The period of stress and resettlement lasted for several centuries. Changes apparent from the archaeological record indicate a pattern of settlement, conquest, and consolidation and the development of tribal coalitions that, in some ways, are differentiated between central and western Europe. In the first place, the degree of Romanization in eastern-central Europe appears to have been less tenacious than farther west in Gaul and East Anglia. In the second, the demographic structure of the resettled populations is more varied. The collapse of the Roman estates happened relatively quickly. This can be seen in examples such as that provided by the Gutshof (a private farmstead or estate) at Nördlingen, a site of Alamanni conquest in Schwaben, where the Roman-style estate was gutted and a large German wooden house was constructed in the middle of the complex between the ruined Roman structures. In addition to the relative weakness of institutionalized Roman systems in place by the mid-fourth century C.E., the demographic breakdown for Austria, Germany, Switzerland, and France differs from that of Anglo-Saxon Britain in models are accurate that assert that invading forces in Britain were predominantly male. Burial evidence for other parts of Europe demonstrates an inclusive population.

GREECE

BY JEFFREY S. CARNES

What is now mainland Greece was settled during the early Neolithic Era (ca. 7000 B.C.E.) by peoples about whom little is known. The arrival of Greek speakers came considerably

later, during the Bronze Age (ca. 4000–1100 B.C.E.), as part of the great expansion of Indo-European language speakers from their original homeland. The location of this homeland has been the object of much speculation, but most linguists would now locate it in central Asia, in the vicinity of the Caspian Sea.

The process of migration and diffusion must have been a gradual one, with the original Proto-Indo-European language changing into its various daughter languages along the way, so that the settlers arriving in Greece will have spoken some early form of Greek. Their arrival came most probably via Anatolia (modern-day Turkey), though it does not seem to have had an immediate effect on the culture or political organization of the region. Rather, the Minoan civilization on Crete, which comprised non-Greek speakers, continued to dominate the Aegean until the rise of the Mycenaean civilization on the Greek mainland starting about 1600 B.C.E. The downfall of Mycenaean civilization (ca. 1100 B.C.E.) was the last in a series of Bronze Age dislocations, causing a cycle of expansion and contraction of populations, with larger states alternating with smaller village settlements and more primitive economies. It was after the collapse of the Mycenaean civilization that Greek speakers (evidently fleeing chaos in Attica on the mainland) first settled Ionia, the region consisting of the islands and coastal areas of the eastern Aegean.

The Greeks' own views of this process were rather different; while they were historically inaccurate, they are well worth examining for the light they shed on how they perceived later population shifts in the historical period (particularly colonization). Thucydides lays out a standard narrative in the opening chapters of his *History of the Peloponnesian War*: that the population of Achaeans (in the northwestern part of the Peloponnese) were conquered by Dorian invaders coming in from the north. This Dorian invasion was dated to sometime shortly after the end of the Trojan War (ca. 1200 B.C.E.) and was said to be the origin of the dominance of Doric-speaking Greeks (such as the Argives and Spartans) in the Peloponnese. The invaders were said to be the sons of the hero Hercules (Heracles), whose persecutor Eurystheus kept them from returning; after a failed attempt and a lapse of a hundred years, their descendants succeeded. During their time of exile they were given aid by the Athenians, which became a commonplace in Athenian mythic propaganda during the time of greatest hostility to Sparta in the fifth century B.C.E. The archaeological record for the region does suggest a shift in population but in about 900 B.C.E., considerably too late to match the chronology handed down in the literary sources.

A similar mythologizing of the historical record may be found in the case of the Ionian migration. The settlement of Ionia after the apparent chaos following the collapse of Mycenaean power was also considered the result of the Dorian invasion. The Athenians, however, claimed that they were the ancestors of all Ionians, who were descended from an Athenian named Ion. For modern historians there is clearly some

connection between Athens and the Ionians: Their dialects are closely related, and they share certain social structures and religious customs. Yet the story in fifth-century Athenian sources is clearly designed to assert the primacy of Athens over Ionian Greeks at a time when the Ionians were the allies (or subject states) in the Athenian naval empire known as the Delian League. The Athenians, by contrast, portrayed themselves as autochthonous: that is, as never having come from anywhere else and in fact being literally sprung from the soil of Athens. (The word *autochthon* means “of the land itself” and could literally refer to origin from the soil, or to a claim to have been in a particular place since time immemorial.) Migration was viewed as a strong negative in mythic terms: To have always been in the same location not only gave a particular people an inalienable claim to their native land but also allowed them to claim inherent superiority to “latecomers.” There was a tendency for Greek cities to invent myths of origin tying them to the land: The name Pelasgian, used to refer to the pre-Greek inhabitants of Greece, came in some places to be synonymous with *autochthon*, and a hero Pelasgus was invented accordingly.

COLONIZATION IN THE ARCHAIC AGE

From approximately 734 to 580 B.C.E. the Greek world underwent a tremendous expansion, with the foundation of dozens of new Greek-speaking cities along the shores of the Mediterranean and the Black Sea. In understanding this process of colonization, the lens of modern colonialism and the ideological biases of the ancient sources themselves must be avoided. Greek colonization in the Archaic Age was not generally an attempt to expand political influence or a means of conquering a distant territory with a view to exploiting its labor and natural resources for the benefit of the mother country. Rather, it consisted of a series of independently motivated decisions to found cities elsewhere, caused by a desire for advantages in overseas trade, by the desire for more and better land, or as the result of population pressures or political strife at home. And just as “Greece” is largely an abstract concept, a way of describing the cultural identity of a vast number of independent poleis (city-states), so, too, is “Greek colonization” an abstraction, one which suggests unity in what was actually a diverse set of phenomena.

There were two basic types of Greek colony: the *emporion* and the *apoikia*. *Emporion* is the Greek word for “market,” and such colonies were in essence trading outposts, with no claim to polis status and relatively loose ties to the cities that founded them. *Emporia* were often jointly established by more than one polis. By contrast, an *apoikia* was an entirely new and independent polis, laid out according to certain specific rules. Settlers in *emporion* presumably remained citizens of their home cities; in an *apoikia* the settlers became citizens of the new settlement.

Greek long-distance trade throughout the Mediterranean dates from the Mycenaean era, but the first evidence of trading outposts dates to about 800 B.C.E., on the island of

Pithecusae (modern-day Ischia, in the Bay of Naples). Historical sources say that it was settled by traders from Chalcis and Eretria, from the island of Euboea just off the coast of mainland Greece. Its population was probably several thousand. Substantial archaeological remains reveal not only a settled city core but also outlying industrial districts devoted to metalworking and pottery production (both of which were Euboean specialties). Its location gave excellent access to Italy, Sicily, and the western Mediterranean, and given its size and degree of organization, it has been suggested that Pithecusae served as a sort of “protocolony,” a model for the settlements founded under more formal auspices a quarter century later. It is presumably no coincidence that Chalcis and Eretria were among the leading cities in the establishment of such *apoikiai*.

Other *emporía* were more clearly limited to trade. The most important of these was Naucratis, on the banks of the Nile some 50 miles inland from the coast. Founded in about 630 B.C.E. by Miletus (an Ionian city on the coast of Asia Minor), it welcomed traders from all Greek cities, as evidenced by the foundation of a Hellenion (pan-Greek temple) in the mid-sixth century B.C.E. Any ambitions it may have had of attaining polis status were kept in check by the pharaoh, and in fact it seems to have become a polis after Alexander’s conquest of Egypt. Similarly, the *emporion* at El Minya (the ancient name is unknown) existed for many years without becoming a polis, despite being an apparently important rival to nearby Phoenician trading centers along the Levantine coast. More remote settlements, such as the Black Sea *emporion* described by Herodotus as a center for trade with the Scythians, also failed to attain polis status.

Colonies in the more formal sense, *apoikiai*, start to show up in the late eighth century. The earliest known colonies are Corcyra (modern-day Corfu, off the western coast of mainland Greece), founded sometime before 734 B.C.E., and Cumae, on the Bay of Naples, founded by the Chalcidians apparently before 725 B.C.E. Corcyra, an Eritrean foundation, lay on the sea route between Greece and southern Italy; Cumae’s location was due to the success of nearby Pithecusae. Thus the earliest known colonies were founded by cities that had already participated heavily in *emporía* and in locations particularly advantageous for trade. Still, trade itself is not enough to explain the foundation of *apoikiai*. The traditional explanation for the wave of colonization is that a surge in population put too great a strain on the resources of mainland Greece and that colonists fled in search of land that was not only more abundant but also more fertile. In fact, both trade and population pressure played a part in motivating colonization, as did other factors, such as the political interests of the cities involved, the desire of some individuals to earn the glory accorded to *oikistai* (founders of colonies), and the commercial and military value of controlling strategic locations such as the Bosphorus and the Straits of Messina.

The course of Greek geographical expansion is easy to trace. Chalcis took the lead in colonizing Sicily, with founda-

tions at Naxos (not to be confused with the island of the same name), Leontini, and Catania, all on the southeastern part of the island; colonies at Zancle and Rhegium gave them control of the Straits of Messina. These were just the first of many foundations on the Italian peninsula: Sybaris, Croton, Paestum, and Tarentum are particularly worthy of mention. The Greek presence in southern Italy was so significant that the region later came to be known as Magna Graecia (“Large Greece”; the name sometimes included Sicily as well).

Other colonies of Chalcis and Eretria were closer to home. The large peninsula on the north shore of the Aegean became known as Chalcidice because of its numerous Chalcidian foundations, including Methone, formed for the refugees from Corcyra, who had been expelled in 733 B.C.E. when Corinth founded a colony there. Thus, even in the earliest days of colonization, rivalries and competition for land could be fierce. Corinth and its neighbor Megara continued their rivalry overseas. In 733 B.C.E. Corinth founded Syracuse, which became the most powerful of the Greek colonies thanks in part to its excellent natural harbor. Five years later Megara founded Megara Hyblaea some 15 miles to the north, a distance very nearly equal to that separating the two mother cities. (The rivalry ended 250 years later when Syracuse destroyed Megara Hyblaea.) Expansion westward into Sicily led to the foundation of Acragas and Selinus, whose prosperity is shown by the magnificent Doric temples that still remain. Both of these were “daughter-foundations”; that is, they were founded by cities that were themselves colonies. (The practice went back to the earliest days of colonization: Zancle was founded in part by Cumae.)

The Megarians also had success in the east, establishing colonies at Chalcedon and Byzantium, which gave them control of access to the Black Sea. Miletus, on the coast of Asia Minor, is said to have founded cities along the coast and along the shores of the Black Sea as far north as the Danube. Farther west, the Phocaeans founded colonies in France and Spain, including Massilia, Nicaea, and Antipolis (present-day Marseille, Nice, and Antibes), while Thera established Cyrene on the North African coast (in modern-day Libya).

The great age of colonization ended by 580 B.C.E., by which time most of the easily colonizable areas had been taken. (Some areas were too remote, while others were inconveniently dominated by Etruscans, Carthaginians, Egyptians, or Persians. The fact that Rome was in its infancy allowed the formation of Magna Graecia.) The major players in the colonization process were not then the great powers of the fifth century B.C.E.: Athens and Thebes had no overseas colonies, Sparta only one (Tarentum, in the arch of the Italian boot).

The procedures for setting up an *apoikia* were well defined, probably dating back to the earliest years of colonization. The first step was the appointment of an *oikistes* (city founder), who would lead the expedition and was responsible for establishing temples to the gods, for naming the city, and for distributing the land. (Equal shares of land seem to have been the norm, even in colonies founded by oligarchic states.)

Typically the *oikistes* was revered by future generations and received heroic honors (that is, he attained a semidivine status and was the object of civic worship).

City foundation was steeped in ritual. There was first of all the necessity of consulting the oracle of Apollo at Delphi, which might give advice on the proper location for the city (though many of the oracles that have come down to us in the literary sources are forgeries). Delphi was also charged with settling disputes that might have arisen, including deciding who the *oikistes* should be. In many cases Apollo himself was considered an *oikistes* and was worshipped in the Sicilian colony of Naxos under the cult title Archegetes (city founder). According to Thucydides, this shrine was much revered by colonists of all cities. There is perhaps a sense in which the colonization movement, by bringing the citizens of various Greek-speaking cities into proximity with other cultures (who were, not surprisingly, often hostile to new settlers), helped establish a sense of common Greek identity. In addition, the age of colonization coincides with the development of the polis, and the foundation of colonies may be seen as a series of experiments in how to govern a state.

A colony was expected to maintain close relations with its metropolis (literally, “mother city”), symbolized in the first instance by the sending of the sacred hearth fire from the metropolis along on the founding expedition. The foundation document of Cyrene specifies the oaths to be sworn by both sides, which oblige the settlers not to return home (this colony was founded because of population pressures) and which commit the metropolis, Thira, to come to the aid of its colony. Such obligations could be of extremely long duration: Thucydides shows the city of Epidamnus in 431 B.C.E. appealing for help to its metropolis of Corcyra; when rebuffed, they carried the appeal to Corinth, which had founded Corcyra 300 years earlier. Thucydides lists a number of instances where colonies fought against their metropoleis. His point is that such instances were rare and noteworthy. Syracuse thus found itself opposed to Athens in the Peloponnesian War because of its ancestral tie to Corinth, despite the fact that it shared with Athens a democratic constitution. The colonial relation outweighed political ideology.

The motives for individuals to join colonial expeditions must have varied greatly. In addition to the obvious financial and personal motives (grants of land, adventure, and the chance for a fresh start), in some cases political strife at home provided an impetus. Colonies could be a place of refuge for those with political (or legal) difficulties, and in some cases daughter cities took in subsequent waves of exiles from their metropoleis. (Modern parallels would include the colonization of Australia and much of the eastern United States.) In Xenophon’s *Anabasis* a group of Greek mercenaries, abandoned far from home by the death of their patron, seriously consider founding a colony (as did the Athenian army when stranded in Sicily, in Thucydides’ account). This shows that founding a city could be born of desperation and also raises indirectly the question of gender. Presumably, city founda-

tions included both men and women but perhaps not in equal numbers, given the rigors of founding a city in hostile territory and the Greeks’ views that most such activities were better done by men. In this case intermarriage with native peoples may have been common, yet the Greek sources are silent on this issue.

The narratives Greek cities developed about their own colonial enterprises are worth looking at. There is a strong tendency to portray the foundation of a colony in what we would think of as mythic terms. (For the Greeks myth and history were not always separate categories.) The impulse to found the city is expressed in terms of crisis, often of a personal nature: strife between brothers, exile as a result of a crime, the physical deformity of the future *oikistes*. Even an impersonal force such as population pressure can be personalized: Thira’s foundation of Cyrene (in a version reported by Herodotus) is said to be the result of a drought sent by Apollo when the Therans ignored his first command to found a colony. The consultation at Delphi involves not merely approval for the colony but the granting of a sign (particularly a command to follow an animal guide to the site of the new city), and in some cases a riddle to be figured out by the *oikistes* (correctly interpreting, for example, “an attack of the earthborn” to refer to an infestation of mice). Further, colonization can be viewed through the metaphorical lens of marriage: Colonists establish a new city as a married couple establishes a new household. It has been suggested that the metaphor expresses the Greeks’ ambivalence about their relations with native peoples. Rather than being expelled, they and their land welcome the newcomers, perhaps with rights of intermarriage.

Whatever its origins, colonization in the Archaic Age had a tremendous impact on Greek civilization, particularly in regard to the settlements in the west. Sicily and Magna Graecia were the Greek version of the New World. The abundance of fertile land created prosperity, reflected in the region’s still magnificent architecture and other material remains, and the region served as a constant source of cultural innovation, giving birth to such important figures as Parmenides, Empedocles, and Archimedes.

THE SECOND PHASE OF COLONIZATION

Colonization in the sixth and fifth centuries B.C.E. tended to become more overtly imperial and designed to promote the overseas interests of the metropolis; this was especially true with the rise of the Athenian empire in the years after the Persian Wars. Corinth was a pioneer in this regard even in the late seventh century B.C.E.: There it became common practice to choose as *oikistai* the sons of the city’s tyrant (sole ruler of a polis, who differed from a king chiefly in the lack of a hereditary claim to power), establishing an overseas dynastic link. Similarly, the Athenian tyrant Peisistratus sent family members to be in charge of colonies at Sigeum and Lemnos. In the fifth century B.C.E., after the tyrannies had died out, it was necessary to secure the interests of the metropolis by

other means. There exists a foundation decree for an Athenian colony at Brea, dateable to about 445 B.C.E., which specifies that “the cities” (that is, Athens’s imperial subjects and allies) are obligated to come to the defense of Brea. Further, the *oikistes* has limited powers: It is the city of Athens that determines the details of the expedition and appoints officials to divide the land. The *oikistes* in this instance seems to have been an official who later returned to Athens; this is certainly the case for the later foundations of Thurii and Amphipolis. The strategic importance of Amphipolis (in the region near Thrace) was great, and after the city was lost to the Spartans in the Peloponnesian War the city changed its *oikistes*, honoring as its founder the Spartan general Brasidas, who had died in capturing it. The Spartans also sent out colonies for imperial purposes, being the dominant participants in the mixed settlement at Heraclea, a strategic location near Euboea.

Athens developed a new type of colony in the fifth century B.C.E.: the cleruchy, a settlement, typically on land seized from a rival state, in which the settlers maintained their Athenian citizenship. (In this respect, the cleruchy comes closer to modern systems of colonialism than does the standard Greek model.) The cleruchs (in Greek, “allotment holder”), drawn primarily from the poorer classes, received an allotment of land (*kleros* in Greek) and had the normal citizen obligations regarding military service and taxes. It seems likely that most cleruchs lived in their appointed cities rather than staying in Athens and receiving income from their *kleroi*. Cleruchies often were established when the native population had been expelled: this is the case for Greek lands such as Melos and Aigina and also for lands with non-Greek populations such as Lemnos and Scyros. In other cases a cleruchy could be established on top of a native population. While some cleruchies seem to have served as military outposts, most of them served Athenian military interests less directly, by effectively expanding the Athenian empire. The cleruchies of the fifth century B.C.E. were all lost after Athens’ defeat in the Peloponnesian War in 404 B.C.E., but several others were established in the fourth century B.C.E. and at the beginning of the Hellenistic Age. Ironically, Athens’s first cleruchy was in Chalcis, which had been one of the pioneers of the colonization movement during its heyday 200 years earlier.

COLONIZATION IN THE HELLENISTIC WORLD

The final wave of Greek colonization came as a result of the conquests of Alexander the Great. Unlike the Archaic colonizations, which were haphazard and the product of many individual decisions in rival cities, the settlements established by Alexander were centrally planned, the product of a single individual’s will. Moreover, they were established with a specific goal in mind: to spread Greek civilization throughout the vast realm he had conquered. Evaluation of Alexander’s colonization program is hampered, however, by the biases of the sources. He was revered as a hero by many later Greeks, who tended to exaggerate his accomplishments. The Greek biographer Plutarch, for example, claims that colonization

was Alexander’s highest achievement and credits him with establishing 70 cities. This is presumably an exaggeration, though there are some 20 known foundations (many named Alexandria, modesty not being a common trait among conquerors). It seems that many of these were originally set up as military garrisons; others were renamed or resettled with new populations.

After the death of Alexander, the Seleucids (who inherited the eastern part of his kingdom) maintained his policy of colonization, with many settlements relatively close to home (in Syria and Asia Minor) but with some in central Asia as far as what is now northern Afghanistan. The Seleucids took over many administrative practices from the Persian Empire, but the cities they settled were indisputably Greek, with Greek-style temples, houses, and public spaces. Inscriptional evidence shows that even the more remote locations stayed in regular contact with Greeks in the Mediterranean. It seems that local peoples kept their traditions as well: Examples from Babylon and Caria show a process of Hellenization, which was more a matter of cultural fusion than of imperialism. Nowhere is this more evident than in Alexandria in Egypt, the most successful of Alexander’s foundations. It became, thanks to institutions like the library (which aimed to have a collection of every book written in Greek), a cultural center for all of Greece, which until Alexander had been culturally as well as politically disunited. But it also welcomed other peoples and their traditions, Egyptians, Jews, and Romans in particular, and was the most complex and interesting city in the ancient world. Alexander’s policy of Hellenization, though founded in brutal conquest, succeeded on a cultural level long after his empire fell apart: The eastern half of the Roman Empire, including Egypt, Syria, and Asia Minor, remained Greek in language and outlook for another millennium or more.

OTHER POPULATION MOVEMENTS

The warfare endemic to the Greek world led to population shifts not related to colonization. There were resettlements of populations displaced by war: the Ionians in the early years of the fifth century B.C.E., after their failed revolt against the Persian Empire, and the Aiginetans in 431 B.C.E. after their defeat by Athens. In these cases the refugees presumably settled in cities in which they had friends or that were sympathetic to their plight. The fate of Melos provides a grimmer example. Defeated by Athens in 416 B.C.E. despite its attempt to maintain neutrality, its adult male population was killed, and its women and children sold as slaves. Slavery was a fact of Greek life, and mass enslavements of prisoners of war was common.

Large groups of individuals also moved for economic reasons: Cities such as Athens and Alexandria had many resident foreigners (called *metics* in Athens), both Greek and non-Greek. Groups of mercenaries, such as the 10,000 soldiers whose expedition under Cyrus the Younger (424?–401 B.C.E.) is described in Xenophon’s *Anabasis*, also had the potential to become permanent residents elsewhere; this sort of settle-

ment, in fact, was encouraged under Alexander. Finally, there were a small number of nomadic peoples on the fringes of the Greek world and minor pastoral nomadism within it. That is, some shepherds and goatherds practiced transhumance, moving seasonally in search of better pastures—typically to higher ground in winter. This practice was limited in scope, however, by the political fragmentation of the Greek world: A move of any great distance involved crossing from the territory of one polis to another and was therefore more difficult than in places (such as Persia) where a large amount of territory was under the authority of a central government.

ROME

BY MICHAEL J. O'NEAL

The history of migration and population movements in ancient Rome corresponds in many respects to the history of the Roman Republic and the Roman Empire. For a period of nearly a millennium, Rome and its influence on culture, politics, religion, art, engineering, commerce, and government spread outward throughout the Mediterranean region into western and eastern Europe, Asia Minor, the Middle East, and North Africa. In the wake of Rome's spread—and sometimes in advance of it—the peoples of these regions, principally their Roman overlords, were often on the move.

Archaeological evidence shows that the first inhabitants of the area around Rome arrived around 1400 B.C.E. By around 625 B.C.E. numerous settlers had moved into the region and had drained the marshes in the low-lying areas around Rome, laying the foundations for the largest and most civilized city of ancient Europe. There they created a marketplace, the Forum, which was destined to become the center of the Roman Empire.

At about the same time, an ancient people called the Etruscans, from the region of Italy called Etruria, north of the Tiber River, moved into the region and contributed to the development of Roman civilization by ruling the area around Rome. Further, by about 750 B.C.E. the Greeks had moved into the southern portions of the Italian peninsula and into Sicily, a large island just off the “toe” of Italy. They, too, influenced the development of Roman civilization to the extent that historians often refer to “Greco-Roman” culture rather than just Roman culture.

ROMAN EXPANSION

The first major historical event that had a bearing on Roman expansion was the establishment of the Roman Republic in about 500 B.C.E. A popular uprising against the Etruscan king led to the formation of a republican form of government, and Rome, with its own constitution, popular assemblies, and Senate, was formed. At this point in its history, though, expansion and population movements were difficult, in large part because of the geography of the Italian peninsula. Mountains, in particular the Apennines, extend across the top of Italy and then down the “boot.” They divide the penin-

sula into regions, and the Po River to the north was a formidable obstacle to the movement of peoples in that direction. What is called “Italy” in modern times did not exist; rather, the peninsula consisted of a number of discrete regions, including not only Etruria but also Umbria, Latium, Samnium, Campania, Puglia, and Magna Graecia (or “Greater Greece,” the southern region inhabited by Greeks).

The process of uniting these regions into a single political entity was long, beginning in the fourth century B.C.E. Sometimes the early Romans defended and expanded their frontiers through negotiation and treaty, including a treaty with Latium, the region that surrounded Rome, leading to the outward migration of the early Romans. Sometimes they did it through conquest, such as Rome's victory over the Etruscans in 396 B.C.E., which allowed the Romans to migrate farther throughout the peninsula. Sometimes, though, there were setbacks, such as the successful invasion of Rome by the Gauls, the Celtic people from north of the Po River, in 390 B.C.E. A century later the Greeks in Magna Graecia recruited King Pyrrhus of Epirus to lead an invasion of Rome; the invasion was successful but at the cost of many casualties (giving rise to the modern expression “Pyrrhic victory,” or a victory that comes at a great price). In both cases Rome was able to rebound and continue its expansion.

The great age of Roman expansion around the Mediterranean began in 264 B.C.E. with the first of three so-called Punic Wars. These wars were launched against the Phoenicians (whom the Romans called the Phoeni, the source of the word *Punic*). The Phoenicians ruled an empire from Carthage, a city they had founded in northern Africa, so they are usually referred to as the Carthaginians. In the First Punic War, Rome seized the island of Sicily from the Carthaginians in 241 B.C.E. Then in 238 B.C.E. it seized the islands of Sardinia and Corsica, which had both been ruled from Carthage. The Second Punic War erupted in 219 B.C.E., when the Carthaginians, under the leadership of the general Hannibal, expanded their empire into Spain and then invaded Italy. (Hannibal is most famous for his use of elephants in crossing the mountains into Italy.) But while Hannibal won a victory over the Romans, he was unable to break up the alliance of states in the Roman Republic, and he had to withdraw when Roman troops invaded Spain and, in 204 B.C.E., Carthage itself. The Third Punic War began in 149 B.C.E. and ended when Rome captured and destroyed Carthage in 146 B.C.E. With its victory over the Carthaginians complete, Rome ruled a strip of North Africa. In the aftermath of these wars the Roman people spread steadily outward from their capital.

To the east Rome continued its expansion, first into Macedonia (in modern times a portion of Yugoslavia but at the time part of the Greek Empire) in 190 B.C.E. A major event took place in 146 B.C.E., when Rome annexed Greece, ending the Greek Empire. Thus, by 146 B.C.E. Rome was the undisputed power in the region surrounding the Mediterranean Sea.

During the first and second centuries B.C.E. Rome expanded into the region known as Gaul, which corresponds roughly with modern-day France and a portion of northern Italy. Gaul, like Italy, was a collection of smaller regions. Rome subdued the region called Narbonensis, along the southern coast of Gaul, in about 120 B.C.E. Later conquests included Cisalpine Gaul (in today's northern Italy) in 81 B.C.E., Aquitania (a large region along the western coast) from 56 to 51 B.C.E., Lugdunensis (also a large region extending from the northwest coast into central Gaul) from 58 to 51 B.C.E., Belgica (corresponding to modern-day Belgium) from 57 to 51 B.C.E., and regions of Germania (Germany) in 17 C.E. Also, in 29 B.C.E. the Roman emperor Octavian conquered Egypt. Again, these conquests led to the migration of Roman people throughout the Mediterranean region.

THE ROMAN EMPIRE

Although these conquests and expansions suggest an “empire,” historians refer to the period up to 27 B.C.E. as the Roman Republic. They use the term *Roman Empire* to refer to the period from 27 B.C.E., when the emperor Octavian imposed his vision of government on the Roman Senate, to 476 C.E., the end of the empire in western Europe.

Further expansion of the Roman Empire took place into the second century C.E.; the most important event was the conquest of Britain in 43 C.E. Thus, by the second century of the Common Era the Roman Empire essentially encircled the area around the Mediterranean Sea and extended as far north as the British Isles. To the west and north it encompassed Britain, Spain, portions of modern-day Germany, and all of Gaul; the northern border of the empire was marked by the Rhine and Danube rivers, where such northern European tribes as the Huns, the Vandals, and the Visigoths massed until they spilled southward and eventually defeated the Romans. Until then, though, these rivers were major barriers to the movement of populations. The empire extended eastward from Italy into Greece, Asia Minor, and such areas as Cappadocia, Armenia, Assyria, and Mesopotamia, then south through Palestine into Egypt. To the south the empire included a wide strip of northern Africa.

Rome's most difficult province was probably Britain. Over three centuries of rule the Romans met with frequent resistance, not only in modern-day England but in Scotland and especially in Wales. During these centuries numerous bodies of troops had to be dispatched to Britain to quell uprisings led by local leaders. The result was a two-tiered administration, with peaceful areas under the control of the Roman Senate but areas of resistance under the emperor and his troops. The areas were controlled by resident governors whose role was primarily military but included keeping up diplomatic relationships with local kings, building roads, supervising cities and their surrounding areas, recruiting troops, collecting taxes, and administering the law. The governor also supervised a large number of managers whose job was to gather intelligence about the activities of local kings

and their followers, communicate with Rome, order and store military supplies, take charge of prisoners, and perform similar administrative functions.

Determining the population of the Roman Empire is almost impossible, given the lack of accurate records. Also, what records do exist remain unclear about who precisely was counted. The best historians can do is offer a range of likely estimates and arrive at a consensus. It is estimated that in 1 C.E. the Roman Empire comprised about 45 million people, out of a world population of 200 to 300 million. Other historians use a figure of about 55 to 60 million. Conservative estimates put the number at about 65 million by the second century C.E., but some historians argue that the number was much greater, perhaps as many as 130 million, or some 40 percent of the world's total population.

Using the lower estimate, historians have concluded that among the population were 600 senators, the top tier of Roman society. Below the senators were some 30,000 equestrians, or knights. The military consisted of some half a million soldiers, many of whom were stationed along the empire's frontiers and included not only Romans but locally conscripted mercenaries. Between 10 percent and 30 percent of the population, or six to nine million people, occupied cities, including one million in Rome. (By the sixth century wars and plague had reduced the population of Rome to just 30,000 to 100,000 people, and it would take 1,500 years for a European city again to reach a population of one million). Finally, historians estimate that the slave population of the empire, imported from throughout the empire typically as a consequence of military conquest, totaled anywhere from two to 10 million, with half a million living in and around Rome itself.

THE ROLE OF ROADS

Roads and road-building technology played a major role in the expansion of the Roman Empire and the movement of peoples. Such a vast empire required means of travel to accommodate military troops, trade, and communications and to allow large numbers of administrators, civil servants, and other officials to move freely about the empire. The colloquial expression “all roads lead to Rome” was in fact true. At the center of the road system was the Forum, the earliest site in ancient Rome. From that central point a traveler could get to virtually any place in the empire on 50,000 miles of paved roads, some of which are still in use in the 21st century. In large part because of the road system, large numbers of Romans could move from the empire's capital to the most far-flung areas of the empire, taking with them all the elements of their culture: the monetary system, art, administration, military tactics and technology, engineering, roads, water and waste management systems, government, and so on.

Roman roads were more than just tracks through the woods. The roads were built in much the same way as modern roads are, with firm underlays capped by paving stones. One innovation the Romans developed was that of the crowned

road; that is, the roads were slightly higher in the center and sloped off to the sides, allowing rain to flow off. Many Roman roads also had gutters at the side to aid in keeping the roads relatively dry and passable. For centuries these roads enabled people to move freely about the empire.

THE MIGRATION MOVEMENT

With each outward expansion of the Roman Republic and the later empire, substantial numbers of Roman people, primarily military troops and civil servants but also colonists and settlers, moved into newly conquered regions. Thus, in about 400 B.C.E. Roman colonies were established along the Po River valley. After the Romans conquered Sicily, Sardinia, and Corsica, Roman settlers established colonies on these islands. Similarly, after the capture of Gaul, colonies of Romans were established throughout the region, and eventually these colonists crossed the English Channel and settled in parts of England. In Germania the Romans drove out the Huns, who moved eastward and settled in the south of modern-day Russia. To the east the Romans established colonies in such regions as Pannonia and Illyria (in modern-day Hungary) and Thrace (part of the defunct Greek Empire).

Additionally, considerable population movement came about as a result of slavery. Slavery led to the movement of populations because of the ongoing need to replenish the supply of slaves. During this time period the average life expectancy of any person was much lower than it is in the 21st century. A person who reached the age of 30 would have been considered old. Archaeologists have deduced this information by examining inscriptions on surviving tombstones. Further, it is estimated that at birth the life expectancy of a slave was no more than about 20 years, only a portion of which would be spent as a slave. Thus, it is estimated that the Romans needed about half a million new slaves each year to maintain the slave population. While many of these slaves were held in the outlying areas of the empire, many were carried to Rome and surrounding areas; it has been estimated that up to a third of the population of Rome was enslaved.

During the period of the Roman Republic, most slaves were prisoners of war captured during any of Rome's military conquests during the period. This source of slaves diminished after the establishment of the Roman Empire, for the number of wars diminished as the empire became more stable. Nonetheless, Roman troops took part in a number of local wars. For example, the Romans crushed the Jewish rebellion in Palestine in 66–70 C.E., and it is estimated that some 97,000 Jews were enslaved. A later Jewish revolt in 132–135 C.E. resulted in the capture of more than 100,000 slaves. As a result of other border skirmishes, Roman soldiers captured slaves and either kept them for their own use or sold them to masters closer to Rome. Other sources of slaves included those seized by kidnappers and pirates, those who became slaves because they were in debt, and those who actually sold themselves into slavery in hopes of later being freed and becoming

THE TOWN OF NUMANTIA

As Roman troops spread throughout the Mediterranean region, they typically met with little resistance, for local, disorganized tribes were no match for the Romans' superior numbers and organization. One major exception was the town of Numantia in modern-day Spain. In what is called the Numantine War, the Numantians successfully resisted the Romans for a long period of time.

Numantia was populated by the Arevaci people, a tribe formed by the mingling of Iberians (the natives of the Iberian Peninsula, encompassing Spain and Portugal) and Celtic migrants from the sixth century B.C.E. In 137 B.C.E., after Rome had invaded the Iberian Peninsula, the Numantians fought the Roman invaders, and in fact some 20,000 Roman troops surrendered to them, even though the Numantian population amounted to no more than about 8,000 people.

The siege of Numantia began in 134 B.C.E. under the leadership of Scipio Aemilianus, the local Roman consul who commanded some 30,000 Roman troops. The Roman army built fortifications around the city, cut off its connections with other towns, and settled in for a long siege. In time the Numantians, who refused to surrender, were starving, and many historians believe that, in desperation, they practiced cannibalism. They attempted to lure Scipio into open battle, but Scipio refused to take the bait. At one point Scipio caught wind of an effort by a party of Numantians to escape to the nearby town of Lusia to seek help. Scipio responded by occupying Lusia and cutting off the hands of all men of fighting age. After eight months nearly all of the residents of the town, rather than surrendering to the Romans and becoming slaves, committed suicide. Only a small handful of the town's citizens survived. With the fall of Numantia, the conquest of Iberia was complete.

Roman citizens. A major source of slaves was children who were abandoned by their parents because they had too many mouths to feed. All of these sources of slaves could have come from anywhere in the empire.

Another source of population movement was religious persecution, particularly in the Common Era, when Christianity began to spread. The religion of the Romans was polytheistic, meaning that they believed in many gods and goddesses. In contrast, the religion of both Jews and Christians was monotheistic, meaning that they worshipped a single supreme being. During the early decades of the Common Era, many Jews in Rome converted to Christianity. They

practiced their religion in secret, however, and suffered relatively little persecution.

The situation changed in 64 C.E., when, under the Roman emperor Nero, Rome burned. Nero, generally regarded as mentally unbalanced, wanted to build a magnificent palace to himself, and many Romans believed that he set the fire deliberately as an excuse to rebuild. To deflect suspicions away from himself, Nero blamed the fire on the Christians, who were widely perceived as a subversive cult. The result was widespread persecution of Christians, many of whom fled Rome for other parts of the empire.

These persecutions continued well into the second century, and they extended to other parts of the empire. In 177 C.E., for example, the emperor Marcus Aurelius persecuted Christians in Lyons, in Gaul, driving them out of the city, and Christians in Italy were persecuted as well. Many of these Christians left for Britain and other areas of Gaul, where the persecutions were not as widespread. In 303 C.E. the emperor Diocletian and his successor, Galerius, began an eight-year purge of Christians in the east, particularly in such places as Syria, Egypt, and Asia Minor, driving them out of the empire or to other places in the empire where the fires of persecution did not burn as hotly. The persecution and consequent movement of Christians came to an abrupt halt when the emperor Constantine converted to Christianity in 313 C.E. and declared Christianity the official religion of the empire.

CONSEQUENCES OF MIGRATION

In general, the formation and spread of the Roman Empire did not lead to massive movements of people. For the most part, peasants and farmers—those who lived in rural areas and very small towns and villages—lived their lives much as they had before the Romans came. They provided food and craft items, and they did not attract much attention from their Roman rulers. Most of the consequences of Roman immigration were felt in the larger towns and cities, particularly in Europe. There people began to use the various products that the Romans brought with them. A good example is wine, which had been unknown in many of these areas prior to the spread of the empire, when beer was the favored beverage. Particularly among the upper classes, many people began to dress like the Romans and otherwise adopt their ways, including elements of their religion. Many towns began to feature buildings—temples, bathhouses, and theaters—that strongly resembled those in Rome. Many of these buildings, as well as military fortifications and roads, still exist and can be seen in Europe.

Similarly, the migration of Romans led to the spread of the Latin language. Latin, which used elements of the Greek and Etruscan alphabets, was the language of the people in the province of Latium, which surrounded Rome. As the empire expanded, first throughout Italy and then throughout the Mediterranean regions, soldiers, administrators, and civil servants took the language with them. In time Latin became

the official language of the entire empire. Official documents, for example, were written in Latin, and Latin became the language of educated people, as well as of the Christian Church. In contrast, local languages were preserved in the Eastern Roman Empire.

By about the eighth or ninth century C.E. communities of Latin speakers, isolated from one another, began to develop their own versions of the language, and these versions evolved into the Romance languages of Europe, including Spanish, Italian, Portuguese, French, and, to a lesser extent, Bulgarian. These languages are called “Romance” languages not because they have anything to do with affairs of the heart but because they evolved from the language of Rome. While English is a Germanic language rather than a Romance language, fully 60 percent of English words derive from Latin through the Romance languages as a result of the much later invasion of the British Isles by the French Normans. (Simple, everyday words in English tend to be Germanic while longer, more formal words tend to come from Latin. Thus, *house* is a Germanic word; *domicile* is a Latin-based word.) Had it not been for the migration of the Romans during the empire, the map of European languages would probably be very different than it is.

It should be noted that the Roman Empire comprised two distinct parts, the western empire and the eastern empire. The western empire included primarily Europe; the eastern empire included such areas as Asia Minor, Greece, and the Middle East. These two regions were markedly different. While the population of the eastern empire was dense, that of the western empire was sparse. Easterners were more urban, and they tended to be more literate and to engage in commerce using a fixed monetary system; westerners were more rural and tribal, and they tended to be illiterate and to pursue agriculture using a system of barter. In the east laws were written; in the west law was based on local custom. While easterners tended to be wealthy, or at least comfortable, westerners were poor.

The spread of the Roman Empire, with its movement of Romans outward, united these two very different regions, often through the use of force. Taxation was heavier in the east as a way of transferring wealth to the poorer regions of Europe. Because all the parts of the empire were within easy reach of Rome (with the possible exception of Britain), it was relatively easy for the Roman emperor to impose a common language, a common currency, a system of weights and measures, a standing army, canals and roads, and, in particular, a class of civil servants. Trade established contact between the regions of the empire, and a well-developed system of laws, a trained bureaucracy, a standing military, and a uniform system of government gave rise to what has been called the Pax Romana, an era of peace when tribes that would likely have warred with one another lived under Roman rule.

In addition to conquest, the military put an end to piracy and artificial barriers to the movement of peoples, such

as tolls collected by local warlords that were essentially protection money. When the military was not fighting, troops constructed dams, aqueducts, canals, bridges, and roads, and by maintaining permanent outposts, they “romanized” the people under their sway. The military and civil servants created what was called *Romanitas*, or a feeling of belonging to a great empire, and for many people achieving Roman citizenship was a major goal. By spreading the culture of Rome and Greece, the Roman migrants gave Europe, in particular, a common cultural heritage that is still felt.

THE AMERICAS

BY LAWRENCE WALDRON

The people who first set foot in the Americas have long been a favorite topic of speculation. Native Americans have been worked into Western myths in an attempt to explain their origins. The various Native Americans, for their part, have always had their own myths, with which they not only explained their origins but also gave themselves a sense of purpose, morality, and hope. Over the past two centuries the geographic origin of America’s most ancient settlers has also been a research interest for scientists. In that time some as-

pects of myth have given way to scientific theories based on empirical evidence. The science of archaeology was one of the first disciplines to propose theories and possible time frames for the peopling of ancient America. Archaeologists and anthropologists were eventually followed by many other scientists on the trail of the very first Americans.

Many different kinds of evidence of ancient American people have been uncovered, and some of the evidence has been difficult to interpret. Scientists have therefore developed a variety of theories and have disagreed about the time of first arrival. In the 20th century alone, professional and amateur anthropologists proposed dates ranging from 200,000 to 12,000 years ago. However, the vast majority of the evidence dates back to a time somewhere between 14,000 and 12,000 years ago.

FROM SIBERIA TO ALASKA

From about 18,000 years ago the last ice age began to wane. Glaciers slowly melted and sometimes refroze in centuries-long cold snaps. This general warming trend continued for more than 8,000 years, and ocean levels began to swell with glacial meltwater. Even as they were fed by the melting glaciers, the oceans at that time were still well below their

Albert Bierstadt (1830–1902), *The Rocky Mountains, Lander’s Peak, 1863*; *Paleo-Indians seemed to have migrated along the base of the North American Rockies and then the Mexican Sierras and the Andes, hunting on the plains in sight of the sheltering mountains.* (Copyright the Metropolitan Museum of Art)

present levels, so landmasses we would not recognize today remained above water. One of these was the sprawling landscape of Beringia, an area encompassing parts of modern-day Alaska and easternmost Siberia. This landmass provided an inhospitable yet solid land bridge between Russia and North America. Siberian hunter-gatherers on the trail of large prey, such as mammoth, musk ox, and saiga antelope, could have crossed some 60 miles of open tundra into Alaska. There, they gradually would have become stranded by rising sea levels. They might have settled near Beringia's rivers for an easy supply of fresh water but would eventually have moved on in search of territories more fertile than this dry scrub land. As the ice age ended, much of Beringia became submerged beneath the icy waves of today's Bering Sea. Ocean levels continued to rise.

The submergence of the Bering Strait (the narrow passage between modern-day Alaska and Siberia) took many generations, so the new settlers would have had an opportunity to return to the Siberia of their forbears. It is possible that some did rejoin their countrymen on the Russian side of Beringia, but today's Native Americans are descendants of the ones who attempted to push farther and farther into the new territory.

Once they were in North America, their path to the rest of the continent was not yet clear. Glaciers still covered much of Alaska and Canada so that these early Americans may have lived for centuries trapped between their submerged land bridge to the north and Canada's glacial ice sheets to the south. In the unstable climate the ice sheets sometimes convulsed violently, occasionally advancing toward the settlers. As they did so, the glaciers slowly crushed and enveloped entire forests, diminishing vital habitat and destroying food and shelter. Often the ice would suddenly retreat again, leaving a flattened landscape in its wake. Even in times of retreat, glacial meltwaters could inundate grazing land and woodlands and cause massive flash flooding as millions of cubic tons of water came bursting out from behind dams of half-melted glacial ice. Enormous boulders and jagged chunks of ice tumbled within these floods, smashing everything in their path.

It was a millennium or more before the two major Canadian ice sheets, the Cordilleran in the west and the Laurentide in the east, parted and permitted the new settlers to enter the rest of the Americas. From there the migrants diversified into more than 2,000 societies with more than 1,000 languages and produced some of the greatest civilizations in human history.

It is apparent from studies of Native American languages and DNA that American settlement began with migrants from Siberia. The linguist Joseph Greenberg and other scientists have proved that ancient America was settled not by just one but by several separate waves of eastward migration from Asia. Greenberg had been suggesting since the 1950s that Native American languages fell into three distinct families. By the 1980s, after many years of

collaboration and comparison among several disciplines, scientists were able to demonstrate that North America had been settled in three separate waves: Paleo-Indians had arrived near the end of the last ice age and spawned the majority of native languages, a second group consisting of Na-Dene speakers (the Athabascan family from whom the Apache and Navajo descend) arrived some 9,000 years ago, and just 4,000 years ago a final group arrived speaking a language from which modern Inuit (Eskimo) and Aleut have developed. Discovering the exact means by which these later migrants arrived, whether by land or sea, has become a new quest of archaeologists.

FROM BERINGIA TO CLOVIS

By the time they were cut off from their Siberian heartland the ancient Alaskan settlers had already begun to adapt to their new home. Different bands of settlers quickly diversified into distinct hunting, fishing, and foraging cultures in reaction to their maritime, tundra, valley, or highland environments. As they began to differ from each other, they also differed considerably from their Siberian relatives in culture, technology, and language. Anthropologists call these distinct people Paleo-Indians ("ancient Indians") to distinguish them clearly from their Asian antecedents. For some 2,000 years they may have lived confined to northwestern Canada, but as the ice age ended and the Cordilleran and Laurentide ice sheets finally melted, the new settlers were free to issue forth into the vast American landscape.

The oldest sites in North America south of the ice sheets are located in the western United States. The sites of Folsom and Clovis in New Mexico date back as far as 11,000 and 11,500 years ago, respectively. At both of these sites stone projectile points from spears and arrows were found among the bones of extinct ice age mammals, indicating that people had been in America at least 10,000 years ago. In fact, the finely wrought projectile points had been found between the ribs of a bison skeleton at Folsom and between the ribs of several mammoths at Clovis. Thus these ancient "kill sites" contained different prey and slightly different kinds of projectiles but illustrated similar hunting techniques. The Clovis and Folsom people appeared to be hunter-gatherers who stalked large prey that would supply them with large amounts of food at a time, which they could eat on the spot or preserve until the next hunt.

When radiocarbon dating was introduced in the 1950s, almost two decades after the first excavations at Folsom, it was determined that Clovis was the older site. All biological organisms absorb carbon isotopes while they are alive. Some of these isotopes decay at a steady rate after an organism's death. Radiocarbon (or carbon 14) testing measures the degree of isotopic decay to approximate the year or period of death of an organism. Radiocarbon dating is commonly used to fix the age of artifacts in conjunction with other contextual information, such as location, materials, and methods of manufacture. Although varying designs of projectile points

had by then been found in Texas and as far east as the Mississippi, these roughly 11,000-year-old hunting artifacts were attributed to a general "Clovis culture," suggesting the primacy of Clovis as the oldest site.

FROM THE ROCKIES TO THE ANDES

It is unlikely that the Clovis culture was a "mother culture" to all the Americas. The first settlers who came through the break in the Canadian ice barrier may not all have settled first in New Mexico or even in the western part of North America. Some may have immediately started migrating southeast, going all the way to the Gulf of Mexico. Some may have gone directly south, right past New Mexico, to settle in Central America. Others may have followed opportunity or comfortable weather all the way to present-day Colombia and Venezuela or to Peru and Bolivia. This would explain the apparent antiquity of some South American sites, many of which seem to have arisen at the same time as the Clovis culture or even before. While controversy surrounds many of the Paleo-Indian sites in Latin America (for excavations there have often been done by Europeans and Latin Americans using techniques not always accepted by North American scientists), the site at Monte Verde in Chile seems to be older than Clovis.

