first cataract, the river narrowed and featured massive, irregular rock outcroppings. (The Nile River flows north to south, so “above” extends southward and “below” extends northward; “Upper” Egypt is to the south, while “Lower” Egypt is to the north.) There was little in the way of arable land, only small, patchwork areas that provided the kind of soil conditions that made Egypt’s land so productive. In short, the river was not very navigable, so the Egyptians did not try.

That was to change. In time, the Egyptians came to realize that Nubia had an immense number of valuable resources. The most important of these were gold, ivory, and slaves, but these three resources merely stood at the head of a long list of items that Egyptians coveted, including various other stones, precious metals, and minerals. Animal products such as ivory can be obtained through trade and slaves through warfare, but metals and mineral products are best procured through colonization, for colonization enabled Egyptians to be on the spot to oversee the immense amount of labor necessary to extract these materials. Eventually, that is what happened.

The earliest Egyptians to move into Nubia were isolated and unorganized traders, adventurers, and plunderers during the Predynastic and Early Dynastic Periods (ca. 3000–2575 B.C.E.). These people were not acting under the authority of the state, which indeed at this point had not consolidated its power. However, they served an important function for the state, for they returned to Egypt with accounts of Nubia’s great natural wealth. At this point there was no significant movement of Egyptians into Nubia. The first expedition of Egyptians into Nubia was led by the pharaoh Djer in the First Dynasty,

prior to 3000 B.C.E. It was during the Old Kingdom, though, that Egypt began to covet Nubia’s mineral resources. These were necessary primarily for the construction projects taking place throughout Egypt. During the Fourth and Fifth Dynasties (2575–2323 B.C.E.), Egyptians moved into Nubia, in the region between the first and second cataracts, and ran a diorite mine and a copper-smelting operation. These operations were overseen and conducted by towns established for the purpose and populated by Egyptians. The power of the pharaohs waxed and waned during the Old Kingdom, so trade and the movement of Egyptians into Nubia was intermittent and unorganized.

It was during the Middle Kingdom that relations between Egypt and Nubia became more frequent and complex. During the Eleventh Dynasty (2040–1991 B.C.E.) the pharaohs once again consolidated their power. They began to colonize Nubia, backed by the weight of their armed forces. Between the first and second cataracts they established forts, at least 10 of them over a distance of about 40 miles. The result was a significant movement of Egyptians to the forts themselves, though little evidence suggests that the troops garrisoned there made any effort to subdue the Nubians, other than to engage in occasional raids to capture slaves.

In fact, it is likely that the forts existed not for offensive or defensive purposes but as a kind of coast guard that oversaw traffic on the river and offloaded and reloaded goods as boats navigated the treacherous second cataract. The positioning of these forts, all but one on the west bank of the river or on islands facing the west bank, suggests that such was their purpose. Meanwhile, Egyptians moved into Nubia to establish trade and diplomatic relations with tribal chieftains, content to allow production of local goods to remain in the hands of locals. As colonists, the Egyptians were primarily concerned with protecting the Nile River and keeping trade relations open. Over a period of centuries Egyptians who were garrisoned at the forts or were involved in trade relations intermarried with Nubians, and they and their descendants were simply absorbed into the Nubian population.

THE NEW KINGDOM AND NUBIA

For hundred of years Egypt’s colonial enterprise in Nubia was interrupted. Egypt was weakened and divided; the Hyksos ruled northern Egypt, an Egyptian ruled southern Egypt from its capital in Thebes, and the Nubians reasserted control over trade between the two nations. But beginning in the Eighteenth and Nineteenth Dynasties this state of affairs changed dramatically. The Egyptians were able to expel the Hyksos and reunite their country. With their power reestablished, they turned their attention again to the south. Ahmose (r. 1525–1504 B.C.E.), the first pharaoh of the Eighteenth Dynasty, reoccupied lower Nubia and refurbished Egypt’s forts. Over a period of a hundred years his successors pushed the frontier between Egypt and Nubia southward some 350 miles to a point below the fourth cataract. In the reign of Thutmose II (r. 1492–1479 B.C.E.) Nubia was entirely subdued; in

Thutmose's words, "Then this army of His Majesty arrived at wretched Kush. . . . This army of His Majesty overthrew those barbarians. . . . They were placed under the feet of the Good God. . . . The land was made a subject of His Majesty."

At this point, "wretched Kush" became a full-fledged Egyptian colony. Large numbers of Egyptians moved to Nubia, occupying the forts and building walled towns, residences, temples, and workshops. Egyptians in Nubia included not only soldiers but also artisans, priests, settlers, and a small army of overseers, mayors, and other civic officials. Archaeologists have discovered hundreds of ordinary tombs (as opposed to the lavish tombs of pharaohs and other high officials), suggesting that there was a mass movement of settlers into Nubia. At this point, too, the old forts below the second cataract became of less importance. They continued to be occupied but largely for the purpose of assisting trade.

Over hundreds of miles above the second cataract large administrative centers grew around new fortifications that had been built. Quickly, these administrative centers outgrew the forts that protected them. Spilling out around them were towns and residential areas inhabited by Egyptians who had migrated to Nubia. Egypt undertook a massive building program, constructing temples as symbols of its imperial power, including one temple built on a site sacred to Nubians at the Nubian capital of Napata, the southernmost extent of Egyptian colonization. Ramses II (r. 1194–1163 B.C.E.), in particular, littered Nubia with temples built for his own glorification. Ruling over Nubia and the southernmost nome of Upper Egypt was a viceroy who was given the title "King's Son of Kush." This viceroy was responsible for collecting taxes and tribute and overseeing the activities of the thousands of Egyptians who had moved to Nubia.

Egyptian migration into Nubia changed the economic life of the Kush. Previously, the country had been inhabited primarily by herders and farmers; many of the people were nomadic. The presence of large numbers of Egyptians, though, turned Nubia into a productive colony. Land ownership was in the hands of Egyptian officials and, particularly, the Egyptian temples. Tribute paid from working the land was used to support a large class of Egyptian priests and their servants, artisans, miners, farmers, administrators, shipbuilders, and craftsmen. Prospectors from Egypt scoured the desert areas to the east of the Nile in search of gold, and their success led to the construction of numerous mines and mining settlements, all populated by Egyptians looking for gold to finance Egypt's military campaigns.

The colonization of Nubia was complete. Nubia was essentially absorbed into Egypt, annexed to it and part of the state. Under the influence of massive Egyptian immigration, the Nubians became almost entirely Egyptian in their religion, economy, and general outlook. No longer were they the "miserable" or "wretched" Kush. Although the highest governmental positions remained closed to them, many achieved relatively high positions in the bureaucracy. They adopted Egyptian customs and ways, and even their tombs were vir-

tually indistinguishable from those of the Egyptians—no minor matter given the Egyptian emphasis on the afterlife and the importance of tombs and funerary goods in easing passage into the afterlife.

THIRD INTERMEDIATE, LATE, AND PTOLEMAIC PERIOD

The first millennium B.C.E. was affected by foreign kings and dynasties. The Twenty-second Dynasty was of Libyan origin, and the Twenty-fifth Dynasty was Nubian. Shortly before the Twenty-sixth Dynasty the Assyrians ruled much of Egypt. The Persian army overwhelmed Egypt twice: during the Twenty-seventh and Thirty-first Dynasties. Alexander the Great came to Egypt, and one of his officers became Ptolemy I and established the Ptolemaic Dynasty (304–30 B.C.E.) before the Romans ruled the land. All these events are barely recorded in Egyptian records or texts but were described by Greek historians. Egypt was Egypt again with a strong Egyptian society, temple-building projects, literature, administration, trade, and foreigners in the role of pharaoh, but all with a more multicultural influence. One example of Egypt's multiculturalism was the island Elephantine near Aswān in Upper Egypt. Elephantine was settled from Early Dynastic times on and had a Jewish colony during the fifth century B.C.E. These Jewish soldiers and their families rapidly abandoned their own cultural markers and were no longer recognizable from archaeological material but only from Aramaic documents. Aramaic was the universal language of the Near East at this time. This community intermarried but retained its distinctiveness. Greek settlements from this time also have been found; the most famous was Naukratis in the western delta.

Again, the difficulty is defining an "Egyptian." While these movements of people had more to do with migration *into* the country rather than *within* the country, the ability of Egypt to absorb foreign cultures and peoples suggests that populations could become Egyptian, thus blurring the lines between movement of Egyptians and movement of foreign communities within the country that became largely Egyptianized.

EXILE

The other side of migration—going into exile—is described in the "Tale of Sinuhe." Sinuhe, who flees in panic after the death of the king (which he hears about during a campaign in Libya), details his long journey from southern Libya, across the Nile, and past the fortresses to Asia, where he remains in temporary exile in the vicinity of Coele-Syria or the north Jordan valley, in Egypt called Retjenu. It has been suggested that he flees because he is implicated in a court conspiracy, but this has not been established. Living there, he is befriended by Palestinians and marries a daughter of the chief of Upper Retjenu—the area of his exile. He settles in the territory belonging to the tribe in the manner of a Bedouin sheikh. Only homesickness and the desire for an Egyptian burial give him the desire to go back to Egypt and praise the new king,

Sesostris I. After his return and an audience with the king, Sinuhe is reinstated, bathed, and given a house and tomb with a funerary endowment and a statue. Thus, his life comes to a good end after a long period in the foreign countries. Sinuhe moves from the periphery of the world back to its center, the better world. The readership of this well-known poem, written in about 1950 B.C.E., was the literate class. It emphasizes the beliefs that Egypt was home for all Egyptians and that loyalty to the king brings prosperity. This text was still being copied seven centuries later as a school exercise.

Other hints that people went into exile come from other types of sources. A memorial slab stele from the beginning of the Twelfth Dynasty describes a kind of police action. Kay, overseer of the desert hunters, is sent to the western oasis to bring back fugitives. From the context of the text it seems clear that these escapees must be people who went into exile and were not banished people.

An example of an unintended exile is given by the “Tale of Woe” from the Third Intermediate Period, possibly the late Twenty-first or Twenty-second Dynasty. The first-person narrator Wermai, a resident perhaps of Heliopolis in Lower Egypt, has to flee from his hometown as a victim of slander, charged with misdeeds against the god. He goes into exile in different regions of Egypt, and he is lonely and hungry. It is interesting that his exile is within his country but outside his beloved hometown, a kind of internal exile. He hopes for a savior, maybe Atum—the solar deity of Heliopolis.

In the “Report of Wenamun,” written in the Twenty-first Dynasty at the beginning of the Third Intermediate Period, the protagonist Wenamun, an Egyptian diplomat, goes into unintended foreign exile along the Syro-Palestinian coast. He undertakes a mission to the Phoenician coast to bring back wood for the bark of Amun-Re, one of the most important gods in the Egyptian pantheon and the main god of the main temple in Wenamun’s hometown, Karnak. This routine trip turns into an odyssey because of the loss of Egyptian power and influence during this time. Wenamun cannot go back for a long time and has to stay in Syria.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Climate, water supply, and war were the factors that controlled migration and population movements in the ancient Near East. These three factors often were tied closely to one another. Water supply was frequently low, and droughts appeared with dismaying regularity. When droughts occurred, people moved. In many cases, they moved into cities, which were the best places to find food. When droughts were too extreme, people moved out of cities into the countryside once more in search of food.

City-states were the predominant form of settlement in much of the region, and they often vied with one another for control of precious water resources. Many cities fell to the armies of other city-states or to wandering nomadic tribes.

Whenever this happened, populations often moved. Frequently, ancient rulers would force conquered peoples to leave their homelands to work as slaves in other places. Conquered peoples also simply fled their native lands, seeking refuge in the lands of other nations.

Tracking the movements of ancient peoples is difficult for many reasons. There are few historical records, and the records that do exist are sometimes contradictory or do not correspond with archaeological evidence. For example, it is impossible to reconcile the events recorded in the Hebrew Bible with contemporary Egyptian records and modern archaeological finds. It is also hard to identify specific populations. Ethnic identities were fluid, and ethnic groups did not always travel as a people. One of the best ways to track population movements is through the dispersion of languages; the path of a language as it moves through a region can be evidence of the movement of a population.

Most of the peoples of the ancient Near East were Semitic, meaning that they spoke Semitic languages. These languages include Akkadian, Assyrian, Babylonian, Hebrew, Phoenician, Nabataean, and Arabic. Semitic languages first appeared in the Arabian Peninsula during the fourth millennium B.C.E., perhaps from a point of origin in Africa. Other peoples in the region spoke Indo-European languages, including the Iranian and Anatolian languages. These people are believed to have traveled into the Middle East from the Caucasus, central Asia, and the Indus Valley. Still other languages in the region have no known linguistic relations. Sumerian, for example, is neither Semitic nor Indo-European, which makes it difficult to determine where the Sumerian people originated.

EARLY HUNTER-GATHERERS

The Middle Eastern climate following the last ice age was mild and allowed people to spread throughout the region between 12,000 and 5000 B.C.E. They congregated in wet areas with adequate rainfall or access to rivers, because these areas had the best fruits and vegetables for foraging and the largest populations of animals to hunt. They avoided the arid deserts.

These prehistoric people lived as hunter-gatherers throughout the Fertile Crescent, a region encompassing Israel, Lebanon, and the floodplains of the Tigris and Euphrates rivers from the mountains of Anatolia to the Persian Gulf. Early hunter-gatherers did not live in permanent homes but instead wandered from place to place following food sources. Starting in about 10,000 B.C.E., however, people living in areas with particularly rich sources of food began to occupy the same sites throughout the year and build permanent homes. Over the next 2,000 to 3,000 years they developed agriculture and learned to breed and raise livestock. Agriculture tied people to their farmlands and made it difficult for them to move. After the advent of agriculture, people moved only if they absolutely had to as the result of some catastrophe or natural disaster, such as sudden climate change or war.

MESOPOTAMIA

The civilizations of ancient Mesopotamia ebbed and flowed with the water supply and periodic droughts. When the rivers flowed reliably, the people of the region built large cities that allowed them to share the water supply. Some people continued to live in the countryside as nomads. When the weather turned arid, as it did several times during the ancient period, the populations of the cities grew as people crowded into urban areas in search of food. When droughts became too extreme for the cities to continue to function, the city residents flowed back into the countryside and resumed nomadic living habits.

The first peoples to build cities on these river banks of the Tigris and Euphrates were the Sumerians. They spoke a language that is unrelated to any other known language. The geographic origins of the Sumerians are unknown, but their ancestors probably migrated down the rivers from Anatolia or northwestern Iran. The Sumerians built cities near the combined mouth of the two rivers sometime between the sixth and fourth millennia B.C.E. Eridu may have been their first city, though Ur and Uruk are also very ancient.

Around 3800 B.C.E. the climate grew drier, changing the timing of the annual river floods. It became much harder to produce or find food. Many people had lived in the countryside surrounding the Sumerian cities, either in smaller towns or in the open as nomads. These people now moved into the cities, which had stores of grains and offered them some hope of finding food. Between 3200 and 2800 B.C.E. huge numbers of people lived in cities; historians estimate that some 80 percent of the Sumerian population lived in southern Mesopotamian cities at this time.

The Akkadian civilization arose in northern Mesopotamia during the 24th century B.C.E. As was the case with Sumerian cities, people flocked to cities on the banks of the upper Tigris and Euphrates when drought made it impossible for them to survive in the countryside. Around 2200 B.C.E. Mesopotamia suffered a major drought. The cities were no longer able to feed their populations, and people dispersed into the countryside to live as they might.

The Akkadian Empire fell around 2100 after its territory was invaded by a nomadic people called the Gutians who came from the Zagros Mountains in Iran. The Gutians also traveled south into Sumerian territory and attacked Sumer's cities. This period was something of a dark age for Mesopotamia. The presence of Gutian raiders throughout the region made travel and farming dangerous. Even after the Gutians had turned civilized and been absorbed into cultured Mesopotamian society over a century or two, the term *Gutian* was still used to refer to hostile barbarians from Iran.

Another group ventured into Mesopotamia during this period, the Amorites, called Martu by the Sumerians. The Amorites lived in Syria and Canaan from the late third through the early first millennia B.C.E. and had a great deal of contact with the Sumerians. Sumerian historians described them as nomads who roamed the landscape without perma-

nent homes or agriculture, though this appears not to have been entirely true. During the Third Dynasty of Ur (2112–2004? B.C.E.), many Amorites lived in and around Ur and other Mesopotamian cities and served in Ur's armies.

Around 2000 B.C.E. ample rainfall returned to Mesopotamia. People again populated the riverbanks and built new cities along the rivers' new courses. The Amorites used this opportunity to seize power in the region. Between about 2000 and 1600 B.C.E. Amorites ruled Mesopotamia as the Old Babylonian regime. They conquered the city of Ashur and moved into the Khābūr River delta area around 1800 B.C.E. The Amorite's capital was the city of Babylon, located on the Euphrates River some distance from the mouth; cities of this period were not located as far south on the river as older Sumerian ones. Babylon attracted large numbers of immigrants from the surrounding countryside, and during the 17th century B.C.E. it was the largest city in the world.

The Assyrians first appeared in the upper Tigris region after 2000 B.C.E. The Assyrian people spoke a Semitic language that was closely related to Akkadian. Assyrians spread through Anatolia, establishing trade colonies in Cappadocia. Their empire reached its peak during the early first millennium B.C.E. The Assyrians were responsible for a great deal of population movement. Their empire covered much of Anatolia, Mesopotamia, and the Levant, including the city of Babylon. Assyrian kings made a practice of deporting conquered peoples to destroy their national identities and make it harder for them to revolt. During the eighth century the populations of Israel, Judah, and Syria were all deported elsewhere. Their new homes included the cities of Nineveh and Gozan and the territory of the Medes far to the east, in modern-day Iran. The Assyrian rulers moved their own nobles into the vacated territories, hoping to create a permanent ruling class in the conquered lands.

THE LEVANT

Several civilizations came from the land called Canaan, which was located in present-day Lebanon and Syria. The Canaanites were the first Semitic peoples to occupy Canaan. Canaanites appear in the Hebrew Bible (the Old Testament in the Christian Bible) as the nation founded by Canaan, the son of Ham and grandson of Noah. Canaanites thought of themselves as a distinct political unit by the 18th century B.C.E.