Several layers, or strata, of artifacts at Monte Verde contain wood and stone tools; the remains of hutlike dwellings; and the fruits, plants, and meat that were eaten in them. In the archaeological practice of stratigraphy, excavation proceeds from the upper strata, or layers, of soil to the lower, with the assumption that objects buried deeper in the soil are older. Radiocarbon testing often bears this assumption out, but sometimes earth movements and water or wind erosion can jumble the contents of the soil deposits. These shifts can complicate the stratigraphic record and corrupt the carbon content of the site, rendering radiocarbon dating unreliable or useless. Monte Verde's location near both a river and a damp bog casts doubts on the carbon test results, which state that the upper level of artifacts is 12,500 years old and that an even lower stratum of artifacts is some 33,000 years old.

While the age of the lower strata (which may have been corrupted by water action or other agents) is in doubt, the artifacts dated to 12,500 years ago are probably that old. If this theory is correct, then Monte Verde is 1,000 years older than Clovis. Sites such as Pikimachay in Peru and Taimaitima in Venezuela and many other South American sites have also yielded stone tools and butchered animal bones. From their technology and materials these sites seem to be of the same approximate age as Clovis and Monte Verde, but like the latter site, they suffer from dubious stratigraphic evidence whereby doubt is cast on their radiocarbon dates. It is noteworthy that a great many South American sites, excavated by unaffiliated archaeologists in the past 30 years, tend to yield radiocarbon dates between 13,400 and 14,200 years ago. If the age of any of these sites proves to be incon-

testable, then South America will have the oldest proven Paleo-Indian site. Older South American dates could establish that Paleo-Indians emerging from Canada's ice-free corridor headed straight for the south. If this were the case, communities in South America could have emerged virtually simultaneously with their Clovis counterparts up north, or even earlier.

Far from the controversy of South America's radiocarbon dates are archaeologists who see that hunter-gatherers from just south of the Canadian ice sheets could indeed have settled the entire length of the Americas in a single millennium. Computer models and comparisons to the movements of historic marooned populations indicate that with opportunistic migration (say, in the pursuit of food sources) and even conservative population growth, Indians could have expanded from Canada to Chile within 100 generations. It seems that once ancient Siberians crossed into the Americas, their settlement of the new landmasses, even with any delay caused by the gradually receding Canadian ice sheets, was remarkably fast.

FROM THE AMAZON TO THE CARIBBEAN

The vast majority of early Paleo-Indian sites are concentrated along the Pacific side of the Americas. This may be more than circumstantial evidence. Paleo-Indians seemed to have migrated along the base of the North American Rockies and then the Mexican Sierras and the Andes, hunting on the wide-open plains but within sight of the sheltering mountains. Their eastward expansion into the North American Woodlands and the South American Amazon may be obscured by the environment itself, tangling the stratigraphic evidence in vegetal undergrowth. However, it may simply be that Paleo-Indians spent much of their early prehistory nearer the western longitudes and open spaces to which they had grown accustomed in their early migration. Either way, most Paleo-Indians seem to have kept the rising sun to their left during their early expansion.

In South America a change in the overall southward migration pattern also marked a change in lifestyle from almost exclusively hunting and gathering to partial and then full agricultural settlement. This agrarian phase, which commenced in different regions between 5,000 and 10,000 years ago, was an important shift in Native American culture. Some anthropologists cease referring to these agrarians as Paleo-Indians, choosing instead to describe them as archaic cultures. Three patterns of migration signal the archaic shift: the exploration of the coastlines in search of diversified food sources (for example, the addition of fish and shellfish to the regular diet), the absolute cessation of migration after phased adaptations to agriculture, and finally a movement into the Amazon forests after developing a certain familiarity with its environment.

Prearchaic Paleo-Indians would have had little incentive to settle in the Amazon forests, since their quarries as hunters were large, migratory animals that favored open landscapes.

However, between 7,000 and 9,000 years ago people in the forested river drainages of Brazil, Uruguay, northern Argentina, and Paraguay began to use a greatly diversified tool kit. At sites along the Paraná River, the familiar projectile points and scrapers are joined by an increased number of wood-working tools, knives, choppers, bolas, anvils, and grinders. All of these are tools adapted to building, subsisting, and preparing food in a wooded environment. The varied vegetable sources within the forest would have provided food, shelter, and clothing to settlers, and they may also have been the inspiration to manipulate the growth of certain desirable vegetation. Bottle gourds, pumpkins, beans, peppers, and avocados were among the crops purposefully grown by 5,000 to 10,000 years ago. By 4,000 years ago archaic Indians had begun to cultivate the staple food manioc, or cassava root, a starchy crop that would transform many societies, chiefly by supporting population explosions.

In the last 2,000 years before the Common Era, many archaic groups settled down and developed into agricultural societies with far-reaching trade relationships. This is the period in which the civilizations of Caral, Paracas, Chavín, and Chinchorro emerged in Peru and Bolivia with agriculture and fishing as the basis of their economies; the Olmec and early Pre-Classical Maya organized in Mesoamerica, having cleverly doctored a wild grass into the high-yield staple known today as maize; and the egalitarian Adena culture emerged in the eastern Woodlands of North America, based on a combination of agriculture, forest gathering, fishing, and the hunting of woodland fauna and migrating ducks. All of these civilizations illustrate the archaic transition to forest life, which in turn contributed to the domestication of plants and the development of agriculture. With the archaic expansion throughout the continents, albeit by small groups, the settlement of the Americas seemed complete. But there was one great Indian migration yet to commence.

The movement of Amazonian peoples to the Caribbean islands represents the last migratory expansion in the pre-Columbian Americas. The first Caribbean settlements appear to have taken place quite early, as Paleo-Indians preceded archaic Indians. Excavations in the 1970s at Banwari Trace in Trinidad yielded the oldest-known human artifacts in the Caribbean archipelago. These 8,000-year-old remains include stone tools, human bones, and a large midden of discarded shells. The human artifacts at Angostura in Puerto Rico date from just 1,000 years after those at Banwari Trace. With habitations at opposite ends of the Caribbean archipelago showing such close dates, it appears that the Caribbean islands were settled very quickly. This maritime expansion of Paleo-Indians testifies to their intelligence, skill, and determination.

Successive groups of Paleo-Indians followed by later settlers appear to have come in canoes from the delta of the Orinoco River. Some may have traveled down the Orinoco from as far away as the foothills of the Andes. Others may have

migrated along the coast of Guiana from the Amazon. With seafaring skills developed on the great and often perilous rivers of South America, they struck out for Trinidad, an island visible from some parts of Venezuela. From there they settled Tobago and Grenada. Within a single millennium they island-hopped all the way to the Bahamas and Cuba, islands located in the far northwest. Given the northern Caribbean's proximity to the Yucatán and the Florida peninsulas, archaeologists have not entirely dismissed the possibility of migrations from North and Central America.

While the earliest hunter-gatherers left mostly simple stone tools as evidence of their habitation, later Indians began arriving in the Caribbean some 4,000 years ago with elaborately decorated pottery, complex weaving techniques, and sculpture made of wood, stone, shell, and bone. It is mostly by their pottery that archaeologists have classified their distinct cultures. Anthropologists and linguists also have identified at least a dozen distinct groups of settlers from at least two major South American language families.

The transition to island life was not always as difficult as might be expected, since many of the local species had originated on the mainland, blown or carried by hurricanes, marine currents, and prevailing winds. The settlers had also brought stalks of manioc and other reproducible food sources, and intermittent contacts with the South American mainland were maintained. In the Caribbean islands, however, these settlers developed insular cultures with unique dialects, arts, and religions. They relied heavily on agriculture and fishing and did only part-time hunting and gathering in the limited island interiors. Since the terrain of some islands was radically different from that of others (ranging from volcanic to sedimentary to coral soil), a vital trading system among the islands developed by the beginning of the Common Era. Eventually, the brave explorers who had arrived with only bare necessities in the second millennium B.C.E. would evolve into the Taíno kingdoms that greeted Columbus in 1492.

Europe

~ Tacitus: Excerpt from *Germania* (98 C.E.) ~

I shall now deduce the institutions and usages of the several people, as far as they vary one from another; as also an account of what nations from thence removed, to settle themselves in Gaul.

That the Gauls were in times past more puissant and formidable is related by the Prince of authors, the deified Julius [Julius Caesar], and hence it is probable that they too have passed into Germany. For what a small obstacle must be a river, to restrain any nation, as each grew more potent, from seizing or changing habitations; when as yet all habitations were common, and not parted or appropriated by the founding and terror of Monarchies? The region therefore between the Hercynian Forest and the rivers Moenus [Main] and Rhine, was occupied by the Helvetians; as was that beyond it by the Boians, both nations of Gaul. There still remains a place called Boiemum, which denotes the primitive name and antiquity of the country, although the inhabitants have been changed. But whether the Araviscans are derived from the Osians, a nation of Germans passing into Pannonia, or the Osians from the Araviscans removing from thence into Germany, is a matter undecided; since they both

still use the language, the same customs and the same laws. For as of old they lived alike poor and alike free, equal proved the evils and advantages on each side the river, and common to both people. The Treverians and Nervians aspire passionately to the reputation of being descended from the Germans; since by the glory of this original, they would escape all imputation of resembling the Gauls in person and effeminacy. Such as dwell upon the bank of the Rhine, the Vangiones, the Tribocians, and the Nemetes, are without doubt all Germans. The Ubians are ashamed of their original; though they have a particular honor to boast, that of having merited an establishment as a Roman Colony, and still delight to be called Agrippinensians, after the name of their founder: they indeed formerly came from beyond the Rhine, and, for the many proofs of their fidelity, were settled upon the very bank of the river; not to be there confined or guarded themselves, but to guard and defend that boundary against the rest of the Germans.

Cyrene (ca. 630 B.C.E.), from *The Histories* (ca. 430 B.C.E.) ~

BOOK 4

Grinus (they say), the son of Aesanius, a descendant of Theras, and king of the island of Thera, went to Delphi to offer a hecatomb on behalf of his native city. On Grinus consulting the oracle about sundry matters, the Pythoness gave him for answer "that he should found a city in Libya." When the embassy returned to Thera, small account was taken of the oracle, as the Therans were quite ignorant where Libya was.

Seven years passed from the utterance of the oracle, and not a drop of rain fell in Thera: all the trees in the island, except one, were killed with the drought. After a while, everything began to go wrong. Ignorant of the cause of their sufferings, they again sent to Delphi to inquire for

what reason they were afflicted. The Pythoness in reply reminded them reproachfully "that if they and Battus would make a settlement at Cyrene in Libya, things would go better with them." So, as there was no help for it, they sent messengers to Crete, to inquire whether any of the Cretans, or of the strangers living amongst them, had ever traveled as far as Libya: and these messengers fell in with a man named Corobius, a dealer in purple dye. In answer to their inquiries, he told them that contrary winds had once carried him to Libya, where he had gone ashore on a certain island which was named Platea. So they hired this man's services, and took him back with them to Thera. A few persons then sailed from Thera to reconnoiter. Guided by Corobius to the island of Platea, they left him there with provisions for a certain

(continued)

(continues)

number of months and returned home with all speed to give their countrymen an account of the island.

The Therans who had left Corobius at Platea, when they reached Thera, told their countrymen that they had colonized an island on the coast of Libya. They of Thera, upon this, resolved that men should be sent to join the colony from each of their seven districts and that the brothers in every family should draw lots to determine who were to go. Upon this the Therans sent out Battus with two penteconters, and with these he proceeded to Libya; but within a little time, not knowing what else to do, the men returned and arrived back off Thera. The Therans, when they saw the vessels approaching, received them with showers of missiles, would not allow them to come near the shore, and ordered the men to sail back from whence they came. Thus compelled, they settled on Platea.

In this place they continued two years, but at the end of that time, as their ill luck still followed them, they went in a body to Delphi, where they made complaint at the shrine to the effect that they prospered as poorly as before. Hereon the Pythoness made them the following answer: "Know you better than I, fair Libya abounding in fleeces? Better the stranger than he who has trod it? Oh! Clever Therans!" Battus and his friends, when they heard this, sailed back to Platea: it was plain the god

would not hold them acquitted of the colony till they were absolutely in Libya. So they made a settlement on the mainland directly opposite Platea, fixing themselves at a place called Aziris.

Here they remained six years, at the end of which time the Libyans induced them to move, promising that they would lead them to a better situation. So the Greeks left Aziris and were conducted by the Libyans toward the west, their journey being so arranged, by the calculation of their guides, that they passed in the night the most beautiful district of that whole country, which is the region called Irasa. The Libyans brought them to a spring, which goes by the name of Apollo's Fountain, and told them, "Here, Hellenes, is the proper place for you to settle; for here the sky leaks."

During the lifetime of Battus, the founder of the colony, who reigned forty years, and during that of his son Arcesilaus, who reigned sixteen, the Cyreneans continued at the same level, neither more nor fewer in number than they were at the first. But in the reign of the third king, Battus, surnamed the Happy, the advice of the Pythoness brought Greeks from every quarter into Libya to join the settlement. Thus a great multitude were collected together to Cyrene, and the Libyans of the neighborhood found themselves stripped of large portions of their lands.

► Military

INTRODUCTION

Murderous conflict among people dates back to ancient times. Rock and cave paintings from the last great ice age show people armed with spears and shields, sometimes trying to kill one another. This does not mean that those ancient warriors had military outlooks on what they were doing; it is possible that anyone in a community would be expected to take arms to protect it or to attack others.

Military thinking may have developed among people who had something special to protect, such as an oasis in a dry land, a crossing for a trade route over a river, especially fertile farmlands, or accumulated wealth, as in a prosperous city. Fortifications to protect a community are very old. In many lands, villages were surrounded by wooden palisades (a strong fence made of stakes) or defensive ditches. The first large-scale fortifications may have been earthen walls. These could be very extensive, surrounding even large cities and requiring thousands of workers to construct. Clay bricks were popular in the Near East and Egypt, where walls more than a dozen feet thick were built around fortresses or cities. Both earth and brick had significant problems. One was that they were subject to erosion by water. Another problem came with the development of siege weapons, which could knock down bricks. Thus, stone eventually became favored. For instance, the Great Wall of China began as mostly earthworks, slowly replaced over hundreds of years with stone.

Some historians have argued that all great empires have been built by warfare, and many ancient peoples believed that a strong military was essential to survival. Of the various kinds of writings that show up in ancient cultures, military ones are among the most common. Theories of warfare and rules for warfare abounded, but the successful military commander was often someone who surprised his enemy by breaking the rules. An advance in technology was often the secret to breaking the rules. For instance, chariots created more mobility on the battlefield for elite warriors, playing key roles in wars and sometimes changing the course of an entire culture, as in the Aryan invasion of northern India. Still, the stirrup made the chariot obsolete by providing a horseback rider with the stability to fire arrows into the enemy or hack with a sword and remain in the saddle.

Militaries became complex organizations as military technology advanced. A government needed to create a chain of command and policies for when and how military forces were to be used. Some cultures organized their armies around heroes, elite warriors who fought for individual glory. Those cultures that learned to organize their armies so that all their troops worked together usually overcame the armies that emphasized individualism. Thus military discipline became a matter of great importance. Governments learned to train their officers and troops.

The military was often the most expensive part of government. If a government wanted a successful army, it had to be sure its army was fed. The soldiers needed proper quarters in which to live, and they required armaments and training in how to use the armaments. This expense meant that standing armies were usually small, with professionals being supplemented by militias or untrained people in times of war.

AFRICA

BY KIRK H. BEETZ

Only three ancient African nations outside Egypt had militaries: Karmah, Cush, and Axum. Not much is known about Karmah, and much of its territory is now under Lake Nasser, the reservoir behind the Aswān Dam, which hampers archaeological research into the kingdom of Karmah and the ancient Nubians. The Karmahns were a mix of Nubians and people from farther south, and the Karmah kingdom existed from about 1900 to 1492 B.C.E. Sometime before 1650 B.C.E. Karmah extended its dominion to just south of the first cataract on the Nile river, beyond where the Aswān Dam is now.

The Karmah military still used stone spears. Its organization is not known, but it seems to have been influenced by the nomadic cultures to the west, which would mean that it favored individual heroism rather than group cooperation in combat. Between 1504 and 1492 B.C.E. Egypt conquered Karmah, sacked the capital, and seized land far to the south of Karmah, bringing nearly all of Nubia under Egyptian rule.

Most of what is known about Kush comes from the Egyptians. The Kushites created their own alphabet, but their language has yet to be deciphered. They regarded themselves as the true inheritors of the ancient Egyptian culture and often wrote in Egyptian hieroglyphics, which have been interpreted and provide some light on Kush's military. Kush arose in Nubia in about 900 B.C.E., filling a power vacuum left when Egypt withdrew after about 500 years of ruling Nubia. Kush organized its military along Egyptian lines. One aspect of its military not shared by Egypt was the use of elephants in parades and as elevated platforms for archers.

By the time Kush took over northern Nubia after the Egyptians withdrew, the Egyptian fortifications in Nubia had become showpieces rather than serious military installations. The fortifications tended to be inside a Nubian city, impressively decorated but not of much value for protecting the city.

Archaeologists think that this means the Egyptians had become very secure in Nubia and had nothing to fear from the local people.

The military's function in Kush was to keep the kingdom's trade routes open and to protect the kingdom from nomadic raiders who would steal crops and loot villages and towns. For this, Kush maintained a standing army, perhaps a few thousand troops at first and possibly as many as 40,000 at the kingdom's height of power. Kush may have had a military academy for training its officers. It is not clear who was and was not eligible to become an officer, but it is known that women sometimes led the army into battle. A queen was called *candace*, and ancient Greeks recorded an attack in 7 C.E. led by such a woman, Candace Amanirenas, against the Romans in Egypt.

There exist some impressive stone structures that may once have been part of Kushite fortresses, but archaeologists disagree over the purposes of the edifices. For maintaining garrisons in its territories, particularly on its frontiers, Kush seems to have followed Egyptian patterns of constructing clay brick fortresses. These had outer walls with towers at their corners and an interior keep also made of brick. Defensive ditches lay outside the walls. Siege engines were rarely used in Egypt and Kush, so an attacking force would have to overcome defenders in the ditches while archers on the walls rained arrows on them. The typical way to lay siege to a fortress was to surround it and wait to starve out the defenders, which could take a few years. The nomads who raided Kush did not have this staying power, and the Kushite army could relieve a fortress long before the raiders could overcome it.

The Kushite general Piye, who invaded Egypt in about eighth century B.C.E., had as the core of his army veteran troops who were highly disciplined. Army units tended to be divided into archers, spearmen, and swordsmen. The spearmen undertook the heaviest fighting. The archers fought behind the spearmen, and the swordsmen protected the archers. Even ordinary Kushites tended to be good warriors, and they were often hired as mercenaries by Near Eastern kingdoms and Egypt. Kush could therefore field an army of fierce fighters, all of whom had some understanding of military discipline.

As he advanced north through Egypt, Piye renovated Egypt's fortresses and city defenses. He eventually took on the duties of pharaoh (r. ca. 750–ca. 712 B.C.E.). His successors continued to rebuild Egypt's defenses. Although they organized Egypt's military intelligently, their weapons and thinking were still in the Bronze Age, whereas the Near East was in the Iron Age. When the Kushite pharaoh Tantamani (r. ca. 664–ca. 657 B.C.E.) tried to reestablish Egyptian influence in Palestine, the Assyrians attacked. Plague helped to destroy the first Assyrian strike force, but superior armor, weapons, and tactics enabled the Assyrians to drive the Cushites out of Egypt around 656 B.C.E.

The Kush government took note of how Assyria had defeated Tantamani's armies and took firm measures to advance into the Iron Age. Although Kush's soldiers appear to

have continued to use shields made of hide, their weapons and tactics advanced to a level unmatched elsewhere among Africans. The military became focused on protecting the southern reaches of Kush as well as protecting its northern and western territories. Commerce in eastern Africa seems to have flourished in part because Kush's army kept the peace among the region's southern tribes.

When Kush's military power faded is not known. It seems to have still been formidable in the 200s C.E., but little else is known of the region during the early years of the Common Era. By 330 C.E. the Kushites had fled their country, and it was occupied by nomadic tribes. By then a new power had risen in eastern Africa, in present-day Ethiopia. This was the kingdom of Axum. It had begun as a trading city that was visited by Arabs and Indians from the east. By the 200s C.E. it controlled much of eastern Africa.

Not much is known about Axum's military. Axum seems to have had a small coastal navy. Imposing forts made of stone and masonry sat atop coastal hills and controlled access to the interior of Axum. In 330 C.E. the nomads who had invaded Kush violated a treaty they had with Axum, and Ezānā, king of Axum, led an invasion of Kush that found only the nomadic tribes Red Noba and Black Noba, who were soundly defeated. Overall, Axum seems to have preferred diplomacy to taking military action, and it emphasized commerce over war, using its military mostly to keep pirates and bandits at bay. Its hilltop fortresses suggest that it had a standing army to man them and that the army was expected to defend Axum from invasion. Perhaps Axum's military played a role in protecting the country from Arab invasions from the seventh century C.E. onward, but this is not yet known.

EGYPT

BY AMR KAMEL

Egypt had no standing professional army before the New Kingdom (ca. 1550–ca. 1070 B.C.E.). When the need arose, provincial governors, temples, and estates provided units under the command of local officials, as in the case of Unas (r. 2356–2323 B.C.E.) in the Fifth Dynasty. The official related in his autobiography that the army under his command, who fought the “Asiatic Sand Dwellers,” was originally composed of men from Upper Egypt, Lower Egypt, and Nubia and that he did not have strong military background or a previous military title. Evidence does exist of a permanent royal army led by professional officers during the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) in lower Nubia, which became a heavily militarized zone, and references to a variety of military titles increased toward the end of that period. During the New Kingdom a large professional army with a fully developed hierarchy fulfilled the pharaohs' plans to form a great empire, including territories in Nubia and Palestine and areas of present-day Lebanon, Syria, and northern Iraq.

The Egyptian military was composed primarily of infantry, which was organized into four divisions named, un-

der Ramses III (r. 1194–1163 B.C.E.), after the gods Amun, Ptah, Re, and Seth. Each division was divided into about 20 companies of 250 men and each of these into five platoons of 50, in addition to 20 administrative supervisors and military scribes for managing provisions and other logistics. By the middle of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.) the Egyptian army had an organized chariot division, which functioned mainly as a mobile platform for archers. The cavalry division was, until the campaign of Sheshonk I (r. ca. 945–924 B.C.E.) of the Twenty-second Dynasty, limited mainly to scouting parties.

The navy was not a separate division of the Egyptian army, and for most of Egyptian history sailors appear to have been regular soldiers who used boats simply as waterborne platforms. These troops were normally stationed in barracks at Thebes, Heliopolis, Memphis, and Piramesse, the royal residence during the Nineteenth Dynasty (ca. 1307–ca. 1196 B.C.E.). For one military campaign abroad the 20,000 soldiers mobilized immediately, and large Egyptian warships, such as *Star of Egypt*, *Soul of the Gods*, *Wild Bull*, *Beloved of Amun*, or *Thutmose Appears in Memphis*, transported troops and supplies via the Pelusiatic Branch of the Nile to Byblos (later called Jubayl) on the coast of what is now Lebanon.

Like any modern army, the Egyptian forces were organized along strictly hierarchical lines. They were under the command of the king, who had an advisory council made up of a vizier (sometimes called the “overseer” of the troops), generals, and senior functionaries. Divisions, companies, and platoons had supervisors equivalent to modern officers and noncommissioned officers. As in every other sphere of the Egyptian bureaucracy, sons were able to follow their fathers’ military profession for the sake of a career and a secure livelihood.

During the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) the Egyptian army was largely considered a national one, with the exception of Nubian archers, who joined the army in the Sixth Dynasty. From then on, notably in the New Kingdom, foreign units began to form with the gradual subjugation of neighboring people in Asia, the Mediterranean, and the region of modern-day Libya. From the time of King Seti I (r. 1306–1290 B.C.E.) the army included a contingent of Sherdan mercenaries, originally from the Mediterranean islands, who were distinct from the Egyptian forces with their swords, spiked helmets, and shields. It was not unusual for foreign mercenaries to reach the senior ranks in the Egyptian army or even to join the king’s elite bodyguard. For instance, the guard of Amenhotep III (r. 1391–1353 B.C.E.) was composed of Nubians and Canaanites. Beginning in the Second Intermediate Period (ca. 1640–ca. 1532 B.C.E.) the Egyptians employed the Medjay, a pastoral people who lived in the Arabian Desert, as police within Egypt and along its southern frontier. By the New Kingdom the term *Medjay* had become virtually synonymous with *police*, which, like the military, were organized hierarchically and headed by the chief of the Medjay.

Many kings during the New Kingdom campaigned in western Asia on a nearly annual basis. As might be expected

from a temporarily mustered force, the troops left Egypt after the harvest was gathered and returned in time for the planting season. Textual evidence refers to the transportation of food and fodder by ships to the large port centers in the eastern Mediterranean region. There is no evidence that the soldiers’ families accompanied the troops during any campaign. Instead, they prayed to the deity Amun in temples or in domestic shrines to return their sons and relatives home safely. The family members of the scribe Dhutmose in the Twentieth Dynasty (ca. 1196–1070 B.C.E.), for example, are recorded “calling upon Amun, Mut, Khonsu, Re-Horakhti in his rising and in his setting and all gods of Thebes” to return their son Dhutmose, who was sent in military mission in Nubia, “back alive from the next war.”

In early times a young man’s military service began at the age of 20, and in later periods the recruits were much younger. A recruit faced a hard school of discipline and toughening up. His uniform was a short kilt or merely a penis sheath, and he wore a feather in his hair as an ornament. Physical exercise and wrestling alternated with training in weaponry. For breaches of discipline the commander would order a thrashing; one text refers to an offender being beaten by his fellow recruits “like papyrus.” Military reviews were held on state holidays or after the return of a victorious army in presence of the kings, to the accompaniment of trumpets, fifes, and drums.

During such festivals officers and soldiers could receive gold awards for bravery and other awards, including decorated axes, daggers, or swords, for other military virtues. Trinkets such as little golden lions, representing bravery, and gold flies, symbolizing perseverance in the attack, could be considered the world’s oldest medals. Esteemed officers could be granted numbers of prisoners, male or female, to be kept as slaves, and sometimes plots of land.

Military strategy was usually adapted according to the natural conditions and situations the Egyptians encountered. Textual and pictorial sources describe, for example, the tactics of the battle of Kadesh, which took place around 1274 B.C.E. during the reign of Ramses II (r. 1290–1224 B.C.E.). Ramses II apparently believed the story of two Hittite spies who presented themselves as Bedouins and reported to the king that the Hittite army had retreated. Ramses II therefore rapidly moved through enemy territory without scouting the area ahead, ignoring one of the most basic military principles. Having crossed the Orontes River without sending troops ahead, he was attacked by the Hittites, and the river lay between him and his supporting troops. Egyptian forces traveling by warship managed to save the Egyptian army from destruction.

Several series of forts, watchtowers, and way stations facilitated the Egyptian army’s march and served as part of a signaling system adjacent to the cliffs along the Nile in Nubia and along the northeastern border with the ancient Near East. The system of military stations in this frontier region was known during the New Kingdom as the Ways

of Horus. Recent excavations in the western Nile delta have identified a parallel chain of forts that were presumably constructed to protect the Egypt's northwestern frontier, which began at Zawyet Umm el-Rakham, about 200 miles west of Alexandria, where Ramses II built his substantial citadel. These forts were surrounded by massive enclosure walls and sometimes ditches. Fortified gateways, watchtowers, loopholed ramparts on the inside, and covered glacis on the outside made them almost impregnable. Granaries and cisterns were attached to the forts. Probably 50 to 300 soldiers were stationed in one fort at a time, depending on its size, which implies that small military units were able to hold their positions.

THE MIDDLE EAST

BY CARYN E. NEUMANN

Throughout the ancient Near East, war made and unmade political and cultural worlds. The social orders of the time were formed and maintained by brute force and compulsion. Long royal reigns produced and were reproduced by military stability. Short reigns reflected weakness in war. As a result, the military played a crucial role in the lives of the ancients.

The first literate civilizations and the first organized armies appear almost simultaneously in the river valleys of the Tigris and the Euphrates. The Sumerians invaded southern Mesopotamia in about 3100 B.C.E. and subjugated the inhabitants, the Subarians. As the Epic of Gilgamesh, an epic poem recounting the deeds of the mythical hero-king Gilgamesh, indicates, rulers were chosen by the army from a hereditary and divinely approved list. The ruler represented a god, and his job was to ensure that the god was satisfied. Rulers fielded armies of 5,000 to 10,000 men who fought in a phalanx, shoulder to shoulder. The Sumerians used copper weapons, spear, and ax. Phalanx tried to break phalanx by shoving, jabbing with the spear, and hacking with the ax. At first, the Sumerians dominated Mesopotamia because their opponents had ill-disciplined, stone-armed forces. In time, however, the Akkadians, Gutians, and Elamites adopted copper weapons and organized tactics. About 1950 B.C.E. a coalition of Subarians, Gutians, and Elamites ravaged Sumer and led the last ruler off as a prisoner.

At the beginning of the second millennium Indo-Europeans tribes invaded the Near East. These tribes had developed the chariot and combined it with the composite bow to produce a highly mobile platform from which they could deliver accurate, rapid fire. The Hittites, the first of these invaders, used the mountains by the Halys River to protect themselves from their enemies before they fanned out to conquer the rest of Anatolia. They viewed war as the only honorable calling for a man. The Aryans formed the military into a separate class, led by the nobility. They organized their army by tribe, clan, and family in units of 180 men. Chariots led the charge and guarded the rear. The chariots did not rush into battle but organized to give each other protection, with

the least experienced charioteer encouraged to learn from the more seasoned soldiers.

The Assyrians dominated Mesopotamia in the ninth, eighth, and seventh centuries. They possessed the largest army in the Near East with perhaps 200,000 Assyrians and another 800,000 men drafted from conquered territory. The Assyrians hired mercenaries, replaced the annual call up of militia with a standing army, and organized their kingdom to ensure a sufficient agricultural base to support the chariot and cavalry units on a permanent basis. They were the first to organize regular cavalry units and to use transportation as a tactic. The Persian army was organized, like the Assyrian army, into regiments of 1,000 men further divided into hundreds and 10s. The 10 would form in file, the leader armed with a lance while the other men had bows or swords. The shields were placed in front as wall behind which all could fire their arrows.

The balance of evidence suggests that in premodern warfare the mobilization of manpower mattered more than any other factor in the long run. To get enough men to win combat that was often hand-to-hand fighting, nations recruited

THE HORSE

Few battles in Mesopotamia and the Near East were won without the assistance of horses, yet while kings and men are celebrated, horses receive little credit for their military contributions. Domesticated horses were initially believed to be natives of the Zagros Mountains in present-day Iran that spread throughout the Near East while pulling chariots. The currently accepted thinking favors a gradual spread of horse from the Russian steppe, so that the inhabitants of Mesopotamia were familiar with these equines from the third millennium B.C.E. onward.

The horse did not immediately replace the mule or the ass, the common beasts of burden in the ancient Near East. Adoption was slow because of the qualities of the animal. Of all domesticated animals, the horse remains the most temperamental and nervous. An animal of flight rather than fight, the first reaction of a horse to danger is to gallop to a safer place. This tendency presents a problem in battle or when hauling men and materials to a battlefield.

Horses also proved more difficult to train, partly because more is expected from them. Horses pulled wagons, carts, and chariots while holding bone and metal devices in their mouths and tolerating a number of straps and weights on their heads and bodies. When four horses were used for a chariot or wagon, only the two closest horses were yoked, with the two outsiders controlled by reins alone. As herd animals, horses were easier to manage in teams than alone. They were also competitive at speed. The outside horses, feeling less pressure against their throats and less yoke pressure on their necks than the inner animals, would have set the pace for the whole team. During the journey the inner horses would periodically exchange places with those on the outside. The ease of training horses to work together explains the initial popularity of chariots over cavalry. Ridden horses did not become a regular feature of armies in the Near East until the first millennium B.C.E.

from outside their borders. The Sassanian state (224–651 C.E.) in Persia is typical. When Shapur II led his expedition into Mesopotamia in 359 C.E., his army included Armenians, Arabs, Albani, Chionitai, Gelani, Segestani, and others. Some of the armed forces consisted of slaves. There is also a tradition of slave-soldiers in the Arabian peninsula, with such soldiers regularly serving in the armies of the Near East.

Still, actual fighting typically turned on individual set battles. Despite the large size of their empire, the Sassanians fielded small combat units. The small operational units and

the need to deal with armed threats in geographically limited zones of confrontations resulted in strategies and plans that were often ad hoc decisions made either by the commander in the field or, given the political dangers of such autonomy, after consultation with the king. The close connection between war and political power put constant pressure on rulers to direct war in person on the field of battle and to prove their worth as monarchs by showing success in war.

Much of the success of a leader rested on the fighting ability of the men under his command. Battle madness of elite warriors is known from the myths of many Near East nations. Berserk warriors, mad for fighting, scorned armor and were among the most feared soldiers. Chiefly swordsmen, they were first identified as fighting in the army of Tukulti-Ninurta, king of Assyria when he defeated the Babylonians in 1228 B.C.E. Tukulti-Ninurta's berserks had armor but threw it off along with their garments in sight of the enemy. The effect on the Babylonians undoubtedly contributed to the victory of the Assyrians.

Fortifications also led to specific types of combat, notably the siege. Siege warfare arose when there was a clearly defined frontier between relatively balanced opposing forces and when large and heavily fortified urban centers were present in the frontier zone. These cities were expensive to attack, limiting the use of siege only to those nations wealthy enough to finance it. When the Roman and Sasanian empires met each other in the great plain between the upper Tigris and Euphrates rivers, both sides wanted the wealth stored in the treasuries of heavily fortified cities controlled by the opposition. Both the Romans and the Sassanians resorted to sieges in the fourth century C.E.

The conflicts followed a close routine for both the besieged and the besiegers. Usually the attacking forces first made a tremendous display of power with the hope of frightening the besieged into surrendering. If this tactic failed, it was usually followed by a parlay in which the besiegers attempted to negotiate the surrender of the city on equitable terms by a mixture of threats and offers of security and safe conduct. If these moves failed, the besiegers then moved to the next step of simultaneous attacks directed at the full circuit of the city's walls. The attackers looked for a weak spot or to induce surrender by demonstrating the seriousness of the besieger's intentions. If this tactic failed, the attackers finally brought in heavy siege equipment and began large-scale mining operations. Throughout this sequence, activity stopped at darkness and resumed at daybreak.

As did the availability of light, weather dictated military tactics. In winter armies retreated from war only to advance when spring returned. Sometimes these responses to natural conditions were translated into traditional cultural prohibitions, such as the time around the spring equinox when Saracens entered a two-month-long sacred period during which they refused to undertake raids against their enemies. The history of warfare in the Near East is one of extreme stability.

There were long periods of peace and a style of combat that remained constant over the centuries.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The first Chinese dynasty that historians and archaeologists can confirm was the Shang (c. 1550–1045 B.C.E.). The Shang were a warlike people, constantly trying to expand their territories through conquest and frequently defending their territories against barbarian raiders. The head of the Shang military was the king, and below him were nobles who were expected to be officers. Governors of Shang provinces led military campaigns on their own. Most of the soldiers in a Shang army were peasants, usually poorly equipped and poorly trained. They did most of the dying.

In the Zhou Dynasty (1045–256 B.C.E.) peasants still made up most of a Chinese army, but the elite status of the aristocratic warriors was emphasized. These warriors fought while on horseback. A battle could be very stylized, with nobles showing off their skills in front of assembled armies. In matters of conquest, however, battles could be very serious affairs, with tens of thousands of troops perishing. The Zhou favored fighting one huge, decisive battle rather than several small ones, and a war was often decided in one engagement. The Qin Dynasty (221–207 B.C.E.) changed the way officers were selected, choosing to promote military leaders on the basis of their performance in battle rather than on the basis of noble birth. It was replaced by the Han Dynasty (206 B.C.E.–220 C.E.), which brought order and discipline to its military policies by establishing a clear chain of command that limited the ability of individual commanders to establish their own armies and wage their own wars in pursuit of political power.

For the rest of the ancient era Chinese governments imposed a draft. Every district of China had an official responsible for finding people to serve in the military. The age requirements varied from time to time, but in general any man between the ages of 23 and 56 was expected to serve two years in the army or the small navy. Weapons and armor were usually provided once the new soldiers had marched to where they were expected to serve. They lived in small forts made of brick or stone.

The Great Wall was one long fortress with numerous towers. Each tower had a way to signal that it was under attack, usually by raising flags. Soldiers were expected to help maintain the wall. They lived in barracks behind the wall where armories and food stores were placed near them, also behind the wall. When an emergency arose, soldiers rushed to defend the wall. At other times they were drilled in how to fight in formation and in how to use their armaments. In this way the government ensured that it always had well-disciplined soldiers available for defense and conquest.

In ancient India wars were fought frequently, and the military was an important institution in its kingdoms. Noth-

ing is as yet known about how the Harappan culture (2600–1500 B.C.E.) of the Indus River valley conducted its military affairs. In the 1500s B.C.E. it was overcome by Aryan tribes invading from the north. These tribes had a heroic culture, which means that they celebrated warriors and military heroism over all else. Their elite warriors used chariots.

By the 400s B.C.E. most kingdoms followed a pattern required by tradition and religious law. Any monarch who wished to remain a monarch needed to retain a standing army, because kings were expected to increase their status through war on other kings. They were members of the Kshatriya caste. This caste encompassed warriors and rulers. It was the king's calling to aspire to become a *maharajadhiraja*, a king of kings. He achieved this by forcing other kings to become his vassals. If he became a king of kings, his son would sacrifice a horse in an ancient Vedic ritual, making his father's status official. The king could then aspire to be a *cakravartin*, a king of the world, by expanding his kingdom's frontiers to encompass almost all of the territories of India that he knew to exist.

Every capital city was heavily fortified, because attacks on capitals were often the most direct way for a king to force another monarch to become his vassal. Defensive works could be impressive. A tall earthen wall, sometimes several miles in circumference, would encircle the city. The wall would be patrolled day and night by soldiers, and its gateways would have squads of soldiers stationed at them. Some cities had ditches and wooden barricades outside their walls. Within the city was a fortress that served as the king's residence. He would make his last stand in that fortress if he had to do so.

An Indian army originally was divided into four parts. One was the infantry. The infantry included guild militias. Each guild of tradesmen, members of the Sudra caste, was expected to maintain a militia that could be called to arms to fight bandits, preserve public order, or fight in a war. Another part of the army was the cavalry. This consisted of horsemen mostly from the Kshatriya caste, but it could include members from other castes. A third part of the army consisted of elephants and their handlers. The elephants were covered in armor and ridden by a driver and two or three soldiers, who were armed with arrows or spears. The fourth part of the army consisted of chariots with their drivers and soldiers. A chariot driver sat on the shaft, while as many as three soldiers rode inside the chariot. Maneuvering a chariot on India's frequently muddy battlefields was difficult, and the chariots could not keep up with men on horseback. After the 600s B.C.E. chariots were supplanted by the cavalry.

According to the Chinese, the people of Japan, called the Wa, were very warlike. Archaeologists have found a settlement on the island of Honshu with two ditches dug around it, as if for defense. A Chinese ambassador to the court of Queen Himiko, during the 200s C.E., noted that Himiko's palace was surrounded by a wooden palisade, with fearsome guards at its gates, which suggests that she had at least a small standing army. The Wa were mostly illiterate and apparently left no military records.

In 108 B.C.E. the Chinese established their first Korean colony, the city of Lolang. From Lolang, Chinese customs filtered through Korea, and it may be from the influence of the Chinese that Koreans developed disciplined armies, notable for their courage and their quick maneuverability. The most advanced militaries in Southeast Asia before the medieval era were probably those of Nam Viet and Funan. The Viets came from the area of the Yangtze River, from which some migrated to what is now northern Vietnam and southern China in 333 B.C.E. In 207 B.C.E. they were conquered by a Chinese general who created Nam Viet, meaning “Southern Viet.” It is possible its military was organized like the Chinese military. Funan stretched from the Mekong Delta in South Vietnam to central Cambodia, from the 100s to mid 500s C.E. It fought often with tribes in South Vietnam. It had strong ties to India and probably followed Indian military customs. Little is known about military affairs in Oceania before the emergence of a kingdom in Tonga in the medieval era.

EUROPE

BY CARYN E. NEUMANN

In all societies of the ancient world the military played a critical role as the protector and shaper of political and cultural life. While the importance of the military in ancient Europe is well known, little evidence of the military’s actual operation has survived the passage of time. The preliterate societies of Europe did not leave written sources, and while the archaeological record provides evidence for warfare in the form of weapons and violent death, it does not reveal much about fighting organizations until relatively late in prehistory.

What is known is that prehistoric societies in Europe generally fought to dominate other groups and to compel their surrender of various forms of wealth. Territorial control was probably not a basic issue, since beyond the level of the farmstead and village there was little sense of fixed political or ethnic boundaries. Most military actions probably involved raiding parties that were composed of individuals who were taking a leave from farming or craft production. After doing their damage and carrying off their booty, they then returned to their normal pursuits.

During the late Neolithic and Early Bronze Age in northern and western Europe, around 2000 B.C.E., there is evidence of the emergence of a warrior aristocracy, an elite group of individuals who shared common values of fighting and ritual feasting and drinking. The archer found buried at Amesbury near Stonehenge with his drinking cup and arrowheads may have been a member of this group, whose burials have been found throughout northwestern Europe. Archaeologists are only beginning to understand the nature of this elite group and its role in Bronze Age society, and at this point it is unclear whether it controlled any significant numbers of specialist fighters.

There is more and more evidence during the Iron Age of the activity of organized raiding parties. In coastal areas

these parties moved by boat, and the Hjortspring boat found loaded with shields and swords in Denmark is probably the remains of one such vessel. In fact, it may have belonged to the losers in a confrontation that took place around 350 B.C.E., since the circumstances of this find suggest that it was a victory sacrifice. Many bogs and lakes in northern Europe have yielded large numbers of weapons, some deliberately broken, that were deposited as offerings by victorious fighting groups.

When the Romans entered northern and western Europe, they encountered native armies whose organization and fighting styles were very different from theirs. While the Greeks and Romans embraced a disciplined style of warfare, the ancient peoples of Europe continued to cling to fighting styles that had changed little since the Bronze Age. Styles arose from beliefs and states of mind. These styles became evident in the choice of dress, weaponry, and fighting technique. One style involved berserk warriors. These men, especially common among the Celts, threw off their clothing when entering a trance of recklessness that goaded them to awesome efforts.

Another style of fighting involved the imitation of ferocious animals. European warriors, especially those from the Germanic nations, were entranced by the idea of changing into animals. They sought to have the qualities of animals, such as ferocity, speed, stealth, and the ability to frighten an enemy. Wolves were the most popular warrior model throughout Europe, though boars, bucks, martens, and horses were also common choices. Bear warriors seem to be mostly Germanic, for few are known among the Celtic tribes.

Warriors who imitated animals were useful because, in ancient times, combat was often reduced to brutal hand-to-hand fighting. Warriors dressed as animals believed that they possessed the fighting abilities of those animals, whether wolves or tigers. As a result of such fighting, there was constant pressure to recruit beyond the bounds of one’s own ethnic group or state in order to acquire the manpower needed to meet or exceed the enemy’s ranks of fighters. The Goths are typical, in that the Goth army that crossed the lower Danube in 376 C.E. consisted of several subethnic groups of Goths (including the Tervingi and Greuthungi) along with Huns and Alans. When Romans fought civil wars, they often recruited so-called barbarians from along the frontier to attack rivals. Alans, Goths, Huns, Iberians, and Isaurians were all recruited on a large scale by the Romans.

The fighting in ancient Europe did not spare civilian populations. Many of the military attacks were simply massacres of people in villages and rural farmsteads for the purpose of terrorizing civilian populations. Rape was part of these attacks. In an era when soldiers did not receive regular pay, soldiers were often recruited with the promise of plunder—including sexual plunder—as their reward. This form of payment was nonetheless regulated because uncontrolled pillage meant, in effect, that the control of the army had been lost. Rape had military value because it wounded the honor of

the enemy. Enemy soldiers unable to protect their women suffered a loss of masculinity that affected morale. Conversely, the rapists experienced an elevation of masculinity.

A potential form of overwhelming superior force lay in the use of the chariot, but the genesis of the chariot is still disputed. The invention of key components, such as the wheel, took place in Europe, while various peoples in eastern Europe experimented with light, bentwood, fast, horse-drawn carts. The horse itself originated in the Russian steppes and was first trained in this region. The absence of the horseshoe, however, meant that mounted troops were at a disadvantage when compared with charioteers. Shooting arrows while riding and controlling a galloping horse remained far harder than firing a bow from a speeding chariot until the invention of the stirrup during the first millennium C.E. Only the mounted bowmen from the steppes, notably the Parthians, were to succeed in mastering this difficult skill in the West.

The European style of battle involving both infantry and chariots initially showed little organization. The objective was to reach a suitable place of battle in order to overwhelm the enemy before he could prevail. Essentially, a campaign differed little from a large raid. Maneuver in battle was largely accidental. Sometimes the initial charge of chariots and horsemen would strike terror into the opposite side, in which case battle quickly became a chase, with only the fleetest men escaping the slaughter. More often, the two masses simply converged to carry on the butchery. The Roman style of disciplined warfare spread gradually throughout Europe.

Styles of warfare among the European people did not include sieges. While the Romans had the money to finance such expensive conflicts, the smaller European kingdoms did not have the resources to do so. For the same reason, they generally did not engage in naval warfare. Ethnic groups such as the Goths in the mid-third century C.E. did sometimes seize ships to use for raiding or, more often, simply for transportation. The practice of fortifying settlements and other important locations dates back to Neolithic times. Fortified sites, called *oppida*, were often built in easily defended locations such as hilltops and peninsulas. Earthen ramparts and ditches were supplemented during the Bronze and Iron Ages by timber and stone walls. A common construction technique used by the Celts to build their *oppida* was called the *murus gallicus*, in which heavy timber beams were used to construct a framework between which stone walls were built.

In ancient Europe climate controlled war. Weather imposed seasonal rhythms that dictated periodic campaigning seasons. In Gaul and on the Rhine frontier the war season was signaled by the beginning of summer. In other regions war began with spring. In autumn and winter roads were slippery with ice, and no grass grew that could be used as fodder for horses and mules. These temporal patterns were so well known that they were regularly presented as part of normal tactical advice. But emergencies could alter tactics. The people along the northern frontier of the Roman Empire sometimes found themselves facing midwinter subsistence

crises that drove them to enter the developed regions of the empire. In 366 C.E. the Alamanni crossed the Rhine. The Lentienses crossed the same river in 378 C.E. They attacked agricultural settlements to fend off famine. By attacking these settlements, the Lentienses could steal and eat the crops grown by the farmers and avoid starvation.

GREECE

BY MICHAEL M. SAGE

The Mycenaean Period (ca. 1600–ca. 1100 B.C.E.) is the earliest for which there is any evidence for Greek military forces. Greece appears to have been divided into a number of small kingdoms that had their own armies. There is evidence that these kingdoms had central military stores, at least for their chariot forces, and that a class of chariot warriors existed. It is not known whether these men were professional soldiers, nor is it known how they were selected. Equally lacking is any information on how armies of this period fought. Archaeological finds indicate that the heavy thrusting spear was the most common weapon, so it is likely that fighting was done in some sort of close formation. Toward the close of this period there is some evidence for standardization of equipment.

At the end of the Mycenaean Period these kingdoms disappeared, and there was a decline in population. The communities of this time appear to have been small and isolated. Most of the evidence for warfare, apart from weapons finds, is concentrated after 800 B.C.E. and consists of portrayals of combat on pottery and descriptions in the Homeric poems, which probably reflect warfare in the period from 750 to 650 B.C.E.