The Israelites appeared in Canaan during the time recorded in the book of Genesis, which is impossible to pinpoint historically. The Old Testament patriarch Abraham was said to have lived in the city of Ur, in Mesopotamia, and to have moved his family to the land of Canaan. The book of Genesis tells of Abraham's pact with his god, in which his descendants were given the land of Canaan. Abraham's descendant Jacob, also called Israel, was the father of 12 sons with whom originated the 12 tribes of Israel. All of his family is said to have immigrated to Egypt during a famine. According to the Old Testament, the Israelites spent some 500 years in Egypt. At the end of this time the patriarch Moses led them

out of Egypt and back to Canaan after 40 years of wandering the desert in the Sinai region. At the beginning of this journey the Red Sea is said to have parted to allow the Israelites to pass through it and then closed upon the Egyptian army.

Historians are not at all sure that any of these events really happened. It is known that some Canaanite tribes lived in Egypt during the first half of the second millennium B.C.E. Some scholars have suggested that the Exodus from Egypt under Moses happened during the 13th century B.C.E. under Ramses II. Still, Egyptian archaeologists have announced that there is no physical evidence suggesting that the Red Sea parted.

If the Exodus did occur during the 13th century, the so-called Sea Peoples may have played a part in the events of the time. The Sea Peoples were a group of seafarers who wandered the eastern Mediterranean during the second millennium B.C.E. Their identities and origins are unknown. They may have come from Crete, the Aegean, southern Anatolia, or the coast of Lebanon and Israel. What is known is that there were numerous marauding seafarers roaming the eastern Mediterranean, especially during the late Bronze Age. Many of them ended up in Egypt after attempting to attack it and being captured during the reign of Ramses III (ca. 1194–ca. 1163 B.C.E.).

The Philistines may have belonged to the Sea Peoples. They moved into Canaan during the 12th century B.C.E. In about 1180 B.C.E. they took the southern Canaanite cities Gaza, Gath, Ashqelon, Ashdod, and Ekron. They appear not to have been Semitic peoples; in the Old Testament they are often described as “uncircumcised,” which differentiated them from Israelites. What little is known of their language seems to indicate that it was an Indo-European and not a Semitic language. Their culture seems to have shared some similarities with Mycenaean Greek culture, and Philistine pottery resembles Mycenaean work of that period. They may have belonged to the Sea Peoples. Some historians believe that the Egyptian pharaoh Ramses III imprisoned the Sea Peoples in Egypt and then settled the Philistines in southern Canaan, where he could tax them.

According to the biblical account, when the Israelites arrived back in Canaan, they found the land inhabited by Canaanites. They attacked and conquered several cities, including Jericho, Ai, and Hazor. Historians are unsure of what happened; if these events occurred in about 1200 B.C.E., they took place in a setting of general chaos and destruction at the end of the Bronze Age. The Sea Peoples and Philistines were active in the region and may have participated in the overthrow of the Canaanite cities.

In any case, the Israelites did move back into Canaan at some point, perhaps around 1200 B.C.E. They divided the land among the ancestral tribes. Around 920 B.C.E. the Hebrews divided into two kingdoms, Israel to the north and Judah to the south. The Babylonian captivity or the first diaspora, as it was called, came when Mesopotamian armies conquered Israel in 722 B.C.E. and Judah in 586 B.C.E. When Israel fell

to Assyria, the Assyrians attempted to move the Israelites en masse to Media. Many Israelites instead fled south into Judah, settling in the capital city of Jerusalem. The Assyrians moved their own people into Israel in an attempt to create a new noble class there.

In 586 B.C.E. Judah fell to Babylon. Much of the nobility was deported to the city of Babylon. Other Jews were enslaved and taken to Assyrian cities to work. Still others fled to Egypt, Persia, or Syria. In 539 B.C.E. the Persian emperor Cyrus conquered Babylon. He allowed the Jews in Babylon to go back to Jerusalem and surrounding areas. There they remained for the next six centuries. In 70 C.E., at the end of the first Jewish-Roman War, the emperor Titus destroyed the temple at Jerusalem and deported some 100,000 Jews to Rome as slaves. Many thousands of others fled the Levant to Mesopotamia and other nations in the Mediterranean region. In 135 C.E. Rome put down a revolt by some of the Jews remaining in Judea. Thereafter, Judea ceased to exist as a political entity, the province was renamed Syria-Palestine, and the Jewish people were dispersed from the region they considered their homeland. This is known as the second diaspora of the Jews.

PHOENICIANS

The Phoenicians occupied the coast of Lebanon between 1200 and 800 B.C.E. Historians have debated the origin of the Phoenician people for millennia. Some modern archaeologists believe that they were simply the descendants of previous Canaanite peoples who lived in the area. Other historians, including the Greek historian Herodotus, argue that the Phoenician people came to Lebanon from some other place, bringing with them their knowledge of the sea. Suggested places of origin include Minoan Crete, eastern Africa, or the land of the Philistines. Some historians believe that the Phoenicians learned their sailing skill from the Sea Peoples.

Wherever they came from, the Phoenician people spread their culture quite a distance. The Phoenician people were skilled traders and seamen. They sailed throughout the Mediterranean on galleys to sell their major products, chief of which was a deep purple dye known as Tyrian purple made from the murex snail. They built settlements along the entire southern coast of the Mediterranean as well as in Sicily, Sardinia, Cyprus, Crete, and Spain. Their most important settlement was Carthage in modern Tunisia, founded in 814 B.C.E. Other major cities included Tyre, Sidon, Tripoli, Hippo (in present-day Algeria) and Abdera (in modern-day Spain). They took with them an alphabet, which the Greeks adopted and later turned into the Greek alphabet, and the worship of a god called Baal.

The heyday of the Phoenicians ended with the rise of the Assyrians. The city of Tyre remained strong, and the Lebanese Phoenician population was concentrated there until 539 B.C.E. when Cyrus the Great conquered the city. Historians believe that many of the Phoenician people migrated to Carthage and the other Mediterranean colonies around that time.

ANATOLIA

Anatolia, modern-day Turkey, was fertile and heavily forested. During the seventh and sixth millennia B.C.E. many people settled on the banks of the Black Sea, then the Euxine Sea (or lake). People flocked to the coasts from surrounding areas, attracted by the rich soil. Around 5800 B.C.E. it appears that the lake flooded. This forced the inhabitants to flee to higher ground, either within Anatolia or in eastern Europe.

During the third millennium B.C.E. northern Anatolia was inhabited by a people called the Hattians, who spoke a non-Indo-European language. They were displaced by the Hittites, who appeared in Anatolia sometime around 2000 or 1900 B.C.E. Historians do not know where the Hittites came from, but it appears that their ancestors may have lived in the Ukraine during the previous two millennia. They were not a Semitic people, and they spoke an Indo-European language. They were excellent charioteers and skilled horsemen.

They created a capital at the city Hattusa, named after the earlier Hattian inhabitants. From there they spread throughout western Anatolia and the Levant. The Hittites arrived in Mesopotamia around 1600 B.C.E. Their arrival ended the Old Babylonian regime of the Amorites. At the height of the Hittite empire (1430–1180 B.C.E.) the Hittites encroached on Egyptian territory in Canaan. The Hittites traded with people throughout Mesopotamia. They depended particularly on Mesopotamian metal for their weapons and chariots and thus needed to keep control of Syria, which gave them access to the Euphrates and Tigris rivers. The Hittite empire collapsed in the 12th century B.C.E. amid the general chaos of the time. It may have fallen victim to assaults by the Sea Peoples.

The ancestors of the Lycians moved into southwestern Anatolia in prehistoric times. They spoke an Indo-European language called Lycian, which appears to have developed from an earlier Anatolian language called Luwian. The Lycians were allies of the Hittites and may have been related to them. The Lydian people also were related to the Hittites; Lydian was another Indo-European language of the Anatolian branch. They inhabited western Anatolia in the area of modern Izmir. The Phrygians are believed to have been part of the Sea Peoples. They moved into central Anatolia around 1200 B.C.E. and may have participated in the fighting that toppled the Hittite capital Hattusa. They inhabited this area through the rest of the ancient period.

HURRIANS AND HYKSOS

The Hurrians were a group of people who migrated into northern Mesopotamia from the Caucasus region around 2500 B.C.E. Their language was neither Semitic nor Indo-European but may have been related to other languages of the Caucasus. They established several small nations in southeastern Turkey and Syria and migrated far to the south, east, and west. During the second millennium B.C.E. there were Hurrians throughout Turkey, Mesopotamia, and the Levant. By about 1000 B.C.E., however, Hurrians had been assimilated into other ethnic groups and ceased to exist as a people.

The people known as the Hyksos rode south through the Levant and entered Egypt in the 17th century B.C.E. The traditional story has been that they invaded Egypt, but new interpretations of the evidence suggest that the Hyksos may simply have migrated to Egypt from Canaan without violence. Historians have long debated who the Hyksos were. They drove chariots and rode horses, like the Indo-European people from the Caucasus and Central Asia. They had Semitic names, like the Canaanites and Hebrews. Some historians think they were a mixture of Indo-Iranian peoples. They may have been Hurrians. Whoever they were, they ruled Egypt for about 100 years before being driven out. Many historians have tried to equate the departure of the Hyksos from Egypt into Canaan with the exodus of the Hebrews from Egypt under Moses, but there is no historical evidence for this.

DESERT NOMADS

The deserts of modern-day Arabia and Jordan were home to a number of nomads who moved freely throughout the Middle East. They often did not have permanent homes. Instead, they regularly migrated from place to place along standard trade routes. The Edomites were Semitic nomads who lived in the Negev Desert in Jordan and southern Israel. They certainly existed during the eighth century B.C.E. and may have been in the area as long as three centuries earlier than that. They supported themselves by running caravans to carry goods between Arabia, the Levant, Egypt, and Mesopotamia.