The fighting forces were led by local chiefs and princes for whom success in warfare was crucial to their standing as leaders. Their war bands were held together by the promise of the rewards they could offer. These bands appear to have been made up of two types of warriors: the nobles, who were relatively well equipped and played a leading part in the fighting, and the mass of poorly armed and poorly protected fighters who followed them. There was mass combat of a relatively open type dominated by missile weapons and the sword, which allowed for individual demonstrations of prowess by the nobles.

A series of important changes marked the end of this so-called dark age around 700 B.C.E. Militarily the most important was the growth of a new kind of community, the city-state, in central and southern Greece. The city-state consisted of an urban core, which served as the political, religious, and economic center, and a dependent countryside of towns and villages. Along with the city-state came the idea of citizenship as a collection of rights and duties, one of which was military service. The strong connection between citizenship and military service is evident in the prohibition of military service for slaves, while in some states full citizenship was reserved only for those who did military service. Given the limited revenues of the communities, citizens were required to serve

The fortifications of Eleutherae, a city in the northern part of Attica, bordering the country of Boeotia (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

at their own expense, and this restricted military service to those who possessed a minimum amount of property.

The nucleus of this army was a heavy infantry made up of soldiers called hoplites, who were well protected by armor consisting of a bronze helmet, a cuirass that covered the body from waist to neck, and a set of greaves for the shins. A hoplite's main offensive weapon was a heavy thrusting spear. This was used in a rectangular phalanx formation in which the soldiers fighting close together mutually reinforced one another, protecting one another with their large circular shields. Their attacks were launched frontally against other armies that were armed and deployed in the same fashion. The key to victory was to break apart the enemy phalanx. These engagements tended to be sharp and short, and, since there was little in the way of well-thought-out logistics, most campaigns were undertaken either to defend against a neighboring state or to take control of some nearby territory.

There appears to have been no organized cavalry force until the middle of the fifth century B.C.E. After that time the cavalry was drawn from those wealthier citizens who could afford to maintain horses. The poorer citizens served as light-armed troops who used missile weapons, especially javelins. These troops were used to open the battle and to cover the movements of the hoplites, who, as the heavy infantry, were the decisive force. In areas of Greece that did not form city-states, older styles of open fighting continued.

Outside Sparta there is little evidence for training methods before the end of the fourth century. There must have been some instruction in marching in formation, but it seems that training in the use of weapons was left to the individual. The Spartans were an exception to this part-time soldiering. All full male citizens were trained and served as full-time soldiers. A rigorous course of physical hardening lasted from the age of six to 18 in groups that segregated the boys from normal family life. Weapons training and marching training were included and repeated when on campaign. In some

other city-states there were special formations of hoplites that seem to have received special training, but Sparta remained unique in fielding a professional army. That advantage allowed it to become the preeminent land power and to create a military alliance in the Peloponnese that further strengthened its dominance.

Greeks serving as mercenaries are known as early as the seventh century B.C.E. For the most part that service was performed in the Near East. There are occasional references to small groups of mercenaries serving in the homeland, but it is not until the Peloponnesian War (431–404 B.C.E.), fought between Athens and the Peloponnesian League (led by Sparta), that there is evidence for large numbers. Mercenaries were predominantly drawn from the poor regions of Greece, such as Arcadia and Achaia; specialist troops, especially from Thrace, were also used. The fourth century saw a rise in the demand for mercenaries as a result of the increased use of light-armed troops whose style of fighting required long training to be effective. In the Hellenistic Period (323–31 B.C.E.) the armies of all the major Greek kingdoms except for Macedonia consisted of mercenaries who served for life, and attempts were made to retain their loyalty by granting them areas for settlement and right to land.

Before the Peloponnesian War the tactics of hoplite battle had been relatively simple. Dense arrays of soldiers in rectangular phalanx formation each attempted to break the order of the opposing phalanx to achieve victory. The simple nature of such encounters was marked by the absence of reserves—since massing men added to the impact of the charge—and by the participation in the fighting of the commander who, once he arrayed his men, had nothing to do but serve as an example to them. But by the last phase of the Peloponnesian War more complicated tactics had been developed by the Spartans. They attempted to use their right wing to encircle the enemy's left and to roll up their phalanx.

By the 370s the Thebans had developed a tactic to counter the Spartan outflanking maneuver by massing their left wing very deeply, up to 50 men in contrast to the normal depth of eight. These changes in tactics were accompanied by the first use of reserves. The Peloponnesian War also saw a further development in the use of combined arms, a strategy that was to develop extensively in the fourth century in smaller encounters. Normally a phalanx of hoplites was used to hold the enemy heavy infantry while it was worn down by repeated attacks of light-armed troops and cavalry. The effective use of combined arms in set-piece battles came with the Macedonians and Alexander the Great. Alexander used the oblique advance first developed by the Thebans to thin the enemy line and, while holding it with his phalanx, delivered the crucial blow on a weak point with his cavalry. In the period after Alexander there was a shift back to the heavy infantry as the decisive arm, given the expense of maintaining cavalry.

Hoplite armies were poorly adapted for siege warfare, and so city fortification remained relatively simple through the fourth century B.C.E. with some exceptions. Often the

fortification consisted of a simple vertical wall made of sun-dried brick on a stone foundation with square towers placed at varying intervals. In the fifth century there was an expansion of fortification from the acropolis to cover the entire urban area. Another major innovation of the mid-fifth century were the Long Walls at Athens (which was dependent on the sea for much of its grain supply), which ran from the city to its harbor at Piraeus and provided a secure connection to the sea. In the next century and continuing into the Hellenistic Period, border forts and fortifications appear and become increasingly complex. The same period also saw an increase in the height of towers and the use of tower platforms for artillery, an innovation that had begun in the course of the fourth century. Ditches also appear with increasing frequency as a means to keep the attackers' siege equipment as far from the walls as possible.

ROME

BY MICHAEL M. SAGE

The earliest Roman army consisted of 3,000 infantry and 300 cavalry with each of the three Roman tribes supplying 1,000 infantry and 100 cavalry. Nothing is known about how this army was gathered or in what manner it fought. It was a militia of citizen-soldiers, as were all later Roman armies until the end of the Republic in 27 B.C.E.

Around 550 B.C.E. a census of property was instituted for all male citizens, and those above a certain minimum level of wealth were obliged to serve while they were between the ages of 17 and 46. The size and amount of a man's property also determined whether he would serve as a heavy-armed or light-armed infantryman or in the cavalry. All service was at the individual's own expense until the beginning of the fifth century, when the state instituted a tax to defray expenses. Each citizen had to complete 16 campaigns in the infantry or 10 in the cavalry. This system remained in force until the end of the first century B.C.E., though requirements changed over time. The introduction of the census was related to the adoption of the phalanx, a densely packed array of soldiers composed of citizens wealthy enough to equip themselves fully. These heavily armed infantry soldiers were protected by metal helmets, breastplates, and large round shields and armed with heavy thrusting spears as their main offensive weapon.

The army was assembled and led by the consuls, the chief executive officers of the Roman state, who were popularly elected. Lesser magistrates with imperium, or the power to command, and proconsuls—those magistrates whose imperium had been extended after their year in office—held independent commands. These generals were assisted by a junior elected official, the quaestor, whose job it was to provide supplies for the army, and by military tribunes who acted as general assistants to the commander. The army was organized in units called *legions*, which in the mid-second century B.C.E. consisted of 3,000 heavy armed infantry, 1,200

light-armed infantry, and 300 cavalry. The number of legions increased over time. In the civil wars of the mid-first century B.C.E. as many as 60 legions were in service. A consul normally commanded an army of two legions and a praetor a single legion. Later armies commanded by proconsuls could be much larger. Caesar in Gaul from 58 to 49 B.C.E. eventually had an army of 14 legions. In addition to Roman citizens, each Roman force included allied Italian cavalry and infantry organized in their own formations and serving under Roman commanders. Normally the number of allied infantry equaled the citizen infantry; the number of allied cavalry was considerably larger.

In the course of the fourth century Roman tactics underwent a major change. In place of the phalanx the army was now organized in three separate lines. In front were the *hastati*, then the *principes*, and finally the *triarii*. Men were assigned to each of these lines on the basis of age, with the youngest men assigned to the front line. Each line consisted of 10 units called *maniples*, which were small phalanx-like formations. In the front two lines the maniples were 120 men strong, divided into two parts called *centuries*, while the maniples of the rear line were half that size at 60 men. Each century was commanded by an appointed officer, the centurion, and the entire maniple was under the orders of the senior of the two centurions. The centurions were the backbone of the army, and its performance in the field depended on them. The main offensive weapons were the javelin and the short stabbing and thrusting sword. (The third line retained the heavy thrusting spear.) The light-armed troops, numbering 1,200, supplemented the 3,000 heavy infantry of the legion.

On the battlefield the maniples of the legion were arranged in checkerboard fashion. The maniples of the first line were separated by gaps from one another. The maniples of the second line covered the gaps in the first line, and the maniples of third line covered the gaps in the second. These gaps permitted the maniples to operate independently and allowed those in front to withdraw to the rear, so that the enemy was faced with fresh troops. Allied troops who gradually adopted Roman equipment and tactics were normally placed on each wing of the legions with the cavalry covering the right and left ends of the battle line.

Several important changes had taken place before the end of the first century in the equipment and structure of the army. By about 100 B.C.E. the *triarii* were armed in the same fashion as the other lines. Next, the basic tactical unit on the battlefield changed from the maniple to the cohort, a unit of between 500 and 600 men. The size of the legion also increased to 6,000 men.

After 88 B.C.E. the Italians became Roman citizens and served in the legions or in the Roman cavalry. Roman cavalry and light infantry disappeared after 100 B.C.E. and were replaced by units from Rome's empire or allied states. As the empire grew, Roman soldiers began serving for prolonged periods far from home. These extended absences were incompatible with a civilian militia system, and the army gradually

became professionalized. Finally, the loyalty of the legions became detached from the state and focused on the various army commanders. This resulted in a period of intense civil war lasting for about 20 years (49–31 B.C.E.) and led to the establishment of a military monarchy.

Under the first emperor Augustus (r. 27 B.C.E.–14 C.E.) the army became completely professionalized, with service standing at 25 years. This professional army was stationed along the distant frontiers of the empire. There were now two types of troops: the legionaries, who were Roman citizens, and the auxiliaries, who were noncitizens but who could gain citizenship at the end of their service. In addition to heavy infantry that fought along with the legions, the auxiliaries provided specialist troops such as archers and most of the cavalry. By 14 C.E. the army totaled 300,000 men divided among 25 legions and an equal number of auxiliaries. The number of legions increased until by 200 C.E. there were 33. Under the empire for the first time troops were stationed in the city of Rome, of which the best known were the nine cohorts of the Praetorian Guard, whose main tasks were to guard the emperor and to keep the peace in the city. The emperor was closely tied to the army, and its loyalty to him provided the basis of his power.

With the professionalization of the army came the professionalization of training. During the Republic there was no formal system of training either before entry or during campaigns. A commander decided whether to train his troops, and most soldiers seemed to have learned their weapons skills on their own initiative. Under the empire a formal training system was instituted within the army. Specialists with military rank were employed to teach basic skills. These remained the same as they had been earlier; physical toughening, marching in formation, care of equipment, and weapons drill. This training was one of the keys to Roman military success, as it instilled a level of discipline and expertise that Rome's enemies normally could not match.

The earliest Roman military fortification was the marching camp, which was constructed daily while the army was en route. The basic fortification consisted of three parts: a ditch, an earthen wall inside of the ditch constructed of the dirt removed from the ditch, and a wooden palisade built on top of the wall from stakes carried by the legionaries. This was not meant as a permanent fort but as temporary protection and was destroyed as the army marched. Toward the end of the first century C.E. permanent stone fortresses replaced the earlier earth and wood structures but kept their basic plan. This reflected the now-static positioning of the legions. Also in this period separate stone forts for housing units of auxiliaries appeared. At the same time much larger fortifications, such as Hadrian's Wall that separated the Roman province of Britain from unconquered Scotland, were built. In the third and fourth centuries C.E. forts and other fortifications became more elaborate in response to increased military threats. Stone was standard, and towers and elaborate gate defenses were constructed.

THE AMERICAS

BY J. J. GEORGE

An organized military, like other developed social institutions, implies a sophisticated authority structure often attributed to advanced societies and is thus linked to the origin of civilization. Nonstate entities typically show less military organization than formal states and rely more on a warrior culture in which every male in society is a serviceable militia member. Arguably, military institutions may be necessary for the transition to state organization and civilized life. Whatever their causal role, military institutions lie very close to the core of civilizations as they have developed. In the Americas fully developed militaries recognizable to modern eyes—state-supported institutions operating in an occurrence of violence to pursue political goals—emerged only toward the end of the ancient period, while earlier military practice took rudimentary but recognizable forms.

The earliest American military institutions probably developed around 1000 B.C.E. among the Olmec in Mexico's Gulf Coast region. The Olmec, an early state or semistate, introduced specialized weaponry, such as maces, exclusive to war- raring as they pursued expansion. Taking prisoners was tied to

political rulership, and kingly responsibilities assumed a military quotient, as indicated by depictions of Olmec kings with bound captives. Defensive tactics are evidenced by a site called La Oaxaqueña, south of the major Olmec settlement of San Lorenzo, which was encircled by a ditch about 30 feet deep by 50 feet wide, probably made for fortification purposes.

Easily defensible and further fortified, the Zapotec mountaintop site of Monte Albán, above what is contemporary Oaxaca, Mexico, was a naturally defensive position, which made it an obvious choice of stronghold. Its central location also helped to unify three converging valleys. Conquest bas-relief monuments at the site, often referred as *los danzantes*, testify to military activity. Similarly, there is evidence of the burning of villages and sacrifice of prisoners cut in stone by 600 B.C.E.—evidence, again, of military progressiveness tied to military expansion. Further evidence of military activity can be found in architectural constructions at Zapotec-affiliated sites called Quiotepec and La Coyatera, where garrisons were built expressly for housing military units with the singular intention of ensuring control over more distant territory. Evidence suggests, however, that the Zapotec military was later based on nobles and lacked standardized weaponry, indicating a lack of command structure and organized units that could fight in formation.

By 500 C.E. at Teotihuacán, often considered the earliest true city and empire in the Americas, a broad military architecture was well in place that indicated a highly organized state bureaucracy. Fortified walls within the city acted both as a partition defining social boundaries within the city and as a defensive mechanism protecting the city limits. The artistic record also provides insight into the nature of Teotihuacán's military. Warriors are depicted wielding atlatls and rectangular shields or thrusting spears and bucklers. The depictions suggest the use of standardized weaponry, which typically indicates state control, formations, and complementary arms use. For example, the atlatlists would engage the enemy with projectile fire, and then the spearmen would close in hand-to-hand combat.

Murals depict gaily clad warriors as eagle and jaguar deities bearing elaborate knives on the ends of which are stuck bleeding hearts, which is suggestive both of a growing war cult and of sacrificial practices meant to indulge the gods, a ritual especially common later in Mesoamerica among the 15th- and 16th-century Aztec. Military recruitment apparently extended to all classes of society, and with military service came the possibility of upward class mobility. Mass recruitment is reflected in standardized weapons and suggests that training must have been standardized and carried out by military societies, formal schools, or a combination of both.

At the peak of Teotihuacán's power, its military armaments underwent profound and standardized changes. Spun-cotton body armor and helmets were introduced to protect the head, body, and limbs. Some scholars have tied the sudden increase in the use of cotton to acceleration in the downfall of Teotihuacán because the state could not afford to provide ar-

mor to everyone. After 500 C.E. Teotihuacán began to decline, and in the ensuing power vacuum regional centers emerged, all on hilltops and fortified, including Xochicalco, Cacaxtla, and Teotenango.

Among the ancient Maya the military was largely an enterprise of the nobility with small forces, no apparent chain of command, no standardized weaponry, and no drill-formation combat. Raids rather than battles occurred first to legitimate kings and their right to rule and, second, to gain tributaries and labor rather than to conquer and control foreign centers or cities. Scholars suggest that raiding included burning enemy villages and killing their defenders but rarely annexing land. Similarly, prior to broad agricultural-related settlement, early hunter-gatherers probably limited warfare to occasional raids in which men used stone tools as weapons and sought booty and glory rather than territorial conquest.

Scholars suggest that technological innovation of almost every kind has historically answered more to military purpose than commonly allowed, and that this is not simply a matter of technological change fostered by wartime demands. The impact and demands of a specific war or war in general, especially as it outgrows simpler warrior societies, is a powerful and persistent social force. Similarly, changing technologies, whether or not they are explicitly military, exert profound institutional effects. What archaeological data there are for North America provide only a glimpse of the most rudimentary technology in the form of projectile points dating from approximately 10,000 B.C.E. Because they were too large to be arrow points, they must have been spear points used to hunt mammoth and possibly for primitive warfare. A hunter-gatherer paradigm of isolated raiding probably best describes military action for much of the ancient period, with changes occurring in areas where agricultural settlement took hold and prompted reorganization of a basic defensive nature. Although evidence exists that suggests primitive warfare, little evidence has been found to indicate the presence of organized military institutions in North America in ancient times.

In South America some of the clearest evidence of military activity in the first few centuries C.E. comes in the form of Moche and Nazca painted vessels showing warriors and war-related scenarios. The two civilizations were contemporaneous but centered in different parts of Peru. Stylistic similarities between the two in later painted vessels are still being decoded in terms of the relationship between their respective iconographies, though it is safe to say that military and conquest activity is portrayed in the narratives of some vessels and thus was an active part of society.

Asia and the Pacific

~ Sun Tzu: Excerpt from "The Art of War"
(sixth century B.C.E.) ~

IX. THE ARMY ON THE MARCH

1. Sun Tzu said: We come now to the question of encamping the army, and observing signs of the enemy. Pass quickly over mountains, and keep in the neighborhood of valleys.
2. Camp in high places, facing the sun. Do not climb heights in order to fight. So much for mountain warfare.
3. After crossing a river, you should get far away from it.
4. When an invading force crosses a river in its onward march, do not advance to meet it in midstream. It will be best to let half the army get across and then deliver your attack.
5. If you are anxious to fight, you should not go to meet the invader near a river which he has to cross.
6. Moor your craft higher up than the enemy and facing the sun. Do not move upstream to meet the enemy. So much for river warfare.
7. In crossing salt-marshes, your sole concern should be to get over them quickly, without any delay.
8. If forced to fight in a salt marsh, you should have water and grass near you and get your back to a clump of trees. So much for operations in salt marshes.
9. In dry, level country, take up an easily accessible position with rising ground to your right and on your rear, so that the danger may be in front, and safety lie behind. So much for campaigning in flat country.
10. These are the four useful branches of military knowledge which enabled the Yellow Emperor to vanquish four several sovereigns.
11. All armies prefer high ground to low and sunny places to dark.
12. If you are careful of your men and camp on hard ground, the army will be free from disease of every kind, and this will spell victory.
13. When you come to a hill or a bank, occupy the sunny side, with the slope on your right rear. Thus you will at once act for the benefit of your soldiers and utilize the natural advantages of the ground.
14. When, in consequence of heavy rains up-country, a river which you wish to ford is swollen and flecked with foam, you must wait until it subsides.
15. Country in which there are precipitous cliffs with torrents running between, deep natural hollows, confined places, tangled thickets, quagmires and crevasses should be left with all possible speed and not approached.
16. While we keep away from such places, we should get the enemy to approach them; while we face them, we should let the enemy have them on his rear.
17. If in the neighborhood of your camp there should be any hilly country, ponds surrounded by aquatic grass, hollow basins filled with reeds, or woods with thick undergrowth, they must be carefully routed out and searched; for these are places where men in ambush or insidious spies are likely to be lurking.
18. When the enemy is close at hand and remains quiet, he is relying on the natural strength of his position.
19. When he keeps aloof and tries to provoke a battle, he is anxious for the other side to advance.
20. If his place of encampment is easy of access, he is tendering bait.
21. Movement amongst the trees of a forest shows that the enemy is advancing. The appearance of a number of screens in the midst of thick grass means that the enemy wants to make us suspicious.
22. The rising of birds in their flight is the sign of an ambushade. Startled beasts indicate that a sudden attack is coming.
23. When there is dust rising in a high column, it is the sign of chariots advancing; when the dust is low but spread over a wide area, it betokens the approach of infantry. When it branches out in different directions, it shows that parties have been sent to collect firewood. A few clouds of dust moving to and fro signify that the army is encamping.
24. Humble words and increased preparations are signs that the enemy is about to advance. Violent language and driving forward as if to the attack are signs that he will retreat.
25. When the light chariots come out first and take up a position on the wings, it is a sign that the enemy is forming for battle.
26. Peace proposals unaccompanied by a sworn covenant indicate a plot.

(continued)

(continues)

27. When there is much running about and the soldiers fall into rank, it means that the critical moment has come.

28. When some are seen advancing and some retreating, it is a lure.

29. When the soldiers stand leaning on their spears, they are faint from want of food.

30. If those who are sent to draw water begin by drinking themselves, the army is suffering from thirst.

31. If the enemy sees an advantage to be gained and makes no effort to secure it, the soldiers are exhausted.

32. If birds gather on any spot, it is unoccupied. Clamor by night betokens nervousness.

33. If there is disturbance in the camp, the general's authority is weak. If the banners and flags are shifted about, sedition is afoot. If the officers are angry, it means that the men are weary.

34. When an army feeds its horses with grain and kills its cattle for food, and when the men do not hang their cooking pots over the campfires, showing that they will not return to their tents, you may know that they are determined to fight to the death.

Greece

~ Xenophon: "The Spartan War Machine"
(ca. 375 B.C.E.) ~

In the first instance, the ephors announce in proclamation the limit of age to which the service applies for cavalry and heavy infantry; and, in the next place, for the various artisans. So that, even on campaign, the Spartans are well supplied with all the conveniences enjoyed by people living as citizens at Sparta. All the implements and instruments whatsoever which an army may need in common are ordered to be in readiness, some on wagons and others on baggage animals. In this way anything omitted can hardly escape detection.

For the actual encounter under arms, the following inventions are attributed to Lycurgos: the soldier has a crimson-colored uniform and a heavy shield of bronze, his theory being that such equipment has no sort of feminine association and is altogether most warrior-like. It is most quickly burnished; it is least readily soiled. He further permitted those who were about the age of early manhood to wear their hair long. For so, he conceived, they would appear of larger stature, more free and indomitable, and of a more terrible aspect. So furnished and accoutered, he divided his hoplites into six *morai* [regiments] of cavalry and heavy infantry. Each of these hoplite *morai* has one *polemarchos* [colonel], four *lochagoi* [captains], eight *penteconters* [lieutenants], and sixteen *enomotarchs* [sergeants]. At a

word of command any such *morai* can be formed readily into either *enomoties* [single file], or into threes [three files of men abreast] or sixes [six files of men abreast].

As to the idea, commonly entertained, that the tactical arrangement of the Spartan heavy infantry is highly complicated, no conception could be more opposed to facts. For in the Spartan order the front-rank men are all leaders, so that each file has everything necessary to play its part efficiently. In fact, this disposition is so easy to understand that no one who can distinguish one human being from another can fail to follow it. One set have the privilege of leaders, the other the duty of followers. The evolutions by which greater depth or shallowness is given to the battle line are given by word of mouth, by the *enomotarch*, and they cannot be mistaken. None of these maneuvers presents any difficulty whatsoever to the understanding.

I will now speak of the mode of encampment, sanctioned by the regulation of Lycurgos. To avoid the waste incidental to the angles of the square, the encampment, according to him, should be circular, except where there was the security of a hill or fortification or where they had a river in the rear. He had sentinels posted during the day along the place of arms and facing inwards; since they are appointed not

so much for the sake of the enemy as to keep an eye on friends. The enemy is sufficiently watched by mounted troopers perched on various points commanding the widest prospects. To guard against hostile approach by night, sentinel duty according to the ordinance was performed by the *sciritai* outside the main body. At the present time the rule is so far modified that the duty is entrusted to foreigners, if there be a foreign contingent present, with a leaven of Spartans to keep them company. The custom of always taking their spears with them when they go their rounds must certainly be attributed to the same cause which makes them exclude their slaves from a place of arms. . . . The need of precaution is the whole explanation. The frequency with which they change their encampment is another point. It is done quite as much for the sake of benefiting their friends as annoying their enemies.

Further, the law enjoins upon all Spartans, during the whole period of the campaign, the constant practice of

gymnastic exercises, whereby their pride in themselves is increased, and they appear freer and of a more liberal aspect than the rest of the world. The walk and the running grounds must not exceed in length the space covered by a *morai*, so that one may not find himself far from his own stand of arms. After the gymnastic exercises, the senior *polemarchos* gives the order by herald to be seated. This serves all the purposes of inspection. After this the order is given "To get breakfast," and for "The outpost to be relieved." After this, again, come pastimes and relaxations before the evening exercises, after which the herald's cry is heard "To take the evening meal." When they have sung a hymn to the gods to whom the offerings of happy omen have been performed, the final order, "Retire to rest at the place of arms," is given.

Rome

~ Josephus, "The Roman Army in the First Century C.E."
(ca. 75 C.E.) ~

BOOK 3, CHAPTER 5 DESCRIPTION OF THE ROMAN ARMIES AND ROMAN CAMPS

. . . 2. As for what is within the camp, it is set apart for tents, but the outward circumference hath the resemblance to a wall and is adorned with towers at equal distances, where between the towers stand the engines for throwing arrows and darts, and for slinging stones, and where they lay all other engines that can annoy the enemy, all ready for their several operations. They also erect four gates, one at every side of the circumference, and those large enough for the entrance of the beasts, and wide enough for making excursions, if occasion should require. They divide the camp within into streets, very conveniently, and place the tents of the commanders in the middle; but in the very midst of all is the general's own tent, in the nature of a temple, insomuch, that it appears to be a city built on the sudden, with its marketplace, and place for handicraft trades, and with seats for the officers superior and inferior, where, if any differences arise, their causes are

heard and determined. The camp, and all that is in it, is encompassed with a wall round about, and that sooner than one would imagine, and this by the multitude and the skill of the laborers; and, if occasion require, a trench is drawn round the whole, whose depth is four cubits, and its breadth equal.

3. When they have thus secured themselves, they live together by companies, with quietness and decency, as are all their other affairs managed with good order and security. Each company hath also their wood, and their corn, and their water brought them, when they stand in need of them; for they neither sup nor dine as they please themselves singly, but all together. Their times also for sleeping, and watching, and rising are notified beforehand by the sound of trumpets, nor is any thing done without such a signal; and in the morning the soldiery go every one to their centurions, and these centurions to their tribunes, to salute them; with whom all the superior officers go to the general of the whole army, who then gives them of course the watchword and other orders, to be by them cared to all that are under

(continued)

(continues)

their command; which is also observed when they go to fight, and thereby they turn themselves about on the sudden, when there is occasion for making sallies, as they come back when they are recalled in crowds also.

4. Now when they are to go out of their camp, the trumpet gives a sound, at which time nobody lies still, but at the first intimation they take down their tents, and all is made ready for their going out; then do the trumpets sound again, to order them to get ready for the march; then do they lay their baggage suddenly upon their mules, and other beasts of burden, and stand, as at the place of starting, ready to march; when also they set fire to their camp, and this they do because it will be easy for them to erect another camp, and that it may not ever be of use to their enemies. Then do the trumpets give a sound the third time that they are to go out, in order to excite those that on any account are a little tardy, that so no one may be out of his rank when the army marches. Then does the crier

stand at the general's right hand, and asks them thrice, in their own tongue, whether they be now ready to go out to war or not? To which they reply as often, with a loud and cheerful voice, saying, "We are ready." And this they do almost before the question is asked them: they do this as filled with a kind of martial fury, and at the same time that they so cry out, they lift up their right hands also. . . .

8. This account I have given the reader, not so much with the intention of commending the Romans, as of comforting those that have been conquered by them, and for the deterring others from attempting innovations under their government. This discourse of the Roman military conduct may also perhaps be of use to such of the curious as are ignorant of it, and yet have a mind to know it. I return now from this digression.

► mining, quarrying, and salt making

INTRODUCTION

Throughout the ancient world people engaged in an endless quest for resources to make their lives a little more comfortable and secure. Food, of course, was at the top of the list, followed by fuel. But once these material needs had been met, the ancients turned their attention to extracting resources out of the earth. They used the materials they found there, including stone, minerals, and metal ores, to make tools, buildings, weapons, and decorative objects. The result was the development of civilizations that were far advanced over those of primitive hunter-gatherer bands.

The Stone Age was defined by ancient peoples' ability to make tools and weapons from stone. The earliest humans used whatever stones lay at hand on the earth's surface, but in time they learned to quarry stone. Historians, archaeologists, and tourists continue to be amazed at the massive stone construction projects carried out in the ancient Americas, Egypt, Mesopotamia, Asia, Greece, and Rome. Using such stone as limestone, basalt, obsidian, marble, and sandstone, the ancients were able to quarry massive blocks of stone, transport them, and raise them into position to create some of the world's most breathtaking monuments, such as the pyramids of Egypt. Meanwhile, they used these and other stones to make tools, weapons, and artwork. Various minerals, too, were used in the production of artwork, jewelry, and religious artifacts, primarily because these minerals were soft and workable and because their colors were aesthetically pleasing.

The emergence of metal and metalworking, however, changed the nature of ancient toolmaking. The earliest metal used extensively was copper. Later, bronze, an alloy of copper and tin, became the favored metal because it was harder than copper. While copper and tin are relatively abundant, iron ore is much more abundant, so following the Bronze Age was the Iron Age, when iron—and, in time, hardened steel—were used in toolmaking. Particularly in Europe, where iron ore was extremely abundant, iron dominated mining in such areas as modern-day Austria and Switzerland. Precious metals such as gold and silver were mined to make jewelry and similar goods. Extracting these metals from the earth required backbreaking labor, carried out with stone hammers, chisels, shovels, picks, levers, and other simple tools. Because the nature of the work was so difficult, it is likely that slaves, criminals, and prisoners of war were often used.

In addition to stone and metal the ancients needed salt. Salt is necessary in the diet, but it was also used in food preservation. So important was salt that the ancient Romans often paid soldiers with salt—the origin of the modern word *salary*—and salt trading was such a profitable business that some trade routes around the Mediterranean Sea were built primarily to transport salt. In some cultures, small amounts of salt could be extracted from ocean water through evaporation. More valuable were salt mines, where large amounts

of salt could be extracted. Salt mining differs from rock mining and stone quarrying primarily because salt dissolves in water. It could therefore be allowed to dissolve to create a brine, which was then pumped out of the mine into shallow cisterns, where the water would evaporate, leaving behind the salt.

AFRICA

BY JUSTIN CORFIELD

In ancient times peoples all over Africa were involved in mining for precious metals, such as gold and silver, and also for copper and iron. The great trading empire of the Carthaginians, based in modern-day Tunisia, was heavily involved in mining ventures along the North African coastline, and its expeditions in Africa may have been in search of more minerals. Certainly some of the Carthaginians' naval expeditions to the west coast of Africa had this in mind, and it is known that they secured gold from mines in modern-day Senegal, though much of the wealth of Carthage came from silver mines in what is now Spain. Gold was also mined at an early date in Sofala, in modern-day Mozambique, and Kilwa, in modern-day Tanzania, but the massive gold and copper deposits in southern Africa in modern-day Democratic Republic of Congo, Zambia, and Zimbabwe were not used until between 800 and 1000 C.E.

The first excavations of both copper and iron in Saharan Africa took place at similar times, according to archaeological evidence. This is somewhat contradictory, because there is a relative abundance of ironworkings throughout the continent while copper deposits are scarce in many parts. Across the continent, however, the transfer of technology was very gradual. That transfer clearly started in North Africa with the Egyptians and the Carthaginians, who used minerals before other African peoples. The Egyptians seem to have begun using iron after the Assyrians manufactured it and used it in battle against them. The Carthaginians developed iron from Phoenician settlers, who regularly used and traded metals. Gradually the use of iron spread into Nubia, where there were large deposits of iron ore that was then turned into iron to satisfy the demand for the metal in Egypt.

The technique of smelting iron ore seems to have spread gradually from Egypt and Nubia. People at two locations, the southwestern and the central part of the Sahara, were involved in mining copper from the first half of the first millennium B.C.E., with iron being smelted in the Sudan at about the same time. Certainly in the kingdom of Meroë in modern-day Sudan, from 650 until 350 B.C.E., the local people were familiar with working iron. This indicates that technology was being transferred by land contact, but the next area that seems to have worked iron was in modern-day Zimbabwe, where some of the settlements show stones cut with the help of iron tools. It therefore seems likely that the methods of mining iron ore and smelting it may have come from traders working their way down the East African coast. Seeming to confirm this,

some ironworkings from the same period have been found at Hydrax Hill, near Nakuru in Kenya.

Some scholars believe that both the technologies of mining minerals and producing metals from them were used by tribal chiefs and ruling oligarchies to establish control over regions and to dominate trade. For these reasons some tribes in Africa kept their methods of smelting secret, giving them a trade or military advantage over their neighbors.

In West Africa, by about 500 B.C.E., the Nok culture in what is now northern Nigeria was also involved in the use of metals. The Nok tended to use iron for weapons and agricultural tools, with copper preferred for making ornaments or decorative and symbolic items. It is possible that the techniques of mining for minerals came by land to the Nok's inland civilization across the Sahara, along the trade routes of caravans that, among other things, took ornaments from North Africa to western Africa and returned with salt.

The development of the use of metals in southern Africa has been heavily researched, and it appears that the people who used metals came to the region in small numbers, possibly from the coast. They made contact with the Khoikhoi and other peoples, bringing with them some metal tools and the knowledge of how to make more from smelting ore. These appear to have been either traders working their way down the east coast of Africa or Berber ship merchants bringing goods down the west coast. Either way, iron must have been rare, and its use was limited to weapons and essential tools. There is some evidence of its use by 200 C.E., but the absence of many iron tools from archaeological sites, some archaeologists have suggested, might be largely owing to the way the metal rusts rather than its absence from the society. It is also possible that iron tools were too valuable to bury and were passed on to children and others at the death of their owner. Certainly it was the Bantu who brought iron with them in abundance when they arrived.

If the spread of metalworking can only be surmised because of a lack of evidence for the technology's presence in some regions, the spread of quarrying stones is even more speculative. Certainly ideas of quarrying came from ancient Egypt and northern Africa, with the use of stone tools in Africa being common in many places until the seventeenth century C.E. Some stone quarries were run by the Carthaginians outside the city of Carthage, largely kept going by slave labor.

Routes of communication have long crisscrossed the Sahara, used by caravans bringing salt to remote places in the desert and also to the relatively heavily populated parts of northern Africa. In eastern and southern Africa so many of the settlements were small enough and close enough to the coast that the acquiring of sufficient salt was never a major problem.

EGYPT

BY AMR KAMEL

Egypt has been favored with rich and abundant stone and mineral sources that extend over the deserts surrounding the

Nile River and into the Sinai Peninsula. The ancient Egyptians quarried and mined these sources, seeking out stone as permanent material for their pyramids, temples, shrines, and monumental tombs, which were furnished with sarcophagi, statues, stelae, and obelisks that were also made of stone.

From the earliest periods of recorded history in Egypt, kings sent major expeditions to various places in the Western and Arabian deserts as well as to Sinai and Wadi Allaqi in Nubia, to gather stones, minerals, and other materials. One expedition dating to the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) that went to the alabaster quarries at Hatnub in the hills of the Eastern Desert consisted of 1,600 artisans, while New Kingdom (ca. 1550–ca. 1070 B.C.E.) expeditions, which were sometimes supervised by the vizier himself or the high priest of Aton, were even larger. During the reign of Ramses IV (r. 1163–1156 B.C.E.), an expedition was sent to Wadi al-Hamam (in Palestine) for building blocks. It included, among others, 170 administrative staff, 130 skilled stonemasons, 2,000 bondsmen for transporting the blocks, 5,000 soldiers, and 50 guards.

In general, after the required materials were quarried or mined, they were transported by donkeys, which were able to move easily along steep and stony mountain paths, to the river Nile bank, where boats and barges would carry them to the building sites.

The ancient Egyptians found the ideal materials for their eternal architecture and sculpture in the great varieties of stone available in the surrounding hills. In the Predynastic Period (ca. 3000 B.C.E.) stone for vases and plates, such as limestone, sandstone, gypsum, and calcite (Egyptian alabaster), were taken from these hills as well as from the Arabian Desert. Also from the Arabian Desert came volcanic porphyry, marble, graywacke, quartz, schist, serpentine, and talc. Slate was quarried in Wadi Hammamat near the Red Sea and used for sleeping and ceremonial palettes. The soft stone gypsum was obtained from Umm el-Sawwan, at the northern edge of the El Faiyûm region of Upper Egypt. Egyptian alabaster (calcite or travertine) was obtained from the Wadi Gerrawi, south of Helwan and opposite Memphis on the western side of the Nile, but the most important quarries were at Hatnub, southeast of Tell el-'Amârna.

Quartzite, a naturally cemented sandstone, was available near Cairo, at Al-Gebel Al-Ahmmar, and found in association with the Nubian sandstones south of Idfu. Another variety of quartzite was quarried in Gebel Abu Dokhân and Gebel Fatira in the Arabian Desert. In the Greco-Roman Period (ca. 332 B.C.E.–ca. 395 C.E.) a variety of porphyritic rocks, including the so-called imperial porphyry, was obtained from Gebel Abu Harba, and Gebel Gattar, from west of Al Ghurdaqah in the Red Sea hills. Basalt, which was used as a special building material because of its black color, occurred in many parts of Egypt; sources close to the Nile and to building sites include Abu Rawash and Gebel Qatrani, north of the Faiyûm Depression. The Faiyûm was the main source of the basalt used in ancient Egypt.

Linen bag of salt for mummification, from Deir el-Bahri, Egypt, New Kingdom, 1550-1070 B.C.E.; salt was used to dry bodies before wrapping and entombing. (© The Trustees of the British Museum)

Graywacke, a dark, varicolored, attractive stone, was obtained from Wadi Hammamat between Luxor and Quseir. Chephren diorite was quarried from Gebel el-Asr, an area in the Western Desert, about 40 miles northwest of Abu Simbel. The pink granite was one of the favorite building and ornamental stones and is widespread in various spots around Aswān and in the Arabian Desert. As pictorial evidence from the causeway of King Unas (d. 2345 B.C.E.) indicates, in ancient Egypt granite was quarried, shaped into objects, and polished before being transported by boats down the Nile.

Sandstone was the principal element in any construction in Upper Egypt and Nubia, while limestone was widely used in Middle Egypt and Nile Delta buildings. The limestone varied in quality. The harder and less brittle white limestone was located on the eastern side of the Nile, opposite Memphis, and along the Mokkatam Hills, near modern-day Tura el-Asman and Masara, and the outcrops continue from there to far beyond Luxor (Thebes). The Egyptians used blocks of limestone from nearby quarries in constructing pyramid complexes and mustabas (tombs) in the Memphite necropolis (city of the dead), but the outer casings and wall facings of these monuments required the superior Tura limestone. Although sandstone became the predominant stone in the cliffs running from Isna to Aswān, it was not widely used until the New Kingdom. It could be obtained at Qertassi in lower Nubia, but the most important quarry was at Gebel es-Silsila, located between Kom Ombo and Idfu, where the vertical walls are still crisscrossed by the outline of various sized blocks.

There are many surviving records, both archaeological and textual, concerning mining expeditions to obtain copper, gold, and tin within the ancient Egyptian territory. (Other minerals, such as silver, lead, and iron, were obtained through trade or pillaging.) The oldest indication of such mining expeditions can be traced back to prehistoric times, when the preserved jewelry from that time was made of Arabian Desert carnelian and sard. Copper ores came from both

the Arabian Desert and from the southern Sinai at Bir Nasib. There is archaeological evidence indicating that Wadi Dara, in Upper Egypt, was one of the earliest-known copper mines, and remains of a copper-working settlement were unearthed at Buhen, on the western bank of the Nile, near the second cataract. Nonetheless, the Nile Valley copper ores for productions of copper metal were relatively limited compared with that of Wadi ‘Arabah region, about 19 miles north of Elat, which apparently was in use as early as the fifth millennium B.C.E. There is no evidence that the Egyptians themselves mined copper at that site; they seem to have employed local inhabitants instead. Iron ores are known in various locations in Egypt, notably in the Arabian and Western deserts, and in Sinai. Even as late as the New Kingdom the technology of iron smelting seems not to have been developed there.

In ancient Egypt gold was obtained from at least 90 gold mines in the Arabian Desert (both Egyptian and Nubian), which possibly were in use as early as the Old Kingdom. The Egyptians recorded in detail their work in the gold mines of Wadi Hammamat and Wadi Allaqi, which were used continually up to the Ramesside Period (ca. 1307–ca. 1070 B.C.E.). There even survives a unique map of a Twentieth Dynasty (ca. 1196–ca. 1070 B.C.E.) gold mine at Bir Umm el-Fawakhir in the Wadi Hammamat.

Turquoise and malachite as well as red agate and red-brown carnelian were highly desired and were obtained from a variety of sources. The main sources of turquoise, mined by the Egyptians from the Third Dynasty (ca. 2649–ca. 2575 B.C.E.) to the end of the New Kingdom, were located in western Sinai at Wadi Mughara and Serabit el Khadim, where at times there was a semipermanent Egyptian settlement.

Galena, which was used for kohl eyeliner, was obtained, from the earliest times, from Gebel el-Zeit mines, located on the Gulf of Suez to the south of Ras Ghārib. Talc and serpentine, softer and easier to work than granite, were used for a variety of objects, including weights, spinning wheels, and beads. Both were common in the Arabian Desert region east of Idfu.

Amethyst was primarily obtained from the Wadi el-Hudi, southeast of Aswān, and it was greatly prized during the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.). In the Greco-Roman Period emeralds were mined from Zabara, Um Kabo, and Sekkait and from Hugrus in the Arabian Desert; peridot was obtained from Zabargad Island (Saint John’s Island) in the Red Sea, southeast of the port of Berenice. Apparently, lapis lazuli, the deep blue gemstone that was frequently used in Egyptian jewelry as early as the Predynastic Period, was imported from the modern-day Badakhshan region in northeastern Afghanistan.

For common use, salt was obtained from the shores of the Mediterranean and from Red Sea lagoons. There is only textual evidence suggesting Khārga Oasis as another possible location of salt extraction, especially during the New Kingdom, but archaeological evidence is lacking. Natron, which was used with other substances for dyes and for

mummification, was obtained from Wadi an-Natrūn, Beheira Governorate, and the Elkab region in Upper Egypt.

THE MIDDLE EAST

BY LYN GREEN

Salt was one of the most ubiquitous substances used by ancient peoples, but relatively little is known about how they extracted it. The Phoenicians were famous traders and producers of salt, which they probably got by evaporating seawater. In fact, all the cultures of the ancient Near East would have relied on surface salt left in salt pans by the evaporation of ancient seas rather than on labor-intensive mining. Many of the earliest minerals and metals to be used and exploited were also those that could be found literally lying around. For example, some of the earliest copper was obtained from malachite or other copper-rich rocks that lay on the surface. The green color of these rocks (which comes from the oxidized copper in them) would make them easy to spot.

Similarly, red or yellow stains on rocks show the presence of iron oxide and would have signaled to ancient prospectors that iron was at hand. Iron, however, was far harder to find on the surface than copper, and some scholars have speculated that early peoples first made use of the iron that they found in meteorites. Occasionally, lead could be found on the surface. For example, beads of lead dating to around 6000 B.C.E. have been found at a Neolithic site in Turkey. There were also places where bitumen and other petroleum products rose naturally to the surface of the earth. Ancient Sumerians used bitumen in place of mortar between bricks, made boats watertight with it, and even inlaid it in jewelry and furniture as decoration. Bitumen sealing was found on the oldest-known boat in the world, discovered in Kuwait and dating back 7,000 years. The Sumerians apparently also made use of the petroleum products they found on the surface as fuels in the crucibles and furnaces they used to extract metals from ore.

Once surface deposits of such metals as gold, copper, iron, and lead were exhausted, ancient Near Easterners had

Stone panel from the palace of Sennacherib, Nineveh, northern Iraq (Neo-Assyrian, ca. 704–681 B.C.E.); together with a companion panel, it shows the transport of a winged bull from quarry to palace, part of Sennacherib's construction work. (© The Trustees of the British Museum)

to work extremely hard to extract the ore—or at least their slaves and criminals did. The conditions of mining in the ancient world were so horrific that only the most despised criminals were sent to the mines. The ore-bearing rock had to be extracted from the surrounding stone without the use of hard metal tools. Instead, the workers pounded at the stone with hammers made from the hardest rock they could find, usually dolorite or basalt. Picks and levers of antler or bone were used to work the larger pieces loose. At Timna Valley in Israel, miners laboriously dug vertical shafts linked by galleries. They brought the chunks of ore to the surface for processing and then to higher ground for smelting.

The pounding of stone on stone produced huge quantities of rock dust that would have been inhaled by the miners. In addition, the ores themselves often contained toxic materials. Lead, for example, is poisonous on its own. The copper found in the Near East often contains large quantities of arsenic. It has been estimated that an ancient copper mine in Jordan produced more pollution (in the form of toxins entering the environment via water, land, and air) than many 19th-century industrial operations. This polluting Jordanian mine at Wadi Faynan was in use from about 4500 B.C.E. and continued to supply copper to civilizations throughout the Near East until Islamic times.

Throughout the first few millennia of its existence, techniques for extracting and refining copper ore would have changed little. Researchers who have studied the production of metals from mines in Turkey and Jordan concluded that the ancient workers first ground the ore into powder with stone grindstones. Then they put the powder in a shallow container and fired it to as high a temperature as they could. Ancient miners could rarely achieve temperatures as high as those used in the 21st century, even when they had fuels such as asphalt or bitumen. Thus they often relied on repeated firing and sometimes the addition of minerals, which would lower the firing temperature.

Although copper containing natural arsenic was harder than pure copper, it was still relatively soft. Ancient miners also sought tin to add to the copper in order to make bronze. At one time scholars believed that the peoples of the ancient Near East had to trade over great distances to get their tin. However, in 1989 an archaeologist claimed to have discovered a source of tin ore in the mountains of Turkey, and radiocarbon dating revealed a mine that had been worked as early as 2500 B.C.E. This discovery has led historians and scholars to conclude that early peoples may have relied much more heavily on small local deposits of minerals, including stone.

For example, unlike the Romans, the peoples of the Neolithic and Bronze Age ancient Near East would not have bothered trading for luxury building stones like marble and granite. Instead, they would make use of local stone wherever possible, even when the stone was extremely hard (and therefore difficult to work) and not particularly attractive. For example, the sculptors of Sumer, where stone was scarce, may have relied on boulders and even reused fragments of

other statues. The types of stone that were most often used in art and architecture were limestone, calcite, gypsum, and shale as well as harder stones such as marble, granite, schist, serpentine, steatite, diorite, and basalt. These were obtained from the Nur, Zagros, and Taurus mountain ranges and from modern-day Azerbaijan, Saudi Arabia, Oman, and southern Iran.

The techniques of stone quarrying and hard rock mining were extremely similar. Before the Iron Age, quarrymen had to rely on stone hammers, bone or wooden picks, and mallets and saws of bronze or hardened copper (which would constantly need resharpening). By the Neo-Assyrian Period (ca. 1050–ca. 609 B.C.E.) kings recorded that they sent men with iron axes and pickaxes to extract stone from quarries. Images of quarrying show men with saws and shovels as well as pickaxes of two different types. The stone they extracted was moved out of the quarry on wooden sledges, which were pulled along over log rollers. There were rarely any roads to the quarries and it would not have been until the stone was loaded onto boats that transporting it became relatively easy. To save time and weight, the stone was often roughly shaped before being transported. Much the same processes would have been used throughout the ancient Near East to obtain and quarry stone for statues, reliefs, and buildings.

ASIA AND THE PACIFIC

BY TOM STREISSGUTH

Prehistoric inhabitants of Asia used a great variety of objects and material produced by the earth. Some of this material was gathered at the surface. Erupting volcanoes, for example, sometimes ejected a shiny, glasslike rock known as obsidian, an extremely hard material that could be formed into tools and arrowheads. Along the Caspian Sea and the Dead Sea, salt collected at the shoreline, and pitch-black asphalt occasionally rose to the surface. These materials had important household uses: salt as a preservative for food and asphalt for burning in cooking fires.

Near Hong Kong archaeologists discovered a stone quarry on a steep hillside facing the South China Sea. Thousands of carefully shaped rocks, some dating to the Paleolithic Era (ca. 30,000–ca. 40,000 B.C.E.), litter the hill and the beach lying at its base. The stones were used as axes, grinders, scrapers, picks, awls, and arrowheads. Many other ancient quarry sites have been unearthed in central Asia, where a dry climate preserves traces of ancient human habitation and industry.

People in China and throughout Asia also put stone and metal ores to work, creating basic tools and weapons that allowed them to gather and hunt their food, build shelter, and decorate their bodies. As settled cities and urban civilization developed, artisans began specializing in the use and handling of metal ores. Through trial, error, and observation, the earliest miners and smiths learned how to find, extract, and use copper, iron ore, and tin. They hammered these ores to separate them from the surrounding rock and then smelted

the ores over charcoal fires, heating them to temperatures that would draw out useful metals in a pure and usable form. Mining technology and the knowledge of smelting techniques arose independently in China, India, central Asia, and southeastern Asia.

Much of the ancient Chinese knowledge of mining and metallurgy is contained in *Shan hai jing* (The Classic of Mountains and Seas), a set of books of mythology and natural science that was produced sometime between the third century B.C.E. and the second century C.E. This classic summarizes millennia of experimentation and observation, classifying minerals and grouping surface rocks with the ores that were likely to be found within and beneath them. By the time it was written the Chinese had long been mining copper, silver, gold, tin, and zinc. The authors carefully catalogued properties of minerals known to them and listed the best methods of finding and working mineral ores and stone. Mining for iron ore eventually led to the discovery of magnetite, a rock that was attracted to iron ore and was used in the first navigational compasses. The Chinese also learned to drill for petroleum, or “weak water,” a sticky black substance that, in certain regions, seeped from the ground surface. The Chinese used petroleum for axle grease and burned it for light.

The Chinese were the first in the world to develop deep-drilling technologies. They first carried out underground drilling for the briny water present in deep aquifers, an underground rock bed yielding groundwater. They raised tall derricks—platforms constructed from wood and bamboo—and used iron-tipped bits to drill deep boreholes. The drills were operated by hand and suspended from the derricks by cables made of long bamboo strips (bamboo was strengthened by contact with water and was much more durable than rope made of hemp). Miners raised and then dropped the bits onto the rock at different angles to chip away at it. The underground water was raised by buckets or, under high pressure, was forced to the surface and then directed to huge iron evaporation pans set up near the boring site. The pans were used to boil off the water, which left a thin film of salt—a valuable commodity that was used to flavor and preserve meat.

Some boreholes, which reached as deep as 5,000 feet, produced natural gas, which could be used as a fuel for light and heat. The wells that produced only natural gas and not water were known as fire wells. Drilling for natural gas at these sites dates to the second century C.E. The gas either was piped directly from the wellhead or, if present in sufficient amounts, was stored in underground tanks made of wood. Ventilators in these tanks allowed the gas pressure to be controlled and the gas to be released and collected when needed. The gas was distributed by bamboo pipelines that led away from the borehole; gas also could be transported using leather pouches.

Ancient mines have been discovered in Mesopotamia, Anatolia, Iran, Afghanistan, and central Asia, where copper and gold mines were being worked around 1500 B.C.E. Central Asia was renowned for silver mining during this period, while Anatolia was home to the world’s earliest ironmaking

industry. Afghanistan was famous as the source of lapis lazuli, a blue gemstone in high demand throughout the Middle East and Egypt for use in statuary, jewelry, and clothing. The Harappan civilization in India, which lasted from about 2600 to 1500 B.C.E., mined copper, gold, silver, alabaster, marble, granite, basalt, and sandstone. The Harappans were skilled in the smelting of copper and tin to make the alloy bronze; their weapons were traded in Mesopotamia, India, and as far west as Greece and central Europe. Harappan artisans used marble and alabaster stone for use in making pottery, and they also worked gold and silver mines for jewelry. After the decline of the Harappan civilization, the Indus Valley in what is now Pakistan continued as an important center of iron and steel production.

Diamonds were mined in ancient India, and rubies, sapphires, and amethyst were mined in what are now Myanmar, Thailand, and Vietnam. Mogok in Myanmar has been a center of gem mining since the Bronze Age. Northern Myanmar also yielded jadeite, the rock from which the highest-quality jade was and is still produced. (The Chinese have mined and worshipped jade since Neolithic times and still use this translucent green stone for decorative sculpture, jewelry, and talismans.) The gem industry in Sri Lanka dates to about 500 B.C.E., when the island’s many high-quality gemstones were set into portable jewelry that was traded throughout southern Asia by Buddhist monks.

EUROPE

BY MICHAEL J. O’NEAL

The extraction of stone, ores, and minerals was an important complement to the farming economy of ancient European peoples. Early farmers mined flint for their tools at sites like Grimes Graves in England, Spiennes in Belgium, and Kremenets in what is now Ukraine, where the high quality flint was extracted from veins several feet below the surface. They also quarried outcrops of stone like amphibolite to grind into stone axes. The best-quality flint and stone would be traded over long distances. When the early farmers of northern and western Europe began to build large stone tombs and monuments called *megaliths*, either they used stones that were lying about the landscape, or they quarried stones and transported them over substantial distances. The bluestones that form the innermost circles of standing stones at Stonehenge came from the Preseli Mountains in Wales, 155 miles away.

Beginning around 5000 B.C.E. metals began to be used first for the manufacture of ornaments and then for tools. The earliest metal to be mined and used extensively in the production of tools, household implements, and other goods was copper. Early copper mines from the fifth and fourth millennia B.C.E. are found at places such as Aibunar in Bulgaria and Rudna Glava in the Federal Republic of Yugoslavia. Subsequently, copper sources were located in other parts of Europe, such as in Liguria in northwestern Italy and at Mount Gabriel in southwestern Ireland.

Copper tools were better than the stone tools of the earlier Stone Age because copper can be hammered and molded into many different shapes. Copper, however, is a relatively soft metal with limited usefulness. Early in the fourth millennium B.C.E. metalworkers discovered that they could toughen copper by mixing it with tin. The resulting alloy, bronze, gave its name to the Bronze Age, which extended roughly between 2500 and 800 B.C.E. Settlements where bronze played a prominent role in the culture and technology of the community have been found in islands of the Aegean Sea, home to the earliest European civilizations, the Minoans and Mycenaeans, as well as in central Europe, Spain, Britain, and Scandinavia.

While bronze was an advance on copper, it still was less durable and more expensive to make than the metal that supplanted it, iron. While iron came to be used extensively in the Near East, it was not until about 1100 B.C.E. that it found its way to Europe. In discussing European Iron Age cultures, historians and archaeologists refer to two primary periods. The first was the Halstatt Period, named after a town near Salzburg, Austria, where extensive salt-mining operations were conducted beginning about 1000 B.C.E. About 500 years later the La Tène culture developed in modern-day Switzerland. This culture produced an enormous amount of iron, and archaeologists have discovered numerous Iron Age artifacts from this region.

Mining for metals was a backbreaking business. While some metals such as gold could be found in nuggets in sandy soil or in water, the mining of copper and iron was more difficult, because the ore had to be dug out of the earth. First, a deposit had to be found. Ancient mining engineers were often able to locate a vein of metal by looking for stains in rock formations, riverbeds, and even in the water itself. Copper oxidizes (combines with oxygen) to form a greenish hue, while iron oxidizes to form brownish-red rust. Once a site had been located, workers dug shafts with picks and shovels. The shafts were generally not very deep, perhaps about 30 feet, but deeper mines—some as deep as 300 feet—have been found.

Bronze Age miners then used stone hammers to break up the rock, but they also used picks and levers made from hardwood or antler. Archaeologists have discovered many hundreds of broken stone hammers at ancient mining sites, and the large number of such tools suggests that a separate group of men were on hand to make and repair tools; otherwise, the miners would not have been able to carry on their work. Another technique that ancient miners used was to heat the rock by building large fires against it. The heating and cooling cracked the rock, often to a thickness of a foot, making it easier to break it into pieces and haul it to the surface.

Iron Age mining was not radically different. Again, shafts were dug using picks and shovels. The ore was broken up with hammers and then carried in sacks up ladders to the surface, where it was further broken down, washed (that is, the ore separated from smaller bits of rock and sand), and made ready for smelting. Large cisterns of water were kept on hand for the washing process.

An important activity in ancient Europe was the mining of salt. Salt was a valuable commodity, for it was used in the preservation of food; it was so valuable that ancient Roman soldiers were often paid with salt, the origin of the modern word *salary*, and the ancient Greeks readily traded slaves for salt (giving rise to the modern expression that people “are not worth their salt”). A major center of salt production in ancient Europe was the area around Salzburg, Austria and the lakes to the east in a region called Salzkammergut (note the syllable *Salz-*, the German word for “salt”). Also, many German and Austrian place names contain the syllable *hall*, the ancient Celtic word for “salt.” This salt was left behind by ancient seawaters that covered the continent before they receded.

When salt occurs in large concentrations and is easily accessible, it can be mined just like any other mineral and carried out of the mine in large blocks, as at Hallstatt, where the miners had special leather backpacks for bringing out the salt. Where it is less concentrated or where groundwater flows through the salt deposits, it can be extracted by an evaporation process. Salt is highly soluble in water, so it can be extracted easily from the ground by dissolving it. Some ancient European salt mines consist of deep shafts dug into the earth, often into mountainsides. After the shafts were dug, ancient salt miners let groundwater do much of the work. Large chambers were opened and then allowed to slowly fill with water, a process that could take up to 15 years. When the chamber was filled with brine, or salty water, it would be pumped out of the mine. At that point, the salty water was placed in large, shallow containers so that the water could evaporate. The salt left behind was fashioned into cakes for transporting. Over the centuries, numerous road systems were built principally for the transportation of salt. The Via Salaria in Italy is a good example.

GREECE

BY JOHN W. HUMPHREY

Mining was first practiced in the lands bordering the Mediterranean long before the Mycenaean Greeks of the late Bronze Age excavated shallow pits at Laurium, southeast of Athens, where silver reserves were later to become the engine that drove the golden age of the fifth century B.C.E. As early as the upper Paleolithic (after ca. 30,000 B.C.E.), nomadic hunters were digging vertical shafts to recover flint, their principal material for flaked tools and weapons, while others in southern France and northern Spain excavated ochres, those natural earths that they used to paint the walls of deep caves with images of their hunting culture. Some metals were available in a pure and native state—gold and copper are two—and could simply be gathered from the surface or sluiced from rivers and worked by Neolithic farmers (8000–3000 B.C.E.) into decorative shapes without the invention of special techniques. Later, the new empires of the Bronze Age (3000–1000 B.C.E.), like Egypt, Mesopotamia, and Mycenaean Greece,

sank deep vertical shafts and extended narrow horizontal galleries in their pursuit not just of precious metals but also of ores that contained copper, tin, and arsenic, which they learned to combine into the first truly useful metal, the alloy bronze.

Mainland Greece, its islands, and the colonized lands of the eastern Mediterranean supplied the Greeks of the Classical and Hellenistic periods (480–31 B.C.E.) with a rich variety of metals and ores. The difficulty was not in supply but in discovering the ore-bearing veins, since the principal prospecting technique available to the Greeks was to search for surface indications of what might lie beneath, a particularly unreliable method, as the ancients themselves knew well. Despite the haphazard nature of their discoveries, they had productive mines throughout the eastern Mediterranean: gold mines are known of in the northern regions of Macedonia and Thrace; gold and silver were both mined on the Aegean islands of Thásos and Sífnos; and silver, which might have been imported for some time from Asia Minor (the coasts and high central plateau of Turkey), became available locally when the Athenians reopened and expanded the shallow Mycenaean workings at Laurium, where the precious metal was actually an impurity in galena, a lead sulfide.

Copper was mined on Cyprus and at the town of Khalkís on Euboea, both places whose names derive from the Greek words for copper and bronze. Oxides and carbonates were found in deposits close to the surface, though when these were exhausted the Greeks dug deeper to recover copper sulfides, all of which would be combined with tin extracted from its ore, cassiterite, which soon began to be imported from the distant mines of Cornwall in Britain. And, finally, the metal that defines the period—iron—was found in quantity in ores from the Aegean islands, Anatolia, and Cyprus.

Knowledge of Greek mining operations comes from both the workings of the Laurium silver mines, which have been cleared and closely studied, and from ancient writers (more often Roman than Greek) who described the extraction techniques that changed little from the Bronze Age to the end of antiquity. While any miner would prefer horizontal shafts dug into the sides of hills and mountains, through which the movement of laborers and material was much easier and safer, necessity forced the Greeks to dig vertical shafts, about 7 feet square in section, to depths sometimes exceeding 328 feet, from which cramped galleries as low as roughly 3 feet high were driven horizontally to follow the veins of ore, their roofs supported by pillars of unexcavated stone and only rarely by shoring with wooden timbers. In this confined environment miners (who were almost always slaves, since no free person would choose to expose himself to such life-threatening dangers) lay for hours on their backs, sides, or stomachs and chipped away at the rock face with a tool kit of iron picks, chisels, and hammers, without even primitive safety equipment and with only the most basic illumination from torches and oil lamps.

Fire, poor ventilation, and absence of drainage all presented hazards. Documentary sources reveal that the ore-bearing rock face was often heated by an open fire and then doused with water (or vinegar), the sudden change of temperature causing the rock to fracture: one can hardly imagine the cumulative effect of the heat, the scalding steam, and the flying shards of ore. Fires were also set to create a downdraft in the shafts to draw in air for ventilation, when natural convection or surface fans made of linen sheets were insufficient. The Greeks appear not to have introduced artificial drainage to their mines, which (as at Laurium) were sunk only to the water table. Generally speaking, mines in the Greek world were controlled by the state (Athens, in the case of Laurium), which issued concession leases to private companies for terms of three to seven years, some of which survive to give detailed information about the administration of these operations.

During the regressive dark ages that followed the collapse of the Mycenaean Bronze Age (ca. 1100 B.C.E.), the Greeks' skill at monumental construction was temporarily abandoned, until the city-states recovered in the eighth century B.C.E. and began to replace with stone structures those temples and public buildings that had, for several centuries, been modestly constructed of wood, clay, and terra-cotta. The building stone was, ideally, quarried near the city, to mitigate the labor and expense of transportation; for this reason, Athens made use of the fine marble from nearby Mount Pendelikón, both for buildings (including most of those on the Acropolis) and stone sculpture.

Sources like the Greek historian and geographer Pausanias of the second century C.E. give information about the location of important quarries and supplement the archaeological evidence from known sites. The quarries were almost always open pits, so the workers avoided most of the life-threatening dangers experienced by miners. The rectangular blocks were first defined by shallow outlines cut with iron chisels; wooden wedges were then inserted in deep sockets cut along the grooves and hammered down, to fracture the stone along its natural lines of cleavage. The blocks were removed with levers, leaving steps that made continuing access to the rock faces easier. They were roughly finished on site using hammers, chisels, and hard balls of dolomite (a kind of limestone or marble) to smooth out rough patches and then transported to the building site for final finishing and erection.

Despite the importance of salt in Greek antiquity, when— together with curing—it was one of the essential means of preserving food (there being no artificial means of cooling in the ancient world), surprisingly little is known about where and how it was generally obtained. Jewish law had required salt to be added to all sacrifices. Homer (ninth to eighth century B.C.E.) records the use of salt for seasoning and gives it the epithet “holy.” Later Greeks saw the serving of salt as an important token of friendship. In Egypt salt pans were constructed for the evaporation of seawater. There was a flourishing trade in salt from the desert oases well into the Hellenistic Period. Salt, like drinking water, was considered such a ne-

cessity for life that public access was guaranteed: A story was told about Lysimachus, a Macedonian general under Alexander the Great and later king of Thrace (306–281 C.E.), who decided to levy a tax on the freely available salt from a spring at Tragasae near coastal Hamaxitos in the southwestern Troad. The salt springs immediately dried up, Lysimachus revoked his edict, and the salt miraculously reappeared.

ROME

BY JOHN W. HUMPHREY

As with Greek mining, understanding of Roman practices depends on a combined study of excavated sites (in this case, especially Rio Tinto and other Spanish mines) and documentary sources (the ancient scholars Diodorus Siculus, Strabo, and the Elder Pliny). But the Romans, unlike their Greek predecessors, often attached to mining a moral interpretation: the violation of earth for unnecessary human desires, an attitude that pervades Pliny's *Natural History*.

The Romans depended for their mineral resources on mines generally located in the western Mediterranean. Gold was mined in Gaul and Spain; silver in Spanish sites like New Carthage and Rio Tinto (though the Romans also reworked and reprocessed, with some success, the old deposits and dumps near Mount Laurium in Attica); lead in Britain; copper in Spain and Britain (also the source for the tin used in bronze making); and iron in Gaul (near Lyon) and Spain, though the most abundant sources were found closer to hand on the island of Elba (which is estimated to have yielded 11 million tons of iron ore in antiquity), and in the early empire at extraordinarily large workings in Noricum (central Austria).

The Romans made no important advances in the design of tools—the typical iron hammers and picks and wooden wedges for fracturing rock faces—or in the techniques of prospecting, which remained surprisingly basic. A comment by Pliny in his *Natural History* reveals that visible surface sightings were the principal means of detection: “Silver is found only in shafts and, because it does not have a shining sparkle like gold, gives no easy indication of its presence.”

In mining processes, however, the Romans made significant improvements to Greek practices. In the search for gold, for example, they developed sophisticated sluicing techniques using aqueducts constructed specifically for bringing sufficient quantities of water to provide forced jets to separate the gold from the alluvium (lose material deposited by running water), best seen at the workings of Las Médulas in northwestern Spain. They also lined the sluices with gorse branches, to trap the particles of gold. Safety was somewhat improved, though not necessarily intentionally. The use of open-pit iron mines on Elba must have reduced the mortality rate of miners, though their environmental impact was huge. Wooden timbering to support the roofs and walls of galleries became more common (as, for example, at New Carthage), though it was still not standard practice. There seems to have been a greater understanding of the effects of poisonous

Lead pig (ingot), Roman Britain (76 C.E.), from *Hints Common*, Staffordshire; lead was obtained as a by-product of silver mining. (© The Trustees of the British Museum)

fumes, but detection techniques were primitive. And, typical of the Romans' interest in hydraulic engineering, deep mines were equipped with mechanical drainage devices to allow mining below the water table and lessen the risk of drowning; these included Archimedean screws and waterwheels with compartmented rims, of which four pairs in Rio Tinto, operated by treadmills, raised the water about 100 feet out of the shafts.

As in Greece, most miners were slaves and criminals, an indication that safety practices had not improved enough to attract free labor. Almost all mines were state property but were leased to corporations of capitalists (the *publicani*) for their administration, though with strict regulations known from surviving contracts.

The Romans throughout their history relied on plentiful native Italian rock like volcanic tufa and limestone travertine, which they quarried for the building blocks of their monumental structures. Marble, which became desirable in the middle Republic as Greek cultural influences began to permeate Roman society, at first had to be imported from the established quarries of the eastern Mediterranean; this was true until late in the first century B.C.E., when extensive marble deposits were discovered in the Carrara Mountains near Luna (modern-day Luni) in northwestern Italy; the quarries begun there by the Roman stonemasons produced excellent white and blue-gray marble and are still in use in the 21st century.

Basic quarrying techniques mirrored those of the Greeks: hammers and iron chisels were used for the initial cutting of rectangular blocks, which were then split from the parent rock by inserting wooden wedges that, when soaked with water, expanded with sufficient force to fracture the stone. The Romans introduced saws for cutting the blocks, and one late-imperial example of a river-powered waterwheel is known, which provided the necessary reciprocal motion to operate the saws. These saws also gave the Romans a significant advantage in producing remarkably thin marble veneers, which

they applied with mortar to the surface of brick-faced walls of poured concrete, producing an elegant appearance that mimicked worked blocks of marble, but at greater speed and considerably less expense. Despite this economy of stone, there seems to have been a fear that the supply would eventually be exhausted, which probably prompted the fantastic stories in Pliny and others about marble quarries in which the stone was magically regenerated.

Salt played the same important role as a preserver of food for the Romans as it did for the Greeks. The city of Rome itself was blessed almost from its foundation with control of the natural salt beds at the mouth of the Tiber River near Ostia, which gave it an economic advantage over its Latin neighbors. The Latin adjective *salarius* (“pertaining to salt”) was applied not only to the road that led from these salt beds to Rome but also to part of the payment to soldiers for their subsistence (our word *salary*). Rock salt was mined for export in some locations (like Cappadocia in central Turkey), but evaporated sea salt was the most important source: terra-cotta salt pots and lead saltpans, in which the brine was heated to drive off the seawater, have been found throughout the Roman Empire, from Egypt and the eastern port cities of Caesarea and Ephesus to towns in remote Britain. The most useful description of techniques used to extract salt is given by Pliny, who notes in his *Natural History* that fresh water (from rain or rivers) was often added to seawater before evaporation, to “make the salt sweet.”

THE AMERICAS

BY KEITH JORDAN

Stone quarrying in the New World dates back to the time of the first human inhabitants during the last ice age, 12,000 or more years ago. Since stone was the primary material used to make tools and weapons throughout the Americas right up to the 16th century C.E., numerous quarry sites have survived to be excavated by modern archaeologists. In most cases stone hammers were used to extract flint, chert, and other useful stones from surface outcrops. In southern New England, for example, Native Americans during the Terminal Archaic into the Early Woodland periods (ca. 1500–700 B.C.E.) extensively worked deposits of steatite (soapstone), from which they carved cooking vessels. They broke up the surrounding rock with handheld hammer stones and used pointed stones to further reduce detached pieces of stone. Stone spades were employed to clear away the fragments.

The oldest-known and longest-lasting large-scale mining operations in the ancient New World were the copper mines of the Keweenaw Peninsula and Isle Royale, Michigan, which were worked from the Late Archaic Period (ca. 3000 B.C.E.) to the time of European invasion in the 17th century C.E. Although Native North Americans did not smelt or cast copper, they produced implements and ornaments by cold hammering nuggets of pure copper or by hand working heated material (a process called annealing). The copper extracted from

these Lake Superior mines was traded across the eastern half of North America and was the source for most of the copper ornaments and ritual objects found in the Adena and Hopewell burial mounds. While local sources in the Appalachian Mountains may account for some of the copper found in southeastern archaeological sites, no evidence of prehistoric mining has yet turned up in this region.

Native American miners in Michigan dug trenches and pits to reach deposits of copper. They used five- to 40-pound stone hammers, or mauls, to break up the surrounding rock and smaller hammers to extract lumps of copper from detached chunks of stone. Some of these hammers were attached to wooden hafts or swung on thongs, while others were probably held in the miner’s hand. The diggers also may have employed a process of alternatively setting fires over bedrock and then dousing the area with water to shatter the stone for easier digging; they then used wooden spades or scoops to dig out the loosened pieces of copper. Stone or copper wedges may have been inserted to pry chunks of metal away from the surrounding rock. In some locales the miners needed to sink their shafts as deep as 50 feet to reach the ore. They presumably removed the usable metal in baskets or skin bags, and baskets and wooden buckets served to bail out the frequently flooded pits. Some excavations were lined with wood or stone blocks to prevent cave-ins.

By 1500 B.C.E. Olmec workers were quarrying basalt, a volcanic stone, in the Tuxtla Mountains of the modern Mexican state of Veracruz and transporting huge blocks to political and religious centers some 60 miles south to be worked into monuments for royalty. The stone was detached by bashing it with smaller stones—a laborious effort in itself. Tons of basalt were then transported to the Olmec sites through 60 miles of jungle, perhaps by floating the material on log rafts down local rivers and then rolling it on logs once on land—a truly astonishing achievement for this ancient workforce.

In addition to material for monumental construction, the Olmec and their contemporaries quarried and traded many other minerals. Obsidian, a volcanic glass used for making extremely sharp blades and spear points, came from surface outcrops in the Basin of Mexico and in southern Guatemala. The source of the blue-green jade favored by the Olmec for ornaments and ceremonial objects was once a mystery, but accidental discoveries now indicate that it is found as easily removed cobbles or boulders along the Motagua River in Guatemala.

The Maya used the local limestone underlying the forests of Yucatán and Guatemala for construction at least as far back as 600 B.C.E. Limestone bedrock was broken up using stone hammers and chisels and by setting fires. Fire was also used to reduce limestone to powder useful in the manufacture of stucco and plaster to decorate building facades and serve as mortar.

In the early centuries C.E. demands generated by the central Mexican metropolis of Teotihuacán and partners in its far-flung trading network seem to have catalyzed the de-

velopment of extensive mineral mining to the north, in the cultural area of the Chalchihuites in modern Zacatecas and Durango. Red hematite and cinnabar and blue turquoise were mined in the north and traded south across Mesoamerica. To reach the deposits of conglomerate rock containing these precious materials, Chalchihuites miners sunk shallow open pits and deep shafts into hills and gouged horizontal excavations along hillsides and canyon walls. Both horizontal and vertical shafts were dug, splitting off into multiple branches connected by tunnels and running up to 3,000 feet underground.

Pillars of rock left untouched by the quarrying held up the roofs of these galleries, which were reinforced as well by wooden cribbing, and blocks of stone not useful for mineral extraction were used to reinforce the walls of the tunnels. The spoils were piled up around the mine entrances, creating mounds as high as 40 feet. Like the Michigan miners thousands of miles to the north, the Mesoamerican miners employed simple stone tools—heavy stone hammers to break the surface and excavate the shafts, small hammers to extract minerals from the surrounding rock. The dry conditions of northern Mexico preserved many wooden artifacts left by the miners, including torches, the handles attached to some of the stone hammers, and buckets to carry water and rock fragments. The bulk of this mining took place between 400 and 600 C.E., the time of Teotihuacán's fall from political power.

Andean cultures created gold jewelry and other objects from the second millennium B.C.E. onward. Gold mining must have been quite extensive, but few traces of it survive in the archaeological record, since the Spanish conquistadors set to work immediately exploiting the same gold deposits and destroying evidence of earlier efforts. What have survived are the remains of some copper mines that were used to extract metal for casting objects and for alloying with tin to create bronze. At Atacama in northern Chile copper salts preserved not only the tools used by miners 1,500 years ago but also the body of one of the miners, killed in a cave-in. The tools found near his naturally mummified remains indicate that the ancient Andean miners, like those elsewhere in the Americas, used large stone hammers as their primary tools, along with baskets to transport the quarried materials.

► money and coinage

INTRODUCTION

The concept that forms the basis of money is that there is something of value that can be used to measure how much goods are worth. In many cultures of the ancient world, at first cattle were used to measure what goods were worth. A house, a farm, a cart, or some other good could be measured in how many cattle it would take to purchase it. This did not mean that cattle were always exchanged whenever someone bought something, though cattle often were exchanged for a purchase. A bushel of wheat might be worth one half a head of cattle, but a horse might be worth four head of cattle. If a person wanted to purchase a horse with wheat, for example, he would have to pay eight bushels.

Bartering goods seems to have been the beginning of all trade. Merchants would have to carry with them items they thought people elsewhere would want, and then the merchants would have to find goods they wanted and dicker with other merchants until they could work out a trade. Such dickering could take weeks, and the merchant might not find anyone who had what he wanted who also wanted what the merchant had. Produce could spoil. Workers could quit if they were not paid. The trade goods could end up being dumped.

In many parts of the world, people hit upon the idea of using as a medium of exchange something everyone liked but could carry on their persons. It had to be available in enough quantity that many people could use it; otherwise, it would be useless because not enough people would know what it was worth, but it could not be too numerous, or it would cause inflation, which would make it worthless because it would take too many to make even a small purchase. It is not known what became the first money, but in much of the world, sea shells, especially cowry shells, served as cash. This may seem strange, but a fisherman mining for cowry shells is not much different from someone digging for gold. In some places metal became valuable once people learned how to use metal to make useful tools. For instance, in ancient China, bronze shovels and knives were used like money, and when the Chinese started minting coins, the coins often looked like small shovels or knives. The Chinese had an agricultural economy, and bronze tools such as shovels and knives would have had universal value in their culture.

Archaeologists seem to agree that coins as they are now thought of were invented in Anatolia, probably by the Hittites but perhaps by the Lydians in about 600 B.C.E. The idea caught on quickly in other parts of the world. The basic idea was that certain metals had agreed-upon value; if coins containing a certain amount of valuable metal were available, people could trade them for goods without worrying about trying to persuade someone with sheepskins to take ceramic vessels in exchange. Purchasers could exchange the coins for the sheepskins and leave sellers of the sheepskins to worry about what they wanted to buy.

AFRICA

BY OLUTAYO CHARLES ADESINA

The concept of money, which can be defined as commodities or tokens that serve as measures or media of exchange in economic transactions, has been well established in Africa since ancient times. The continent had some of the most varied forms of money currencies in the preindustrial world. Early on, Africans developed dynamic commercial relationships that required the adoption of money. The particular type of money was dictated by the type and scale of commercial activities. The money in use ranged from coins to copper ingots, raffia cloth, beads, cattle, and cowrie shells. Other objects used and accepted as means of payment included symbolic

tools like daggers, representations of valuable objects, and precious metals.

In different parts of Africa, market and trading transactions were accomplished by means of currencies, though few societies possessed the market or exchange systems that required a universally acceptable form of currency. In other societies barter arrangements appear to have characterized the daily economic life. Historical records in Africa have affirmed the existence of several forms of exchange within a particular system of markets. One early form was the simple exchange mechanism known variously as the barter or the silent trade. This took the form of the exchange of goods for goods or the exchange of goods for services. In the exchange of goods and services, diviners and priests, drummers and singers were paid with goats, oil palm, and roosters. These transactions were carried on by people who might or might not have known each other. There was the common account of the Carthaginians' silent trade for West African gold. The system involved a lot of uncertainty in the value of goods. It also required that a person locate someone who wanted the particular good being offered. Barter was quite limited compared with trade with money.

The earliest evidence of the cultural use of money occurs in Egypt with the adoption of cowrie shells as currency. The trans-Saharan trade that began between North and West Africa, around 1000 B.C.E. spread the use of cowrie shells as currency. The trade expanded significantly with the influence of the Carthaginians from about the fifth century B.C.E. Carthage, the great trading nation established by the Phoenicians in 814 B.C.E., began to issue minted coins in the fourth century B.C.E. The circulation of money received greater impetus from the Romans, following their expansion into North Africa three centuries later. Gold and cowries were the major currencies, and this trans-Saharan trade might have been responsible for the diffusion of cowries into the interior of Africa as far afield as the Niger Bend.

Ancient African monies took other forms in addition to cowrie shells. Livestock and plant products were utilized as money in different societies at different epochs. Cattle became a vital form of money, most especially in pastoral societies. Pastoral communities especially in East and southern Africa interacted with and exchanged some goods with hunter-gatherer communities.

Many groups in Africa also used metallic currencies such as gold and silver coins. This use owed much to Roman and Greek influences. The earliest coins in Africa can be traced to the sixth century B.C.E. in Cyrenaica on the northern coast of Africa (modern-day Libya). Silver and electrum (an alloy of gold and silver) coins were in use here. One of the coins was the Valentine coin in circulation between 500 and 480 B.C.E. Embossed in the coin was the image of silphium, a plant used as a spice and contraceptive that was quite important to the Cyrenaic economy. About 25 B.C.E. in Mauretania a bronze coin depicted Cleopatra Selene, the queen of Mauretania who was the daughter of Cleopatra VII by Marcus Antonius. One

side of the coin featured an embossed crocodile, which symbolized Egypt, a land she had the hereditary right to rule..

Around 270 C.E. the kingdom of Axum (in modern Ethiopia), which emerged about the time of the birth of Jesus, began minting its own coins. It became the only currency issued by Africans without outside influence. The coin facilitated the Red Sea trade and had the tendency to promote the nation's religion and prestige.

Human society in Africa in the ancient period adopted several materials that could be exchanged for other articles. Both special purpose currencies and general purpose currencies developed in prehistoric Africa. The cowrie shell and gold and silver currencies were general purpose currencies. They served as a means of exchange, an acceptable tender in making payments or settling debts, a standard of value, and a store of wealth. The value of money depended on supply and demand, measured by the goods for which it was exchanged and by other forms of money. Highly organized societies often possessed currency that had a greater number of general purposes than simpler societies. In other words, the more complex a society, the more likely it was to possess some form of general purpose currency.

Special purpose currency may be an artifact useful for other things, such as a tool or ornament. It may also include rare items, art, and jewelry. Such materials can be collected for the sheer pleasure of collecting them. They are better prized the rarer and the less forgeable the articles are. Special purpose currency is restricted to specific spheres of the economy, such as hunter-gatherer communities and serves only some of the functions of money. (This form of money is also referred to as an *intermediate commodity*.) It is more secure from loss or theft, harder to forge, and its value is more accurately judged by observation and measurements.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

The ancient Egyptian economy was based on three principles: barter and market exchange, redistribution, and reciprocity and tributes. The underlying connection between these three principles that aided the evolution and wealth of the Egyptian society was that of a centralized state authority (the pharaoh) and the temple institutes. Daily economic transactions and storage were based on the exchange of goods and commodities rather than on the use of money. That held true at least for the Pharaonic Period (ca. 3050–712 B.C.E.). The import and use of money and coinage were inaugurated toward the first millennium B.C.E. with the advent of foreign mercenaries in the armies of the pharaoh. Even at that time, though, ancient Egyptians did not appraise the value of coined money. They regarded them as artistic objects in gold or silver appreciated only by metalworkers.

The Egyptians used four units of value to price and trade commodities, including the deben, senyu, hen, and kher. These units coincided with quantities of certain commodi-

ties: weights of silver and copper/bronze and units of capacity of grain and sesame oil. More specifically, the deben was a measure of weight used mostly for copper but also for precious materials such as gold and silver. One deben of copper weighed about 3.3 ounces. Silver and gold deben are not mentioned in ostraca (pottery shards that contain inscriptions) but only in papyri, since the former were used and distributed only among the low-class populace. On the contrary, papyri generally recorded greatly valued transactions among the high officials and the palace.

The senyu was a weight in silver equal to one-half deben or about a quarter ounce. Its use was inaugurated during the Nineteenth and early Twentieth Dynasties (ca. 1307–ca. 1155 B.C.E.). The senyu could be used to express a value in the same column of figures with deben. One could find in an ostraca the value of certain objects in senyu but the total of the column in deben of copper. The hen was a measure of volume equal to about a half quart. Its value could vary according to the substance or liquid to be measured, but generally it was regarded as equal to one deben. Finally, the kher was a measure of the volume of grain, either emmer or barley, equal to about 20 gallons, and it was valued at two deben. The kher was most commonly found as a unit of value for baskets, both because the volume of a basket was equal to its value and because baskets were inexpensive.

The ratios among the four units as well as their exact values are not fixed in the sources. For example, one document values a basket at one-quarter senyu for a volume of one-half kher. As mentioned earlier, one kher is equal to two deben, which means that one senyu equals four copper of deben in value. In another document, though, one senyu of garment was equal to five copper of deben. Weight and price, both expressed in deben, were hardly distinguishable from each other. In the Egyptian mind there was no difference at all, for the deben was not money. Cases of inflation and price fluctuation have been recorded. Quite often one deben of silver was valued as 100 deben of copper. This uncertainty in the value system was a strong indication that the Egyptians were not looking for money profit in their transactions; it was the objects themselves that they tried to obtain.

The picture changed during the Late Period (712–332 B.C.E.) with the advent of foreign mercenaries from Greece, Syria, Israel, Persia, and other areas in the ancient Near East in the Egyptian army. The first reference for the import and use of foreign coins for payment is found in the writing of the ancient Greek historian Diodorus Siculus. He mentions that the king Achoris (r. 393–380 B.C.E.) offered to pay Athenian and Spartan mercenaries in coins. Later in the fourth century B.C.E. two series of coins were introduced. The first was based on the Athenian gold unit and struck on the Persian standard with Egyptian motifs. The second consisted of tetradrachms, struck by the Persian king Artaxerxes III (r. 359 or 358–338 B.C.E.) shortly after his conquest of Egypt in 342 B.C.E.

Alexander the Great and his successors, the Ptolemies, introduced coins that were purely Greek in style and

The el-Amarna Hoard, from el-Amarna, Egypt (14th century B.C.E.); these ingots and metal rings represent Egypt's earliest money. (© The Trustees of the British Museum)

inscription. They were struck in gold and silver and were based on the denominations of the Greek drachm, approximately one-eighth ounce in weight. Still, the standard silver coin of the Ptolemaic Dynasty (304–30 B.C.E.) was the tetradrachm, which became an international currency of the Mediterranean world in the fourth century B.C.E. Gold and silver coins bore an image of the ruler under whom they were minted or of a distinguished ancestor. The distinctive feature of Ptolemaic Dynasty coinage is the repeated use of the bust of Ptolemy I on the obverse, or “heads” side of the coin, throughout the period. Bronze coins bore similar motifs and portraits, though very little is known about the dates and means of their manufacture.

The establishment of coined currency in Egypt by the Ptolemies did not progress without difficulties. One major problem encountered was the silver standard used in the Greek world, which was based on a 10-to-1 ratio of silver to gold. In Egypt silver was imported, which meant that its value was high and thus inexpedient for coin production. Also, commodities value in dynastic Egypt was based solely on weights in copper. To solve this problem, the Ptolemies introduced bronze coins in multiple weight groups, some featuring very large coins that corresponded exactly to the deben (a

little more than 3 ounces). Thus, it seems that a dual currency was in use throughout the Ptolemaic Dynasty: a silver-based currency used for foreign trade and a copper standard for internal trade and economic transactions.

The Roman occupation of Egypt did not alter the coinage form and production. Coins were by then of much inferior quality and value, incorporating similar Pharaonic and Ptolemaic stylistic motifs and images on the obverse. In addition to the use of coinage for the transactions, contemporary documents recorded the much more frequent use of trading in kind (wine, oil, beer, for example) outside Alexandria before the economic reforms of the emperor Diocletian (r. 284–305 B.C.E.).

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

For most of the ancient period people living in the Near East did not use money. Instead, they conducted business by bartering, exchanging goods or services for other goods and services presumed to be of equal value. A bartered transaction could involve nearly any item or service, including land, livestock, grain, silver, copper, farm labor, or anything else essential to ancient life.

Long before coinage or paper currency was invented, people began trading commodities in standard measurements. The most common precurrency gauges of value were units of grain measured by volume and silver measured by weight. The standard units of weight were the shekel, which weighed about 0.3 ounces, and the biltu, or talent, which was the largest measure of weight-based value. One talent of gold weighed between 50 and 100 pounds, depending on the time and place. People were conducting exchanges in shekels and talents during Old Testament times, well before the advent of coinage in the sixth century B.C.E.

All metals were valuable, even in the days before they were made into coins. Metals were measured in terms of their weight in silver; even gold was valued by its equivalent in silver. Gold was considered the most precious metal and was valued at eight to 15 times its weight in silver. Next came silver, lead, copper, and iron after its introduction around 1200 B.C.E.

Coins were not invented until about 600 B.C.E. when the earliest electrum (an alloy of gold and silver found in nature) coins appeared in a hoard found in the temple of Artemis at Ephesus on the coast of Asia Minor, dating to the mid-sixth century B.C.E. But the first silver and gold coins known in the Near East date to the reign of Croesus, king of Lydia (r. ca. 561–547 B.C.E.), whose fabulous wealth sparked the phrase “rich as Croesus,” used to this day. Croesus’s capital was Sardis, and his Croesids, with their opposed lion and bull heads on one side and deeply impressed square shapes on the reverse, were staters varying in weight between 1 and 8 grams; there were also smaller denominations representing one-third, one-sixth, and one-twelfth of a stater.

Soon the practice of minting and using coinage spread throughout Greece and, with Greek colonists, to Sicily, southern Italy, southern France and Spain. But coinage also spread eastward. In 546 B.C.E. the Persian emperor Cyrus captured Sardis and took over its mints to produce Persian coins. Darius I became emperor in 521 B.C.E. and began issuing gold coins known as Darics. These archer coins depicted an image of Darius running with a bow and spear. The Persian emperor Xerxes the Great (r. 486–465 B.C.E.) continued to issue Darics. Darics were famous and desirable in the ancient world because of their high value; pure gold coins were rare.

Currency became more widely accepted during the Hellenistic Period (323–31 B.C.E.). Seleucid, Attalid, Ptolemaic, Parthian, and other monarchs established national systems of coinage, creating single sets of coins that could be used throughout their kingdoms. They build national mints to produce all those coins to ensure consistency of weight and composition. After Alexander the Great conquered the Persian emperor Darius III in 330 B.C.E., Persia and most of the Mesopotamian region adopted Greek coins or made local, imitative issues based on the Attic weight standard. These coins were predominantly silver. The main coins were the drachma and the tetradrachm. Kingdoms throughout the region, including Pontus and Parthia, minted their own silver coins. Parthian coins of the Hellenistic Period were produced at the

mints in Seleucia. They typically depicted the king’s portrait on one side and the goddess Tyche or some other deity on the other, usually in some pose in which the goddess presented the king his crown. The images on coins are an extremely useful source of information on the ancient world. Persian satraps, or governors, often had their portraits stamped onto coins. Coins are the only source of portraits of some rulers, such as the kings of Bactria in modern Pakistan. Other coins contain religious imagery, such as depictions of gods.

THE RICHES OF CROESUS

All the kingdoms of Asia Minor seemed fabulously wealthy to their European neighbors to the west, particularly to the Greeks, who turned this reputation into several legends that remain well known. The biographer Plutarch and the poet Virgil describe King Midas of Phrygia and the famous blessing and curse that made everything he touched turn to gold. The historian Herodotus, however, is the main source for the story of Croesus, whose wealth was an entirely historical fact, real and visible to the Greeks of the fifth and fourth centuries.

Croesus was king of Lydia around 560 B.C.E., ruling his kingdom between the Halys River and the Aegean Sea in Asia Minor. Croesus was believed to be the wealthiest man ever to live; he was the origin of the expression “as rich as Croesus.” Before making major decisions, Croesus liked to consult the oracle at Delphi so that he could get advice from the god Apollo. He also liked to send gifts to the temple before asking questions, perhaps thereby assuring himself of a positive reply. Herodotus, writing a century after Croesus’ reign, provides this list of Croesus’ gifts to the temple: 117 ingots of gold, totaling 240 talents (18,000 pounds) in weight, a lion made of gold weighing 10 talents (750 pounds), a large bowl of gold and another of silver, each approximately 500 pounds, and various other gifts. Finally, “along with these Croesus sent, besides many other offerings of no great distinction, certain round basins of silver, and a female figure five feet high, which the Delphians assert to be the statue of the woman who was Croesus’ baker. Moreover, he dedicated his own wife’s necklaces and girdles.”

Croesus came to a bad end; his kingdom was taken over by the Persians, and he threw himself (or someone threw him) onto a pyre to burn alive. His treasures remained in the temples at Delphi until the middle of the fourth century, when they were melted down to pay for a vicious civil war over possession of the god’s shrine.

Silver coins of various cultures found at Persepolis, Persia (modern-day Iran) (Courtesy of the Oriental Institute of the University of Chicago)

Coins offered several advantages over barter. They were easier to move than grain and livestock. The state guaranteed the quality and amount of metals in coins. Coinage allowed the state to take more control of commercial transactions, which served to increase the power of nations. Despite these advantages, coins were still not perfect. They were not standardized from state to state. Most early series of coins did not include small denominations, so they were useless for small transactions. Historians believe that the first coins were used mainly for large payments by states to armies or other states.

Early coin making was a laborious process. Mints first made blanks—blank coins of the correct size and weight but with no marks on them—by pouring molten metal into a clay mold. Most of the earliest coins were made of electrum, but the gold component of the alloy soon became too expensive, and most cities and states switched to silver coins. Minters took great care to ensure that their molds were the right size and that the molten metal contained the correct combination of ores. The mint would then make the blanks into actual coins by imprinting it with dies made of iron or bronze; they would place the blank in the die and strike it with a hammer. The die would leave an image on the coin, such as an eagle or a king's head. The minters would then engrave the back side by hand. Sometimes mints remade old coins with new dies, stamping the old coins with new images instead of making fresh blanks. Most ancient coins were rather rough; they were usually not perfectly round, and the edges of the die used to mark them could be clearly seen within their borders. During the 200s C.E. Middle Eastern minting techniques improved, and coins became much thinner and flatter.

During Roman times Roman coins were legal tender in much of the Mediterranean world. By the first century B.C.E. Roman coins were accepted throughout Greece, western Turkey, and the Levant and in many places farther east as well. During the Roman Republic (509–27 B.C.E.) the main Roman coins were called the sestertius and the denarius. During the Roman Empire, lasting until 476 C.E., the common coins were the aureus and the denarius. Romans also minted coins customized to individual localities. For example, in Asia Minor Romans minted coins called *cistopori*. In Syria they made local coins called *tetradrachms*. Individual provinces continued to mint their own coins as well; most of these coins were made of bronze, and people knew how much they were worth in relation to Roman coins.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Barter never entirely disappeared in ancient Asia and Oceania because many people lived outside the countries that developed cash economies. Furthermore, in hard economic times, people often ventured outside cash economies to trade on their own through barter. The desire to attach an objective value to goods developed in Asia sometime before 1500 B.C.E. By that time the Vedic culture that was moving into north-

ern India was valuing goods on the basis of how many cattle they were worth. Farther east in central Asia, nomads valued goods by how many horses they were worth. The first medium of exchange that functioned like money was the cowrie shell. Through most of Oceania, the region in and around China, and India cowrie shells were used as early as 1000 B.C.E. in the way coins would later be used: to buy goods without having to trade other goods.

The first coins made of metal probably originated in Anatolia, a region that is inside modern Turkey. Archaeologists tend to credit either the Lydians or the Hittites with minting coins that were intended to be used as money in about 600 B.C.E. Fairly quickly, the practice of minting coins made its way to India, with coins appearing in the 500s B.C.E. At first, the Indian coins were silver bars, weighing about half an ounce to an ounce and a half. By then, Indians had formed the custom of wearing armlets of metal and of using these armlets to purchase goods in their marketplaces; thus the concept of money was already familiar to them. This helps to explain why coins for purchasing goods and services were quickly accepted throughout most of India. The major exception to their use was among Stone Age tribes still living in jungles scattered through India.

The first Indian coins were probably produced by guilds, called *srenis*. Run by the fourth-level caste, the Sudras, guilds were responsible for regulating their trades. They may have introduced coins from a desire to standardize prices within their individual guilds. By the 400s B.C.E. minted coins had appeared in a variety of shapes and sizes, some bulky and good only for large purchases and others round, square, or in a variety of other shapes. The multitude of organizations that minted coins through the end of the ancient era created chaos. Not only *srenis* but also rich merchants, temples, towns, and kingdoms all made their own coins.