The Nabataeans lived in Jordan and Arabia. They were Semitic nomads who moved throughout the desert on trade routes between the Euphrates and the Red Sea. Some historians have suggested that the ancestors of the Nabataeans may have been in the desert during the time of the events in the biblical book of Genesis, but the first real documents mentioning them date to the fourth century B.C.E. The people called Arabs lived in Arabia and Sinai. The earliest mention of Arabs dates to 853 B.C.E. Assyrian records describe Arab queens who led tribes of caravan traders.

PERSIA

The Elamites created one of the earliest civilizations in Persia. They moved into western Persia around 3200 B.C.E. Their civilization was centered on the city Susa, which had been built around 4000 B.C.E. by even earlier inhabitants. The Elamites spoke a language that was not related to any of the surrounding languages, including Sumerian and the Semitic and Indo-European languages. Historians believe that the Elamite language may have been related to the Dravidian languages spoken by the earliest inhabitants of southern India. This could suggest that the Elamite people were descended from the people of the Indus Valley and migrated to Persia from what is now Pakistan, but there is no good evidence to prove this hypothesis.

The Persians were an Indo-Iranian (Aryan) people who migrated into Persia from central Asia during the second millennium B.C.E. These people split into two groups with

separate languages, the Persians and the Medes. Some of them intermarried with the Elamites. Around the ninth century B.C.E. the Persians occupied the land in southern Iran, southeast of the territory of the Elamites. The Medes took the land to the north, along the southern coast of the Caspian Sea. The Scythians, a nomadic people from Pontus, moved into Media in the seventh century B.C.E. The Scythians also spoke an Iranian language.

The Persians began to spread through Mesopotamia under Cyrus the Great, who unified Persia in 559 B.C.E. Under his leadership Persians moved into Media, Lydia in Asia Minor, parts of central Asia, and Babylon. Under his son Cambyses (r. 529–522 B.C.E.), Persians took over Egypt. Darius I (r. 522–486 B.C.E.) led Persian armies into the Indus River valley, Thrace, and all the way to Greece. Xerxes I (r. 486–465 B.C.E.) also led a Persian army into Greece. These Persian expeditions were populations of their own; Xerxes' forces may have numbered 60,000, which was a large number of people to move across the countryside.

Although the Persians usually allowed the inhabitants of their conquered lands to keep living in their homes, they also deported many of them to other places. Many Greek slaves ended up living in Persia. Persians themselves made new homes in conquered territories. Both of these phenomena facilitated the spread of cultures from place to place.

To the east of Media was the land of the Parthians. This land was occupied by horse-riding nomads from the Caucasus and Iran. They spoke an Indo-European language of the Iranian family. During the third century B.C.E. the Parthians used their cavalry to occupy most of northern Persia, Assyria, Babylonia, and Elam and moved east into Bactria.

ASIA AND THE PACIFIC

BY CRAIG G. R. BENJAMIN

The history of ancient Asia and the Pacific is characterized by migrations on an often vast scale, and in Asia by the interaction of those migrants with the sedentary agrarian settlements, kingdoms, and civilizations already established in the region. Ever since the evolution of *Homo erectus* some 1.6 million years ago (the first hominid to migrate out of Africa and into Asia) and certainly since the migration of groups of *Homo sapiens* out of Africa perhaps 100,000 years ago, the valleys, steppes, and desert tracks of Asia have acted as conduits along which successive waves of migrants have passed. In inner Asia the emphasis really was on passing through, at least until comparatively recently, because even in the more benign environments of the region the generally harsh climate and forbidding terrain often made permanent settlement difficult. The sporadic evidence available indicates that before approximately 50,000 years ago there were only occasional attempts to settle even the more hospitable regions around the fringes of the Inner Asian heartland.

However, by the Upper Paleolithic Era (about 40,000 to 50,000 years ago) more reliable archaeological evidence from

a large number of sites ranging from the Ukraine to eastern Siberia and southern Mongolia indicates the presence of substantial numbers of hunter-gatherers who had migrated into Inner Asia. In the millennia that followed, these communities gradually adopted a seminomadic, semisedentary way of life, so that by the middle of the fourth millennium B.C.E., subsequent waves of migrating pastoralists from the southern Russian steppes were confronted by semiagrarian communities already in occupation of the more fertile niches. Confrontations between aggressive, often militarized migrants and sedentary farmers generally progressed from invasion to occupation to cultural assimilation.

This tension between residents and invaders remained the fundamental dynamic of much of inner and eastern Asia during the pre- and protohistoric eras. There is evidence of periodic aggressive migrant activity right across the southern Siberian and Mongolian steppes from the first millennium B.C.E. until the Mongol invasions of the sedentary kingdoms of Eurasia during the 12th and 13th centuries. But it would be incorrect to suggest that all interactions between migrating pastoralists and farmers were necessarily confrontational, as there is also evidence of long periods of relatively stable, mutually cooperative relationships between the two.

The geography of Asia remained a crucial determinant. With the available routes for large-scale movement often limited by impassable deserts and high mountain ranges, it was inevitable that the migration of a group or tribe into any given area would affect other communities already occupying sites along those routes. Because of this, a second characteristic of ancient Asian migration was a domino effect whereby any substantial migration from one region to another would often result in the disruption of a whole series of other groups ahead of the invading tribes. It hardly mattered what the cause was of the original migration. Once a group had chosen (or been forced) to uproot and relocate, they had few options other than to follow a very limited range of possible routes, and this inevitably brought them into conflict with other communities already settled along the selected path. If the invading party was strong enough, the occupants were expelled, and they in turn moved ahead along the same route, disrupting and expelling other communities until each had found a new location in which to resettle, or achieved some compromise with the invaders.

PASTORALIST MIGRATION AND COLONIZATION IN THE BRONZE AGE

The most significant migrations in ancient Asian history were those undertaken by nomadic pastoralists speaking Indo-European and Indo-Iranian languages. These migrations were an indirect result of the appearance of agriculture in southwestern Asia from about 9000 B.C.E. A range of at least three alternative lifeways subsequently emerged over the following millennia. Certain communities embraced farming and became solely dependent on agricultural produce for their livelihood. Others remained nomadic hunter-gatherers

by migrating into areas outside of the sedentary zones, often following conflict over resources with the farmers. And yet others adopted elements of both lifeways, opting for the semi-sedentary, seminomadic lifeway of nomadic pastoralism.

Pastoralists (people who are dependent chiefly on their herds of domestic stock for subsistence) went on to play a major role in the history of ancient Asia. While sheep, goats, and cattle had all been domesticated from at least 6000 B.C.E., it was only when humans had learned to exploit the traction power of animals as well as their secondary products (including blood, milk, and hair), that they were able to extend their range by colonizing large areas of grassland otherwise unsuitable for sedentary agriculture.

The impact of migrating pastoralists on the Eurasian landscape was immediate and profound because of their military virtuosity and their capacity for rapid mobilization. Archaeological evidence indicates periods of considerable disruption in the steppes from at least the middle of the fourth millennium B.C.E., which can be explained only by the influx of migrating pastoral nomads into the region. Three waves of migration (ca. 3400–ca. 3200 B.C.E.; ca. 2600–ca. 2400 B.C.E.; and ca. 2000–ca. 1800 B.C.E.) can be detected, representing the invasion of Inner Asia by various groups of Indo-European and Indo-Iranian-speaking pastoral nomads.

Groups of nomads began to appear in western, central, southern, and eastern Asia from the mid-fourth millennium B.C.E. The speed of migration of the earliest pastoralist communities, whose horse-riding skills and equipment were probably rudimentary, was slow and gradual. There is evidence of widespread migratory episodes through the region by pastoralists with ox-drawn carts and powerful tribal leaders. The substantial number of ornamental metal objects discovered at steppe-land burial sites dating from the late fourth millennium B.C.E. is evidence of the arrival of powerful chiefs and aristocracies. If the region was indeed one of low population densities, the invading nomads would have occupied sparsely populated lands and easily expelled the residents.

But the impact of the Indo-European migrations varied considerably across ancient Asia, depending on the level of social and technological development already achieved in the occupied regions. Although the invaders were able to establish themselves as ruling aristocracies in Mesopotamia and across the Fertile Crescent in general, they were rapidly assimilated into the prevailing more advanced cultures. In the less-developed regions of inner Asia, however, it was the invaders who imposed their languages, culture, and social organization on the geopolitical landscape.

The nomadic invasions of Mesopotamia and Asia Minor between about 2500 and 1600 B.C.E. have been well documented. Groups such as the Kassites, the rulers of Mitanni, the Hurrians, the Luwians, and the Hittites all made a significant impact upon the sedentary urban-based states of the Fertile Crescent. The progress and effects of Indo-European migrations into central and eastern Asia are less well understood. Chronological disagreement between western and Russian ar-

chaeologists over the dating of Indo-European migrations is just one of the problems associated with the subject. But there is no disputing Russian archaeological evidence of nomadic invasions from the western steppes through southern Siberia and the former Soviet Republics of central Asia, extending progressively further east with each wave of migration.