During the Maurya Dynasty (321–185 B.C.E.), the pana became the most common denomination of coin. It weighed about an ounce and was 70 percent silver, 25 percent copper, and 5 percent base metals such as lead. It was joined by the masa, worth one-sixteenth of a pana, and the kakini, one-sixty-fourth of a pana, as well as the cowrie shell, which was one-eightieth of a pana. After the reign of Asoka (r. ca. 268–ca. 233 B.C.E.) these coins were adulterated (that is, made inferior by replacing valuable metal with less valuable metal, such as replacing copper with lead) and lost their value for trade. During the 100s C.E. a new golden coin called a *dinara* was introduced; it was named for Roman coins that were popular in India. The *dinara* was supposedly worth 48 panas, but given the chaos in Indian coinage at the time, its actual value in the marketplace probably varied from place to place.

Indian coins were typically punched. A blank coin was made in a mold. It was placed on a carved die, and a punch with a carving on one end then was placed over the blank coin and struck with a mallet. The result was a coin with images on both sides, often a portrait of a monarch with his name on one side and marks identifying the mint on the other. Some

Indian kings are known to archaeologists only because their portraits and names are on coins.

Prior to the minting of coins in China, cowrie shells, bronze knives, and bronze shovels were used as money. Minted coins made of metal appeared in China before 450 B.C.E. Early ones were made of bronze and resembled in their shapes the knives and shovels that had been previously used for money. Coins were slow to catch on as money, but as urban areas grew and demand for goods increased, coins came to be used more and more, probably because they cut past the inconveniences of trading goods for goods. By about 250 B.C.E. coins were generally accepted throughout China, though a barter economy continued among peasants, especially in the outer provinces. Early Chinese coins were bulky and heavy, primarily useful for making large purchases. Military officers were still frequently paid in goods, even after the end of the Han Dynasty (202 B.C.E.–220 C.E.). Rolls of silk, rather than coins, were often used to pay people for their services.

The government of the Qin Dynasty (221–207 B.C.E.) tried to standardize China's coins. In 112 B.C.E. it introduced a five shu coin. This coin was circular, with a square punched in its middle, which allowed it to be strung with other coins. Typically, five shu coins would be strung together in units of

Fragments of a stone mould and bronze knife money, from northeastern China (ca. 350 B.C.E.); the inscription indicates that it was the “legal tender” of the Chinese state of Qi. (© The Trustees of the British Museum)

100. The coins were 80 percent copper and 20 percent other metals, usually lead. They were punched after the manner of Indian coins, with the blank coins being heated to soften them before punching.

Copper coins remained the fundamental coinage of ancient China, but the government did not always have control over their size and contents. Mine owners minted their own coins. Their shapes varied, with oval becoming common by the first century C.E. They tended to have symbols representing their value where Indian coins would have portraits, and on their other sides they would have the name of the minter and the approximate date the coin had been struck. The dates were not precise because the punch with the date would be used until it wore out, probably within a few months of use.

In 9 C.E. the Chinese government introduced 28 new denominations of coins, made of gold, silver, copper, tin, iron, lead, cowrie shells, and tortoiseshell. They came in many patterns, including circular, spoon-shaped, and shaped like a person standing. Apparently, the new coins did not catch on. In 25 C.E. the Chinese government again exerted control over coinage, reestablishing the five shu coin as the basic denomination. Gold ingots were sometimes used as money, but only for large purchases, because an ingot was worth about 10,000 five shu coins.

In the Japanese islands Chinese copper coins were used as money starting perhaps in the first century C.E. When Queen Himiko (flourished in the 200s C.E.) sent tribute to the Chinese emperor, she would receive gifts in return. Among these gifts would be sacks of copper coins, which would then be circulated among the Japanese.

EUROPE

BY KIRK H. BEETZ

Until the early 200s B.C.E. Europe outside Italy and Greece probably did not mint coins. At that time, the favorite coins among Europeans were Macedonian coins from the 300s and 200s B.C.E. Eastern Europeans were particularly fond of Macedonian coins featuring chariots, from the era of Philip II (r. 359–336 B.C.E.) and Alexander the Great (r. 336–324 B.C.E.) and preferred them to Roman coins. Until the Roman Empire imposed silver coinage on most of Europe, eastern and southern Europeans preferred silver coins, but western and northern Europeans preferred gold coins. The problem with silver coins was that their silver content could be adulterated (corrupted or debased) without the visible loss of silver. Among western and northern Celts, gold was thought to be more trustworthy because when it was mixed with less valuable metals, the loss of gold would be visible.

For most of its history before the coming of the Roman Empire, Europe relied on barter for buying and selling goods. Among the Celts, cattle were the most valuable asset for most people, and goods were often valued by how many heads of cattle they were worth. This continued to be the case in Ireland and parts of Britain even at the fall of the Western Ro-

man Empire in 476 C.E., even though southern Britain was the closest region in northern and western Europe to having a true cash economy at the time Julius Caesar conquered Gaul in 58–50 B.C.E.

As early as 1500 B.C.E. Europeans used copper ingots, gold ingots, and torques of gold, silver, copper, or bronze as mediums of exchange. A torque was a thick neck ring worn as decoration and as a sign of social status; torques were often exchanged with merchants for goods. The Germanic peoples of northern Europe and Scandinavia wore armlets that they could remove to exchange for goods. The armlets were sometimes gifts from kings to their followers. A king could improve his reputation and secure the loyalty of his followers by distributing armlets, known as *rings*, among them.

The first coins minted in Europe outside Rome and Greece were meant to be used like the Germanic armlets. A chief or king would have coins minted with his or her likeness and a mark that showed where the mint was located. The numbers and words on the coins would be copied from Greek coins. It was unlikely that what the numbers or words meant was important, because until the Roman conquest most Europeans were illiterate. It was the resemblance to the coinage of Macedonia that was important.

Celtic chiefs manufactured coins to display their power and to give to followers as symbols of the followers' indebtedness to their chief. When diners left the chief's house, the chief would present them with a gift as they were leaving. These gifts were often coins, and the more coins the chief gave, the more indebted the recipient was. In about 100 B.C.E. the Greek historian Posidonius observed Louernius, a chief of the Celtic Arverni tribe, stage a great feast lasting several days to display his wealth. He then rode his chariot through the countryside while tossing "pieces of gold and silver" to the crowd that followed him. These "pieces" were probably coins, and their distribution among the people was intended to bind those people to Louernius.

The coins were not necessarily for spending. The portrait of the chief or king on one side reminded the coin's holder of the power of that chief or king, and possessing the coin showed that its owner shared in that power. It was important that a coin have the amount of gold or silver in it that the minter claimed was in it, because some of the chief or king's reputation, and therefore some of his or her power, lay in the actual value of the coin, even if it was not meant to be spent. Thus, the Celts manufactured coins, but the coins were not inevitably part of a cash economy. In most of Europe north of southern France, even where there was an abundance of coins, barter remained the basis of trading until Roman times. Among many Gauls and the Germanic peoples, coins were hoarded, probably valued more for the gold or silver in them than as cash.

During the late 200s B.C.E. carving dies became a specialized craft. Dies were the stamps used to impress designs on blank coins. First, minters would weigh the metal for the coins. Then they would melt the metal, usually using ingots

of metal smelted by metalsmiths. The minters had ceramic rectangles with rows of holes in the shape, usually circular, of the coins to be minted, and the minters would pour the liquid metal into the carved holes. After the metal had cooled, they would have blanks, which were coins that had yet to be stamped. Their dies had two parts, one engraved with the image for one side of the coin and another with the image for the other side of the coin. A blank would be placed on one of the engravings, and the other engraving would be placed over it. The die was held together by hand while the minter struck the top of the die hard enough to impress both images into it. It is likely that a wooden mallet was used.

By about 70 B.C.E. southern Europe was developing a cash economy in which coins were the primary medium of exchange. There are indications that some tribes were becoming sophisticated in their use of money. For instance, Julius Caesar noted that when Gauls married, the wife was expected to contribute a dowry. The husband was expected to contribute the equivalent of the wife's dowry and invest the total money. If the husband died, the wife would receive the total value of the investment. This indicates that banking existed in parts of Europe by Caesar's time and that banking was safe enough to entrust with a woman's future prosperity. Further, it indicates that money as wealth had become part of the thinking of many Europeans.

Even after Caesar's conquest of Gaul, Europeans never stopped minting their own coins, even though they may have minted fewer of them during the Roman era. Local peoples who wanted to show their independence from Rome sometimes minted their own coins to display their independence. In other cases, wealthy people minted their own coins because local business depended on reliable coins and their local economies did not trust Roman owing to the fact that the Roman government often adulterated the silver in coins to counteract inflation, which in the long term just fueled inflation. By 400 C.E. almost all of Gaul had slipped back to the barter system. As different Germanic tribes moved through Europe during the 400s C.E., their leaders tried to display their legitimacy as rulers by issuing coins.

GREECE

BY PAUL McKECHNIE

Even before coins were invented in the ancient Greek world, the Greeks had a conception of relative value. In Homer's *Iliad* and *Odyssey* value is sometimes expressed in terms of the number of oxen an item is worth. For example, in the *Iliad* Achilles holds a wrestling competition in which the first prize is a bronze tripod worth 12 oxen, and the runner-up gets a slave woman worth four oxen. In the *Odyssey*, when the suitors attempt to apologize for their misbehavior at Odysseus's house, their leader offers compensation, saying, "Each of us shall pay you a fine worth twenty oxen, and we will keep giving you gold and bronze till your heart is softened."

Oxen, however, were not exactly "money." Sometimes they were used in payments—as when Lycaon was ransomed for 100 oxen when he was captured by Achilles. More often they were a conventional measure—as when Glaucus and Diomedes, discovering that their fathers were friends, agree to exchange armor: Diomedes' bronze suit of armor was worth nine oxen, but (according to Homer) Zeus made Glaucus lose his mind and exchange his gold suit of armor, worth 100 oxen, for it.

In the seventh century B.C.E. in Asia Minor (particularly Lydia) to the east of Greece, stamped precious metal coins began to be produced. Before then, precious metals had been used as a means of exchange, and sometimes they had been made into unmarked disks of a set weight. Coinage hastened economic change. One of the consequences of the widespread use of money was that people could save and accumulate their spending power.

In the sixth century B.C.E. Greeks began minting coins, usually in silver. Cities stamped coins with their individual marks. Some of the earliest Greek coins are from Aegina, marked with a turtle, and from Corinth, marked with Pegasus, Bellerophon's mythical winged horse. Peisistratus (d. 527 B.C.E.), a contender for power at Athens, began minting coins marked with an owl (symbolizing Athena, goddess of Athens) and an olive branch. "Owls" were minted at Athens and widely recognized and trusted for centuries.

There were hundreds of city-states in Greece, and many had mints and coins that were not necessarily acceptable outside their own cities but were made of precious metal and could be exchanged for local currency by bankers or melted down and reminted. Some Greek coins in museums today are overstruck with marks showing that they were once weighed and passed for use somewhere other than where they were minted. Different cities used different weight standards, so a drachma in one place did not necessarily have the same value as a drachma elsewhere. The two most widespread weight standards were the Attic standard (used at Athens) and the Aeginetan standard.

According to the Attic standard, money was measured in the obol, drachma, mina, and talent. The obol was the smallest denomination, and the drachma was worth six obols. The larger units (minas, talents) were not single coins: a talent, for example, would represent a heavy chest full of coins. Back in the sixth century B.C.E. the most widespread kind of coin was a didrachm, also known as a stater, but by the fifth and fourth centuries B.C.E. Greek cities minted mostly tetradrachms, which were worth four drachmas. Smaller coins, including fractions of an obol, were minted in silver, but not until the fourth and third centuries B.C.E. did bronze coins begin to be regularly minted in Greece.

For centuries the conventional daily pay for ordinary work in the eastern Mediterranean was unchanged. Rowers on Athenian warships in the fifth century B.C.E. were paid one drachma a day, and in the first century C.E. vineyard laborers were to receive one denarius a day, which was equivalent.

Skilled and specialized work, as in building the temple at Epidaurus in the fourth century B.C.E., might attract higher pay.

Credit, banking, and insurance were rudimentary. A financially sound borrower, when times were not difficult, might hope to borrow at 1 percent per month simple interest. Profiteering or scarcity of money might drive interest rates up two to four times as high. Bankers would accept deposits and pay interest to depositors, but checks were unknown. Insurance was likewise unknown, except that under Athenian law a loan to finance a trading voyage need not be repaid if the ship was lost at sea: The interest rate, when a trading venture succeeded, was correspondingly high, recognizing the share of the risk that the lender had accepted.

Gold coins were uncommon in Greece until the time of Alexander the Great (r. 336–323 B.C.E.). When Alexander captured the treasury of the Persian Empire at Persepolis in 330 B.C.E., however, he and his men claimed 120,000 talents when, according to the ancient Greek historian Diodorus Siculus, “the gold was estimated in terms of silver.” Most of the Persian treasure was in gold, which the Greeks assumed to be worth 12 times as much, weight for weight, as silver. They thought silver was 120 times as valuable as bronze. When this gold came to the Mediterranean area, the price of gold fell. Alexander’s treasurer, Harpalus (ca. 355–323 B.C.E.), worsened the shock by absconding with 5,000 talents of Alexander’s money and traveling back to Greece, where he spent freely.

In the Hellenistic Period (323–31 B.C.E.) the rulers of the empires that took over Alexander’s conquests minted coins picturing themselves; previously it had been almost unprecedented for a human being to be pictured (though gods and goddesses might be shown). In these centuries Greek coins were minted and used far into Asia. Indeed, the Greek kingdoms of Bactria and India, for which there is scant surviving literature, are almost best known from the coins they minted. Soon after the time of Alexander in the western Mediterranean, Greek moneyers began to mint Romano-Campanian coins—essentially Greek coins produced for Rome.

ROME

BY LUCAS G. RUBIN

The Romans adopted coinage fairly late, around 300 B.C.E. The earliest Roman currency was based upon the use of lumps of bronze called *aes rude*. These bronze pieces were difficult to use because they had to be weighed in order to determine their value. These inefficient tokens were later replaced by cast bars known as *aes signatum*, which were in turn replaced by bronze pieces of various denominations, one of which was known as an *as* (two or more were *asses*). The Romans also experimented with early types of silver coins based upon the Greek drachma, but they failed to obtain widespread use. During the Second Punic War, the Romans introduced a silver coin, the denarius, which was to form the basic unit of Roman currency for the next four centuries. The first denarius

was valued at 10 asses and went through periods of reassessment and revaluing. Gold was not regularly coined until the later Republic (which spanned 509–27 B.C.E.).

By the time of the emperor Augustus (r. 27 B.C.E.–14 C.E.), the Roman system of coinage was firmly established around the denarius, which became the dominant currency of the Mediterranean basin and the lands controlled by Rome. Along with the denarius, a gold coin (*aureus*) was produced, worth 25 denarii, and also a range of fractional bronze denominations of various amounts. This system remained more or less static until the introduction of an important new denomination, the *antonianus*, in the reign of Caracalla (r. 211–217 C.E.). The *antonianus* was minted as a “double denarius,” though its silver content was actually less than two denarii. This was, in fact, one step in a steady progression of reducing the silver content (called *debasement*) of coins that were about 94 percent pure in the first century C.E. to less than 1 percent by 270 C.E. Significant reforms were undertaken by the emperor Aurelian in 274 C.E. to correct this trend, but the problem of debasement and inflationary currency was not fully addressed until the reforms of Diocletian.

Diocletian (r. 284–305 C.E.) radically overhauled the economy, establishing a new coinage system shaped around a silver *argenteus* and instituting an edict on maximum prices in 301 C.E., both radical attempts to control the vagaries of pricing fluctuation. This eventually failed as well, and different systems of bronze and gold coinage became the norm over the course of the next few centuries until the final collapse of the Roman Empire in the west.

Facilities for the production of coinage were established in Rome with the institution of the first Roman coined money. During the Republic, the primary mint was believed to be located in or near the Temple of Juno Moneta on the Capitoline Hill. By the Imperial Period (14–180 C.E.) there were also several provincial mints, including a major facility at Lugdunum (modern-day Lyon, France). By the first century C.E. the mint in Rome had been relocated, and it is possible that its remains are partially preserved within the church known as the Basilica San Clemente. By the end of the third century C.E., in response to the increased disunity, discord, and distress within the empire, there were several major centers of imperial production scattered throughout the empire.

In the Republic the administrative board most commonly associated with the minting of coins was the *IIIviri aere argento auro flando feriundo* (*tresviri monetales* for short). This was a college of lower magistrates who oversaw the striking of bronze, silver, and gold coinage and whose establishment probably coincided with the institution of the denarius. During the empire the officials and personnel involved in minting activities became sufficiently more complex, with a range of different workshops, skilled laborers, and technical support staff reporting to a senior administration responsible for the production of coinage.

Ancient coins were minted by striking heat-softened blanks, usually cast or cut from a specially prepared bar. The

Cast ingots of bronze (early third century B.C.E.), used as money in Rome before the invention of silver coinage (© The Trustees of the British Museum)

coins were then laid on an anvil that held the obverse die and struck with a hammer by a punch that contained the reverse die. By the nature of this process, the obverse die lasted three to four times longer than the reverse die and was considered the more important side, the side upon which the most important images and inscriptions were incised. In general, the obverse side of a coin would contain a portrait head, most commonly of a deity in the Republic and of the emperor during the empire, while the reverse contained a range of images—individuals, structures, gods, and events. Emperors were usually presented with a range of standard and honorific titles. Julius Caesar was the first living Roman to have his portrait on a coin.

The various designs that appear on both the obverse and reverse of a coin can provide valuable material for the historian. Coins were a useful vehicle for the dissemination of information and offer an important resource for evaluating official communication and propaganda. The Roman government, for instance, could advertise its military success to the whole empire by minting and distributing a commemorative issue. The emperor Vespasian, for instance, minted a coinage series commemorating the end of the first Jewish revolt (70 C.E.) that portrayed a personification of the province of Judaea mourning beneath a Roman soldier. Conversely, the government could attempt to mask national problems by minting coins that celebrated nonexistent virtues or military successes. For example, an emperor might choose to mint a coin series celebrating national unity (“Concordia”) at times of civil war. Such propagandistic issues were particularly popular during the crisis-plagued period of civil wars and instability of the third century C.E. In rare instances, coins provide the only known evidence for some would-be emperors and usurpers. Similarly, some coins contain representations of buildings and famous statues that no longer, or only partially, remain. These images, though highly stylized, can provide a wealth of information about the basic form and decorative schema of a wide range of public structures. One example of

this is the Temple of Neptune in Rome, whose representation survives only on a coin and whose location even within the city is unknown.

Other forms of studying coins can provide information about economics (through analysis of metal content in coins), the numbers of coins in circulation, circulation and movement of coins (through analysis of wear patterns), and patterns of economic exchange (by mapping the distribution of coin finds). The content of metals (especially silver) can reflect economic difficulties. The pattern of debasement is interesting, as it demonstrates a naive approach to managing decreasing access to silver. The resulting inflationary crises were significant and ultimately devastating to the Roman economy and its stability.

One particularly interesting area of inquiry is the pattern of coin hoards in the Roman world. A coin hoard exists when more than two coins are found together. Three major types of hoard can be identified: purse, emergency, and savings. The purse hoard is a small collection of coins, usually of fractional denominations. Such an assemblage is similar to the money carried in one’s wallet for everyday purposes. At Pompeii, for instance, a tremendous number of purse hoards were found in association with human remains. The purse hoard can be valuable in demonstrating certain aspects of a cash-based economy, by suggesting the types of coins that people regularly carried. The emergency hoard consists of coins collected and hidden hastily, sometimes buried alone or under the floor of a residence to prevent it from being discovered. Such hoards are usually distinguished by their haphazard collection of coins and frequent inclusion of precious metal in other forms, as well as jewelry and gems. In contrast, the savings hoard is distinguished by its often-striking regularity in the types and quality of the coins gathered together. Like an emergency hoard, these coins were usually placed in a ceramic vessel or strongbox; in this regard, they are similar to a piggy bank (and have been found in such containers). Savings hoards of Roman coins have been found as far away as India.

The prevalence of Roman coins throughout the empire suggests that there was a strong degree of popular acceptance for their use. Although it can be assumed that some form of barter also existed within the economy, the overwhelming amount of evidence—from coins and hoards, price lists, and the frequent mention of economic interchange in Roman literature—illustrates the widespread use of money and coins.

THE AMERICAS

BY PENNY MORRILL

In Mesoamerica from the 10th century B.C.E. and up to about 200 C.E., the Olmec on the Gulf Coast, the early Maya, people in the Oaxaca region, and the peoples of Tlatilco, Teopantecuanitlan, and Chalcatzingo in central Mexico lived in villages surrounding ceremonial centers. Village life was dedicated to subsistence farming. There was always a need for utilitarian stone tools, ceramics, and clothing as well as ritual objects. The development of the ceremonial centers and an elite class requiring luxury and ritual goods created a demand for a greater variety of products; thus, a growth in specialty production and regional exchange networks developed. These same changes in the social hierarchy and in production specialization were taking place among the Chavín at Chavín de Huántar in central Peru.

Archaeological research has verified that jade and obsidian in Mesoamerica acquired a high value, as did gold and textiles in Peru. However, there is no archaeological evidence for a specific value given an object, whether for use by villagers or for the elite shaman-lords. It is not possible to ascertain what was bartered or exchanged for gold or jade. For these early cultures in the Americas and others in North America there is no archaeological proof to date for the use of currency in exchange for goods.

► music and musical instruments

INTRODUCTION

Music is produced by making something vibrate. A singer makes the vocal cords vibrate, but the principle is the same for instrumental music. Sometimes music is created by making a membrane vibrate, such as the animal skin of a drum, or by making a string or a column of air vibrate. All such music was made in the ancient world. The ancients, though, left behind no written scores, so historians of music can only speculate about how ancient music sounded.

The desire to make music runs deep through human history and into the human psyche. The most ancient hunter-gatherers no doubt learned that they could make music with their voices. The earliest musical instruments were probably drums and rattles used in religious observances, celebrations, and perhaps as a form of communication. In time, percussion instruments evolved into hand bells to produce music in ancient churches and temples. Sometimes glass crystals served the same purpose.

Among ancient stringed instruments were various forms of lyres, harps, and zithers. Paintings depicting harps, for example, are found on the walls of ancient Egyptian tombs, and an early form of the guitar was used in such places as ancient Persia and India. Generally, these instruments were played by plucking, either with the fingers or with a pick.

Ancient wind instruments date back to the dawn of history and include flutes of bone found in ancient Europe and horns of metal—yet another legacy of the later development of mining and metallurgy. These early horns are the ancestors of modern-day trumpets, trombones, and the like. In Asia bamboo was perfectly suited for making flutes, for bamboo is already hollow; with the addition of a row of holes,

bamboo flutes are little different from modern metal flutes. In the Americas flutes were often fashioned of cedar and are still used by Native American tribes to play haunting melodies. Also used in some parts of the world were instruments made of reeds and similar materials. These instruments evolved into modern-day clarinets, oboes, and other reed instruments.

Music in the ancient world had purposes that are little different from its purposes in modern life. Farmers—and probably slaves as well—chanted songs to make their labor lighter and to make the time pass. Soldiers used music in marching as well as to celebrate military victories. Music was used during festivals, parades, and celebrations and to accompany theatrical presentations, such as mimes. In the ancient world, epic poems, legends, and tales were often sung or chanted to make them more memorable not only for the audience but for the poet or storyteller as well. Music also played a key role in religious rituals. Like modern people, the ancients believed that music was a way to honor or appease the gods and to take part in the divine spark that gave people life. Music has no tangible existence; it disappears as soon as it is produced.

AFRICA

BY DAVID OTIENO AKOMBO

Throughout Africa vocal music has been sung for millennia. All cultures in Africa have used vocal music, believing that vocalization of thought through some musical medium such as song and chant is effective in reaching out to the supernatural deities ruling the land. These ancient beliefs are supported by contemporary production of vocal music in various cultural settings.

Even though vocal music is a distinctively older genre in the African musical repertory, compared with other genres of instrumental music and declamatory dirges (songs of mourning) such as those performed by griots (oral historians who recount cultural tradition through song), a systematic study of the variety of its forms has lagged for two reasons. One is that the use of vocal music among Africans is still an area of esoteric knowledge. Another is that the ownership of vocal music is communal rather than individual. For example, when a work song is composed, the composer delegates the work to the community, and the community owns it as they sing it within the context of their social events. When an individual musician composes a puberty song to be sung at ritual ceremonies such as Orunyeye, a tribal courtship dance of the Nyoro (also called Banyoro, Bunyoro, or Kitara) people of western Uganda, the community and the new initiates will eventually claim ownership of both the song and the dance. This sense of collective ownership of song and dance artifacts makes it difficult for the work of art to remain purely a solo piece, for it is transformed into a group performance intended as a collective social phenomenon.

Classification of African musical instruments is generally fraught with difficulty. According to one widely accepted

classification of musical instruments, there are four broad categories of instruments: membranophones, which produce sound by a vibrating membrane; idiophones, which produce sound by vibrating themselves; chordophones, which produce sound by vibrating strings; and aerophones, which produce sound by vibrating columns of air.

It has been theorized that the possible sequence of instrumental evolution in Africa can be traced from drums to pipes to strings. Since rhythm antedates melody, Africa's oldest instruments are hypothesized to have been percussive—specifically, hands and feet used to create rhythm. Other percussion instruments included pieces of wood or even skulls of animals. The drum has been the instrument of religious ritual among many African peoples from prehistoric to present times. Later ancient Africans added pipes, such as bamboo woods and horns that easily transformed into the aerophones. The chordophones, similar to lyres, were also created from various artifacts, such as the hunting bows of the Kamba people of Kenya.

Geography influenced the origins of ancient African musical instruments. For instance, people living in sub-Saharan Africa migrated slowly, with strong and weak tribes scrambling for richer valleys. These migratory patterns reshaped the musical instruments found in sub-Saharan Africa in three ways: Vegetation from swamps and forested areas gave rise to large membranophones and idiophones, aerophones such as reeds were found mainly in the semiarid regions, and unaccompanied choral singing was established mainly in open grassland.

The African scales (series of notes differing in pitch, varying with the frequency of vibration) and modes (set patterns of notes played over an octave using the white keys of a keyboard) took centuries to develop. It is difficult to determine how many modes actually exist, since the music is functional as opposed to contemplative, like that of Western forms. The musical scales and modes of African music are based mainly on impassioned speech and as such have never been fully conventionalized. In essence, musical melody is subordinated to some form of meaningful tone by following the natural inflection of speech within the language. This is because most African languages are tonal; hence, the base meaning of the words will change according to the intonation, the rise and fall of the voice's pitch. As such, these idiosyncratic attributes have influenced the way Africans view their scales and modes and have made it difficult to point to the exact tonal and modal characteristics of African music.

These African modes can also be heard when a drummer plays in the speech mode by reproducing the tonal and rhythmic patterns of speech on the drums. This type of transfer is drawn from ritual, work, or play, and so the modes are externally motivated. This is, in a sense, contrary to the conventional Western staff transcriptions, because the African scales differ in microtones and the pitch classifications are completely dissimilar.

For much of the history of the people of Africa, vocal music has been a universal experience. Such beliefs in the power of music are found throughout the world. Sound is used to reach outward toward the deities. In turn, it is through the vibratory matrix that sound provides that the deities themselves, it was thought, descend from the spiritual abode to participate in the human world. Vocal music is the vortex of religious ritual. The main purpose of vocalization was to appease the supernatural powers, solicit divine protection, and give thanks to the guardian spirits of the community. For millennia Africans have tended to approach their cultural activities, such as healing, through vocal music. In addition to these roles, Africans also relay these songs as entertainment. When the community likes the songs, they all join in and develop other tones to create naturally blended harmonies.

African musical instruments have a complex sociocultural significance. In keeping with their intricate musical system, Africans have used every known type of portable instrument; thus, it is important to examine African society in the cultural contexts in which instruments are played. While they may be used to produce a human experience, they are also used to teach societal norms, including respect for the aged and a continuing relationship between dead ancestors and the living. Instruments were used as media for communication and for imitating animals and birds to create the symbiotic relationship between animals and people. This coexistence is an ancient African tradition. The belief that the highest gods were part animal and part human led Africans to look upon animals with great reverence and love; accordingly, instruments were sometimes played to imitate the sounds of the animals.

Since ancient times African instruments have been used in the cycle of human life, including daily, social, political, and religious life. African musical instruments also serve as artistic works and as cultural symbols. They may represent specific social hierarchies, such as the *atsimevu* drum of the Ewe people of Ghana that symbolizes the commander. The *sabar* master drummer of the Wolof tribe of Senegal is conferred status through the performance of his drum and is, therefore, a leader in the community. His repetitive drum patterns symbolize stability in the community.

EGYPT

BY EMILY JANE O'DELL

While we have many depictions of musical instruments and musicians from the tombs of ancient Egypt, we know very little about the actual nature of the music itself. The frequent portrayal of musicians and musical events suggest that music was an integral part of both religious and secular gatherings, but without any notation it is virtually impossible for Egyptologists at this point to know what the music sounded like and how it was composed, written, and disseminated.

Musicians in tomb representations usually are shown playing in an ensemble and frequently are accompanied by

singers, hand clappers, and dancers in palaces and temples and at funerary events. Musicians in ancient Egypt were both male and female, though female musicians did not appear until after the end of the Old Kingdom (ca. 2575–ca. 2134 B.C.E.). Men and women played together in ensembles, especially in the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.), but in the New Kingdom (ca. 1550–ca. 1070 B.C.E.) women played in groups without men. These ensembles ranged in size, but some were composed of as many as 10 sistrum players and 10 hand clappers. Women wore light dresses and braided their hair with small balls hanging from the ends of their tresses, whereas men wore kilts. Both men and women could be overseers of these ensembles. There were titles for musicians (most meaning “temple singer”), and the abundance of designations suggests that musicians could function in many different capacities. Women singers were usually referred to as songstresses or chantresses.

Music was used to accompany ancient Egyptian religious rituals, such as the recitation of religious and funerary texts. Some gods and goddesses were associated with music. One of Hathor's incarnations was as the goddess of festivity and mistress of music. Priestesses of Hathor used sistrums to produce percussive rattling. Blind Horus was a god of the harp. Interestingly, many musicians in ancient Egypt are portrayed as blind or wearing a blindfold. The goddess Meret was appealed to in order to bring sacred texts to life. Thus, Meret could be said to be a goddess of sacred chanting. The male deity Bes is shown in ancient Egyptian art playing instruments, in depictions in Egypt as well as abroad. Music also was used to praise Osiris and Isis and Amun-Ra, among other gods and goddesses.

Music was used in both religious and royal contexts for rituals and festivals, and it was also used in daily life in the secular sphere. Family members would dance and sing for their deceased ancestors at their tombs. In the New Kingdom there are even examples of laborers who sang in the fields. During the New Kingdom a genre of harper's songs emerged, so called because a harper was illustrated alongside the text of these poems. These texts, which would have been sung at a banquet at the tomb in honor of the tomb owner, are quite rare when compared with the rest of the Egyptian corpus, owing to their insistence on the celebration and appreciation of earthly life over the afterlife.

The ancient Egyptians used a variety of instruments that would have produced a range of sounds, scales, tones, and tunes. There were a number of percussive instruments. Sistrums, as noted previously, were used to produce a rattling sound, especially in praise of Hathor and Isis. Sistrums were metal rattles held with a handle that would often be in the shape of the goddesses Hathor. On top of the hand was an oval-shaped frame that held metal horizontal rods on which beads were placed to shake and make noise when rattled. In fact, some large stone columns in the Hathor chapel of Queen Hatshepsut's mortuary temple at Deir el-Bahri and in the temple of Queen Nefertari in Abu Sir resemble Hathor sis-

trums. Hand clappers produced sound with their hands, but they could also use “clappers,” which were a set of boomerang-shaped instruments that could be struck together to create sound. These clappers eventually became decorated with hands to serve as a visual pun on the act of clapping. Clappers, like sistrums, also could be decorated with the face of Hathor. Wooden drums appeared in Egypt in the Middle Kingdom and seemed to have been introduced from Palestine. There were barrel-shaped drums as well as tambourines.

Ancient Egyptian musicians also played string instruments, especially the lyre and lute, which were similar to those found in other Middle Eastern areas. The harps, however, were distinctly Egyptian in shape and first appeared around 2500 B.C.E. in Egypt.

Harps were made of ebony but could be elaborately decorated with gold, silver, lapis lazuli, and malachite. One style of harp was arched, while the other was angular. Arched harps would have had between three and 10 strings, whereas angular harps would have had 21 to 29 strings. Angular harps appeared in Mesopotamia around 1900 B.C.E. and eventually usurped the arched harps that were there. However, the arched harp was the most popular kind in Egypt, and it took much longer for the angular harp to prevail over the arched harp than it had in Mesopotamia. Ancient Egyptians played three types of lyres. The thin lyres hailed from Syria, whereas the thick lyres, larger and with more strings, came from Anatolia. Giant lyres came to prominence and popularity in the Amarna Period (ca. 1353–ca. 1307 B.C.E.), and some could even be played by two musicians at a time. While lutes arrived in Egypt in the New Kingdom from the Middle East to much popularity, they became virtually nonexistent when Egypt became a member of the Hellenistic world.

Ancient Egyptians also played a variety of wind instruments—including flutes, divergent double pipes, and parallel double pipes—all of which were constructed from reed pipes. The tomb of King Tutankhamen (r. 1333–1323 B.C.E.) also contained trumpets that were made of silver and bronze fitted with gold and silver mouthpieces. Trumpets seemed to have been reserved for military occasions. We do not know the notation of ancient Egyptian music, so it is uncertain how the music would have been sung and arranged. It seems apparent from some textual evidence that there were antiphonal songs, containing verses to be sung in alternation, similar to call-and-response songs, and perhaps also a rondo form, in which a principal theme is repeated between contrasting musical sections. While music was an integral part of ancient Egyptian religious and secular life, we may never know how the music sounded and how exactly it would have added to the atmosphere of sacred and daily life gatherings.

THE MIDDLE EAST

BY LYN GREEN

In the ancient Near East music was an essential part of the daily life of both gods and mortals. Human beings could

bridge the gap between the ordinary world and the divine through music and song. Music was also a sort of international language, as ancient texts tell of musicians and musical instruments being sent from country to country. In the 14th century B.C.E., for example, the Egyptian king recorded the visit of a foreign princess accompanied by a retinue that included many entertainers.

A great variety of musical instruments are mentioned in texts or represented in art: stringed instruments, wind instruments, and rhythm instruments. Defining ancient musical instruments, especially stringed instruments, can be a challenge, since their shapes often are not only different from those of today but also changed over time and from region to region. We do know, however, that the peoples of the ancient Near East had what we would classify as drums, cymbals, tambourines, pipes, lyres, harps, and lutes. Musical instruments seem to have been highly prized, and some were elaborately crafted and decorated.

A cuneiform tablet from the 26th century B.C.E. is the oldest-known record of musical theory and records names of musical instruments. It cites 23 types of musical instruments as well as musical terms, such as the names of notes. By the Old Babylonian Period (2004–1595 B.C.E.) examples of musical notation appear, as do more tablets of musical terms. In addition, we have the lyrics of numerous hymns, which would have been chanted or sung by trained choirs. Other types of vocal performance are believed to have resembled modern Arabic and Asian singing.

Drums made of bull hide and wood appear in sizes from small hand-held drums to giant, shoulder-high instruments. Pipes were made of all kinds of materials, including reed, bone, wood, and metal, and came in many shapes. There is so little information about wind instruments, however, that we cannot say whether ancient Near Eastern musicians had flutes, trumpets, or other wind instruments familiar to us in their modern forms. We do know that the hollowed horns of animals, such as ibexes and bulls, were blown in the temples.

Although drums and tambourines are undoubtedly very ancient, some of the oldest pictures of musicians depict stringed instruments such as harps and lyres, and these are also some of the oldest instruments ever found. In the Third Dynasty of Ur (ca. 2112–ca. 2004 B.C.E.), in modern-day Iraq, rulers were buried with their servants, animals, and a great quantity of treasures, including beautifully made harps and lyres. These instruments were crafted of wood inlaid with lapis lazuli, shell, and bitumen and lavishly covered in gold foil and ornamented with sculptures of bulls' heads. Over the millennia the weight of earth entering the tombs crushed them flat, and the organic parts, such as the strings and sound box, decomposed, so that what we see in museums today are reconstructions based on photographs and records of the excavation and on ancient images of music making. (One of the lyres conveniently featured an image of a lyre being played on its sound box.)

Relief plaque of harpist from the Old Babylonian Period (ca. 2000–1600 B.C.E.) (Courtesy of the Oriental Institute of the University of Chicago)

Impressions on clay seals reveal that the harp was known in ancient Persia from about 3000 B.C.E. onward. The earliest harps had an arched shape, but after about 1900 B.C.E. angular versions replaced them. In some angular harps the sound box was horizontal, in others vertical. The instruments had between 15 and 25 strings probably made of animal sinew. (The early arched harps had far fewer strings.) Some Persian angular harps were large enough to rest on the ground, and others were small enough to be carried. There are many depictions of the smaller versions from the rest of the Near East as well.

Like the harp, the ancient Near Eastern lyre came in two sizes: small and portable and large and stationary. In some cuneiform texts the small lyres are called *zinar* and the large ones *hunzinar*. The lyre differs from the harp in that the lyre's sound box is on the bottom and the strings are suspended from a horizontal bar that passes between the instrument's two upright arms. Three different lyres were found at Ur, all on the large side. However, they pale in comparison with the giant lyres of the Late Bronze Age, which stood taller than the

musicians. Images of these instruments show that they were played by two people, one at either end or side of the lyre.

Lutes arrived relatively late in the Near East—the first mention of them comes from around 2000 B.C.E. Having only a couple of strings, they did not look much like the medieval European lutes familiar to us, and the instrument remained a novelty in many areas. For unknown reasons lute players are often shown dancing and even depicted naked, unlike other musicians in ancient Near Eastern art.

Given the close association between music and religion in the ancient Near East, it is not surprising that many of the most important positions held by singers or musicians were connected with religion. In Sumer the highest-ranking position in some cities was that of precentor, the leader of singing or chanting in religious worship. Musicians and singers in Mesopotamia formed guilds and sometimes lived in the temple colleges, though many of these performers were not full-time temple employees. Over time some musicians began playing or singing for funerals and magic rites and became private, rather than public, servants.

Several Mesopotamian gods and goddesses were associated with music. Ea, god of wisdom and freshwater, was the patron god of all music, and Ishtar/Inanna (goddess of love and war), her husband Tammuz/Dumuzi, and the storm god Ramman were the patrons of singing and pipe playing. Even the many divinities with no direct links to music all apparently loved it, for most of the important religious rituals required singing, music, or both.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Music was an important art form throughout ancient Asia and the Pacific. People sang, chanted, and played instruments of various types. In China people were making music long before recorded history. In Henan Province archaeologists have found a flute made of a bird bone that dates to 7000 B.C.E.; other prehistoric instruments may be even older. Music was a well-developed art form in China during the Zhou Dynasty (1045–256 B.C.E.). The imperial court had its own musicians and styles of music, while the ordinary people played and sang folk music. During the Qin Dynasty (221–207 B.C.E.) the emperor created a bureau of imperial music to regulate the music played throughout China; this bureau established rules for court music, military music, and folk music. Although musicians played for emperors, they had low social status. Ancient Chinese musicians invented a number of instruments to play music on the Chinese five-note scale. The flute was one of the earliest instruments. In the first three millennia B.C.E. flutes were usually made of bamboo, which was readily available and easily worked, allowing common people to make flutes.

Stringed instruments were widely played in ancient China. One of the most common was a seven-stringed instrument called the *qin*, or *guqin*, which resembled a modern zither and was played by plucking. The *qin* is still played in

modern China. Ancient *qin* were only about one-third the size of modern ones and were played with open strings. The modern form of the *qin* is believed to have been invented during the Han Dynasty. According to myth, the *qin* was invented around 3000 B.C.E. by the legendary kings Huang Di, Fu Xi, and Shennong; the tale says that the first *qin* had only five strings and that two more were added later. Actual historical mentions of the *qin* date to about 1000 B.C.E., and archaeologists have found *qin* in tombs that date to about 500 B.C.E. Other ancient stringed instruments included the *pipa*, a four-stringed fretted lute; the *ruan*, a four-stringed lute with a round body resembling a banjo; and the *konghou*, or harp, invented around 600 B.C.E.

Bowed fiddles (stringed instruments played with a bow instead of by plucking) were invented in Persia around 1000 B.C.E., and travelers in central Asia carried them east along the Silk Road. The Mongols developed this design into several types of bowed instruments called *huqin*, a name meaning “barbarian instrument” in Chinese. During the Han Dynasty, Chinese music was heavily influenced by the music of the Mongols and other peoples of central Asia, and Chinese musicians adopted some central Asian instruments, such as the *morin khuur*, a fiddle played with a bow of horsehair by Mongol horse herders. During the Song Dynasty (420–479 C.E.) Chinese musicians began playing the *erhu*, a two-stringed bowed fiddle that was played sitting down as the musician held the base of the instrument on his knee.

Music was widely performed and sung in India by the time people began writing down the Vedas, the oldest Hindu texts, starting between 2000 and 1500 B.C.E. Much of Indian music had a religious purpose. The Vedas were transmitted orally through chanting. Priests intoned sacred hymns in a musical style with notes associated with particular syllables and a prescribed rhythm. Often groups of priests and believers would chant mantras (sacred words or phrases) together; a leader would call out the words and tune, and the group would repeat the mantra after him. According to Hindu doctrine, singing the correct musical notes was essential to summoning the spiritual power of the words. This style of vocal music was called *Carnatic music* and was the predominant musical form in all of India from about 2000 B.C.E. until the end of the ancient period. Indian people also played instruments to accompany vocal chants. The main instruments were the flute, temple bells, and several stringed instruments, such as the sarod, which resembled the guitar.

Ancient Japanese people developed a complex musical tradition. To the Japanese, poetry and songs were closely linked and in some cases indistinguishable. Japanese musicians recited or chanted poems to a musical accompaniment on a stringed instrument, a flute, or a drum. The Japanese divided their music into categories, such as court music, military music, and popular music. Listening to a particular style of music evoked for them the culture from which that music originated.

Much of what historians know about Japanese music comes from songs and poems from the later Nara Period (645–710 C.E.), which scholars have used to reconstruct some ancient Japanese musical principles. Archaeologists have found statues of musicians dating to the ancient Jōmon (ca. 13,000–ca. 300 B.C.E.) and Yayoi (ca. 300 B.C.E.–ca. 300 C.E.) periods, but Japanese musicians of these periods did not write down any of their musical pieces. The Nara Period texts *Kojiki* (Records of Ancient Matters) and *Nihon shoki* (The Chronicles of Japan) were the first recorded archives of Japanese history; these documents contain many songs of ancient origin. By the time scholars started writing about music, they had a well-established body of work to describe, which means that modern historians can surmise a fair amount about ancient Japanese music that predated the sixth century C.E.

The evidence for ancient Korean music is fragmentary and comes mostly from Chinese sources. Korean had both formal court music, performed at seasonal festivals and ceremonies, and more casual folk music, played and

Red sandstone railing pillar in the form of a flute player (second century C.E.), Mathura, northern India (© The Trustees of the British Museum)

sung by common people. Historians know that a seven-stringed zither of Chinese design was played in Korea during the third, fourth, and fifth centuries C.E. Koreans also played a uniquely Korean stringed instrument called the *komun'go* starting in the fourth century; numerous tomb paintings from that period depict the instrument. This instrument was placed in a horizontal position and played by striking the strings and pressing them against frets. People in central Korea played a vertical harp that may have been influenced by central Asian instruments.

Southeast Asian music was influenced by that of India and China. Burmese music most resembled ancient Indian music; Burmese musicians adopted the Indian harp as a favorite instrument. In Java during the second and third centuries B.C.E. smiths used bronze to create gonglike instruments that were carried into battle by soldiers. By the fourth century C.E. these gongs had evolved into the gamelan, a collection of bronze gongs played by a group of musicians. People believed that the gamelan had supernatural powers over the weather and human emotions; they were often played in ceremonies to bring rain or at weddings.

Pacific islanders composed many hymns and chants that they sang a cappella, or without the accompaniment of instruments. The people of Tahiti sang chants in a microtonal scale, a scale that contains more notes within an octave than the traditional 12 notes of the Western scale. Islanders also used drums to accompany vocal music. In Australia traditional music was part of ritual and entertainment. Songs commemorated the history of clans and heroic deeds, mourned the dead, and told of religious traditions. The most common instrument was the didgeridoo, a pipe made of wood; although the earliest historical record of the instrument comes from cave paintings from the fifth century C.E., historians believe that the didgeridoo may be the oldest wind instrument in the world, which means Aborigines could have been playing it in 7000 B.C.E. or earlier.

EUROPE

BY SIMON O'DWYER

Music in Europe has its origins some 40,000 years ago with the arrival of the modern human being. A number of bone flutes have been recovered from caves in France and Germany, including a swan-bone flute found in the Geissenklösterle Cave, Germany, dated to about 37,000 B.C.E. and generally considered to be the oldest surviving musical instrument in the world. Many of these early flutes were recovered in proximity to cave paintings, and audio experiments in caves in France suggest that the paintings occur in areas of caves with good acoustics and not in those with bad acoustics. Thus it would appear that music and visual art were associated from the very origins of both.

Musical instruments that survive from the European Stone Age tend to be animal- or bird-bone whistles and flutes, simple stone flutes, and rock gongs (rocks that produce

a resonant tone when struck). One notable exception is the remarkable set of wooden tubes known as the Wicklow Pipes, recovered from an ancient cooking place in County Wicklow, Ireland. These six cylindrical pipes of varying lengths are finely carved from yew wood and presented together in a panpipe arrangement. Carbon-dated to about 2135 B.C.E., the pipes each have a socket carved at one end to accept a mouth-blown tone generator that was not present with the find. The sockets would allow a player to fine-tune the pipes by moving the tone-generator extension inward or outward. Such a facility is highly unusual in the Late Stone Age and clearly demonstrates that the musicians then were achieving accurate and complex music.

In the Middle to Late Bronze Age (ca. 1500–600 B.C.E.) two distinct types of metal wind instruments emerged. Some 60 cast-bronze trumpets known as *lurs* have been found in northern Germany, Denmark, and Scandinavia. They are made in a double opposing conical curve over 6 feet in length with a circular decorated plate at the bell. Thus the instrument, when played, curves around the upper body of the player, and the plate is presented over the head facing forward. The *lurs* were made in pairs with opposing curves so that two paired players would make a balanced right and left presentation. Many of the instruments have chains attached, believed to have made sounds that contributed to the performance. It is generally thought that *lurs* were played as part of religious or royal ceremonies.

The second great family of metal wind instruments emerged in Ireland and perhaps Britain around 1100 B.C.E. In Ireland no fewer than 104 horns are known to exist, while a fragment of one and a drawing of another survive from Scotland and England, respectively. This number represents about 40 percent of the entire world collection of prehistoric metal wind instruments. A single find, known as the Dowris Hoard, from County Offaly, Ireland, contains 26 bronze horns—the largest such group ever found anywhere—accompanied by 39 bells or rattles.

The Bronze Age horns of Ireland and Britain were all cast from a two-part clay mold with a central core held in place by bronze pins. The Irish examples, found throughout the island, occur as two distinctive types. About half had a mouthpiece or mouth hole fitted into the side of the horn, while the rest employed a more conventional end-blown arrangement. The way in which both kinds of horns were found together suggests that they were played in pairs or multiples of pairs of end-blown and side-blown instruments. Recent research and reproduction have revealed surprisingly rich and complex musical properties for the horns. By employing tone variation and circular breathing techniques, a good player can produce a variety of sound and rhythm. It is particularly noteworthy that the horns can be used to play an overtone series over the fundamental note. This is a playing technique whereby a series of higher notes are produced above a continuous drone. Normally it can be achieved only by specialized singing, which is practiced in Nepal, Tuva, and Tibet. It

is now generally accepted that these Bronze Age horns were played throughout the islands as entertainment and in ceremonies such as religious rituals and celebrations of the inauguration of kings.

The 39 bells or rattles found as part of the Dowris Hoard are known as *crotals*. The name *crotal* is a Gaelic word derived from the Latin *crotalum* meaning “rattle.” Each is roughly the size and shape of an avocado, hollow, with a loose pebble inside and a ring fitted at the top. Sounded by hand or perhaps attached to a belt around the waist of a dancer, they can produce a light, tinkling rhythm. Oddly, with a single exception (from County Antrim, in what is now Northern Ireland), these 39 *crotals* found together are the only ones of their kind known to exist. Perhaps a distinctive musical subculture was thriving in the area of County Offaly in the Late Bronze Age.

The European Iron Age (ca. 500 B.C.E.–300 C.E.) saw the emergence of long trumpets and horns made of sheet bronze (bronze beaten or compressed into thin sheets that can then be formed into tubular or other shapes). The most common of these was the *carnyx*, a great war or ceremonial conical trumpet presented vertically over the player’s head and having a stylized bronze head of a boar, dragon, or snake at the top. Fragments of these trumpets have been found across northern Europe. The most important find, near Bordeaux, France, included five complete instruments in company with other plundered artifacts of war. A small number of more conventional sheet-bronze horns survive from northwestern Europe. Of these, the two most famous examples are the Ard Brinn (ca. 200 B.C.E.) from a place of that name in modern-day County Down, Northern Ireland, a two-part, conical, S-shaped instrument almost 10 feet in length, and the Loughnashade (“Lake of the Treasures”) from County Armagh, Northern Ireland (ca. 100 B.C.E.). Accurate reproductions have been made of each, and surprising discoveries have come to light as to how they were made and to what uses they may have been put.

The more notable is the Loughnashade, which was probably assembled in the S position. Today the two quarter-circle parts of the trumpet are displayed assembled in the National Museum of Ireland in a semicircular, or C, position. Studies of the first reconstruction have established, however, that the circular tubes were probably originally connected in an opposing, or S, position and then played while being held up vertically over the player’s head. The distinctive circular plate is positioned at the end and faces forward. Thus, these war trumpets would have functioned in a similar manner to the *carnyx*.

There is a tendency among scholars of ancient musical instruments to ignore the achievements of prehistoric northern Europe in favor of the great civilizations of Egypt, Greece, and Rome. However, the great antiquity of the bone flutes and the very fine design, manufacturing, and musical qualities of the metal horns and trumpets from the northern European Bronze and Iron Ages clearly point to a rich and inclusive musical tradition spanning many thousands of years. A re-

gion that the Romans labeled as savage or barbaric produced some of the most beautiful instruments, both in appearance and in sound, that have ever been made and played.

GREECE

BY JEFFREY S. CARNES

The Greeks considered a life without music the grimmest sort of existence. Music permeated ancient Greek culture at every level, from officially sponsored public festivals to the daily lives of working-class men and women. Already in the Homeric era it was everywhere: In the *Iliad* Achilles strums his lyre and sings heroic songs while sitting out from the fighting; boys and girls sing harvest songs later in the poem; the *Odyssey* gives examples of singers at banquets and women singing at the loom. In a real-life context the historian Thucydides reports that Athenian prisoners of war working in the quarries of Syracuse were forced to entertain their captors by singing choral odes of the tragic poet Euripides.

Greek instruments were surprisingly few in number. Lyres of various descriptions and a pipe instrument called the *aulos* were far and away the most common. Lyres have either box-shaped or bowl-shaped sound boxes. The latter type was called a *lyra* or sometimes a *chelus*—literally “tortoise,” since a tortoiseshell typically formed the sound box. The face of the instrument was composed of ox hide; this supported the bridge, while curving arms made of horn or wood extended above the sound box. A horizontal bar connected the arms, and the strings (made of gut or sinew and usually seven in number) were fastened to this. The *lyra*, like all Greek stringed instruments, was plucked (the bow was a later invention); the pick, or plectrum, usually made of bone or ivory, was considerably larger than a modern guitar pick.

The *lyra* was small and not capable of producing much volume; sources suggest that it was played mostly in home and classroom settings. For public performances musicians preferred various types of box lyres. Pictorial evidence for these goes back as far as Mycenaean painting (ca. 1200 B.C.E.); the instruments look to be heavily built. The most evolved form was the *kithara*, in use from approximately 600 B.C.E. Other stringed instruments, such as harps, were of secondary importance. On all of these it seems the strings were normally played open rather than stopped.

The most important wind instrument was the *aulos*, consisting of two cylindrical tubes, each equipped with finger holes, and sounded with a double reed, like the modern oboe. It could produce not only strong volume but also moving dramatic effects. The *aulos* was the instrument of choice to accompany choral poetry (including tragedy) and provided music at large public events as well as smaller private gatherings. Other wind instruments included panpipes (a wind instrument composed of a series of pipes bound together), flutes, and the *hydraulis*, a water-powered organ invented in the third century B.C.E., which was the world’s first keyboard instrument. Brass instruments served primarily to give signals in military

The Greek god Apollo with a kithara, a stringed instrument similar to a lyre (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

contexts; percussion instruments (which included cymbals, castanets, and hand-held drums) were used in entertainment and in ecstatic religious worship.

Our knowledge of how Greek music actually sounded comes largely from numerous ancient works on music theory, based on the tuning of stringed instruments. The fundamental unit of the Greek scale was the tetrachord: four tones, with the top and bottom forming an interval of a fourth and the other two varying. An octave scale or mode could be built up of two tetrachords, with varying combinations possible, named after their alleged national origin (for example, Dorian, Lydian, or Phrygian). The sequence of intervals in most was different from our major and minor scales. The Dorian, for example, roughly corresponded to a scale played entirely on the white keys of a piano starting on E. The modes, however, had varying tonal centers: In a modern scale, the lowest note is the tonic, with the function of other notes determined in relation to it; for a Greek mode the tonal center might lie elsewhere. Tuning of instruments was also different: Octaves were not necessarily divided into equal parts as in modern equal-temperament systems. Furthermore, the size of intervals could vary: Modern systems use only the whole tone and the semitone, but the Greeks made frequent use of quarter

tones and other small intervals (non-Western musical traditions and some innovative jazz and modern composers make use of such intervals).

Greek music was almost entirely melodic rather than harmonic; that is, in most cases only one note was played or sung at a time. Choruses sang in unison or in octaves; although the musical accompaniment may have played a different note from the sung one, there was no counterpoint or complex harmony. The rhythm of Greek music was complex and tied closely to the rhythms of Greek poetry, which it frequently accompanied. There exist nearly 50 examples of Greek musical notation; recreations of Greek music based on these examples tend to sound exotic to Western ears, sometimes reminding listeners of Indian or Middle Eastern music.

Audiences for musical performances ranged from a few guests at a symposium (a drinking party in someone's home) to 30,000 or so spectators in a theater. Most musical genres were also poetic genres. Epic poetry was accompanied by the *phorminx* (a type of kithara), lyric by a lyre or kithara. Perhaps the most significant and certainly the most spectacular genre was choral poetry, in which a group of performers sang and danced (the word *chorus* means "dance") to the accompaniment of an *aulos*. This was a diverse genre, ranging from the victory odes of the poet Pindar to the choral sections of tragedy (a dramatic form that developed when individual performers were added to engage in dialogue with the chorus). In typical Greek fashion both choral poetry and solo performances of songs with kithara accompaniment became objects of competition at major festivals: Musicians as well as athletes could be Olympic victors. Literary sources describe (not always with approval) the virtuosity and innovation of composers and musicians in this highly competitive environment.

Music was an important part of education, and to be an accomplished lyre player was a valued sign of upper-class status. Moreover, music was thought to have important effects on moral character. Plato, drawing on the work of earlier theorists, rejected musical modes that supposedly promoted excessive emotion and approved of only those believed to engender courage and moderation (the Dorian and Phrygian). Similarly he condemned the *aulos* for its overly expressive nature. Aristotle's *Politics* contains an extended discussion of the effects of music on the souls of citizens. For the mathematician-philosopher Pythagoras the harmonies present in music, based on mathematics, were a sign of the harmony of the world as a whole—a mystical line of thought followed by many other ancient Greek philosophers.

ROME

BY AMY HACKNEY BLACKWELL

Ancient Romans loved music. Music was a part of most social gatherings, from dinner parties to parades. Farmers sang folk songs as they worked in the fields, women sang as they went about their daily chores, and admired performers were

treated as celebrities. Despite music's popularity, ancient Romans left behind little information on their music and musical practices. The Greeks wrote a great deal about music and considered musical training an essential component of a gentleman's education, but it appears that Romans did not feel the same way about music as a subject. They considered it a necessary component of religious ceremonies and public celebrations and thought it entirely appropriate for young people to learn the basics of music, but they did not dwell on its philosophical implications the way the Greeks did.

For many Romans music was trivial entertainment, nothing more. Roman poetry, unlike Greek poetry, was designed to be recited without music. Romans who did write about music preferred to dwell on the musical artistry of Greek music, not on Roman compositions or performances. Aristocratic Romans considered professional musicians somewhat disreputable and often bewailed the lax morals of musicians and actors. With the exception of a few celebrated professionals, most musicians were of the lower or middle classes and did not associate socially with the upper classes.

Young nobles of both sexes studied music as part of their education, but respectable Romans did not encourage their children of either sex to aspire to be professional performers paid for their work. Music teachers were generally slaves, often Greek. Girls were expected to learn enough music to perform at home for their families. Noble children occasionally performed publicly, such as on one occasion when the Roman poet Horace trained a choir of children to sing at the Secular Games in 17 B.C.E.

Music was essential to numerous public events. Sacrificial rituals were not complete without pipe players. Practitioners of foreign cults brought their music with them to Rome; the worshippers of Isis, for example, played daily hymns to their goddess. Parades usually included singers and dancers who performed to the music of drums, tambourines, pipes, and lyres. Musicians played trumpets and pipes during funeral processions. In the theater comic plays were accompanied by musicians playing pipes, brass, and percussion instruments; actors often sang and danced to this accompaniment. Pantomime, a popular dramatic form, consisted mainly of silent actors moving to music created by pipes and singers. Wealthy people often hired musicians and dancers to entertain their guests at parties. The most popular musicians achieved fame throughout Rome; for example, the writers Cicero and Horace both mention the famed piper and singer Tigellius.

Romans did not leave behind any musical scores, so historians have never been able to reconstruct Roman musical styles or melodies. Historians do, however, know something about the musical instruments Romans played. They used stringed, wind, and percussion instruments. Singing was also common.

Ancient stringed instruments were all plucked with the fingers or with a pick called a plectrum; no instruments of this time were played with a bow. The lyre was one of the

CARMINA: MAGIC SONGS

Although Romans did not leave behind much evidence of their musical compositions, there are numerous examples of a type of song called a *carmen*, the plural of which is *carmina*. *Carmen* was a generic Latin term for a song; the word derived from the verb *cano*, meaning "to sing." It originally referred to anything chanted, particularly religious incantations or magic spells. To perform magic spells, people would sing or chant verses in a specified order and perhaps perform other ritual actions such as spitting. Repetition of the verses was necessary to make the magic work; three or nine were common numbers for required repetitions. Spells could be used for anything, from winning love to cursing an enemy. *Carmina* were considered serious business in Rome's early days; the Twelve Tables, Rome's most ancient laws, forbade the casting of a *malum carmen*, or an evil spell.

Although by the time of the Roman Republic (509–27 B.C.E.) the term *carmen* generally meant just a song, the word continued to have a sense of enchantment. Priests sang several types of *carmen* at festivals. The historian Livy (59 B.C.E.–17 C.E.) describes priests dancing and leaping through the streets as they chanted their hymns. The *carmen arvale* was a song to the Roman god Mars and the Lares, Roman household gods, performed during the sacrifice to the Dea Dia, a goddess whose festival occurred in May. The *carmen saliare* was a hymn sung by the *Salii*, priests of Mars, during the parade to celebrate their annual festival. For this parade the priests dressed up in ancient armor, carried ancient weapons, and performed an ancient dance that involved leaping and jumping; the name *Salii* refers to their leaping performance. Historians believe that these songs were slow and solemn.

Not all *carmina* were religious. When Roman soldiers paraded through the city during a triumph, a parade celebrating a major victory over an enemy of Rome, they sang the *carmina triumphalia*, a collection of ancient songs that either praised their general or mocked him satirically in order to ward off the evil eye.

most ancient stringed instruments, supposedly invented by the Greek god Apollo, who made the first lyre out of a tortoiseshell strung with cow intestines. The lyre consisted of two arms and a crossbar affixed to a sound box, with strings strung from the crossbar to the base of the instrument. Some lyres used a tortoiseshell as a sound box; others were made of wood and hide painted to resemble a tortoiseshell. Lyres had between four and seven strings made of gut, sinew, or flax.

The player plucked the strings with a large plectrum made of wood, bone, or horn.

Roman musicians often played the kithara, a stringed instrument that produced a more piercing sound than the lyre. (The word *kithara* evolved into the English word *guitar*.) Kithara could be much larger than lyres, though there were also small ones that were often played by women. The kithara could be tuned more precisely than the lyre. Some Roman sculptures depict kithara with triangular tuning pegs that look as though they were turned with a key to adjust the tension of the strings.

Lutes, which had round sound boxes, long necks, and three strings, were also popular. Ancient lutes were very similar to lutes played in Europe in the medieval period. People also played several different kinds of harp. Both harps and lutes were plucked with the fingers, usually of the right hand; the player used the other hand to damp strings that he did not want to sound.

Romans played several types of wind instruments. One of the most common was a pipe called a *tibia*, played throughout the Mediterranean region. The *tibia* took several forms. One was a flute made of a single pipe held sideways to the player's head and played by blowing across the mouthpiece and covering combinations of holes with fingers. Another version had two reeds and two pipes fastened side by side. Players fingered one pipe with each hand. A player might wrap a cloth band around his head to support his cheeks while playing.

The panpipe consisted of several tubes attached to one another side by side. The player blew across the ends of the tubes to create different notes. The Roman version of the panpipe had tubes of different lengths, unlike the Greek version, which used tubes of the same length plugged with wax to achieve different pitches. Panpipes were considered a rustic instrument most appropriate for rural settings.

Both Greeks and Romans played bagpipes. Romans loved a type of pipe organ called a *hydraulis*. The earliest form used a hydraulic mechanism to blow air across the pipes. Operators used levers to pump air into a vessel of water; this compressed the air and forced it over the ends of the pipes, making noise. By the second century of the Common Era the hydraulic mechanism had been replaced by a bag inflated by bellows. The *hydraulis* was large and loud. It was commonly used at the Colosseum to enliven gladiatorial events. Romans also used several types of trumpet, both straight ones called *tuba* and curved types called *cornu*. The army used trumpets to deliver military orders and in parades. Civilians used them whenever they needed to signal the start of some event, such as a theatrical performance or the beginning of a festival.

Musicians used several kinds of percussion instruments to keep the beat of musical performance. The simplest form of percussion was snapping, clapping, or stomping in time to the music. Musicians also used drums, castanets, wooden clappers, and cymbals. Tambourines called *tympani* were a very common instrument used in parades and at parties; dancing girls often played them as they danced.

THE AMERICAS

BY LAWRENCE WALDRON

It is difficult to imagine the sound of ancient American music from the scant evidence available today. Early musical instruments were often made of biodegradable materials, such as wood, hides, and horn, and few of them have survived to inform the theories of anthropologists and ethnomusicologists, those who study music in its sociocultural context.

Ceramic instruments outlast those made of organic matter, and various ceramic drums, wind instruments, and noisemakers have been found in Central and South America. Anthropologists working in those regions have also uncovered ceramic eating and drinking vessels on which are painted scenes of musical rituals and celebrations. Scholars also can compare the remains of ancient instruments with later, similar versions to extrapolate the sounds and uses of ancient music. Still, most of what is known about ancient American music is inferred from a very imperfect archaeological record, many artifacts being made of materials that may not have been the most typical in their time.

Music in ancient America was produced using three major classes of instrumentation. Wind and percussion instruments seem to have played the most important role in rituals and festivals. A variety of idiophones—devices that make specific, unusual, and often atonal noises—constituted the third class of musical instruments. Wind instruments were made of wood, reeds, ceramic clay, or bone; as the name suggests, they were blown like flutes or trumpets. A vast range of percussion instruments were beaten for rhythm, most of them resembling drums from other parts of the world. Idiophones were the most widely varied instruments. Some were struck like percussion instruments, but many were shaken, turned, twirled, spun, or even worn in dance to produce a plethora of sounds. Stringed instruments rarely played a part in ancient American music.

If later Native American music can give any clue to earlier forms, ancient musical instruments may have been used to accompany singing, chanting, and speech during rituals and sacred spectacles. Here the voice would have been the chief source of tone and melody, while rhythms and sounds from musical instrumentation may have functioned theatrically: to draw or fix the audience's attention, to mark important passages in sung or spoken performance, or perhaps to aid in memorization of myths and legends. Fully instrumental music was seldom part of ancient American performances.

It is easy to assume that drums were universal, but some groups in South America evidently had no use of them even at the time of European contact. Nevertheless, percussion instruments were very widespread in the ancient Americas, and their design ranged widely as well. The most rudimentary may simply have been wooden planks beaten with sticks, sometimes over a chamber dug out of the ground, a method customary among some Pacific Northwest Coast Indians. Cultures in both North and South America, however, devel-

oped a variety of skin drums. These were essentially wooden tubes or barrels across the mouths of which were stretched membranes of animal skin. They could be played either with sticks or with the hands. Some Mesoamericans made slit drums, hollow lengths of logs into which slits were cut to vary the sound of the instrument.

From Costa Rica to Bolivia ancient Indians developed ceramic variations on the more common wooden skin drum. By the beginning of the Common Era, Indians of the wooded regions of the American Northwest Coast were already expert at joining and bending wood with heat, making it possible to give skin drums almost any desired shape, thereby producing a variety of sound qualities as well. Many drums may have been carved or dyed with symbolic or decorative motifs.

Southwest Indians of what is today the United States played double-headed drums, while Indians of the Northeast used wooden kettledrums to accompany their cane flutes and singing. From paintings on ceramic vessels anthropologists know that Andean peoples such as the Moche and their ancestors made tambourines and gongs, instruments easily carried in royal and religious processions.

With their airy, sometimes shrill tones, ancient flutes, whistles, and trumpets produced sounds that resembled those found in nature. The human voice, the stirring wind, and various species of birds could all be imitated by Native American wind instruments. Among North American and Amazonian Indians, with their rich shamanic traditions, wind instruments could also be used to represent spirits of the natural world and the hereafter. In their ritual performances the ancient Plains Indians of North America played flutes fash-

ioned out of cedar and perhaps other woods. They also made eagle-bone whistles whose exact use remains unclear, though it may have been connected to mystical practices.

Northwest Coast Indians played reed instruments whose tones could be varied by the force of the player's breath. Indians living in coastal regions throughout the Americas often adapted marine materials to make idiophones, such as clamshell clappers. They also acquired wind instruments ready-made from the sea: conch shells blown at religious and military ceremonies.

Using wooden panpipes or ceramic ocarinas (sculpted clay vessels blown like woodwinds), Andean Indians developed richly melodious and harmonic music. This was probably one of the few ancient American musical forms enjoyed for its own sake rather than in a supporting ritual role. In fact, the Andeans produced several whimsical devices that served to delight the listener. Potters excelled at creating utilitarian ceramic vessels that whistled when the water inside them was agitated. They also made pots that contained closed chambers filled with ceramic beads, which made rainlike noises when the vessels were shaken.

Mesoamericans seem to have used music both for religious ritual and for the entertainment of royals. The early Maya developed clay, wood, and cane trumpets, to which they sometimes added a gourd on the end as a resonator. Some of these wind instruments may have been inspired by even earlier Olmec prototypes.

Some instruments were used to produce singular, peculiar noises that may not have had any clear tones like, say, those of sweetly blown ocarinas or flutes; others may have supplemented the powerful beats of drums with more tonal, delicate, or rapid percussions. In the North American coastal Northwest rattles of animal skin filled with pebbles were shaken at shamanic rituals and possibly during pronouncements from tribal leaders. Northwest coastal Indians also made rattles from gourds, turtle shells, and insect cocoons, any of which could be filled with seeds or stones and attached to a handle. Clappers, to be played on their own or to accompany drums, were made by splitting sticks to create two separate tongues that slapped against each other when the instrument was shaken.

Plains Indians made rattles of rawhide, while Southwest Indians used hollowed horns. Employing their wide trade contacts, southwestern peoples imported metallic bells from the Late Pre-Classic Maya far to the south. The bells, attached to cords or bands and either shaken by hand or worn by dancers, produced a constant rhythmic ringing at sacred dances. The Maya themselves probably learned metal casting through their indirect contacts with South America, where there may have been similar instruments employing metallic resonance.

Some Indians of the North American West are known to have played music on their hunting bows, strumming the string as they held it between their teeth. A change in the shape or position of the player's mouth changed the sound of the plucked

Whistling vessel in the form of a macaw, Peru, Moche culture (ca. 100–700 C.E.) (© The Trustees of the British Museum)

string. Interestingly, this musical weapon seems to have been the only string instrument used in ancient America.

► natural disasters

INTRODUCTION

Natural disasters are a fixture of life on earth. From the dawn of history to the 21st century, people have had to contend with floods, fires, earthquakes, volcanic eruptions, storms, plagues of destructive insects, and other deadly visitations of nature. These and other natural occurrences wreaked havoc on farms, cities, and coastal communities and disrupted patterns of farming, fishing, and other activities. In the ancient world these events often led to the loss of entire communities, as people were often unable to flee natural disasters. They also destroyed ancient monuments that represented some of the high achievements of ancient cultures.

Few written records of these natural disasters exist. Once major exception is the Roman Empire, which left behind written records of major volcanic eruptions, such as the eruption of Mount Vesuvius in 79 C.E. that buried Pompeii and other nearby cities. The archaeological ruins of Pompeii have provided historians with a unique look at the region's culture, for the city was covered in volcanic ash and lava so quickly that people were "frozen" in their homes going about their daily tasks. Ancient Mexico was also devastated by volcanic eruptions, and ancient Japan was the frequent site of volcanic eruptions as well as tsunamis.

In the absence of written records, historians have had to rely on archaeological evidence for natural disasters. Using sophisticated tools, as well as old-fashioned digging, they have uncovered the effects of natural disasters throughout the world. Around the Mediterranean Sea, for example, countries such as Greece and the many islands in the region were sus-

ceptible to earthquakes. It is believed that a major earthquake devastated the island of Crete, home of the Bronze Age Minoan culture, in about 1700 B.C.E. Lost in this earthquake was the magnificent palace of King Minos. While written records from the Minoan culture survive, historians have not been able to decipher them. These records could very well contain records of the earthquake, but archaeologists know that the palace was destroyed because excavations have shown that a new palace was built on the ruins of the destroyed palace. Earthquakes were also responsible for obliterating four of the ancient Seven Wonders of the World: the Hanging Gardens of Babylon, the Lighthouse of Alexandria, the Colossus of Rhodes, and the Mausoleum of Mausollos at Halicarnassus.

Sometimes the effects of natural disasters were less visible but no less disruptive. Along the coast of South America, for example, people had to contend with changes in ocean weather patterns that killed off the fish and seafood populations on which the people depended. Throughout the history of the ancient world famine was a constant threat, as prolonged periods of drought or higher-than-normal temperatures could lead to shortages of food and widespread death from starvation over long periods of time.

Ancient peoples tended to attach religious significance to natural disasters. The ancient Chinese, for example, thought drought and extreme high temperatures were signs that demons were loose in the land. They often saw such disasters as a form of punishment, a sign that the gods were displeased with humans. In ancient China a series of major disasters over the centuries actually led to the fall of emperors, who, the people believed, were being punished for brutality or for living in luxury.

AFRICA

BY LEAH A. J. COHEN

Research on historic and prehistoric natural disasters in Africa is still a new field and continues to result in major new findings. One of the oldest Holocene natural disasters to be uncovered in archaeological and geologic research in Africa is the eruption of Mount Menengai around 8,000 years ago. This eruption occurred in the East Africa Rift Valley in present-day Kenya and produced a 5- by 7.5-mile caldera, or volcanic crater. Another eruption took place about the same time in Madagascar (a very large island off the southeastern coast of Africa), creating a number of crater lakes and hot springs. There are little data on how these eruptions affected the local population of humans or animals or the surrounding vegetation.

A volcanic eruption at Mount Jebel Marra (in present-day Sudan) has been dated to around 3,500 years ago. The blast formed a 3-mile-diameter caldera and sent lava flows more than 18 miles. Again, little is known about this natural disaster's effects on local human and other populations. A Carthaginian navigator in the fifth century B.C.E. reported witnessing an eruption of what was probably Mount Cameroon, a large volcano in West Africa. There has been no modern research on the impact of this event on the local area, nor has it been dated using modern dating methods.

About 4,000 years ago people in northern Africa were responding to an extreme 300-year drought. This drought created barren, inhospitable sand dunes in areas of the Sahara that had previously been occupied since the end of the last ice age. Mass migration resulted in increases in population in places near water, such as the Nile River valley. Historical records suggest that this population growth may have been a factor in mounting conflict in the Egyptian empire.

"Plagues" of locusts are a particular area of new research on natural disasters in Africa. Locusts are a species of grasshopper. Hatching from eggs in the ground at specific periods (in some cases there are years between outbreaks), they grow into adults and swarm en masse across the landscape, devouring most of the vegetation, including crops, in their path. There is evidence of the presence of such locusts in western Africa from three to five million years ago, but little is known about these ancient outbreaks.

The record on natural disasters in Africa is far from complete. Numerous events undoubtedly remain to be uncovered and investigated. Some of what is suspected about past natural disasters in Africa comes from modern anthropological accounts of local myths. For example, people who currently occupy the area around Lake Nyos in Cameroon (on the western coast of central Africa) have a legend that the lake causes numerous deaths from time to time. Although little is known about the historical basis for this myth, a disaster in the 1980s resulted in the sudden death of over 1,800 people near the lake. Scientists have since discovered that the water was releasing large amounts of carbon dioxide into the

air, but much remains unknown about this occurrence and whether earlier events of the same kind might have given rise to the myth.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

According to ancient Egyptian conceptions, the creator god fashioned the cosmos out of chaos, a dark, watery abyss that surrounded the universe and the created world. He then established *maat*, the divine and political order. *Maat* (also personified as a goddess of the same name) was the cornerstone of the Egyptian belief system and Egyptian ethical values. Harmony in nature, as well as in social and private life, was the result of the establishment and perpetuation of *maat*. By contrast, natural disasters or political and social decline occurred when chaotic forces prevailed over *maat*.

Despite the often dire consequences of earthquakes, floods, storms, and fires, Egyptians do not seem to have been interested in keeping historical records of such events. Evidence of natural disasters is limited to religious and magical texts, which often allude to them mainly in terms of various mythological concepts and traditions. The Pyramid Texts, engraved on the walls of the funerary chambers of a succession of pharaohs, form the oldest funerary and religious corpus of the ancient world. The first of these texts, in the pyramid of the last ruler of the Fifth Dynasty, Unas (r. ca. 2356–2323 B.C.E.), describes the return of the pharaoh to life in the appearance of a new god, violent and powerful: "The sky flies cloudy, the stars darken, the [celestial] bows move, the bones of the Akeru tremble, the Moving-ones, as for them, become silent after they have seen Unas apparent and provided with *ba*, as a god who lives of his Fathers and feeds of his Mothers." The Akeru were a group of subterranean genies, leonine watchers of the netherworld. Their bones could well have been interpreted as the stronger parts of the earth's body, the rocks. Some scholars view this passage as the first historical reference to the Egyptian explanation of earthquakes.

Another passage from the Pyramid Texts, this one from the tomb of the pharaoh Pepi Neferkare, whose reign (ca. 2246–2152 B.C.E.) remains the longest in human history, clearly describes heavy rain and floods, seismic events, and some sort of conflagration: "The water of life which is in the sky comes! The water of life which is in the earth comes! The sky burns for you, the earth quakes for you, before the god's birth."

Evidence of seismic phenomena also appears in a famous tale from the Middle Kingdom known as "The Shipwrecked Sailor." A man reaches a mysterious and beautiful island unharmed after having survived a storm at sea. He discovers plenty of food there and makes a burnt offering to the gods to thank them. The description is particularly precise and without doubt refers to a seismic event. As in the Pyramid Texts, however, such an event is closely interrelated with symbolical

Rock inscription at Seheil, Egypt, recording a seven-year famine (Courtesy of the Oriental Institute of the University of Chicago)

connotations: The earth's motion on the island of the shipwrecked is a sign of divine manifestation or epiphany.

All of these texts place disastrous natural phenomena in a positive framework. The dark and negative effects of natural disasters on people's lives are found more often in Egyptian magical texts, such as the *Calendars of Lucky and Unlucky Days*. Dating to the reign (ca. 1290–1224 B.C.E.) of Ramses II, the *Calendars* cast the fortunes of each day of the year in terms relating to a mythical event or, at least, a mythical depiction of a natural event, an archetype. For example: "Third month of the Inundation-season; fourth day: Uncertain! Uncertain! To move by this earth under the forepart of Nun. As for anyone who sails in this day: destruction in his house." (Nun was a god personifying the primeval waters out of which the creator god emerged.)

Similarly, a literary work of the late 13th century B.C.E., the "Dialogue of Ipuwer and the Lord of All," blames natural disasters for the downfall of the Egyptian political authority and society of the First Intermediate Period (ca. 2134–2040 B.C.E.) and Second Intermediate Period (ca. 1640–1532 B.C.E.). The protagonist of this lament, Ipuwer, describes Egypt as afflicted by natural catastrophes and in a state of social collapse. The poor have become rich and the rich poor; servants are leaving their masters and acting rebelliously; and warfare, famine, and death are everywhere.

An inscription on the so-called Famine Stele from the time of Ptolemy V Epiphanes (r. 205–180 B.C.E.) records a disastrous famine that took place during the reign of the Third Dynasty king Djosser (r. ca. 2630–2611 B.C.E.). The text states that Djosser was worried because Egypt had been gripped by a drought for seven years, during which time the Nile did not flood. Djosser asked for aid from the priests of Imhotep (a historical high official and architect who had been deified as a god). The priests investigated in the archives of the temple of the moon god Thoth (who also presided over scribes and knowledge) in Hermopolis and informed the king that the god was angry and for this reason did not allow the Nile to flow properly. Djosser ordered offerings sent to try to placate the god. The following night the king had a dream in which the ram god Khnum, who had created life on a potter's wheel, promised an end to the famine. The king issued a decree settling vast riches and resources on Khnum's temple in Elephantine.

The ancient Egyptians seem to have had relatively limited interest in disastrous natural phenomena and, except for the oldest funerary conceptions in the Pyramid Texts, rarely mentioned them even in metaphorical terms. The most frequently described phenomenon, the earthquake, is understood as a marker of epiphany and as a model for the movement of life.

THE MIDDLE EAST

BY LYN GREEN

Natural disasters such as floods and earthquakes afflicted parts of the ancient Near East with relative frequency. Anatolia (modern-day Turkey) and Persia (modern-day Iran) are still the sites of frequent earthquakes, which in ancient times were perhaps even more disruptive than they are today: Not only did they bring death, disease, widespread destruction of property, and loss of livelihood on their own, but they also could open up a society to outside attack. One geologist has used an attack on Jerusalem in 31 B.C.E. as an example of how the weakening of city fortifications caused by a quake could result in military disaster. Other scientists have tried to link the end of the Bronze Age cultures of the Near East with earthquakes and their aftermath.

Among the many disasters that nature could visit on humankind in the ancient Near East there were also the oft-cited examples of plagues of locusts. The biblical story of Exodus tells of the various plagues that swept through Egypt, the eighth of which was a plague of locusts. Swarming locusts easily cut a path of destruction through cultivated fields, denuding them of their crops. Another Old Testament book, Joel, also speaks of a locust plague and more: "That which the palmerworm hath left hath the locust eaten; and that which the locust hath left hath the cankerworm eaten; and that which the cankerworm hath left hath the caterpillar eaten."

Many seismically active areas of the world, including those in the Near East, exhibit volcanic activity as well.

Volcanic eruptions can have disastrous effects far beyond their immediate vicinity. Ash or other debris in the atmosphere reduces the amount of sunlight reaching the earth, thus lowering the temperature in the affected area. Less sunlight means smaller crops, and lower temperatures can produce shifts in patterns of precipitation, leading to either flooding or drought. Soil debris from Mesopotamia suggests that some sort of catastrophic event—perhaps a volcanic eruption or even a meteorite impact—occurred in the Near East around 2350 B.C.E. Some scientists have speculated that this event caused an abrupt climatic change in the area, in turn leading to a change of dynasties in southern Mesopotamia. However, the climate change appears to have occurred over the course of some 100 years following the mysterious catastrophe, making it unlikely that this single event caused the shift in weather patterns.

Seismic disturbances are not the only catastrophes linked with shifts in cultures. Probably as a result of the renewed interest in comets in the 1990s, some scientists have attempted to explain cultural changes in the Near East as the long-term consequences of comet impacts. For example, there is a great deal of evidence for sudden climate changes (leading to widespread drought) and changes in water levels of seas and lakes, disastrous floods, earthquakes, and volcanic eruptions in the third millennium B.C.E. Scientists have suggested various explanations, including a comet or asteroid exploding in the earth's atmosphere, as is believed to have happened near Tunguska, Siberia, in 1908. The power of such an explosion or impact, equivalent to thousands of atomic bombs, could have produced huge fires, seismic tremors, tsunamis, and gargantuan clouds of debris. Such an event would have been universally seen as a message from the gods, would doubtless have been recorded as a notable event in any king's reign, and probably also would have been transformed into myth, but clear written evidence is lacking.

Despite the frequency of earthquakes, not to mention windstorms and sandstorms, drought, and (in some areas) wildfires, the one type of natural disaster that had the most impact on all the cultures of the ancient Near East is floods, or rather the story of the Flood, which appears in the literature of ancient Mesopotamia as well as the Bible. Swirling floodwaters are an integral part of every ancient story of creation from Egypt to Babylonia. Symbolically they represent the chaos from which order can emerge and which the creator deity tames and transforms into something beneficial. However, many scholars see these stories as reflections of real events.

The earliest-known stories of a flood that covered all the earth are told in several ancient Mesopotamian epics. In one version a man called Ut-napishtim is warned by Ea, god of wisdom and of freshwaters, that the gods are angry with humans and that the chief god, Enlil, is about to flood the earth in order to get some peace and quiet. Ea gives Ut-napishtim interesting directions on how to build a boat (for example, it is to be in the form of a cube) and tells him to go into the

vessel with his family and a few animals. Enlil, assisted by the storm god and the god of the Underworld, floods the earth from both above and below, effectively killing all those irritating human beings and forcing even the gods themselves to flee. Ut-napishtim and his family and livestock float off into the Zagros Mountains, where after seven days they eventually come aground on the sides of a high peak.

Although this story was lost for thousands of years, when it was rediscovered it was immediately familiar to anyone who had read the biblical book of Genesis. In both cases a man who is wiser and godlier than others is chosen to survive the destruction of humankind by an angry deity. Like Ut-napishtim, Noah is divinely warned of the impending disaster. He, too, builds a huge boat according to divine direction and fills it with animals. The flood described in the Bible, however, lasts 40 days and 40 nights rather than just one week, and Noah brings with him pairs of living creatures. Noah's Ark also ends up in a slightly different set of mountains, those of Ararat.

Modern scholars have made many attempts to relate the ancient flood stories to scientifically documented phenomena such as the era of rainy weather that followed the last ice age, but without any conclusive result. This uncertainty is unsurprising, given that the story is about 5,000 years old and the events it chronicles are probably much older—typical of the problems that face those historians and scientists known as catastrophists, who try to connect ancient natural disasters with specific historical events.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The ancient people of Australia offer a good example of how hunter-gatherer cultures learned to cope with natural disasters. Australia is a vast territory with a variety of habitats such as rain forest, grassland, and desert. Its weather cycles can last for years at a time, which means that its droughts can persist for several years. Australia is also prone to wildfires that can burn hundreds of square miles of territory at a time. Still, the ancient Australians learned to live with both drought and fire.

The ancient Australians were mobile and lived in small groups. During good times they had more than they could eat available to them because of their minimal population; during droughts their low population density allowed them to find enough to at least survive. Droughts meant not only a decrease in the amount of food that would otherwise be available but also dry forests and grasslands. Lightning could easily start fires. The ancient Australians sometimes ventured near fires rather than running away, because a fire drove game out into the open, which they would kill or capture for food. After fires burned out, what might look desolate to outsiders was for the Australians a potential bounty because among the earliest plants to appear would be edible ones—especially those that had evolved to cope with drought by retaining water, which

meant the ancient Australians would eventually have moist food to eat. Thus, because they lived in small groups that allowed them to move quickly and they did not have towns or farms to defend, the ancient Australians survived what could be catastrophic disasters for other cultures.

Natural disasters can be swift, catastrophic events, or they can be slow occurrences—at times aggravated by human technology—that over centuries destroy what humans build. The Harappan civilization of ancient India (ca. 2600–1500 B.C.E.) offers examples of both. Its largest settlements were built near rivers. The Harappans irrigated their lands with water that flowed from the north, carrying with it silt that built up in the rivers, raising the beds of the rivers until they changed their courses, sometimes flooding settlements. Further, watercourses deposited salts in the soil that were not washed away because rainfall was insufficient to do so. Over hundreds of years the Harappans began to go hungry because their poisoned land could not grow as much food as it once had.

Their cities were increasingly subject to floods as the rivers jumped their banks, but the Harappans either repaired their damaged cities or built on top of the silt deposited in them. Even so, there was one flood that may have been too much for them. The Indus River valley is subject to frequent earthquakes. Sometime after 2000 B.C.E. an earthquake reshaped the territory near the delta, blocking the river's way to the sea and causing it to flow backward and cover Harappan cities in the Indus River valley. The Harappans built huts on top of where their cities had been; however, they were easy to overcome by nomads from the north who swept into India on chariots.

Of all the natural disasters to which India was subject, flooding attracted the most community effort, probably because it was the most likely to respond to human action. Accounts of floods are a part of Indian mythology, and various gods were believed to intervene to help human beings or to harm them. Thus, one way Indians coped with floods and storms was to pray to gods to spare human beings from the wrath of nature. India's peoples also took practical steps to tame water and make it useful. They built levees to contain rivers in their banks, dams to create reservoirs, and irrigation canals to take water to where farmers could use it. One such irrigation system, dam, and reservoir that created a fertile valley was built in Gujarat. In 150 C.E. the dam was destroyed by a storm, but it was rebuilt. In about 500 C.E., after the dam was again destroyed, they did what people often did when natural disasters overtook them too many times; they moved away.

The Silk Road stretched through central Asia from northwestern China to the ancient Near East. Along this road were impressive cities that were full of life with thriving economies and arts, yet they were doomed by a creeping natural disaster. The world's climate was changing, and the regions north of China and in central Asia were becoming colder and drier. This process of drying out is called *desiccation*, and along the Silk Road the land was drying out. Archaeologists are begin-

ning to piece together the lives of the ancient peoples in the cities of the Silk Road, aided by the dryness and cold, which has preserved corpses thousands of years old. The cities of the Silk Road were abandoned when there was no longer enough water to drink.

Although droughts and floods were concerns throughout Chinese history, from the time of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) to the end of the Six Dynasties era (220–589 C.E.) they were of special concern to the rulers of China. Droughts brought famines, and famines brought rebellions. Floods could kill people by the millions and destroy crops and cities. In each case, an emperor could pay with his life because it was the duty of emperors to remind the gods to provide good weather and prevent natural disasters. An emperor ruled by divine right, and natural disasters showed that the gods were not listening to him, meaning he had lost his divine right to rule and could be killed and replaced.

Thus, the Chinese government devoted much time, wealth, and manpower to finding ways to control water in times of flood and drought. About 80 percent of China's rainfall is in the summer, and its rivers fill with silt; the Yellow River can look like thick, flowing mud. A buildup of silt can raise riverbeds, which can result in their changed courses. Therefore, the Chinese dredged their rivers to keep the riverbed low. They also made levees ever higher, but this sometimes resulted in floods when a levee gave way to the pressure of flowing water. To relieve the water pressure, the directional flow of a river was controlled.

Possibly the greatest example of this is the work directed by architect Li Bing on the Min River in the 200s B.C.E. He had a man-made island built in the middle of the river to divide its flow into two directions. One direction was the old course of the river; the other direction sent the river east into a channel that carried water to irrigate about 2,000 square miles of farmland. A spillway sent excess water away from the channel to the main river; meanwhile the channel relieved the river of pressure against its banks, reducing the chance of flooding.

Little is known about disasters in Japan and Korea in ancient times. Japan certainly had earthquakes, but how the Japanese coped with them is not known. The work of archaeologists indicates that Honshu's northeast coast was struck by tsunamis, but dates for these events have yet to be established. Korea probably had floods, but as is the case for Japan, there is an absence of documentary evidence for the ancient era.

EUROPE

BY CARYN E. NEUMANN

Natural disasters frequently struck the ancient world. Without knowledge of science, the ancients struggled to make sense of earthquakes, tsunamis, floods, and volcanic eruptions. Additionally, such celestial events as eclipses and meteor showers, though they had little direct catastrophic impact on human life, were regarded as natural disasters by prehistoric people

because they were such a deviation from the normal appearance of the sky. Stunned by the evident power behind such events, they could explain them only as the work of the gods. Detailed accounts of natural disasters in Europe, outside Rome and Greece, are rare. Archaeological evidence and the theories of astronomers fill in some of the gaps in the historical record.

The Stone Age hunters and gatherers had to cope with changing environments during the ice age. While these changes lacked the suddenness that is normally associated with natural disasters, the new conditions often caused people to modify their lifestyle and occasionally to retreat into warmer parts of southern Europe when the cold became too intense. After the ice age, the climate warmed up, but rising sea levels in many parts of northern Europe caused coastal settlements to become inundated. In 5900 B.C.E. a tsunami in the North Sea was caused by a massive submarine landslide off the coast of Norway that affected the entire North Atlantic basin.

Although the evidence is the subject of controversy, some scholars have argued that the Black Sea basin was flooded around 5000 B.C.E. by a breakthrough of a geological formation at the Bosphorus that allowed Mediterranean water to flow through in a torrent. If this indeed happened, then this flood would have rapidly displaced the farmers and hunter-gatherers who lived around the Black Sea, forcing them to move quickly inland to avoid being drowned.

It is difficult to minimize the risk associated with volcanoes. A major group of volcanoes, both active and inactive, stretches across the Mediterranean through Anatolia and into the Caucasus. Besides the damage caused by lava and falling ash, volcanic eruptions can trigger landslides and giant waves. Prehistoric volcanic eruptions in 4700 B.C.E. prompted the sides of submerged hills in Lake Lucerne in present-day Switzerland to slump. The sliding sides of the hills displaced water and resulted in tsunami-like effects. Waves almost 10 feet high struck the lakeshore opposite the submerged hills within a minute of the slide of earth. The waves had lengths greater than half a mile, which is entirely different from the situation with ordinary wind-induced surface waves; they resembled mountains of water rising in the center of the lake and undoubtedly terrified witnesses. Any structures around the lake and any watercraft on it would have been destroyed by the waves. Sardinia apparently suffered a similar event. In Sos Furrighesos, Sardinia, a wide landslide in about 3000 B.C.E. smothered a settlement that had lasted for about 100 years. The survivors rebuilt in the same area, devising a new style of decoration for tombs that had survived undamaged. The tombs severely damaged by the landslide were abandoned.

The response of the Sardinians is typical of ancient people. In preindustrial societies people recovered from a disaster by harmonizing their responses to nature rather than employing technological solutions to manage and control nature. Individuals and small groups, rather than governments,

took actions that were flexible and easily abandoned if they proved unsuccessful. Deaths and other losses from natural disasters were perceived as inevitable. Gods, not humans, were in charge. The mind-set of the ancients was dominated by notions of supernatural punishment or vengeance. Lacking scientific knowledge, ancient Europeans believed that the course of a volcanic eruption could be affected, if at all, only through divine appeasement.

GREECE

BY JOHN THORBURN

Although the ancient Greeks did not face threats from tornadoes, hurricanes, or typhoons, a tradition of dangerous winds does exist in their culture. Whereas the modern definition of “typhoon” restricts this type of storm to the western Pacific Ocean and the oceans around India, the English word is related to a Greek word, *typhos*, which means “whirlwind.” According to Greek mythology, Typhon was a hundred-headed monster that tried to overthrow Zeus and the other gods. Ultimately, Zeus blasted Typhon with a lightning bolt and pinned the monster beneath Mount Etna on Sicily, where his fiery breath causes that volcano to erupt. Another well-known myth connected with wind is the story of Boreas, the god of the north wind, who abducted Oreithyia, the daughter of the Athenian king Erechtheus, and whisked her away to Thrace and impregnated her. She gave birth to twin sons, Zetes and Calais. Like their winged father, the twins could fly and assisted the hero Jason in his quest for the Golden Fleece.

Besides stories about powerful winds, Greek mythology also preserved tales of a major flood, which share similarities with the Sumerian Epic of Gilgamesh and the Flood story in the Old Testament. According to the Greek tradition, Zeus decided to destroy the human race because of their wicked behavior and thus prepared to send a flood. Deucalion, the son of Prometheus, and his wife Pyrrha, the daughter of Prometheus’s brother Epimetheus—thanks to a warning from Prometheus—built a boat and managed to survive the high waters, which drove them from their home in northeastern Greece. After traveling in their boat for nine days and nights, Deucalion and Pyrrha landed on Mount Parnassus in central Greece.

Like Noah in the book of Genesis, Deucalion is said to have released a dove to determine if the weather would be favorable. After landing on Parnassus, Deucalion and Pyrrha went to the shrine of the goddess Themis and consulted her oracle about what they should do next. The oracle told them to throw the bones of their mother behind them. Initially, the couple thought this oracle meant they would have to dig up the bones of their dead mothers. Eventually, though, they realized that stones were the “bones” of Mother Earth. Accordingly, Deucalion and Pyrrha picked up stones and threw them over their shoulders. The stones Deucalion threw turned into men, whereas those Pyrrha threw became women. In this way, the couple repopulated the earth.

Although Greek mythology preserves stories of threats from wind and flood, the most dangerous natural disasters faced by the Greeks were connected with earthquakes, whose causes the Greeks traced to the god Poseidon, whom they nicknamed the “Earthshaker.” In 373 B.C.E. an earthquake destroyed Apollo’s temple at Delphi. Between 228 and 226 B.C.E. an earthquake toppled the giant statue of the sun god Helios, known as the Colossus of Rhodes. The island of Rhodes also suffered a serious earthquake again around 142 C.E. Ancient sources tell us that earthquakes severely damaged cities, such as both Myrina and Philadelphia in 17 C.E., and they destroyed others, such as Boura (also Bura and Bira) and Helice in 373 B.C.E. An earthquake may have disrupted the Minoan culture on Crete around 1700 B.C.E. and eventually caused the abandonment of the Cretan city Knossos about 2,100 years later.