These waves of pastoralist expansion can be followed by tracing the incidence and variety of barrows (called *kurgans* in Turkic) that mark the burial sites of the different nomadic migrant cultures. The so-called Kurgan theory argues that the earliest Indo-Europeans emerged in about 5000 B.C.E. in southern Russia (north of the Black and Caspian Seas), when hunter-gatherer populations gradually adopted both semi-sedentary agriculture and mobile stock herding. From here the Indo-Europeans migrated out to the west, south, and east in the three waves of Bronze Age migrations noted earlier.

Much of the archaeological evidence for the Early Bronze Age comes from the western steppes, particularly the pit-grave *yamnaya* pastoralist culture that flourished from between the Bug and Dniester rivers in the west to the Ural River. The pit-grave culture provides evidence of horse riding and the use of wheeled vehicles on the steppe that might have been vital in the logistics of mass migration, including both two-wheeled and four-wheeled wagons that were probably pulled by oxen. Many of the metal goods discovered in *yamnaya* sites, including daggers, axes, and maces, had been imported from agricultural metal-working zones, indicating that pastoralists, farmers, and artisans of the western steppes were already linked into a single regional system of exchanges as early as the mid-fourth millennium B.C.E.

By the Middle Bronze Age pastoral nomads had migrated farther to the east, occupying parts of southern Siberia and the central Asiatic steppes, driven perhaps by overpopulation in the western steppes or by climate change. The most significant pastoralist culture of the central and southern steppes is that of the Afanasevo (named after the site of Afanasyeva Gora excavated in 1920). Their cultural artifacts excavated from a number of burial sites show many similarities to those of the pit-grave cultures, suggesting that the Afanasevo culture was a product of pastoral nomadic migrants from the west combined with the assimilation of indigenous hunter-gatherer populations. The Afanasevo culture perhaps represents the most easterly extension of Asian steppe cultural migration. However, the movement may not have halted at the Altai but perhaps extended southward at some later date into the Gansu and Tarim Basin (present-day Xinjiang Province) of western China.

Linguistic and archaeological evidence also exists for an overlay of Indo-Iranian-speaking cultures upon the earlier Indo-European strata as well as the physical displacement of the Indo-European invaders. That there were two major Indo-European branch language groups spoken by the different groups of nomads is indisputable. By the Late Bronze Age (ca. 2000–ca. 1500 B.C.E.) there is evidence of further widespread disruption across the steppes, indicating a third

wave of large-scale migration, this time most probably by pastoral nomads speaking an Indo-Iranian branch. These later migrants occupied regions as far east as the western and southern regions of the Tarim Basin, wedging the earlier Indo-European migrants into eastern Xinjiang.

The steppe-bronze culture that emerged in the wake of this invasion is known as the Andronovo. The Andronovans lived in small, fortified villages and towns in large houses that were at least partly subterranean. Their economy was based on stockbreeding (cattle, sheep, goats, pigs and horses), and their way of life was one of mobile pastoralism with occasional periods of semisedentary agriculturalism. The immediate predecessor to the Andronovans was the Sintashta culture (ca. 2300–1900 B.C.E.), which was based in the southeastern Urals, particularly near modern Magnitogorsk. Associated with the emergence of both the Sintashta and subsequent Andronovo cultures was the appearance of many fortified settlements and royal burials with chariots, indicative perhaps of the troubled nature of this period.

However, the chariot did not make any significant military impact on ancient inner Asia. Although the introduction of the chariot transformed warfare in Southwest Asia and India, it was less practical in the steppes of central and East Asia and was replaced from about 1500 B.C.E. by more effective horse-riding archer warriors using compound bows. It was pastoral nomadic forces of this type that the Chinese Zhou and Han chroniclers later described when discussing the “barbarians” to China’s north, including the Wusun, Xiongnu, and Yuezhi.

The Andronovan culture continued to spread eastward through present-day Kazakhstan and into eastern central Asia. Archaeological evidence indicates the eventual existence of a dividing line that developed in Mongolia between both the Indo-European Afanasevan and Indo-Iranian Andronovan migrants from the west and the ethnic Proto-Mongolians in the east, representing the most easterly expansion of the migrants through northern Inner Asia by about 1800–1500 B.C.E. To the south, beyond the reach of Soviet and Russian archaeologists, the evidence is less plentiful, but both Indo-European and Indo-Iranian pastoral nomads must also have spread into the eastern steppes, particularly along already well-trodden routes through the Tarim Basin, until they were brought to a halt perhaps by the indigenous peoples who dwelt in eastern Mongolia and along China’s northwestern borders.

COLONIZATION OF THE BORDER REGIONS OF ANCIENT CHINA

From early in the 20th century explorers began finding mummified remains at a number of sites in the Tarim Basin. More recently several hundred such “mummies” (actually the remains of dried-out bodies) have been discovered in the region. The oldest of these corpses dates from about 2000 B.C.E. and the earliest Indo-European corpses from perhaps 1750 B.C.E., which suggests at the very least that from the Late Bronze Age

a significant and increasing proportion of the population of Xinjiang began to be of Indo-European/Caucasoid ethnicity. Many of the bodies have been subjected to DNA and textile analysis, but the results have been inconclusive.

Archaeological research into the prehistoric cultures of the Tarim Basin has provided evidence of a number of cultures, the earliest of which appears to be the Qawrighul (early second millennium B.C.E.), whose remains have been found about 50 miles west of Lop Nur. Mummies of the Yanbulaq culture (located near Hami and dated to about 1750–700 B.C.E.) were mainly of Mongoloid stock, though also found were eight Caucasoid types, which represent perhaps the oldest Europoid human remains so far discovered in the Tarim. The presence of three different grave types has led some researchers to suggest that this is evidence of the movement of Caucasoid migrants into a region in which Mongoloid populations had already established themselves from the east.

One possibility is that Afanasevo groups migrated south from their homeland in the Altai-Yenisei region. One branch headed toward the Huanghe River, where they may have interacted with the ethnic Chinese Qijia culture, and another moved southwest into the Gansu and Tarim areas. As noted earlier, subsequent migrations of Indo-Iranian-speaking nomads also entered the Tarim and established their languages on top of the earlier Indo-European dialects, but they were never able to achieve linguistic supremacy in the north and east, where Indo-European variants remained dominant. The obvious route for both the Indo-Europeans and Indo-Iranians was south through a mountainous funnel that opens up near Urumqi and which then offers passes to both the Dunhuang region of the Gansu or southwest into the Turpan Basin and the eastern Tarim.

At the same time that Indo-European groups were migrating south to take up residencies in the Gansu and Xinjiang sometime between the 18th and 17th centuries B.C.E., farther to the east and to the north of the main zones of irrigated agricultural communities along the valley of the Huanghe, large communities of Mongoloid nomads also began to emerge between the 18th and 12th centuries. These and other pastoral nomadic communities are listed in the chronicles of the Chinese Zhou Dynasty. Farther north again, in northern inner Asia and southern Siberia, the Karasuk culture replaced the Andronovo between the 13th and 10th centuries.

Evidence of the importance of livestock to the Karasuk indicates that they followed more mobile lifeways than did the Andronovans, though the discovery of large dugout dwellings in the Minusinsk basin also indicates the retention of a semisedentary way of life. The basin of Minusinsk is made up of undulating land on either side of the Yenisey River. It is one of the largest prehistoric graveyards in all of Eurasia, with numerous barrows having yielded vessels, amulets, and weapons. Archaeological evidence clearly shows that from the middle of the second millennium B.C.E. a succession of cultures and ethnicities occupied the region, each of which gradually adapted to a sedentary, agricultural way of life.

MIGRATION OF THE YUEZHI (TOCHARIANS) AND SAKA (SCYTHIANS)

The most significant Indo-European-speaking group that may have migrated into Xinjiang and the Gansu late in the Bronze Ages was the Yuezhi (also known as the Tocharians), who were destined to play a significant role in the history of ancient Asia. The ancestors of the Yuezhi were pastoral nomads who probably migrated to the eastern steppes during the Middle Bronze Age. They eventually found themselves sometime in the second millennium B.C.E. occupying a strategic part of the Gansu corridor, where they exercised some sort of commercial control over extensive areas of the Tarim Basin. Adopting a seminomadic, semisedentary lifestyle, they prospered through trade and achieved a considerable reputation amongst the Zhou and Han Chinese because of their wealth, prestige, and force of arms.

In the second century B.C.E., however, the Yuezhi were forced to move away from the borders of Han China by their rivals the Xiongnu (who may have been the ancestors of the Huns, militarized nomadic people whose fifth century C.E. migration to the west would play a critical role in the downfall of the Western Roman Empire). Leaving the Gansu in 162 B.C.E. and heading north into the Ili valley, they moved into a region already occupied by Saka peoples (also known as the Sai to the Chinese or the Scythians to Greco-Roman historians). As a result, these Ili basin Sakas were themselves displaced and forced to migrate to the south along the western edge of the Tarim Basin, before finally crossing into Kashmir. Here at least one group of Scythians would rule for up to 180 years, almost without interruption, until the reign of the last Indo-Scythian satrap of Kashmir, Zeionises.

The Indo-Scythians were eventually defeated by Kujula Kadphises, the first king of the Kushans, sometime soon after about 45–50 C.E. The Sakas then fragmented into a number of smaller statelike divisions and spilled out into the Punjab and northern India, establishing the significant Saka kingdoms, whose era in Indian history dates from 78 C.E. In this way events that unfolded along the borders of Han China early in the second century B.C.E. were directly responsible for significant developments in the history of ancient Central Asia and India well beyond the area of their immediate impact. The migration of the Ili basin Sakas that led eventually to the establishment of Saka kingdoms in northern India some 250 years later is a good example of the domino effect of migration in inner Asian geopolitics and of the critical role of migration in the history of ancient Asia.