One of the most significant earthquakes in Greek history occurred in 464 B.C.E. in the area around Sparta. So many Spartans died as a result of the earthquake that their slaves, called helots, revolted against their masters. The revolt continued for many months and became so serious that in 462 B.C.E. the Spartans called upon their rivals, the people of Athens, for military assistance. The Athenians agreed to help, but when their forces arrived the Spartans changed their minds about wanting assistance from Athens. This rejection angered the Athenians and further strained relations between the two cities.

As is common in areas frequented by earthquakes, the Greeks were also familiar with volcanoes. Like with other natural disasters, mythological traditions were connected with volcanoes. The monster Typhon, trapped beneath Mount Etna, was said to cause that mountain’s eruptions. Signs resembling volcanic activity on the island of Lemnos were attributed to the workshop of Hephaestus, the craftsman of the gods.

Beyond the realm of mythology, we know that on mainland Greece, near the southeastern coast, the Methana volcano sent a flow of lava over 500 yards into the nearby Saronic Gulf in the third century B.C.E. Several Greek islands in the southern part of the Aegean Sea have volcanoes. The island of Melos (modern-day Mílos) has experienced volcanic activity and was, along with some other nearby islands, formed by such activity. Off the coast of southwestern Turkey the Greek islands of Kos, Gyalí (also spelled Yali), and Nísiros (also Nísyros) were all formed by volcanic activity.

The most famous volcanic eruption in Greek history took place on the central Aegean island of Thíra (modern Santorini) around 1600 B.C.E. This eruption, also one of the most powerful known in the history of the world, completely blew apart the western half of the island and led to the abandonment of the island for the next four centuries. Fortunately, some of the inhabitants seem to have evacuated the island before the eruption. As in the case of Roman Pompeii, volcanic ash from the eruption buried a city; in this case Akrotiri, a town on the island of Thíra, was covered. Excavations of the site

have revealed a vibrant civilization that shared much in common with that on the island of Crete to the south. In fact, the eruption on Thíra may have disrupted civilization on Crete. In the early second century B.C.E. further eruptions and lava flows from Thíra’s volcano formed two small islands in the volcano’s caldera, or crater. Some modern scholars have suggested that Thíra was the mysterious island of Atlantis, which Plato describes in both the *Timaeus* and the *Critias* and says suddenly vanished into the Atlantic Ocean because of earthquakes and flooding. Plato’s description of the island’s immense size, its location west of Africa, and his time frame for the destruction of Atlantis make it an unlikely equivalent for the tiny Aegean island of Thíra.

ROME

BY DAVID R. SEAR

Rome dominated the Mediterranean world for more than 600 years, from the time of the pivotal victories over the Carthaginian Hannibal in 202 B.C.E., Philip V of Macedon in 197 B.C.E., and Antiochus the Great of Syria in 190 B.C.E. to the collapse of Roman power in the West in the fifth century C.E. Inevitably, over such a long period of time and in a region so extensive and geographically diverse the occurrence of natural disasters was of some frequency.

With population levels generally much lower than in modern times many of these disasters, especially those in remoter regions, went unrecorded, or at least no knowledge of them has come down to us. Others, however, were fully documented, most famously the eruption of Mount Vesuvius on the Bay of Naples on August 24, 79 C.E., just two months after the accession of the emperor Titus (r. 79–81 C.E.). The writer Pliny the Younger (61 or 62–ca. 113 C.E.) was an eyewitness to this catastrophe, which buried the towns of Pompeii, Herculaneum, and Stabiae (modern Castellammare di Stabia) in ashes and took the life of Pliny’s own uncle and adoptive father, Pliny the Elder (23–79 C.E.). Pliny’s account is contained in letters to his friend, the historian Tacitus (ca. 56–ca. 120 C.E.). Later eruptions of Vesuvius took place in 203 C.E., 472 C.E., and 512 C.E., but less is known of these events.

A valuable source of information on many of the important historical events of the Roman Empire is provided by the reverse types and inscriptions of the imperial coinage. The currency was used extensively by the Roman government as a vehicle for official propaganda and frequent reference was made to contemporary events, especially when the emperor and his advisers considered that by so doing the popularity of the regime could be enhanced. An excellent early example of this is to be found on the coinage of the emperor Tiberius (r. 14–37 C.E.), stepson and successor of the Roman Empire’s founder, Augustus (r. 27 B.C.E.–14 C.E.). The Roman historian Tacitus records that a great earthquake had shaken the Roman province of Asia Minor (western Turkey) in 17 C.E., causing extensive damage to at least a dozen

Roman wall painting showing a coastal landscape (early first century C.E.), from Boscoreale, Campania, Italy; Boscoreale was only one of many sites on the Bay of Naples that were overwhelmed by the catastrophic eruption of Mount Vesuvius in 79 C.E. (© The Trustees of the British Museum)

famous cities. The worst affected was Sardis (also Sardes), the old Lydian royal capital, and Tiberius made a grant of 10 million sesterces toward its restoration as well as remitting all taxation for a period of five years. This magnanimous gesture was recorded on a handsome sestertius type showing a seated figure of the emperor accompanied by the inscription *CIVITATIBVS ASIAE RESTITVTIS* (“the restoration of the cities of Asia”).

Earthquakes in the Mediterranean basin were of quite frequent occurrence in Roman times, as they are today. The empire’s eastern provinces were especially affected, and in the winter of 114 and 115 C.E. the Syrian capital of Antioch (modern-day Antakya) was badly damaged by a major seismic event. The emperor Trajan (r. 98–117 C.E.) happened to be wintering in the city while on campaign in the ancient Near East and had a lucky escape when, reputedly through divine intervention, he was led from a building just prior to its collapse. This miraculous deliverance was recorded on the coinage of 115 C.E. by a type bearing the inscription *CONSERVATORI PATRIS PATRIAE* (“to the preserver of the Father of his People”) and showing a colossal figure of Jupiter protecting a much smaller image of the emperor.

Fire posed a constant threat to the populations of large cities in the Roman world. Our knowledge of these events tends to be focused on Rome itself, though similar events were certainly taking place in the empire’s other great urban centers. The most famous conflagration is that which occurred in the capital in July 64 C.E. during the reign of Nero (r. 54–68 C.E.). Whether it was deliberately set by the

eccentric emperor (as charged by the historian Suetonius) we cannot be sure, but the devastation of central Rome on this occasion allowed Nero to launch an ambitious rebuilding program, much of which was personally beneficial to him; for example, he had built the Domus Aurea, or Golden House, an extravagant new imperial residence. Contemporary coin types again make reference to these events. An extensive series in gold, silver, and brass was issued throughout Nero’s final years (64–68 C.E.) showing a handsome seated figure of the goddess Roma symbolizing the restoration of the city after the disaster of the fire. Another type, appearing on gold aurei and silver denarii only, depicts the restored Temple of Vesta in the Roman Forum. It is a testament to the frequency of fires in central Rome that Nero’s restored structure was the sixth temple to occupy that site and was itself to be destroyed in yet another conflagration late in the reign of the emperor Commodus (r. 180–92 C.E.).

THE AMERICAS

BY KEITH JORDAN

The cultures of the ancient Americas have not left us any written records of natural disasters and their impact, either because those cultures did not possess writing (as in North America and Peru) or because (as in the case of the Maya) they used their hieroglyphic scripts to record the military and political prowess of kings rather than the adversities presented by nature. We have no New World Pliny the Younger to bear literary witness to volcanic eruptions (as he did for

that which destroyed Pompeii in 79 C.E.) or even the counterpart of the vague and flimsy allusions to the Thira eruption discerned in Egyptian texts, the Old Testament, and the writings of Plato.

In the absence of written records, we have very little evidence for the cultural impact of natural disasters on the indigenous peoples of North America for this period. The most significant and widespread environmental change affecting ancient North American culture history was certainly the end of the last ice age 10,000–12,000 years ago and the subsequent extinction of many species of large mammals, such as mammoths, mastodons, giant sloths, and wild horses. Since these animals provided food sources for the earliest Native American hunters, their demise forced a shift in lifestyle away from highly mobile big-game hunting to a less nomadic hunting and gathering way of life.

What we do have in Mesoamerica is the archaeological and geological evidence of massive volcanic eruptions that buried settlements, adversely affected agriculture, and occasioned migration and population shifts. While polities in the immediate vicinity of the disasters collapsed and were abandoned because of these events, other political centers may have benefited by the influx of migrants and a gain in religious prestige. In Peru climate change and catastrophic weather events on the coast, related to the phenomenon of El Niño, may have led to the collapse of ritual centers and their associated ideology, paving the way for the spread of a new religious cult originating at Chavín de Huántar in the highlands.

In the basin of Mexico the eruption of the volcano Xitli devastated the city of Cuicuilco during the Late Formative to Early Classic phases of cultural development. Precise dating of this geological event is still a matter of dispute, but it occurred over about a decade sometime between 400 B.C.E. and 400 C.E., perhaps close to 50 B.C.E. Cuicuilco, situated in what is now the southern outskirts of Mexico City, was first blanketed with ash and then buried under up to 33 feet of lava. The resultant volcanic layer covers a 30-square-mile area and has made excavation of the site difficult, forcing early-20th-century diggers to resort to explosives to clear buried structures. It is possible that because of earlier volcanic episodes, the site had been wholly or partly abandoned prior to the main eruption. Some scholars speculate that both the displaced population and the city's possible loss of religious prestige in the face of what would have been interpreted as the wrath of the gods contributed to the growth and influence of the city of Teotihuacán in the northern part of the basin. Ironically—or perhaps appropriately—stone sculptures retrieved from beneath the lava flow indicate that a deity in the form of an old man, corresponding to the later Aztec fire god, was among the chief gods of Cuicuilco.

In present-day El Salvador extensive ashfall from an eruption of the volcano Ilopango around the turn of the fourth century C.E. seems to have rendered local agricultural

land unusable and precipitated an exodus from the area. As in the case of Cuicuilco, a rising city may have benefited from this calamity. In this instance it was the Maya city-state of Copán, north and east of Ilopango in western Honduras. Refugees from Ilopango's eruption, drawn by the rich lands of the Copán region, may have increased the city's population, which in turn contributed to the city's rising influence over the next several centuries.

In Peru the recurrent phenomenon of El Niño seems to have massively and negatively affected the cultural history at several junctures in the last three millennia. Named in historic times for the Christ child because of its appearance around Christmas, El Niño is a warm-water current that reaches the coast of Peru every year, usually for only a few weeks. The cause of this eastward-moving current is a decrease in easterly trade winds, which leads to the flow of warm water from the western Pacific to Peru. Every three to seven years a major El Niño event occurs in which the warm current affects the Peruvian coast for longer than usual—up to months—creating havoc with the coastal environment. Cool-water marine life dies off in the warmer temperatures, and torrential rains create extensive flooding onshore.

Some of these events are of truly catastrophic magnitude. Some evidence suggests that major events of this kind beset the coast of Peru around 500 B.C.E., killing the cold-water fish that were a staple of the local economy and destroying desert irrigation systems through flooding. These disasters may have led to the decline of coastal ceremonial centers (though some archaeologists think they were already in decline owing to other factors) and with them the prestige of the cults they supported. This change may have left the area receptive to new religious ideologies emanating from the highland site of Chavín de Huántar. The new beliefs are reflected in the adoption of highland deity images and other motifs in coastal ceramics and textiles.

Interestingly, an increase in social stratification and centralized political power may have occurred in the Chavín area sometime around 400–200 B.C.E. as a consequence not of floods but of drought, leading to increased competition for resources, a situation frequently conducive to the rise of strong leaders and growing differentiation of social classes.

Egypt

~ “The Shipwrecked Sailor,” ca. 2200 B.C.E. ~

... THE wise servant said, “Let thy heart be satisfied, O my lord, for that we have come back to the country; after we have been long on board, and rowed much, the prow has at last touched land. All the people rejoice and embrace us one after another.

The sailor then answered, “Now I shall tell that which has happened to me, to my very self. I was going to the mines of Pharaoh, and I went down on the sea in a ship of one hundred and fifty cubits long and forty cubits wide, with one hundred and fifty sailors of the best of Egypt who had seen heaven and earth, and whose hearts were stronger than lions. They had said that the wind would not be contrary, or that there would be none. But as we approached the land, the wind arose, and threw up waves eight cubits high. As for me, I seized a piece of wood; but those who were in the vessel perished, without one remaining. A wave threw me on an island, after that I had been three days alone, without a companion beside my own heart. I laid me in a thicket, and the shadow covered me. Then stretched I my limbs to try to find something for my mouth. I found there figs and grain, melons of all kinds, fishes, and birds. Nothing was lacking. And I satisfied myself; and left on the ground that which was over, of what my arms had been filled withal. I dug a pit, I lighted a fire, and I made a burnt offering unto the gods.

“Suddenly I heard a noise as of thunder, which I thought to be that of a wave of the sea. The trees shook, and the earth was moved. I uncovered my face, and I saw that a serpent drew near. He was thirty cubits long, and his beard greater than two cubits; his body was as overlaid with gold, and his color as that of true lazuli. He coiled himself before me. “Then he opened his mouth, while that I lay on my face before him, and he said to me, “What has brought you, what has brought you, little one, what has brought you? If you say not speedily what has brought you to this isle, I will make you know yourself; as a flame you shall vanish, if you tell me not something I have not heard, or which I knew not, before you.’

“Then he took me in his mouth and carried me to his resting-place, and laid me down without any hurt. I was whole and sound, and nothing was gone from me. . . .

“Then said he to me, “Fear not, fear not, little one, and make not your face sad. If you have come to me, it is God who has let you live. For it is He who has brought you to this isle of the blest, where nothing is lacking, and which is filled with all good things. See now, you shall pass one month after another, until you shall be four months in this isle. Then a ship shall come from your land with sailors, and you shall leave with them and go to your country, and you shall die in your town.’ . . .

“Then I bowed in my obeisance, and I touched the ground before him. “Behold now that which I have told you before. I shall tell of your presence unto Pharaoh, I shall make him to know of your greatness, and I will bring to you of the sacred oils and perfumes, and of incense of the temples with which all gods are honored. I shall tell, moreover, of that which I do now see (thanks to him), and there shall be rendered to you praises before the fullness of all the land. I shall slay asses for you in sacrifice, I shall pluck for you the birds, and I shall bring for you ships full of all kinds of the treasures of Egypt, as is comely to do unto a god, a friend of men in a far country, of which men know not.’

“Then he smiled at my speech, because of that which was in his heart, for he said to me: “You are not rich in perfumes, for all that you have is but common incense. As for me, I am prince of the land of Punt, and I have perfumes. Only the oil which you say you would bring is not common in this isle. But, when you shall depart from this place, you shall never more see this isle; it shall be changed into waves.’

“And behold, when the ship drew near, according to all that he had told me before, I got up into an high tree, to strive to see those who were within it. Then I came and told to him this matter, but it was already known unto him before. Then he said to me, “Farewell, farewell, go to your house, little one, see again your children, and let your name be good in your town; these are my wishes for you.’ . . .”

The Middle East

~ The Bible, excerpt from Exodus
(fifth to seventh centuries B.C.E.) ~

CHAPTER 10

1 Then the LORD said to Moses, "Go in to Pharaoh; for I have hardened his heart and the heart of his servants, that I may show these signs of mine among them, 2 and that you may tell in the hearing of your son and of your son's son how I have made sport of the Egyptians and what signs I have done among them; that you may know that I am the LORD."

3 So Moses and Aaron went in to Pharaoh, and said to him, "Thus says the LORD, the God of the Hebrews, 'How long will you refuse to humble yourself before me? Let my people go, that they may serve me. 4 For if you refuse to let my people go, behold, tomorrow I will bring locusts into your country, 5 and they shall cover the face of the land, so that no one can see the land; and they shall eat what is left to you after the hail, and they shall eat every tree of yours which grows in the field, 6 and they shall fill your houses, and the houses of all your servants and of all the Egyptians; as neither your fathers nor your grandfathers have seen, from the day they came on earth to this day.'" Then he turned and went out from Pharaoh.

7 And Pharaoh's servants said to him, "How long shall this man be a snare to us? Let the men go, that they may serve the LORD their God; do you not yet understand that Egypt is ruined?" 8 So Moses and Aaron were brought back to Pharaoh; and he said to them, "Go, serve the LORD your God; but who are to go?" 9 And Moses said, "We will go with our young and our old; we will go with our sons and daughters and with our flocks and herds, for we must hold a feast to the LORD." 10 And he said to them, "The LORD be with you, if ever I let you and your little ones go! Look, you have some evil

purpose in mind. 11 No! Go, the men among you, and serve the LORD, for that is what you desire." And they were driven out from Pharaoh's presence.

12 Then the LORD said to Moses, "Stretch out your hand over the land of Egypt for the locusts, that they may come upon the land of Egypt, and eat every plant in the land, all that the hail has left." 13 So Moses stretched forth his rod over the land of Egypt, and the LORD brought an east wind upon the land all that day and all that night; and when it was morning the east wind had brought the locusts. 14 And the locusts came up over all the land of Egypt, and settled on the whole country of Egypt, such a dense swarm of locusts as had never been before, nor ever shall be again. 15 For they covered the face of the whole land, so that the land was darkened, and they ate all the plants in the land and all the fruit of the trees which the hail had left; not a green thing remained, neither tree nor plant of the field, through all the land of Egypt. 16 Then Pharaoh called Moses and Aaron in haste, and said, "I have sinned against the LORD your God, and against you. 17 Now therefore, forgive my sin, I pray you, only this once, and entreat the LORD your God only to remove this death from me." 18 So he went out from Pharaoh, and entreated the LORD. 19 And the LORD turned a very strong west wind, which lifted the locusts and drove them into the Red Sea; not a single locust was left in all the country of Egypt. 20 But the LORD hardened Pharaoh's heart, and he did not let the children of Israel go.

► Nomadic and Pastoral Societies

INTRODUCTION

Historians and archaeologists take a keen interest in the ways in which ancient societies were organized and how they scratched a living out of the resources available to them. The earliest Stone Age peoples were largely hunter-gatherers, meaning that they lived in small bands and survived by moving from place to place, usually following seasonal patterns, to find game, fruits, berries, roots, nuts, and leafy vegetables. Most Native American tribes and the aboriginal people of Australia provide good examples of nomadic communities. These early people were called *nomads*, meaning that they lived in temporary settlements.

As early human communities made the transition from hunting and gathering to agriculture, many came to depend on herds of animals, including cattle, sheep, goats, llamas, camels, and yaks. They already knew about the behavior of the animals they hunted, especially those that ran in herds, so herding was a way to ensure a steady and reliable source of food using similar knowledge and skills. These animals provided people with meat, milk, cream, and butter. They also supplied hides for leather, horns and bones for tools and other objects, and dung to burn for fuel or use as fertilizer. Ancient herders even discovered that enzymes from the stomachs of these animals are useful in coagulating milk to make cheese. In the ancient world, where people struggled to survive, virtually every part of the animal was used in some way.

Communities that relied on herding for their livelihood are said to be *pastoral*, a word derived from the Latin word *pastor*, meaning simply “herdsman.” Ancient herders needed to find grazing land for their herds, so many maintained a nomadic life, moving from place to place to find vegetation for their herds. These nomads not only provided food for large numbers of people but also played a role in the diffusion of ideas. In moving about, they made contact with other communities, lessening the isolation of these communities and sharing knowledge, technologies, medical practices, and the like. They were also traders, bringing their products to communities of agriculturalists and exchanging them for crops and other goods that they could not provide for themselves.

Some, however, settled into relatively fixed communities; historians use the word *sedentary* to refer to ancient communities that were more or less permanent and fixed. These pastoral communities, like agricultural communities, played a major role in human development. By tying people to the land and a defined community, they allowed people to form towns and eventually cities that gave rise to the major achievements of the ancient world.

It should be noted that historians disagree about the sequence of developments that led to pastoralism. Some see it as a natural outgrowth of hunting and gathering. Thus, they believe that pastoralism was the second step in a sequence that began with hunting-gathering and led to agriculture. Others, however, believe that pastoralism was the third step in this

sequence, so that farming predated pastoralism. These historians argue that as human populations became denser and more pressure was placed on farms to be productive, people turned to pastoralism as a way to exploit land farther away from towns and cities.

AFRICA

BY KIRK H. BEETZ

The history of ancient African nomads and pastoralists is one of people trying to adapt to climate and geography. It is a story with many twists and turns. For instance, the Fulani in central Niger have a history stretching back perhaps 6,000 years; during that time, they have been nomadic pastoralists, herders who migrated from highlands to lowlands and back according to the seasons, herders with fixed homes, and farmers of grain, and they have shifted from one way of life to another more than once as they adjusted to changes in rainfall.

The Fulani are often cited by people studying the ancient Saharan pastoralists, because some of their religious rituals duplicate ones found depicted in Saharan rock paintings dating back to 3000 B.C.E. For instance, in one rock painting dating back 5,000 years a cow is depicted being herded through a doorway of palm fronds shaped like a large letter U, with people dancing nearby and others tending to the cow. This ritual is still performed by the Fulani; it is intended to protect people from illness. One should take care in making inferences about an ancient culture that has had several thousand years to develop and change, but archaeologists nonetheless infer from modern Fulani customs that their ancient Saharan society was patriarchal and one in which individual people developed their places in society through complex family relationships, making those relationships more important than any fixed territory. As the nomadic Fulani moved across the grasslands of the Sahara, family relationships would be the social constants of their lives, rather than villages.

Another people thought to have a lineage as ancient as that of the Fulani are the modern Beja people of Nubia, who were called “Blemmye” in ancient times. Like the Fulani, they had a nomadic pastoralist culture that changed over thousands of years as the climate of North Africa changed. They, the Fulani, and other herders are thought by archaeologists to have been nomads when they began herding cattle; they wandered with their herds across vast grassy plains, moving according where they found food for their cattle. Wars would have been fought over possession of cattle, not territory. Some pastoralists used their cattle for food, but others kept them as signs of wealth. The development of territorial conflicts would have come after the Sahara began to dry up around 3000 B.C.E. As rivers dried, wells would have been needed to water the herds, and those wells would have been protected from outsiders. The response of the Blemmye to the drying of the Sahara was to move to sources of water to the east of the Sahara and settle in villages near water, seldom moving their herds far from their villages.

Most archaeologists believe that the desert of the Sahara is a combination of natural climate change and the activities of humans. Archaeologists infer from the conduct of modern pastoralists at the southern border of the Sahara that ancient herders took little care to preserve their environment, allowing their herds to overgraze land to the point that even seasonal rains were not enough for plants to be able to renew themselves. Except for a brief period of increased rainfall in about 500 B.C.E., the Saharan desert has steadily expanded. The cutting back of forests at the southern edge of the Sahara by pastoralists and grain farmers is thought to have increased the pace of climate change by reducing the moist updraft of air generated by the dense African forest south of the Sahara. The moisture released into the air would have been blown northward, where it would have fallen as rain.

The nomadic pastoralists eventually became transhumant populations, meaning that they migrated to different grazing areas according to the seasons. For instance, some Berbers, perhaps including the Imazighen, known as the Meshwesh to the Egyptians, would drive their herds into the Atlas Mountains in spring, when rain caused new growth of grasses, and then into the flat lands in fall, where they could water their

herds at oases and wells. This practice continued until modern times, when the seasonal rainfall became too little to sustain the cattle, sheep, and goats of the local people.

It is not known exactly when people in southern Africa began herding animals, though it was probably after people began herding cattle in North Africa, because the cattle of the people of southern Africa seem to have derived from the cattle of the north. The first animals to be herded were sheep. The practice of herding sheep probably passed into North Africa from the Near East and then through western Africa south through the Kalahari and into the grasslands of southern Africa. It is possible that herders from the Sahara fled south to escape the desert, bringing their animals and customs with them. One theory holds that several thousand years ago southern Europe, North Africa, and western parts of southern Africa were all one cultural group in which knowledge of herding animals spread quickly. Archaeologists cite similar painting styles in North Africa and Spain and similar depictions of humans in paintings to link them with western regions of southern Africa.

Herding cattle could have been transmitted in at least three ways. One was through the western forests and the

Petroglyph showing herders and cows, from Sahara Desert at Tassili, Algeria, North Africa (© Board of Regents of the University of Wisconsin System. Photographer: Jeanne Tabachnick)

Kalahari of Africa, and another was along the east coast from the Blemmye to herders south of the kingdom of Kush through grasslands until reaching southern Africa. One other possibility is a complex route due south through the center of Africa. The latter view is based on linguistic studies of the Khoikhoi, also known as Hottentots. The Khoikhoi lived from the southern coast of Africa to the central African forests, and linguists have established that the Khoikhoi language was spoken by people in central Africa near the Sahel steppes that spread west to east south of the Sahara. The northernmost Khoikhoi may have acquired cattle from the Sahara and transmitted them south until they reached the Khoikhoi of the southern African plains. These Khoikhoi were nomads who adapted cattle to their wandering lives, moving their herds to new pastures whenever the latest pasture ran short of food for the cattle. The Khoikhoi who lived near the southern coast of Africa were transhumant, migrating north to take advantage of the winter rains on the plains and then migrating back south for the summer.

Complications for the theories of transmission of herding through western and central Africa are twofold. One is that there were large rain forests without suitable pasture, thus discouraging adoption of pastoralism as a way of life. The other was the presence of the Baka, who lived in areas stretching from Cameroon to eastern Africa. They had a culture well adapted to the rain forest. They were fully nomadic, moving through the forest to follow game. To this day some Baka continue to be fully nomadic. They built no villages, using plants and perhaps elephant skins to create shelters that they would abandon when they needed to find more game. Their lives may have focused on elephants, which provided them with large amounts of food. Reliance on following game for survival meant that the Baka could not support large, dense populations, making their population sparse. The Baka were often hostile to intrusions into their forests by other cultures, and their poisoned arrows and spears would have made moving cattle through their forest very difficult.

There was probably no part of Africa that was untouched by nomads, but pastoralists were somewhat restricted to open territories, though some cut down forest to create more pastures. Their adaptations to the Sahara were long-term failures, partly because their overgrazing probably increased the speed of the Sahara's drying as well as helping make the desert larger. The Khoikhoi apparently did not have a similar problem; their effort to expand into new pastures was motivated not so much by degradation of the land but by population growth.

EGYPT

BY MARK ANTHONY PHELPS

Pastoralism predated agriculture in the Nile Valley. Domesticated cattle imported from southwestern Asia were unquestionably in the Delta by the middle of the sixth millennium. Some scholars argue that two cow bones found in Nabta Playa

in the Western Desert and dating to 9300 B.C.E. are domesticated, but the theory has not found many proponents. Early pastoralists continued to engage in foraging activities in the Nile Valley and western oases. Agriculture was imported from southwestern Asia in the fifth millennium. The advent of agriculture necessitated moving the animals between the times of planting and harvesting. As the Nile Valley became more intensively farmed, herders in Lower Egypt began to seasonally migrate to the Delta with their herds.

Another factor in the presence of nomadism in the region is the drying of the Sahara. The eastern Sahara (comprising Chad, Libya, Sudan, and Egypt) experienced a wet period from about 8500 B.C.E. to 4000 B.C.E. The subsequent drying period, which continues to the present day, corresponded with a dramatic rise in Nile Valley agricultural settlements. Cattle were the first animals that were herded on a large scale, but as the Sahara was becoming drier during the fifth millennium and native grasses were dwindling, sheep and goats came to replace cattle in many areas. Evidences of both are found in the El Faiyûm region and at Merimda by about 5000 B.C.E.

Settlements have been discovered from the Neolithic Period in the Western Desert. These seasonal settlements are spotted by the presence of hearths. Cattle were the predominant species herded, though sheep and goat remains also have been found. Burial sites show a particular ceramic style, known as tulip beakers, which seem to have been produced solely as grave goods. Pigment and palettes also are found, as is jewelry. These goods indicate a broad trade network, extending to the Red Sea and the Sinai Peninsula.

With the advent of the pharaonic period of Egyptian history (ca. 3000 B.C.E.), the role that pastoralism played in society can be studied through texts and artwork. Branding scenes are found, as are scenes of the process of milking and of aiding cows in the process of calving. Artwork also shows differing breeds of sheep and goats. Before the Middle Kingdom (2040–1640 B.C.E.) sheep were hairy and thin tailed and had twisted horns. During the Middle Kingdom they became woollier with a thicker tail. The fat-tailed sheep common to the Mediterranean basin entered the Nile Valley during Roman times. Goats also changed in artistic depiction, as the breed that had been common throughout the Old Kingdom (2575–2134 B.C.E.) gave way during the reign of the Hyksos of the Second Intermediate Period (1640–1532 B.C.E.), evidenced by horn structure (going from a scimitar-shaped horn to a twisted shape). Egyptians did not eat pork until the Eighteenth Dynasty (1550–1307 B.C.E.). Large herds of pigs are mentioned in written sources from this time, and evidence from middens (refuse heaps) indicates that craftspeople consumed pork frequently during this era. The use of pork increased with the advent of Roman rule.

Distinguishing pastoralist societies, in which a portion of the population is engaged in herding during certain seasons, from mixed farming societies is difficult. Typically, seasonal camps provide evidence of some sort of herding (animal dung

and animal remains). The more distant the sites are from the floodplain and agricultural villages, the more likely that they are those of pastoral nomads. Sites that date to the dawn of the pharaonic era and are probably the remains of nomads are found in peripheral Upper Egypt south of Aswān. One is the Kiseiba Plateau in the Western Desert, which contains a number of seasonal sites. The presence of Red Sea shells in the Nile Valley points to trade with groups operating in the Arabian Desert, presumably as pastoralists.

With the advent of writing in Egypt, the presence of pastoral groups gains concreteness. The best known of these groups is the Medjay. They may have originally come Lower Nubia. Precisely how they became displaced and settled in the Arabian Desert is not clear. The Semna Dispatches of the Twelfth Dynasty (ca. 2000 B.C.E.), a collection of military reports from an Arabian Desert outpost, mentions the Medjay. They were compelled by drought to sneak into the Nile Valley, a survival mechanism common to nomads throughout Egyptian history. Tomb paintings from the Twelfth Dynasty represent Medjay herding cattle. Nomads appear in tomb paintings as lean, with short hair and beards. They carry long sticks with a roll of matting attached, which they used for bedding as well as for shade. They also are depicted with bundles of pots and food.

The presence of the Medjay in Egyptian society is underscored by their use during the Second Intermediate Period as mercenaries, especially by Kamose against the Hyksos (ca. 1550 B.C.E.). Eventually the term *Medjay* came to denote a corps within the Egyptian army. After Ahmose I's ousting of the Hyksos, the Medjay were the primary component of the police force of the Nineteenth Dynasty (1307–1196 B.C.E.). In the Merneptah stela (ca. 1209 B.C.E.) the Medjay are depicted as being at rest thanks to the warring prowess of the pharaoh, who has pacified Palestine. Curiously, a few lines below this is a reference to pastoralists, demonstrating that there has been a shift in what the audience understands as the prime occupation of the Medjay. During the New Kingdom (ca. 1550–1070 B.C.E.) the Medjay probably served as a source of labor for the Egyptians in Arabian Desert gold mines. Given that there are references to the military operations against the Medjay in monuments of Akhenaton and Thutmose IV of the Eighteenth Dynasty, it seems the Medjay had returned to life beyond the fringe of Egyptian control, probably again as pastoralists.

Increasingly, fields belonged to large-estate owners, who employed herdsmen to take care of their flocks and herds. These herdsmen specialized in particular animals. Nomads typically herded several species. This diversity cut the economic risk of disease and broadened their economic options with regard to trade. Evidence provided by roadside forts skirting the Western Desert points to the need to police nomads to allow for overland trade. As Roman influence waned in Upper Egypt and Lower Nubia, with forts being abandoned, the political and economic voids left were filled by nomadic groups. These groups took over gold mining and overland trade.

THE MIDDLE EAST

BY JEN PIRO

The term *pastoralism* in its most basic sense means the herding of domestic animals such as cattle, sheep, goats, or (in the Near East) camels as a main, or even the only, source of livelihood for a given group of people. However, that definition covers a very broad range of activities. Anthropologists generally further categorize pastoralist societies according to two criteria: how settled (or how mobile) the society is, and how much (or how little) it engages in agriculture in addition to herding. The result is a spectrum of pastoralist societies.

At one end of this spectrum are *sedentary* pastoralists, who live in permanent settlements (typically villages) and feed their herds year-round on pastures relatively nearby. If, as often happens, these people also engage in agriculture, they may be classed as *agropastoralists*. At the other end of the spectrum is *nomadic* pastoralism. In a purely nomadic pastoralist society all or almost all of the population moves with the herds from place to place and from one elevation to another in search of pasture throughout the cycle of seasons, living in temporary encampments and often traveling hundreds or even thousands of miles over the course of a year.

Because of their continual movement, pure nomadic pastoralists have little opportunity to practice agriculture. However, another form of pastoralism, *transhumant* pastoralism, offers that opportunity. In transhumant pastoralist societies some of the people range with the herds as nomads, while most remain in a permanent “home” settlement as agriculturists. It is important to note that both groups regard themselves as part of the same society; they merely perform different tasks. Obviously no clear lines separate the various kinds of pastoralism. They blend together at the edges as more or fewer people live in permanent settlements, engage in agriculture, and so on. Moreover, a given society may adopt different forms of pastoralism over time.

In Near Eastern prehistory the emergence of nomadic pastoralism, centered on herding sheep and goats, was a pivotal development. It played an integral role in transforming the economy and society of the region and influencing the course of ancient Near Eastern civilization. But while scholars agree that the rise of nomadic pastoralism was a critical turning point, they disagree on exactly when it took place. Some archaeologists claim that nomadic pastoralism could have emerged as early as the seventh millennium B.C.E. Others suggest that the mid-fourth or third millennium B.C.E. is a better estimate. Still others argue that although different forms of pastoralism existed before the second millennium B.C.E., pure nomadic pastoralism arose only in historical times on the borders of ancient empires. Part of the problem is that early forms of pastoralism are not always clearly identifiable in the archaeological record. Also, nomadic pastoralism appeared in different parts of the Near East at different times and under different environmental, social, and economic conditions.

Some of the earliest evidence for nomadic pastoralism in the region comes from the central Zagros Mountains (in modern-day Iran). Archaeological finds of temporary campsites in marginal ecological zones unsuitable for agriculture and of isolated cemeteries along seasonal migratory routes far from permanent settlements are examples of such evidence. Moreover, historical texts from early urban centers in the general vicinity attest to social, economic, and political relations—and sometimes battle—with nomadic groups in the Zagros by the mid-fourth millennium B.C.E.

Much research has focused on explaining how nomadic pastoralism emerged as a new way of living out of village-based herding in the Zagros region. Traditional views on this subject theorized a direct transition from agropastoralism to highly mobile nomadic pastoralism. However, recent investigations have demonstrated that the shift occurred in several intermediate stages before arriving at an economy emphasizing nomadic pastoralism by the fourth millennium B.C.E. Besides the spread of seasonal camps and isolated cemeteries like those already mentioned, the archaeological evidence includes a reduction in the number of permanent settlements and the broad distribution of small quantities of distinctive pottery at sites throughout the west-central Zagros, perhaps reflecting far-flung trade associated with increasing mobility.

The archaeological evidence also indicates growing interaction between the west-central Zagros and the lowlands to the west and southwest in the late fifth and fourth millennia B.C.E. As pastoral groups moved down to the lowlands in the winter months, they would have come into contact with settled farming communities and formed trading relationships. Archaeologists believe that economic exchange was a significant and mutually beneficial aspect of nomad-villager relations. Villagers received animal products and raw materials from the mountains in exchange for agricultural goods that the nomads lacked owing to their highly specialized economy. Manufactured items, especially pottery, also would have been exchanged—as would ideas, styles, and other cultural information. Nomadic pastoralists may have served as intermediaries in longer-distance trade connecting different regions.

The economic ties forged between highland pastoralists and settled villagers may have contributed to the development of social complexity on a regional scale. During the late fifth and fourth millennia B.C.E. a number of sites in southern Mesopotamia and southwestern Iran began to exhibit signs of increasing socioeconomic and political complexity (for example, monumental architecture, urban planning, and the use of seals to regulate certain economic activities) that eventually led to the rise of early states. Mobile pastoralist populations in the Zagros may have helped to urbanize their neighbors to the southwest by, among other things, stimulating local economies through surplus production and trade. The rising urban demand for animal products and raw materials would have encouraged pastoralists to intensify production and exchange, strengthening economic ties between both groups. The growing economic interdependence between nomadic pastoral so-

cieties and early towns may have influenced such sociopolitical developments of the following millennia as the control of production and distribution of goods by centralized institutions, the emergence of inequalities in wealth and status, and the formation of a shared social identity among nomadic groups. Meanwhile, the construction of forts along the foothills of the Zagros by early Mesopotamian state societies indicates that relations with the nomads were not always amicable.

Far southwest of the Zagros, nomadic pastoralism may have also appeared in the “marginal” environments of the Negev and Sinai and nearby desert/steppe zones of what are today Jordan, Syria, western Iraq, and northwestern Saudi Arabia. However, scholars disagree as to whether prehistoric nomadic pastoralism could have existed in this region, and if so, when it began. Some argue that nomadic pastoralism arose in the mid-seventh millennium B.C.E.; they point to the spread of new forms of material culture beyond areas favorable for intensive agriculture and into marginal zones during this time. Archaeological evidence of this migration includes distinctive stone tools, architectural remains such as stone circles and circle complexes, rock art, and a rise in sheep and goat herding, possibly in response to the declining numbers of wild gazelles. Moreover, the growing numbers and size of sites in desert/steppe areas appear to reflect close symbiotic relations between nomadic groups and their settled neighbors in the agricultural zone. After their first incursions into these marginal lands the nomadic pastoralists spread rapidly throughout the region over the next few millennia, culminating in the conquest of southern Mesopotamia by the Akkadians in the late third millennium B.C.E.

Other researchers doubt that pure nomadic pastoralism in this region dates to the mid-seventh millennium B.C.E. Some argue that a nomadic pastoral economy could have arisen only after milk and wool began to be systematically exploited in the fourth millennium B.C.E. Some suggest that earlier systems could have been cases of transhumant, rather than purely nomadic, pastoralism. (However, archaeologists also diverge in their estimates of when transhumant pastoralism began.) Finally, some scholars question whether these marginal lands could have sustained a pastoral nomadic system in prehistory. In historical times nomadic groups who migrated into the region from other areas usually shifted to other forms of pastoralism to diversify their economy. According to this viewpoint, pure nomadic pastoralism was possible only after dromedaries were domesticated in Arabia in the late third millennium B.C.E. and spread across the desert environments of the Near East by the early first millennium B.C.E.

Historical texts and archaeological materials from ancient Near Eastern empires attest to the presence of nomadic groups both within and on their borders. When the Romans began their conquest of the Near East, they faced a long-established network of interaction and interdependence among settled and nomad populations. These nomadic groups practiced different types of mobile pastoralism,

ranging from fully nomadic camel breeding to seminomadic sheep and goat herding mixed with farming. Some of these societies, such as the Nabataean Kingdom in Arabia, became wealthy and powerful through merchant activities, transporting goods from all over the ancient world in their camel caravans. Both Rome and Persia, who were dueling for power in the ancient Near East, often developed alliances with nomad tribal chiefs, sometimes granting them official governmental titles in exchange for their loyalty. Such attempts to enlist the services of nomadic tribes increased the power and standing of their leaders and strengthened their military capability, which they sometimes used against their patrons. From the fourth century B.C.E. onward the ascending power and influence of nomadic groups began to undermine the Roman and Persian Empires and ultimately contributed to their collapse.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The ancient Australians were mostly nomadic. One of their skills for survival was mobility: When fires or floods came, they moved out of the way. They even learned to turn fire to their advantage by setting fires that would drive game to them and would clear grassland or forest so that edible plants could grow. Thus, the ancient Australians shaped their environment to suit their needs.

Hunter-gatherer populations in the islands of the Philippines may have been seminomadic, moving within a set tribal range from place to place, relocating when game or edible plants ran short. It is possible that the island of Honshu in Japan had people on its eastern coast who lived by the sea in summer and moved inland in winter, eating seafood when on the shore and perhaps venison when the deer moved down from the mountains in winter.

The earliest nomads of eastern Asia probably followed wild game on their migrations. Some took to following reindeer; as the glaciers of the north melted and the reindeer shifted their own migrations northward in response, those people following the reindeer learned to endure bitter cold. Some of them migrated from northeastern Siberia to Alaska during what may have been as many as seven separate migrations from Asia to the Americas.

Most of what may have happened among the nomadic peoples of eastern Asia beyond the reach of the knowledge of the Chinese is unknown. In the northern reaches of China, perhaps as recently as 1500 B.C.E., nomadic peoples hunted elephants and rhinoceroses. These scattered, thin populations of people posed little threat to the young civilization of the Yellow River region until they learned to herd cattle, sheep, and Bactrian camels. Herding helped their populations grow, and they often bumped into China when they wanted to expand their pastures.

There were hundreds of nomadic tribes, but the names of only a few are known. The Xiongnu were a federation of

cattle-herding tribes, very warlike. They harassed China until about 106 B.C.E., when a Chinese army drove them away from the Silk Road and into central Asia. Most historians believe their descendants became the Huns, invaders of Europe in the 400s C.E. The Yuezhi were shepherds who were driven out of their lands by the Xiongnu, but in 130 B.C.E. they settled in what is now Afghanistan. The Fergana in what is now Turkistan bred superb horses, which they supplied, sometimes unwillingly, to China in the 400s B.C.E.

In the 300s C.E. five nomadic groups, the Five Hu, invaded northern China and ruled it for about 150 years. They formed 16 states in northern China. In 383 C.E. they united under one leader and formed an army of 900,000 men that tried to conquer the rest of China. The cavalry was made up almost entirely of nomads, but the infantry was composed of Chinese conscripts, many of whom deserted during the Battle of Fei River, when the nomads were decisively defeated by the Chinese army. In 398 C.E. the Toba tribe led a confederation of 119 tribes and formed the Northern Wei state (ended ca. 534 B.C.E.).

Little is known about the nomads of western Asia, and archaeology is only just beginning to uncover their past. The principal nomadic peoples of Asia north of the Near East and east of Europe were the Cimmerians and the Scythians. Both lived in the steppes of Asia. So little is known about the Cimmerians that they were long thought to be mythical. The Cimmerians and Scythians raided the Near East and southeastern Europe, carrying away booty and slaves. The Scythians sometimes kidnapped Greek artists, who created sculptures for the Scythians. Many historians credit the Scythians with inventing the first stirrup, a leather loop. In 529 B.C.E. Persia's Cyrus the Great (r. 559–529 B.C.E.) died in battle against the Scythians.

Little is known for certain about activities in central Asia, between the Near East and northwestern China, but there must have been a lively mix of nomadic tribes. Nearly all of them spoke Indo-European languages, though some spoke languages from the Far East. The Aryans are probably the most famous of these Indo-European-speaking groups. The word *Aryan* is often used as if the Aryans were a single tribe, but the ancient Indian writers who wrote down the oral history of the Aryans about 500 B.C.E. used the word *arya* to describe the languages spoken by the nomads, not their tribe. The word *Aryan* comes from the word *arya*. The Aryans were probably several different tribes.

The nomads of central Asia had probably had trading relations with the Harappan civilization of the Indus River region for hundreds of years before moving into Harappan territory. At the height of their civilization the Harappans had built city walls over 13 feet thick and perhaps as high. Had they been healthy, it is unlikely that the Aryans could have overcome them, but a series of natural disasters had ruined the Harappans' cities, and they were probably easy targets for the warlike Aryans.

The Aryans were cattle herders, and they measured the value of goods by how many cattle the goods were worth.

The Scythians were one of the principal nomadic peoples in ancient Asia. Their domain was situated east of Europe and north of ancient Mesopotamia.

They probably moved into Harappan territory looking for pasture for their cattle about 1500 B.C.E. They esteemed warriors over all others. When they found no outsiders to fight, they fought with one another. Their oral history hints that they fought many battles.

From 1500 to 900 B.C.E. the Aryans raided and eventually invaded throughout northern India. Their elite warriors rode into battle in chariots pulled by two horses apiece. Each chariot had a driver who rode on the chariot's shaft. The elite warrior was an archer who had two assistants who supplied him with arrows or the weapons he needed if he chose to dismount and fight hand to hand. The other peoples of India had nothing to match the chariots for speed and maneuverability, because they lacked strong horses like those that had been bred in central Asia. About 900 B.C.E. the Aryans be-

gan settling along the Ganges River in northern India. By about 500 B.C.E. they had become part of the settled peoples of northern India, fending off attacks by nomads from the northeast of India, who may have been driven out of their homes by the Chinese. Still, some of the Aryans remained nomadic cattle herders in remote parts of northern India into the 21st century.

EUROPE

BY LÁSZLÓ BARTOSIEWICZ

Archaeologists and anthropologists who study ancient societies use the term *nomadic* to refer to societies that do not have permanent settlements but rather relocate them, usually in response to the availability of key resources such as game and

grazing land. The hunter-gatherers who inhabited Europe until the appearance of agriculture between 9,000 and 6,000 years ago could be called *nomads* in the sense that they relocated their settlements periodically. Archaeologists try to figure out how often campsites were moved and for what reason. For example, the hunter-gatherers who recolonized northern Europe after the retreat of the ice sheets migrated in pursuit of herds of reindeer, which were abundant in the territory of modern-day Germany, Poland, Denmark, and Sweden.

After the introduction of agriculture based on the cultivation of crops, the sort of nomadism that characterized the ice age inhabitants of Europe generally disappeared. Farmsteads, and eventually villages and towns, were built in fixed locations near fields, streams, and communication routes. Initially, domestic animals such as cattle, sheep, and goats were used only for their meat, which they could provide only once, when they were killed. Eventually, however, these animals became valued for the products that they could supply while they were living, such as milk and wool. Such products can be collected from the animal over and over, making the living animal valuable. People began to amass large numbers of livestock, and with their animals they began to accumulate wealth.

In some areas domestic animals became the foundation of the farming economy. Instead of fertile soil, herders sought rich pasture for their livestock. Grazing animals deplete grass, so it is necessary to relocate from exhausted grazing land to fresh pasture periodically. Such societies returned to a nomadic way of life, but one much different from that of the ice age. Such mobile people who move their herds in search of pasture and water are known to archaeologists and anthropologists as *mobile pastoralists*. Mobile pastoralism is a complex way of life, determined by the relationships among agriculture and animal husbandry in society, by natural geography and the kinds of livestock, and by the ownership of herds. These factors combined in different ways to create a wide range of adaptations in livestock management in ancient Europe. While hardly ever manifested in their pure form, several basic types of mobile pastoralism can be distinguished on the basis of known historical and ethnographic examples.

Nomadic pastoralism is the traditional form of land use in the Old World, from deserts to savannas, mainly practiced in the ecozone of the tropical and subtropical arid regions. In the classic sense, it is practiced by entirely mobile human populations, who often follow seasonal routes, generally along a north-south axis, in search of pasture for their herds. These paths are not necessarily followed repeatedly, but they tend to be bound to vegetation along the courses of rivers or near other sources of freshwater. Aside from this technical definition, the term *nomadic* also refers to sophisticated civilizations, such as the Scythians and the Xiongnu, both flourishing before the Christian era. The Eurasian steppes saw a succession of nomadic empires that largely relied on nomadic pastoralist communities.