Eventually, after passing through Ferghana and Sogdia, the Yuezhi defeated and evicted another resident group of Sakas, who may have been responsible for the conquest of the disintegrating Greek kingdom of Bactria. These displaced Saka tribes were forced south of the Hindu Kush, where they eventually resettled in Sacastan (present-day Sistān) sometime after 123 B.C.E. Some decades later (ca. 80 B.C.E.) the Yuezhi crossed the Amu Dar'ya en masse and occupied

Bactria, where they went on to establish the Kushan Empire (ca. 1–450 C.E.) which became major player in the Silk Roads trade during the first two centuries of the Common Era.

IMPACT OF THE ARYAN MIGRATIONS ON ANCIENT INDIA

The earliest evidence of human activity in India or Pakistan so far discovered goes back to the Second Interglacial Period between 400,000 and 200,000 B.C.E. The spectacular Indus Valley civilization was the most extensive prehistoric civilization of the region and dates from about 3000 B.C.E. It was preceded by an agrarian village culture in the Baluchistan hills and the Makran coast. The Harappan civilization was an urban-based state structure (similar to that which developed in the late fourth millennium in southern Mesopotamia), and its two principal cities of Mohenjo Daro and Harappa displayed an advanced sense of civic planning and organization. By the early second millennium B.C.E. the Indus civilization had declined, to be replaced from about 1500 by (probably) an invasion of migrating Indo-Iranians (sometimes called Aryans) from the north, part of the third wave of Bronze Age nomadic migrations noted previously. The Aryan (meaning “noble ones”) tribes were led by aggressive warrior aristocrats on horse-drawn chariots armed with good-quality copper and bronze weapons.

These Indo-Iranian invaders probably set out from their southern Russian homeland late in the third millennium but may have settled for some centuries in Bactria and the Iranian plateau before resuming their migration south through where the Hindu Kush passes into northern India. Our knowledge of Aryan culture is largely derived from the Rig-Veda and it is possible to trace, through geographical references in the Rig-Veda, the slow but certain progression of the Aryans from the Indus Valley down the western portions of the Ganges and its tributaries. After possibly playing a limited role in the decline of the Indus Valley civilization, the Aryans took up residence in the Punjab before eventually entering the Deccan and the Ganges Valley, home of the so-called Painted-Grey Ware culture (ca. 1100 to 500 B.C.E.)—agrarian communities based on the domestication of crops and animals.

The archaeological and literary record indicates that by the first half of the first millennium B.C.E. there are unmistakable signs of a superior technology arriving in both the Deccan and the Ganges Valley, evidence of the invasion of India proper by the Indo-Iranians, who soon abandoned pastoralism and also adopted an agrarian lifeway. By the sixth century B.C.E. monarchical states (like Kosala and Magadha) began to dominate the Ganges Valley, absorbing or establishing dominance over the smaller republican states of northern India and shifting the focus of Indian culture eastward, away from the valley of the Indus. The immediate aftermath of the Aryan invasions of the Deccan and Ganges Valley was a heroic age. It is to this age that the great Indian epic, the Mahabharata, refers in its description of a war between two rival coalitions of noble charioteers.

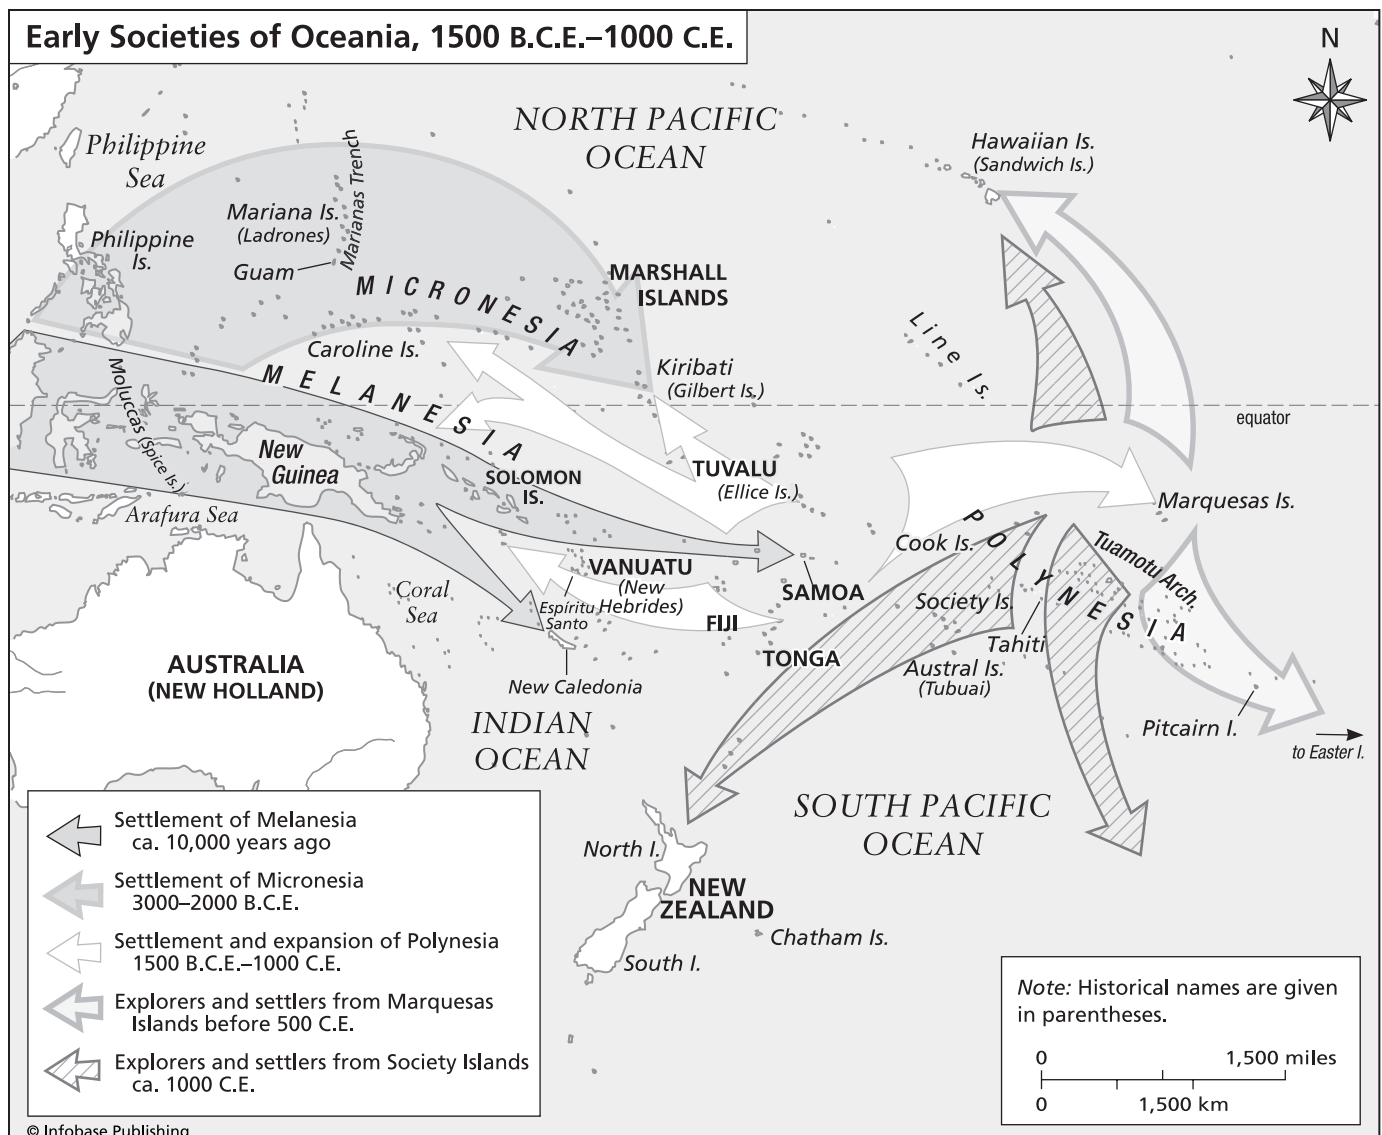

MIGRATION AND COLONIZATION OF THE ANCIENT PACIFIC

Turning from the Asian continent to the Pacific Ocean, the occupation of the islands of Hawaii is perhaps the most striking example of the extraordinary achievements of the Polynesian peoples, who are responsible for the colonization of a large number of isolated islands in the central Pacific. Over a period of approximately 2,500 years (from ca. 1500 B.C.E. to ca. 1000 C.E.) voyagers from Fiji, Tonga, and Samoa migrated to and colonized islands across an ocean area of millions of square miles. By the 16th century, when European navigators began to explore the Pacific, virtually all the habitable islands were already settled.

These maritime migrations were made in outrigger and double-hulled canoes built with stone, bone, and coral tools.

By alternately paddling or sailing (using sails woven from coconut or pandanus leaves) Polynesian migrants regularly completed voyages of more than 2,000 miles across the Pacific. Navigation was done by skilled mariners using observations based on ocean currents, winds, and the setting points of stars. Navigators also employed a system of dead reckoning, memorizing the distance and direction being traveled until the destination was reached.

When European explorers first arrived in the islands of Polynesia, it was immediately obvious that the Polynesian inhabitants must have shared a common ancestry. Island residents were similar in appearance, and their language, technologies, domesticated species, and cultures varied very little across thousands of miles of ocean area. It is now believed that all Polynesian peoples came from common an-

Among the peoples of ancient Oceania were the Polynesians, who colonized a large number of isolated islands in the central Pacific after 1500 B.C.E.

cestors who had developed a distinctive fishing and agrarian culture in the islands of Tonga and Samoa. There is also general agreement on a chronological sequence for the migration of the Polynesian peoples.

Archaeological evidence and DNA analysis suggest that early humans had migrated (by land and sea) to New Guinea and Australia by at least 60,000 years ago. In Australia these migrants maintained a hunter-gatherer way of life until the arrival of Europeans in the 17th and 18th centuries, but in New Guinea several groups adopted an agrarian lifestyle. From about 1600 B.C.E. members of the so-called Lapita culture began to migrate from New Guinea in Melanesia farther east to Fiji, Samoa, and Tonga, and it was at the eastern edge of this region (that is, in Samoa and Tonga) that a distinctive Polynesian culture emerged.

By about 300 B.C.E. migrants from Samoa and Tonga had discovered and colonized several island groups farther to the east, including the Cook Islands, Tahiti-nui, and Hiva (or the Marquesas). Some 600 years later (by 300 C.E.) migrants from (probably) the Marquesas discovered and settled Easter Island, and sometime within the next century (by ca. 400 C.E.) voyagers from the Cook Islands, Tahiti-nui, and the Marquesas discovered and colonized Hawaii. The final wave of Polynesian migration and colonization took place sometime between 800 and 1000, when groups of migrants from the Society Islands or the Cook Islands settled Aotearoa (New Zealand).

The pattern of migration outlined here is supported by ethnobotanical evidence, particularly through the incidence and spread of different plants (taro, breadfruit, banana, coconut, and sweet potato) and animals (pig, dog, chicken) from the western Pacific through central Polynesia and on to Hawaii. Linguistic evidence also supports the direction and dates of the migratory pattern, with the Hawaiian language being closely related to the Marquesan language (proto-Central Eastern Polynesian). Both languages also share similar phonological changes from Proto-Central Eastern Polynesian (the hypothetical original language). Computer simulations likewise support the idea that Hawaii was settled by migrants from the Marquesas, as does archaeology; artifacts found at early Hawaiian sites are very similar to those found in the Marquesas. The colonization of the islands of the Pacific by Polynesian maritime peoples remains one of the most extraordinary examples of long-distance migration in human history.

EUROPE

BY SUSAN MALIN-BOYCE

Human migration is the term used for both voluntary and involuntary population movements. Throughout prehistory and into the modern era people have chosen to relocate, have left their land and homes under duress, or have been traded as slaves. For prehistoric migrations it is generally impossible to ascertain whether movement was elected or forced. Recon-

structing the timing of migrations and numbers of migrants is also largely unachievable. Even a massive movement of peoples leaves almost no trace for archaeologists to recover. Therefore, migration is generally inferred from patterns of resettlement, the appearance of new subsistence regimes, and the widespread distributions of new technologies. The bulk of the evidence for change is interpreted from the analysis of material remains. For prehistoric Europe early migratory expansion populated regions that had never been occupied by people. These colonization episodes are frequently identified by such data as the first appearance of tools or settlement traces and in rare cases by burials. Later events are marked by dramatic changes in material culture, and debate is frequently focused on the mechanism of these apparent material and social transformations. Analogy is used to infer the scale and form of ideological conquest or social emulation. Historical migrations provide ample material for explanations that rely on analogy.

Causes that contributed to prehistoric migrations are various and sometimes appear contradictory. They included environmental factors such as climate changes caused by glacial advance and retreat or by drought. Warfare was another primary vector of change, forcing the abandonment of whole regions in advance of warring armies, such as the Huns by 395 C.E. Wars also attracted mercenaries, and eligible members of populations frequently went to war for the potential rewards—the plunder used to compensate armed volunteers. Mercenaries may have left an area in large numbers, as in the Marne region during the first historical migration of the Celts around 400 B.C.E.

Trade is an equally attractive draw for people who have had access to certain commodities. When a trade infrastructure is disrupted and the flow of goods stops, large groups of people may go in search of resupply. The sack of Rome around 390 B.C.E. may be attributable to such motivations. During the protohistoric period—the period during which firsthand and secondhand accounts were written by literate peoples about events involving preliterate populations—there is evidence that groups sometimes migrated seasonally, probably to alleviate subsistence pressure on their home territories. In these cases warring parties crossed into regions controlled by other groups and pillaged or extorted provisions on a temporary basis. Harassment of the resident population ceased when the interlopers were routed in combat or bought off. For mass movements such as the spread of agriculture or early migrations from Africa, combinations of factors both pushed and pulled people into and across Europe. In the examples provided here these factors are explored based on the archaeological record and accompanying anthropological theory.

Several major migration events are presented using a somewhat arbitrary two-part classification scheme: first, migrations that colonized Europe, and second, migrations that transformed preexisting social organizations via the introduction of new technologies or ideologies. Even within this simple bi-partite scheme there is overlap. The movement of *Homo*

sapiens neanderthalensis into Europe and the replacement of that population by modern *Homo sapiens sapiens*, along with the encroachment on hunter-gatherers and herder-horticulturalists by agriculturalists, were colonizing episodes. These population movements extended across vast territories and occurred over many thousands of years. The social reorganization of the metal ages and corresponding Urnfield/Celtic migrations were part of a process during which societies ruled by chiefs developed an increasingly centralized authority. Finally, the migrations of Germans and Huns that precipitated the eventual decline of the Roman Empire were part of a series of strategically directed migration events targeting people and places with more wealth and resources than the migrating forces controlled. It is significant that migration in prehistory frequently served very different purposes than it does today. Many populations prided themselves on their mobility, and movement over vast distances was not necessarily perceived as a hardship. For the brief historic period from about 400 B.C.E. until 400 C.E., this model of migration as a socioeconomic opportunity is well illustrated.

Several models have been developed to account for the successive episodes of population increase following glacial maximums (times of maximum extent of ice sheets), during which people and other animals were restricted to areas with microclimates that allowed survival. Human populations appear to have increased during these episodes, as can be seen in the example provided by the Dordogne region in western France. Cave sites and rock shelters there attest to the presence of concentrated populations in the deeply eroded river valleys that provided a refuge from the glacial advance. During the warmer interstadials (a short period of relatively warmer climate within an ice age) people left the area, again following the grazing ungulates (mammals with hooves). The success of these groups frequently depended on their ability to anticipate and plan ahead, using tool-making technologies and food-storage facilities that ensured group survival. Throughout the period that hunter-gatherers occupied Europe they continued to migrate. Even in areas where settlement first appears—typically coastal settings with abundant resources—transhumance, or the seasonal movement of people between grazing lands) is evident. Regular movement occurred between summer and winter camps, where access to different resources promoted dietary variability and intergroup dependence.

THE DOMESTICATION OF EUROPE

The spread of agriculture and animal domestication is a colonizing process that established largely sedentary communities across temperate Europe beginning as early as 7000 B.C.E. This expansionist movement emerged out of the Levant and migrated north and east into western, central, and eastern Europe. According to one theory, the diffusion of farming communities—whose subsistence economy was based on wheat and barley, along with sheep, goats, cattle, and pigs—spread like a wave geographically and over time. Farming com-

munities were established from Hungary to Scandinavia in less than 2,000 years, beginning around 5600 B.C.E. Another model used to explain this distribution relies on the division of communities, with steady movement into optimal farming and grazing territories away from other farmers.

The Linear Pottery culture (also called Linearbandkeramik, or LBK), named for its distinctive pottery, is the culture associated with the beginning of the Neolithic and the spread of farming and animal husbandry into areas formerly occupied by hunter-gatherers and herder-horticulturalists (ca. 5500–4500 B.C.E.). Chemical analyses of teeth and bones confirm a relatively high rate of immigration for the Rhineland in Germany well into the Middle LBK Period, and the demography and numbers of immigrants diminished by the Late LBK Period. Evidence from this research project also suggests a high degree of mobility within the region.

People who occupied environmental zones that attracted farmers, such as the loess belt (an area of fine-grained soil suitable for cultivation), were eventually forced to change their course of seasonal migration or were incorporated into the new subsistence system. While the coexistence between groups with differing lifestyles was probably beneficial at a time when regions were sparsely populated, the practice of land clearance for farming may eventually have threatened wild populations of animals upon whom the nomads depended. Evidence from coastal Scandinavia demonstrates not only a shift to the domesticated economy but also a subsequent rejection of wild sea species that had previously dominated local diets. In these areas of settlement continuity, from the Mesolithic to the Neolithic, migration probably played a less determinative role in subsistence strategies. Dependence on domesticated species became pervasive, however, and human migration was the mechanism by which plant and animal domestication initially transformed European populations.

THE INDO-EUROPEAN EXPANSION

The Indo-Iranian, Indo-Aryan, and Indo-European migrations describe the movement of language groups, technologies, and ideas that have been interpreted as a sign of massive population shifts. Competing hypotheses outline the mechanisms for this transformation of European cultures. One model suggests that the expansion developed at around 2000 B.C.E. during the terminal Neolithic Period. In this model warrior societies, whose technologies included horsemanship and bronze metallurgy, diffused in waves from the steppes that crossed Europe and Asia to dominate agriculturalists. Community subsistence in the affected areas continued to be based on agriculture and animal management, but economic strategies were supplemented with metallurgy and a form of petty warfare that was maintained through an elaborate social hierarchy by an increasingly elite warrior class. Linguistic evidence links this expansion with agricultural subsistence technologies from an origin in Anatolia.

The impact of peoples from the steppes was felt across Europe as they made forays into neighboring regions to con-

duct petty warfare. The transmission of steppe material culture and ideals was partly a result of conquest and partly from peaceful trade, adoption, and emulation. Steppe cultures were mobile, engaged in a nomadic lifestyle in which they raised horses, cows, sheep, and goats and depended on raiding and trading to acquire grain and other staples not produced within their own communities. Technologies that included the composite bow and mounted-horse warfare made the steppe raiders nearly impossible to subdue. As theirs was an extremely successful way of life, the duration of their impact and influence was thousands of years. The replacement of these groups from the steppes by subsequent migrants from the south and east continued from an initial cultural development in the Ukraine well into the historic period. Mediterranean cultures and Celtic cultures were profoundly influenced by Scythians by about 500 B.C.E., and Scythians and Sarmatians, both Indo-Aryan-descended cultures, are described by the Greek historian Herodotus at about 440 B.C.E. in his firsthand accounts.

THE BRONZE AGE REORGANIZATION AND HISTORIC CELTIC MIGRATIONS

As it was with the initial spread of agriculture, all of Europe was eventually transformed by the horse riders. The difficulty for archaeologists is in determining the roles to ascribe to conquest and to emulation. Evidence for the adoption and adaptation of materials and ideas does not necessarily mean that force was the primary mechanism of change. The elite transmission of ideas and technologies is sufficiently top down in its influence that only a very few individuals need to be impressed by the efficacy of a weapon or material, such as bronze, to ensure its adoption within the community and eventually throughout the region.

The proto-Celtic expansion seems to have occurred during the Urnfield Period (ca. 1300–ca. 750 B.C.E.) of the Late Bronze Age and to have changed the landscape of central and western Europe by about 1100 B.C.E. An increase in the number of small settlements across Europe suggests a rapid influx of people who brought with them the technological and ideological elements first seen on the Eurasian steppes. From areas such as the Rhineland and Switzerland into France, the pattern of technological and cultural dissemination appears to have expanded almost like a pulse. The development of Celtic culture is now thought to have taken place within the areas of the Rhineland and the Marne as an indigenous expression of sociopolitical change. Artistic styles from the La Tène region, which are the hallmark of Celtic culture, demonstrate an association with Scythians and Mediterranean peoples.

Relations between Celts and their neighbors probably promoted migrations such as the first historical migration that began sometime around 400 B.C.E. This movement reached Rome to terrorize its urban population nearly a decade later, following the battle of Allia in 387 B.C.E. The impact of the Celts' looting of the city lingered with the Romans long after the Celts had been supplicated with a ransom and had re-

turned to Gaul. At issue for this multicomponent movement of people are its causes. Whole regions seem to have emptied of those who were suitably equipped and fit to fight. In the Champagne region there was a dramatic decrease in warrior burials, suggesting that the warrior class left their communities and migrated south for plunder. Depopulation is also evident from settlements in Burgundy and throughout southern Germany. Classical sources, such as those of the Roman historian Livy (59 B.C.E.–17 C.E.), recorded events surrounding the invasion of the Italian peninsula and the sack of Rome several centuries after they had occurred. In Livy's account, along with that of the Greek scholar Dionysius of Halicarnassus (fl. ca. 20 B.C.E.) and the Greek geographer Strabo (ca. 64 B.C.E.–after 23 C.E.), the Celts were drawn south in search of plunder that included exotic produce. Olive oil, figs, and wine had been traded up the Rhône corridor for several hundred years. Access to these riches ranked highly as a motivator for migration.

An example of a well-documented historic migration appears in Julius Caesar's *Commentarii de bello Gallico* (Commentaries on the Gallic War), his self-serving account of his campaigns in France. Caesar fought the Helvetii in 58 B.C.E., and in his commentaries he describes the process and objective of that group's migration. According to Caesar, their motive for migration was to acquire territory through the conquest of Gaul. Once the decision to migrate had been made, three years was allocated as the time for preparation, and an individual named Orgetorix (fl. first century C.E.) was given the responsibility of organizing the movement. Orgetorix developed an alliance with members of the Sequani and Aedui in an effort to further his own cause; the conspiracy backfired, resulting in his demise.

The Helvetii chose to carry out the migration anyway and established a date to gather for the proposed move. They were joined in their journey by members of other Celtic groups, including the Boii, all of whom had set fire to their own villages and towns to discourage anyone from staying behind. At issue was the path of migration into Gaul; there were only two options, and one led south through a Roman province that was protected by Caesar. Eventually Caesar turned the migrants back to their formerly held territory. Caesar makes it clear in his account that he wished the Helvetii to remain in their own lands lest the empty area become occupied by Germans, who would readily have moved into the fertile vacated zone between the Alps and the Roman province.

GERMANIC MIGRATIONS AND THE HUNS, GOTHs, AND VISIGOTHS

Like the Celts before them, German tribes placed tremendous pressure on Roman provincial administrators in Gaul and northern Italy. Roman commentary on the Germans appears in Caesar's works and in the descriptions of the Roman historian Cornelius Tacitus (ca. 56 C.E.–ca. 120 C.E.) in *Germania*, written 150 years later, in 98 C.E. Tacitus provides information on German social organization, primarily with respect

to the attitudes and behaviors of warriors. According to Tacitus, Germans held land based on social status, councils met regularly, leaders may have been elected for life, and landless warriors attached themselves to particularly effective chiefs in anticipation of the glory and spoils of battle. A pithy quote tells how spiritless it is to toil over a plow when one's needs could be met by the loss of a little blood.

In Caesar's time land was not held privately, and agriculture was deemphasized in favor of pastoralism. Animals were often acquired through raiding, and warfare was endemic. Roman coinage provides clues to the pressures that warfare placed upon the empire. Coins were a widely distributed medium of communication that leave little doubt that the Romans felt a continual need to reinforce the image of victory over German peoples in commemorative issues for individual Roman leaders and, in some cases, for specific conflicts. Most images of Germans depicted on coinage were of bound and subjugated Germans, both male and female. Often when the images of German people were absent, they were represented by their distinctive weaponry.

In the account of Caesar's meeting with the German chief Ariovistus (fl. ca. 71–58 B.C.E.), who was spending the summer in lands held by the Celtic Sequani near the Seine, Caesar indicates that the Germans had been joined by a number of other groups, all of them eager to take advantage of the seasonal fruits extracted from the harassed Sequani. Ariovistus had led his people into the region to reduce stress on the valuable resources of his home territory across the Rhine River. He boasted that his undefeated people were superior to Caesar's own soldiers in courage and pointed out that their skill with weapons had enabled them to avoid living under a roof for 14 years. Caesar ultimately interceded with force, defeating Ariovistus and his multitribal army and pushing them back across the Rhine, but the account promotes an understanding of the Germans' esteem for independence and for the role of mobility in maintaining it.

The movement of waves of Germans marks the beginning of a period of migration that started around 300 C.E. and continued well past the collapse of the Roman Empire. Extraordinary disruption, both internal to the imperial Roman provinces and external among various Germanic groups competing for resources, may have favored the most aggressive or persuasive warriors, and tribal or group affiliation appears relatively fluid, depending upon the motivations and objectives of the group members. Entry into temporary alliances between otherwise competitive groups was facilitated by common cultural referents that promoted petty warfare as an economic strategy and by the Germanic warrior-class ideology. This type of economic base differed dramatically from the Roman system of agrarian estates and town markets that immediately preceded it.

Breaches of the frontier by migrating peoples cut swaths into imperial territory, further decimating the Roman system of distribution and communication. The initial phases of German resettlement, the mechanism by which one group

successfully replaced another on the landscape, can be said to follow models proposed for Britain: that is, a complex combination of internal uprisings against a crumbling Roman regime coupled with continual external assaults by groups of people attempting to be incorporated into the various systems, whether for trade, general access to goods, relative stability and security, or access to land. There seem to have been many reasons for migrating people to try to get into Roman-held regions.

Germanic peoples who migrated into Roman-controlled territories included groups such as the Friedenhain-Prestovice from Bohemia, the present-day Czech Republic and Slovakia, who had been on the Roman payroll in defense of towns on the Danube and were settled before the withdrawal of Roman forces from Raetia. Moving westward, the Alamanni or Swabians occupied the area of present-day Switzerland, the German state of Baden-Württemberg, and the Bavarian administrative district of Swabia. The Bavarii, also identified as Boioarians (again from Bohemia), occupied southeastern Bavaria and Austria, having moved into territory vacated by the Ostrogoths. These peoples were associated with the Marcomanni and with the Celtic Boii from Bohemia. They appear to have been forced west into Raetia under pressure from Czechs in Bohemia, who were being pressed by Serbs and Slavs. All of these groups were moving westward in advance of the Huns, who had reached the Danube in 376 C.E.