Transhumance is a more specialized form of mobile pastoralism in which part of the livestock is moved to seasonal pastures over the course of the year, usually from a permanent home settlement. Ethnographic examples show, for example, that large herds of sheep may be thus moved with only a few goats or cows that supply daily milk for the herders. Many of them, however, as well as pigs and chicken, remain in the main settlement. Transhumance thus involves a degree of specialization both in terms of the animal species herded and the part of the population, usually families of herdsmen, who are assigned to this task. Transhumant pastoralists tend to cover shorter distances and follow routes used by many generations. The most common form, vertical transhumance, moves herds to summer pastures at high altitudes. Today this system remains best known in the Alps in Europe. Ancient references to it in peninsular Italy are found in the Roman scholar Varro's *Rerum rusticarum libri III* (Agricultural Topics in Three Books)

Inverse transhumance means that inhabitants in mountain areas take their flocks to low-lying winter grazing areas in better-protected valleys, a form of animal husbandry that was documented not only for Vlach shepherds living in the Carpathians in the Middle Ages but indeed during the time of Augustus in the early Common Era. The Roman poet Horace, in his *Epodes*, mentions flocks exchanging Calabrian fields for Lucanian ones while it is cool.

Horizontal transhumance refers to the cyclical movement of herds in plains, largely dependent on the seasonal extremes of water conditions. This makes its archaeological evidence especially elusive. The hypothesis has been put forward that the first farming communities of the Starčevo/Körös cultures, who inhabited the low-lying section of the Carpathian Basin, practiced seasonal exploitation of floodplains and must have herded their sheep between seasonally inundated areas. According to recent ethnographic documents, large stock (cattle and horses) were seasonally grazed between shoals and river bars in the inland delta of the Danube River between modern-day Slovakia and Hungary. At the other extreme, examples of aridity's imposing seasonal limitation on grazing have been identified since the Chalcolithic (fifth to fourth millennium B.C.E.) in the Middle East.

Because they are mobile, these types of pastoralism share many traits and are often confused with each other. Identifying them in the archaeological record is difficult because these mobile lifestyles leave little evidence behind. The presence of nomads is indicated primarily when archaeologists find a single layer of settlements, temporary in appearance, and the remains of mobile domesticated animals, such as horses, cattle, or sheep (as opposed to pigs, which are considered a more sedentary animal). Identifying transhumant pastoralism is difficult because excavations usually recover architectural remains of centralized settlements, while the lightweight, transient structures in temporary summer pastures leave much less of a trace and might also occur outside intensively excavated areas altogether.

Earlier research suggested that nomadism developed directly from the hunting of wild herd animals that eventually became domesticated, as might have been the case with reindeer. Most nomadic animal keeping, however, seems to have come from the need to exploit marginal areas so that the animals would pose the least threat to the cultivated fields of sedentary agriculture. Although friction and even warfare sometimes took place between farmers and nomadic pastoralist groups, intensified by ethnic differences, the two could also coexist in mutually beneficial relationships.

In Europe their influence is represented by cultural contact or direct incursions, apparent in the archaeological record. It is thought that there were pre-Scythian waves of immigration from the southeast around the seventh century B.C.E., on the basis of the finding of luxury artifacts in the Thracian-Cimmerian style—a style that refers to the Thracians and Cimmerians who lived in east-central Europe and north of the Black Sea. These artifacts include weapons, horse tacks, and jewelry, recovered from a small number of burials. The work of the Greek historian Herodotus from the fifth century B.C.E. is probably the best-known classical source treating ancient Eurasian nomads, especially the Scythians who ruled the eastern European steppe north of the Black Sea at the time. His work also created negative stereotypes of strange and savage nomads that play a role in present-day perceptions.

Arts and crafts that traveled with the nomads, such as weapons and jewelry, as well as the remains of special mortuary practices, including horse burials, are most commonly used to identify nomads in the archaeological record. “Nomadic” influx in Europe culminated in the Great Migration roughly between 300 and 700 C.E., representing a transition from antiquity to the Middle Ages. It included, among other Germanic tribes, the Franks, Goths, and Vandals, as well as Bulgars and Slavic tribes. Equestrian peoples on the northern and eastern fringes of the Roman Empire contributed eventually to its transformation and demise. This is best illustrated by the short-lived rule of the Hunnish Empire, another nomadic society, in the Carpathian Basin during the middle of the fifth century C.E. It is therefore the warlike advance guard of these people that is known from both archaeological and historical sources of the Great Migration. Although their equestrian military tactics must have relied on traditional skills developed during a nomadic life, in fact, very little is known of their animal husbandry practices and of the ownership of their herds. It is known, however, that many of these warriors were the most visible members of complex societies with organized power centers that had a segment of the population that was sedentary.

GREECE

BY SPYROS SIROPOULOS

The term *nomad* refers to a small social unit better known as a “band” without a specific, permanent area of residence or settlement. Bands usually number less than a hundred mem-

bers; the next largest kind of community is the tribe, with people inhabiting permanent settlements, such as villages. In the ancient world people were dependent upon the land; landscape determined much of their way of life. Greece is a small country, with many beaches, without many fertile areas, and with only a few valleys surrounded by mountains. Traveling from one area to another in ancient times was not extremely time-consuming or arduous because there are no difficult passages through the Greek mountains. Many people moved around with the seasons, leaving their marks behind on the landscape. Archaeologists cooperate with geologists and others to study remains of ancient pollen traces to read these marks. Their common efforts can determine the locations of ancient communities and whether they changed the environment, by deforestation, by planting domesticated trees, and by other types of cultivation.

From the beginning of the Neolithic Period in about 7000 B.C.E. domesticated animals, such as sheep, goats, oxen, and swine, appeared. The dates of the domestication of certain animals vary with the regions. Scientists have dated finds of domesticated sheep at 9000 B.C.E. in northern Iraq, cattle in the sixth millennium B.C.E. in northeastern Iran, goats at 8000 B.C.E. in central Iran, pigs at 8000 B.C.E. in Thailand and 7000 B.C.E. in Thessaly, donkeys at 7000 B.C.E. in Iraq, and horses around 4000 B.C.E. in central Asia. Goats and sheep soon became very popular. Swineherds and shepherds are often mentioned by Homer in the *Odyssey*, from the one-eyed giant Polyphemus, who was a shepherd, to the swineherd Eumaius, who played a major role in Odysseus’s reestablishment on the throne of Ithaca.

The Balkan region was always a good place for grazing oxen, since the mild climate favors pastures. Animals were kept mostly to provide a supply of meat. Pigs, too, were favored. Goats and sheep mainly provided milk; dairy products were a substantial part of the ancient Mediterranean diet. The wool and hides of these animals were valuable commodities, too, since they not only served the practical needs of the community but were also used as trading materials. As for oxen, they were useful not only for meat and milk but also often served as draft animals, pulling carts and plows of farmers, as late as Hellenistic times.

The needs of animals dictated, to a great extent, the way of living in pastoral society. Seasonal migration in search of pastures was essential. Of course, animal products alone were not enough to sustain the pastoral communities. Small-scale farming was practiced, and exchange of goods with farming communities was common.

The social scale of the pastoral communities was usually simple. The family was the principle social module, with the elder person being the leader. Status was immediately related to the number and the quality of the animals owned. Formation of larger bands was common when the weather was good and the land was fertile. Antagonism toward neighboring bands was set aside, and smaller teams came together for migration in order to ensure the protection and safety of all.

Daily life in these societies revolved around animal husbandry and the fulfillment of basic needs, such as the preservation of food, which was vital for the sustenance of the community. Food, such as grain, was stored in holes in the ground, covered with a simple rock. Milk was drained through cloth and turned into cheese that could be preserved for a longer time. Meat was cut and smoked over fire or cured and smoked. Spinning of wool and making clothes was the task of women. Only wars with other tribes disrupted this life; such wars were not uncommon. Disputes over grazing sites and thefts of animals were the most usual reasons for fights.

Since the nomadic way of life is characterized by mobility, monuments and other permanent signs of culture are absent. This is very far from the traditional view of Greek society seen in the Archaic and the Classical periods (600–323 B.C.E.). This is not to say that there were no cultural aspects to the life of these communities. Myths and rituals abounded. Also, it seems that singing, accompanied by the flute, was part of the culture of pastoral societies. Homer gives such information in the *Iliad*, and the historian Diodorus Siculus describes a celebrated bucolic hero, the shepherd Daphnis.

The nomadic and pastoral way of life adapted itself to harsh environments, where it was difficult to maintain permanent settlements. Climatic conditions in Greece were never that harsh, however, and the few fertile areas were big enough to sustain main bands. Seasonal migration from more mountainous areas in summer to the plains in winter was always part of life, but the ancient Greeks soon passed from the nomadic stage to a more sedentary agricultural way of life. Animal husbandry remained important, but it became part of a less mobile life organized around permanent settlements in villages and towns. As early as 6000 B.C.E. Greeks had become farmers. Archaeologists have discovered agricultural tools, such as flint sickles and clay slabs, in the fertile areas of Thessaly and the Peloponnese, Thrace, and Macedonia.

ROME

BY MARK ANTHONY PHELPS

Pastoralist traditions were an integral part of ancient Roman society. Many concepts were tied to a pastoral lifestyle. For example, *pecunia*, the Latin noun translated as “money,” finds its root in the older meaning of “wealth in flocks or herds.” Prehistoric rituals preserved in Roman society include the Parilia, a ritual for fertility for the flocks, and the Fordicidia, in which pregnant cows were killed and their fetal calves were burned in the spring and pregnant sows and their fetuses were sacrificed in the winter. A festival for ensuring the harvest of crops, the Ambarvalia, involved the killing of a pig, a sheep, and a bull, followed by an examination of the victims for omens. Historians of religion see the offering of animal sacrifice as evidence of a pastoral economic component in a society. Rituals involving sacrifice are also tied to the cults of Juno, Mars, and Jupiter (all originally gods of ag-

riculture, transformed by Rome’s emerging political power). The Romans later considered sacrifice as a mark of barbarianism but still continued these rituals.

The geography of the immediate environs of Rome, however, could not support a large population of animals, at least not before those environs began to be expanded by conquest. Some historians thus see legendary struggles, such as the conquest of the Sabines, as an attempt at securing access to mountain pastures. The Sabines in Roman legend were a group of pastoralists living near the site of Rome. According to legend, the founding generation of Romans was made up entirely of males who were without kinship ties. This group of men attacked the Sabines, carrying off their women and livestock. Though it is speculative, this legend may have some basis in fact.

The transhumance that was practiced in prehistory in the Apennines continues in the 21st century. (Transhumance dictated that some people live in villages while others go out with the flocks and herds.) Sheep, goats, and pigs have always predominated. During Roman history the southern third of the Apennines was more intensely grazed. The typical transhumance cycle in this region has the flocks going higher into the mountains as the heat and dryness of the Mediterranean summer increases. The herders return after harvest, as the animals feed upon the stubble of the harvested fields and then on fodder crops once the stubble has been exhausted.

The rise of the villa does not seem to have interfered with the traditional pastoral interaction with village life. Villas focused on the cultivation of vines, fruits, and grains and tended to be near the coast or in river valleys, areas not traditionally devoted to animal husbandry. It is clear that larger operations (with herds numbering in the hundreds or thousands) were concerned with the production of wool. Among the ways this is evidenced is by the presence of a higher percentage of rams. These operations were often run by large estates, though arrangements typically were made to graze the flocks on distant pasturage. Lower percentages of rams in small herds indicate that herders were engaging in either subsistence or small-scale production of milk. The Romans considered sheep’s milk more easily digestible than cow’s milk, though they preferred the taste of cow’s milk. Goat’s milk was more common than either of the others, but it was considered least digestible of all.

Despite the advice offered in the works of the classical authors known as agronomists (among them, Varro, Cato, and Virgil), there was no streamlined system employed by the Romans either in Italy or elsewhere in the empire. Further, the Romans did not interfere in the methods employed by local pastoralists. Roman presence did alter demand for animal products, in the form of taxes and requisitions for military needs. Roman improvement of roads and development of aqueducts and new trade networks often expanded local production as well. Wool and woolen garments for export have been noted at some sites, such as Timgad in modern-day Tunisia, but surveys done throughout the empire show

no dramatic change in lifestyle practiced by pastoralists anywhere after the advent of Roman political domination. The lone exception is found in the areas in which former troops were settled. Some of those settled engaged in pastoral pursuits. Beef consumption dropped noticeably with the demise of the empire. The breakdown of trade networks and the lack of military consumption played roles in this shift. The move to raising sheep and goats cut down on expenses as well as risk for farmers in a world that was making the transition to a more localized economy.

Pastoralism left its mark upon the Roman psyche. The pastoral lifestyle became the idyllic antidote to the rancor and chaos of city life (as characterized by the Roman poet Horace in his *Epodes*, written in 30 B.C.E.). Beginning with Virgil's *Eclogues* (42–37 B.C.E.), the Latin genre of pastoralism emerges. The genre emphasizes rustic purity and innocence. Virgil used his work to underscore political and social events occurring in the Roman world as well.

THE AMERICAS

BY DAVID VALLILEE

The term *nomadism* derives from the Greek word *nomás*, meaning “feed” or “pasture.” Generally, it has been defined as a circumstance in which people have no permanent home and wander in search of food for themselves and pasture for their animals. It also applies to peoples whose subsistence is based largely on hunting migrating mammals, with the result that the location of their temporary shelters is determined by herd movements and a need to avoid excessive hunting in one place. Nomadic pastoralism is a life that is based on herding domesticated animals and often requires moving the animals to the best pastures. For example, pastures in arid regions may not be useful outside of the rainy season, while pastures in mountainous and colder regions may not be accessible in winter. These conditions require that livestock be moved between different regions seasonally. Nomadic pastoralists may travel to a wide variety of places according to the availability of pastureland, whereas transhumant pastoralists move between fixed locations each season, typically between lowlands and mountains.

In a general sense, all the early inhabitants of the American continent during the Paleo-Indian Period (ca. 13,000–8000 B.C.E.) can be described as nomadic, with no fixed year-round settlements and with livelihoods based on hunting and gathering that required frequent movement. While scholarship of the Paleo-Indian Period previously focused on the hunting of now-extinct big game or megafauna, such as mastodons, mammoths, ground sloths, and saber-tooth tigers, scholars now agree that the Paleo-Indian hunters relied more heavily upon species of mammals that did not become extinct: bison, caribou, moose, elk, and ox.

The Archaic Period (ca. 8000–1000 B.C.E.) in the Americas generally is viewed as a gradual period of transition from nomadic hunting and gathering societies to sedentary, ag-

riculturally based societies. Despite the introduction of agriculture, many cultures retained a hunting-and-gathering component in their diet. For some a seminomadic existence based on seasonal movements that followed animal migrations continued throughout the period. Toward the end of the Archaic Period small year-round settlements—and in rare cases large settlements, such as Poverty Point in Louisiana (ca. 1600–1300 B.C.E.)—began to appear, and nomadism became less common.

In many of the mountainous regions of South America, parts of northern Mexico, and the Great Plains and Great Basin regions of North America, however, nomadic existence and reliance upon hunting remained central throughout the Archaic Period and later (until 500 C.E.). The Paleo-Indian Period in central Mexico was characterized by small nomadic families, or microbands, who moved their camps three or four times a year, hunting horses, antelope, and, occasionally, mammoths and other now-extinct species of megafauna. They also hunted smaller game: rabbits, turtles, birds, gophers, rats, and other small mammals. Extensive archaeological study of the Tehuacán Valley (in the state of Puebla, Mexico) has led to a number of conclusions about the Archaic Period in central Mexico. One conclusion is that in the Tehuacán Valley (ca. 8000–5000 B.C.E.) subsistence depended upon plant collecting, trapping of small mammals, and hunting of a variety of animals and birds. The cultivation of maize (corn) first appeared in the region around 5000 B.C.E. Beans, amaranth (a grain), chili peppers, plums, avocados, squashes, and gourds were also cultivated. Between about 5000 and 2300 B.C.E. agriculture gained an increasingly larger proportion of the Tehuacán Valley diet (25 percent), but hunting of mammals also continued. Year-round occupation of hamlets began approximately between 3400 and 2300 B.C.E., after which nomadism for the Tehuacán Valley can be said to have ceased.

With the extinction of mammoths, prehistoric horses, and camelids in the Great Plains region during the early Archaic Period, a shift to bison hunting became ever more central to survival. The tools of this period, particularly finely carved, razor-sharp spear points, were essential components for increasing the success of bison hunting. Hunting parties drove herds of bison over cliffs, such as at the Head-Smashed-In bison jump in southern Alberta, Canada, and into canyons, ravines, and corrals (bowl-shaped rock formations), where large numbers of bison could be slaughtered quickly.

The settlement systems of the Archaic Plains Indians adhered to a flexible and mobile pattern with an emphasis on hunting bison augmented by hunting smaller animals (deer, raccoons, beavers, rabbits, squirrels, muskrats). Shelter typical of the period included open-air and rock-shelter field camps, and post-in-ground structures, while portable perishable shelter—presumably hide-covered tepees—were probably the most prominent. After the Archaic Period, these patterns of subsistence continued.

The Archaic Period Desert culture (ca. 9000–1000 B.C.E.) located in the Great Basin area was primarily a foraging so-

ciety. At one site, Danger Cave in Utah, millstones used for grinding grain, seeds, and nuts, along with some of the earliest basketry in North America, have been excavated. The Co-chise culture (ca. 7000–200 B.C.E.), which evolved out of the Desert culture, hunted and trapped small mammals (deer, antelope, and rabbits) as well as small reptiles (snakes and lizards). The people migrated with the seasons, inhabiting the desert floor in the winter and higher elevations (mesas) in the summer. They also gathered wild plants, such as yuccas, prickly pears, junipers, and piñons. Some archaeologists believe that the first evidence of the cultivation of maize (corn) north of Mexico occurred in this region around 3500 B.C.E. This may have been a result of contact with Mesoamerican cultures to the south.

In the early part of the Archaic Period in South America the mastodon, prehistoric horse, and ground sloth species died out, and hunters shifted to deer, camelids (such as llamas and alpacas), guanacos, guinea pigs, and other small mammals. Coastal sites began to exploit marine resources (fish and shellfish), especially after 5000 B.C.E. Maize was first cultivated in the Peruvian highlands around 3500 B.C.E. and a shift to agricultural and agropastoral subsistence became widespread in South America by 2000 B.C.E. The emergence of ceramics, another indicator of sedentary non-nomadic existence, occurred at roughly the same time, around 1800 B.C.E.

It is likely that the llama and alpaca were domesticated around 3000 B.C.E. In the late Archaic Period and afterward, hunting on the high plains of mountain regions in South America combined with domestication of camelids resulted in a system of regular migration (transhumant nomadism) between different altitudes, from the valleys in the wet, summer season to higher elevations in the dry, winter season.

► numbers and counting

INTRODUCTION

Systems of numbers and counting emerged and developed at different times throughout the ancient world. The earliest, most advanced systems came from Mesopotamia and the Indus Valley of India. In contrast, numbers and counting were much slower to develop in ancient Europe. In most cases, the ancients were not interested in developing complex systems of mathematics to solve abstract problems. Counting and numbers arose as a way to help people solve practical, day-to-day problems.

Thus, counting was typically synonymous with measurement. The ancients needed to take accurate measurements of, for example, fields and tillable ground in order to assign land to farmers, particularly in areas of the world where boundaries could change because of flooding, as in ancient Egypt and Mesopotamia. They also needed to calculate the volume of crops or the number of bricks needed for a construction project. Linear measurements were needed for such activities as constructing buildings, and some cultures, such as the Mesoamericans and the Mesopotamians, developed fairly sophisticated forms of geometry for this purpose.

The ancients lacked sophisticated tools for making these kinds of measurements and for fixing consistent units of measurement. Accordingly, they often turned to the physical world, including their own bodies, to devise units of measurement. A

good example is the cubit, a unit of length from a person's elbow and the tip of the middle finger. Sometimes, these units varied depending on what was being measured. The common cubit was used for everyday purposes, but the "royal cubit" was used for public construction projects. For counting purposes, the fingers and toes proved useful, giving rise to systems of counting that were based on the number 20, as in ancient Mesoamerica. Still today, many people in the British Isles use "stone" as a measure of weight.

Counting was used for other purposes as well. The ancients devised systems of counting to create calendars, which in turn required mathematical calculations of the movements of heavenly bodies. As trade and commerce began to emerge, systems of counting were needed to keep track of accounts. Also required were primitive monetary systems, which began as objects such as clay tokens used to keep track of quantities and transactions and later evolved into true money.

The development of systems of numbers and counting was bound up with the development of writing. For this reason, the ancient Europeans fell far behind other regions of the world; lacking systems of writing until much later, they had no means of recording measurements. Some historians believe that ancient scripts found in eastern Europe may have included numbers, but so far they have been unable to decipher these scripts, so historians remain uncertain. In contrast, the ancient Asians and Mesopotamians had systems of writing that record mathematical measurements, and historians have been able to reconstruct these systems with some completeness.

AFRICA

BY OLUTAYO CHARLES ADESINA

The development of a sense of quantification was basic to the construction of number and counting systems in Africa. The concept of numbers and counting represented a certain apprehension of reality and became the foundations of mathematics, which in turn provided the key to existence. Despite this awareness, however, ancient Africans never formulated uniform numerals and systems of counting. Neither did they devise a set nomenclature for native methods of counting. Various cultures and ethnic groupings ultimately worked out different ways of thinking about mathematics and numerals. The sense of quantification, however, had universal application to reality.

These diverse groups had numeral systems that ranged from the simple to the complex. The Yoruba of West Africa, for instance, adopted an intricate system woven around addition, subtraction, and multiplication. They formulated different terms for numbers from 1 to 10 as well as for 20, 30, 200, and 400; the rest were multiples or compounds. Thus 11, 12, 13, and 14 were reckoned as 10 plus 1 or plus 2 up to 14, while 15 to 20 were reckoned as 20 less 1 to 5. But as there were such groups as the Yoruba, the Galla, the Danakil, and the Shiko whose numerical scale extended to 1,000, there also existed those such as the San (Bushmen) of South Africa, who

possessed numerals not greater than 10. Among such groups, and even among those with more highly developed civilizations, higher numbers were represented by the use of words equivalent to "much" and "many."

Evidence suggests that base 10 and base 20 counting systems were popular among Africans, probably originating from the number of human fingers and toes. As in other ancient cultures, standards of length, numbers, and measures existed with reference to parts of the human body. To several groups, fingers became an important instrument of calculation. Ancient Africans developed the quinary and denary scale of numeration, or counting by the fingers of one or both hands. Toes and fingers and their multiples were used at different stages of enumeration. Part of the culture of counting that ancient Africans transmitted to their offspring was the capacity to handle the various kinds of currency in use. Similarly, games and puzzles formed part of the prehistoric system of numeration.

With the adoption of a numeral system, ancient Africans were able to develop a concept of mathematics. Ancient astronomy became a significant tool in this regard. Conversely, numbers and counting also became major tools for understanding nature. Thus, the celestial order helped in the creation of an earthly order. This philosophy led to a number of complex number symbolisms. The seconds, minutes, days, and months derived from the celestial arrangement became an integral part of a numeral system. Early humans divided the day into temporal hours with length conditioned by the time of the year, the summer having a longer period of daylight than the winter.

In various parts of Africa wood, bone, and stone were adopted as instruments of counting. The bone was a counting tool for simple arithmetical procedures. There existed tally sticks, bones with orderly notches that represented the number of days in a moon cycle or days spent by a group in one geographic location. A piece of baboon fibula with 29 notches, dating to around 35,000 B.C.E. and found between South Africa and Swaziland, is the oldest-known mathematical artifact. Several groups in Africa adopted such bones as calendar sticks. Other examples include the Ishango bone found on the border of Zaire and Uganda. This small animal bone, which has been dated to around 20,000 B.C.E., is inscribed with markings thought to represent numbers. It is assumed to have been used as a counting tool for mathematical purposes. Commodities also were used in this regard. Such products as salt and slaves were used more often as accounting units or standards against which goods were valued. In the western Sudan cowries (shells) adopted as currency were strung together and used in counting.

Among ancient Africans, mathematics was concerned with numbers and their operations, with which calculations could be achieved. This belief translated into the "multitude" and the "magnitude." It encapsulated arithmetic, philosophy, geometry, and stereometry (the measurement of volume). Rather than being an abstract concept, mathematics became

a major tool for understanding nature and existence. Ancient Africans used the reality of mathematics to make inferences from general truths to particular truths and constructed an order that enabled them to understand life. Mathematics became a tool for achieving perfection, truth, and stability. The entire universe, it was believed, is an arrangement of numbers. There are an infinite number of proofs for the harmony of mathematics and human existence in ancient Africa.

EGYPT

BY BRADLEY SKEEN

From the early Predynastic Period (ca. 6500–3500 B.C.E.) to the Greco-Roman Period (332–30 B.C.E.), native Egyptian civilization made extensive use of practical mathematics in architecture, astronomy, calendar making, and above all geometry (the measurement of agricultural fields). However, Egyptians showed little interest in pure mathematics in any abstract sense. The rope stretchers or surveyors who retraced the boundaries of fields after the Nile flood commonly used the Pythagorean theorem in their work, but they could not have stated it in an abstract form or given it a formal mathematical proof.

Aside from the incidental representations of numbers in numerous texts, our knowledge of Egyptian mathematics

comes from two main sources: the Ahmes Papyrus and Moscow Papyrus. Both are small textbooks that would have been used in scribal schools. They demonstrate techniques to solve simple mathematical and algebraic equations, but only by representing specific examples from which the student must infer general rules and procedures, exactly the opposite of the modern approach to mathematics. Ordinary people would have been illiterate and also unable to perform any but the simplest mathematical operations “in their heads.”

Egyptians used a decimal, or base 10, number system just as we still do today. While this system ultimately derives from the fact that human beings have 10 fingers, Egyptians may have been the originators of this formal mathematical system distinct from the older Babylonian mathematical system that was partially base 10 and partially base 6 (for five fingers and one hand). In hieroglyphs, the oldest form of Egyptian writing, only the number 1 (a straight upright line representing a finger) and multiples of 10 could be directly shown. The number 10 was indicated by a heel bone, 100 by a snare, 1,000 by a lotus flower; 10,000 by a more detailed sketch of a finger, 100,000 by a tadpole, and 1,000,000 by a man holding his hands stretched widely apart, still an innate gesture to indicate a large size. There was no conception of zero as a number. Other numbers could be written only by giving combinations of these signs that added up to the number in question, as if

The Rhind Mathematical Papyrus, showing mathematical problems and solutions, from Thebes, Egypt (1550 B.C.E.) (© The Trustees of the British Museum)

in modern writing we showed the number 149 by this combination of symbols: 1 1 1 1 1 1 1 1 1 1 10 10 10 10 10. Moreover, the individual components of the number could be shown in any order that the scribe found pleasing or best suited to the space available in the text. Thus, even reading a simple number would require performing a series of additions (though no doubt this would have become more or less automatic for experienced scribes).

Similarly, fractions could, in general, be represented only by unit fractions; that is, 1 over the divisor. Thus, a more complex fraction would have to be represented by a series of unit fractions equal to it. For example, $\frac{2}{15}$ would have been written as $\frac{1}{10} + \frac{1}{30}$. Fractions were denoted by drawing the sign for *mouth* (an oval) over the numeral. There were, however, special signs for $\frac{2}{3}$ and $\frac{3}{4}$.

Operations like multiplication also were carried out as a series of additions. For instance, if a scribe wanted to square 13 (that is, 13×13), he might start by making a table like this, doubling each row and also keeping track of how many 13s were in each row:

13	1
26	2
52	4
104	8

Then, knowing that $8 + 4 + 1 = 13$, he would add $104 + 52 + 13$ to produce the answer of 169. With practice, much of this work could be done automatically without writing out the whole process.

Hieratic (or cursive) script was used for everyday writing and supplemented the formal hieroglyphic script found in inscriptions and official documents. In this style of writing, the numbers from 2 to 9 came to be represented by an abbreviated sketch of what the group of upright strokes in hieroglyphic form typically resembled. In this way something like our individual numerals existed.

Egyptian mathematical notation and procedures were at once highly practical and terribly cumbersome and inelegant. Counting and mathematical problems recorded in Egyptian sources were intended to provide solutions to the practical problems of everyday life, including the distribution of provisions, the valuations of commodities against precious metals (because Egyptian civilization lacked coinage), and various forms of farm accounting. It is easy to see that the reverent awe in which the ancient Greeks and many later people held Egyptian mathematical thought was quite undeserved. It was based on the inherent difficulty of reading the hieroglyphic script and the glamour of the antiquity of Egyptian civilization rather than any sophisticated or mysterious Egyptian mathematical science.

In the Hellenistic and Roman periods (after 330 B.C.E.), Greek scholars working in Egypt, especially at the Museum in Alexandria, made tremendous advances in both theoretical and applied mathematics. For the most part, they drew on Greek and Babylonian mathematical science, not that of na-

tive Egyptian civilization. Euclid (fl. 300 B.C.E) perfected the concept of the formal mathematical proof. Claudius Ptolemy (ca. 90–168 C.E.) created a system of mathematical astronomy that is both ancestral to modern astronomy and remained unchanged until the time of Copernicus in the 16th century. However, Eratosthenes (ca. 276–ca. 194 B.C.E.) drew upon the Egyptian tradition of geometry as land surveying in his calculation of the circumference of the earth. He relied on the skills of native surveyors to determine the distance between the cities of Alexandria and Syene (modern-day Aswān); since he also knew the number of degrees of arc that separated them on the earth's surface, he used that information to calculate the total size of the whole earth.

THE MIDDLE EAST

BY JUSTIN CORFIELD

Various numbering systems were used in Mesopotamia during ancient times. The earliest was that of the Sumerians and is known to have been used from at least 2800 to 2600 B.C.E. It involved lines of signs listing numbers from left to right. This system was developed by the Elamites, who occupied what is now Iran, and at the same time by the Akkadians, whose numeral notation system provided a basis for that developed by the Babylonians. It is known that the Babylonian numerals had appeared between 1900 and 1800 B.C.E., though some scholars think they may have been introduced in Akkad 500 years earlier. The Babylonian system was the first that used a place-value numeral, in which the value of a particular digit depends not just on the character but also on where it appears in a number, as in the difference between 82 and 28. Curiously, neither the Sumerians nor the Akkadians (from whom the Babylonians drew their numerical system) used place-value numerals.

The Babylonians had a sexagesimal system, that is, with a base of 60. They wrote numbers by making marks on soft clay using a wedge-tipped stylus. A symbol similar to a letter Y denoted the units. One of these symbols indicated 1, two for 2, and so on up to 9. To denote the "10s," a symbol similar to a left angle was used. Thus "<<

The reason for the algebraic achievements of the Babylonians is unknown, because it is commonly believed that all pre-Hellenic mathematics, including theirs, was largely used for practical matters rather than for pure mathematics, or mathematics engaged in for its own sake. One tablet in the Plimpton Collection at Columbia University, New York, dating to 1600 to 1900 B.C.E., was initially thought to have been a set of business accounts, but some scholars have suggested that it was part of a much larger tablet. The numbers on it are not listed in a haphazard order but follow a pure mathematics inquiry.

Because of the Babylonian interest in mathematics and astronomy, the base of 60 survives in the number of min-

utes in an hour and partially in the number of degrees for an equilateral triangle and in the 360 degrees in a circle. The Babylonians were able to use their system for reciprocal numbers, square roots, cubes, and cube roots of numbers. There is evidence that mathematics was taught in schools, and some tablets survive with mathematical problems and with the working out of pure mathematical theories.

The Assyrians followed the same system as the Babylonians; indeed, they seem to have added nothing to the Babylonian advances in mathematics. They used the numbers for purely applied purposes, such as for building temples and palaces, for computing taxation owed to their rulers, and for military reasons. As a result, when the Achaemenid Persian Empire (538–331 B.C.E.) was established, it was from Babylonian science and numbering that it drew its inspiration. Although the Persians did embark on a number of pre-mathematical inquiries, their primary focus was applied mathematics.

There were many other numeral systems that operated in the Near East at the time, including that used by the Jews. The Hebraic numeral system uses the additive principle, in which the numeric values of the individual letters are added together to form the whole. Different numerals denote each number from 1 through 10 and then 20, 30, 40, and so on until 100; different numbers are used for 200, 300, 400, 500, and so forth. There are 27 Hebrew numerals in all. The Hittites also had their own numbering system, as did the Phoenicians.

By the time Alexander the Great conquered the Achaemenid Persian Empire in the 330s B.C.E., Greek numerals tended to dominate notation in the ancient world. In many ways it had come about as Greek learning permeated much of the Near East, even before Alexander's conquest. This remained the case throughout the rest of the ancient world, so much so that Greek mathematicians dominated the field during the Roman Empire.

ASIA AND THE PACIFIC

BY FRANK J. SWETZ

The development of Asian counting systems and mathematics was greatly influenced by two pervasive civilizations: the Hindu empires of the Indian subcontinent and the dynastic empires of imperial China. Through conquest, trade, and religious evangelization these civilizations spread their customs, beliefs, and rituals over much of the Asian region. In particular, Korea, Annam (northern Vietnam), and Japan became the intellectual heirs of China. Contacts resulted in the adoption of Chinese mathematical practices.

From the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) onward the Chinese had been using a decimal system of counting and recording numbers. The earliest evidence of such numbers has been found on Shang oracle shells and bones used for fortune-telling. More formal systems of numeration appear in bronze inscriptions of the following Zhou Dynasty (ca. 1045–ca. 256 B.C.E.). Finally, during the Han Dynasty

(ca. 202–ca. 220 B.C.E.), this decimal numeration system was standardized. By the early centuries of the Common Era, Chinese use of number symbols had evolved into four distinct systems: a form for common use, a more elaborate form for legal and administrative documents, a commercial form that allowed for quick recording, and a scientific, counting-rod, or rod-numeral, form that lent itself to calculations on a computing board. It was the latter set, the rod numerals, that was most influential in terms of mathematical facility and cultural transmission and eventual adoption in the territories influenced by China.

Rod numerals actually represented configurations of a set of wooden computing rods employed on a counting board. They were basically tally symbols representing numbers; thus 3 would be represented by three vertical rods, recorded as a numeral by three vertical strokes. In designating digits, this process continued up to recording 5 by using five vertical strokes; for numbers above 5 a horizontal stroke would be added, serving as a cap over the vertical strokes. This horizontal stroke represented a count of 5. The vertical strokes added below it would then represent units to be added to the 5. So a horizontal stroke covering one vertical stroke would represent the number 6 and a horizontal stroke with four vertical strokes would stand for the number 9. These symbols were used to designate collections of units—100s, 10,000s, and so on (alternating powers of 10). For the remaining alternating powers of 10—10s, 1,000s, 100,000s, and so on—the orientation of the strokes was changed; vertical strokes were replaced by horizontal strokes and horizontal by vertical. Thus, alternating 10's positions in a decimal-based numeral would be symbolized by contrasting sets of strokes.

In this system numerals would be written from left to right, with the highest power of 10 occupying the left-most position in the numeral. An empty space in the numeral indicated an empty position on a counting board (a “zero”). A detailed description of Chinese counting rods and their computational procedures is given in *Sun zi suan jing* (The Mathematical Classic of Master Sun), written about the year 400 C.E. This rod counting and numeration system was most efficient and was used throughout Asia for many years until it was replaced by the abacus.

Common Chinese numerals were (and still are) written in a vertical column with the highest place value at the top. These columns of characters are unique in that they serve as numerals, counting symbols, and number words or phrases. There are separate characters for each grouping of 10s—10, 100s, 1,000s—and, in a numeral, each 10's grouping would be preceded by a counting character; thus a reader would note two characters (words), such as *three hundreds* or *five tens*. In such a numeration system there is no need for a “zero” symbol as a placeholder, the name of the particular 10's place is just missing from the designation.

The positional value scheme of the Chinese numerals was very efficient and flexible, allowing for the recording of large numbers, up to 10^7 ; it could even, conceptually, express

numbers up to powers of 10^{80} , but such numbers were limited to ritual use. The Chinese common or standard numeral system and the computational rod system were adopted and readily used in Japan, Korea, and Annam. Chinese mathematical techniques were also adopted by these cultures, as were the Chinese classical manuals describing applications of mathematics. The most famous and influential of these manuals was the *Jiu zhang suan shu* (Nine Chapters on the Mathematical Art), written in about 100 B.C.E.; this was a bureaucratic handbook of the mathematics needed to run an empire.

The earliest epigraphic evidence of a counting system in India can be traced back to the Maurya Empire (321–185 B.C.E.) and to the activities of its greatest ruler, Asoka (r. ca. 286–231 B.C.E.), who constructed cast-iron pillars listing the precepts of his rule. On these structures is found evidence of a decimal system of numeration, the Kharosthi numerals. These numerals are basically tally symbols but conceived around the use of base 10. The tally symbols eventually evolved into a cursive form that could be written down easily. Like the rod numerals of China, this system also left an empty space to indicate the lack of an enumerator for a power of 10 (a “zero”). Numerals were written horizontally from left to right with the digit representing the highest power of 10 occupying the position farthest to the left. This later Brahmi form spread throughout the Hindu sphere of influence.

Indian scholars also devised a collection of computational algorithms to accompany these numerals. These algorithms could be undertaken using the writing materials at hand and did not require an auxiliary computing device. Early Hindu traders and missionaries, brought this knowledge and these techniques to their clients and converts throughout Asia, specifically into the Malay Archipelago, including the present-day Philippines, Sri Lanka, the Srivijaya maritime empire of present-day Sumatra, the Khmer kingdom of Angkor (Cambodia), the Champa kingdom (central Vietnam), Majapahit (Java), and among the Mon people (Thailand). This decimal system of enumeration and its variants became very popular along the trade routes of the East Indies, where it was also adopted and perpetuated by traveling Arab merchants who would eventually introduce it into Europe.

Before the Common Era an extensive trade system was established among the peoples of the Pacific region both between themselves and with foreigners. It is most likely that these contacts promoted various systems of counting and enumeration. Language similarities within the traditional counting systems of the Chamorro people of the Mariana Islands, the Ilocano and Kapampangans of the Philippines, the Napu and Batak of Indonesia, and the inhabitants of Fiji and Samoa all support this conclusion. For example, all their ancient, traditional languages share the same word for the number 5, *lima*, a proto-Malay word for *hand*, referring to the origin of finger counting. Similarly, Tongans and Tahitians employed a decimal system of counting, one that could accommodate enumeration into the millions. The Hawaiians, descendants of these people, also employed a base 10 count-

ing system, one in which groupings of four—4, 40, 400, and so on—bore special significance in counting specific items such as taro and coconuts.

This early prevalence of decimal notation, in many cases, depended upon exposure to foreign, external influences imparted by traders and missionaries. Thus, coastal peoples and inhabitants of administrative urban centers may have used decimal counting, but their isolated hinterland peers employed other systems. For most of these remote peoples there is little historical evidence in existence as to their ancient counting practices, but anthropological research among traditional peoples of the Pacific region, especially those of Papua New Guinea, supplies insights into their ancestors' mathematical systems. Findings indicate that probably these isolated peoples had limited number vocabularies and employed a variety of counting bases, among which the base 5 was popular in emulating the number of digits on the human hand. Many of their number terms would have been more qualitative than quantitative, comparable to words such as “couple,” “herd,” and “flock” that not only designate a general number but also convey further information about the objects under consideration. These people also might have employed several counting systems, that is, using different number words for counting special items, such as yams, pigs, and canoes, and for doing time reckoning. Some of these societies were known to have used four or five such different systems for their counting purposes.

EUROPE

BY AMY HACKNEY BLACKWELL

Ancient Europeans did not develop mathematics and counting to nearly the degree that the peoples of the Mediterranean region did. Most ancient European peoples outside Greece and the Roman Empire did not write at all, so almost no written records remain that could show the level of mathematical knowledge in Europe. People in Mesopotamia and the Mediterranean used mathematics to trade and build objects, but the Celts, Germans, and other European peoples did not leave traces of numerical systems for accounts, records, or architectural calculations. One of the earliest uses of numbers was to keep track of days and seasons. Bones dating from as early as 11,000 B.C.E. contain regular scratches that may have corresponded to the phases of the moon. People early gained a sense of the numbers that were important for keeping track of time, such as 28 to 30 days per month and 12 months per year.

Prehistoric European peoples were good enough at astronomical calculations to build stone structures precisely engineered to catch the sun at a particular time on a certain day. For example, the tomb at Newgrange in Ireland, built around 3500 B.C.E., is designed so that the rising sun on the winter solstice (approximately December 21) falls on a design deep within a grave chamber. Stonehenge and other giant stone sites also are placed in such a way as to catch the sunlight on particular days of the year.

The Druids, Celtic spiritual leaders, became quite adept at the mathematical computations required to keep the calendar in order. The Celts considered several numbers to be sacred or spiritually significant. The number 3 was extremely important. Celts saw the world as composed of three components: earth, sea, and sky. The human soul also was thought to have three components. Celtic deities often appeared as triads, such as the three Irish goddesses of war. The number 9 was important as well, because it was three times three and possibly because it was the length of a lunar week. The number 5 symbolized the family and, in Ireland, the kingdom. The number 27 was the number of warriors in a Celtic king's royal court and in his war band; it contained the combined spiritual power of 3 and 9, which when multiplied equals 27. The number 33 was also important, representing the total number of gods in the divine court.

The Celtic peoples used mathematics to create their elaborate knotted decorative patterns, which appeared in Celtic metalwork and stone carving. The earliest patterns used parallel lines and carefully drawn circles, but by the first century C.E. Celtic patterns were quite complicated and required a solid understanding of geometry. Celtic artists designed their patterns on a square grid. The number of lines on the grid determined the number of strings or lines in the pattern. A two-by-two grid would produce an image from two pieces of string or lines. A four-by-four grid required four pieces of string or lines. By using a solid geometrical plan, a Celtic artist could create a complex design that was entirely complete within itself, with all lines woven together and no strings left untied. Almost all Celtic knot patterns were made on even-numbered grids; it was impossible to tie all ends on patterns made from odd-numbered grids, so they were rarely used. Historians believe that knot patterns may have evolved from basket weaving, which also required a practical knowledge of geometry.

Ancient Celtic and Germanic languages had their own counting words. Counting words in the different Celtic languages were similar to one another because of their common origin in Proto-Celtic. They also resemble the counting words in other Indo-European languages, including modern languages such as English or French. (This is easiest to hear when reading them aloud.) In Proto-Celtic, the numbers from 1 to 10 were as follows: *oinos*, *dwossu*, *treis*, *kwetwar*, *kwenkwe*, *sweks*, *sektn*, *okto*, *nauin*, *dekn*. In Brythonic, spoken in Wales, Brittany, and Cornwall, the numbers were *oino*, *dau*, *tri*, *petuar*, *pempe*, *hweh*, *seht*, *oht*, *nau*, *dek*. In Goidelic, spoken in Ireland, Scotland, and the Isle of Man, these numbers were *oino*, *dassu*, *triss*, *keuur*, *kwessik*, *swe*, *sehtn*, *oht*, *nowin*, *dehn*. And in Gaulish, spoken by the Gauls in France, the numbers ran *oino*, *do*, *tri*, *petor*, *pempe*, *suekos*, *sextam*, *oxtu*, *nau*, *decam*.

Numbers in Germanic dialects resembled those in Celtic dialects. In Proto-Germanic, 1 through 10 ran *ainaz*, *twai*, *orijiz*, *fidwor*, *fimfi*, *sehs*, *sibum*, *ahto*, *niwun*, *tehun*. In Proto-German, the numbers were *eins*, *tswass*, *drioss*, *fiossr*, *fimf*,

sehs, *sibun*, *ahto*, *niwun*, *tsehun*. In Gothic, spoken by the Visigoths during the early centuries C.E., the sequence was *ains*, *twai*, *dries*, *fidwor*, *fimf*, *saiehs*, *sibun*, *ahtau*, *niun*, *taiehun*.

During the classical Greek and Roman periods European peoples began using Greek and Roman number systems. Greek numbers were more common in eastern Europe and Roman numbers in the west. The most widespread use of numbers was in commerce and in wills and testaments. Both Greek and Roman numbers had some deficiencies; neither of them was well suited for computations with very large numbers, and expressing fractions was difficult with both. Nevertheless these were the best mathematical systems available at the time and they were certainly an improvement on the existing unwritten European numerical systems.

GREECE

BY JEFFREY S. CARNES

The Greeks had two number systems in common use: the acrophonic and the alphabetic. The acrophonic system used the straight line for the number 1, but the initial letters of the numeral words for higher numbers. Thus they had Π (pi for *pente*, or 5), Δ (delta for *deka*, or 10), Η (eta for *hekatón*, or 100), Χ (chi for *chilioi*, or 1,000); and Μ (mu for *myrioi*, 10,000). *Myrioi* was the biggest numerical unit—all higher numbers were expressed as multiples of *myrioi*. Multiples of 5 could be expressed by combining pi with another symbol: thus pi with a delta hanging from it would be 50 and pi with a mu hanging from it, 50,000. Other multiples were expressed by repeating the sign: 42,324, for example, would be ΜΜΜΜΧΧΗΗΗΔΔ|||I. This system was used in public inscriptions in Athens until about 100 B.C.E., and until about 200 B.C.E. in other cities.

The alphabetic system is the older of the two, but it was refined and came into widespread use in the fifth century B.C.E. It probably originated in Ionia (the area on and around the coast of Asia Minor) and consists simply of the letters of the Ionian alphabet, with the addition of three obsolete letters left over from the Phoenician alphabet: Ϛ (stigma), Ϟ (koppa), and Ϛ (sampi). This brings the total up to 27, making it usable as a quasi-decimal system: the first nine letters (alpha through theta) represent 1 through 9; the next nine, 10 through 90; and the final nine, 100 through 900. The lack of a zero as placeholder kept it from being a true decimal system, and, in fact, the order of numbers might vary. For this reason it was useful to distinguish numbers from letters: in inscriptions this could be done with a space or a raised dot; in print the convention came to be that numbers were written with a following superscript prime mark: thus ψοα', 771. A preceding subscript prime indicated multiplication by 1,000: ψοα', 771,000. There was no zero in common use, though astronomical treatises sometimes used one consisting of an omicron with a line over it: $\bar{\omicron}$. (This, along with the base 60 system for measuring minutes and seconds of angles, was borrowed from the Babylonians.) There existed as well the

use of letters to list items in order (the *Iliad* was divided into 24 books, which were given consecutive letters of the alphabet), but this is not a true counting system.

Neither of the number systems was very easy to use for calculation, but they were designed for recording numbers, not manipulating them. Calculation was done with devices such as the abacus: The word comes from the Greek word *abax*, meaning a “board” or “slab,” which would be divided into columns (sometimes covered with sand); numbers were marked in writing or represented by pebbles.

Although the Greeks acquired mathematical knowledge from the Babylonians (and to a lesser extent the Egyptians), their original contributions to the field were immense. The work of the mathematical pioneers Pythagoras and Thales (both from the sixth century B.C.E.) is shrouded in legend: the first mathematician whose work is directly known is Hippocrates of Chios, active at Athens in the late fifth century. He is said to have compiled an “Elements of Geometry,” which anticipated the work of Euclid by more than 200 years, and to have worked on the problem of squaring the circle (that is, the construction of a square with area equal to that of a given circle). The greatest significance of his work is that it exhibits the concept of formal proof, which remains the single greatest contribution of the Greeks to the development of mathematics.

The existence of irrational numbers was a problem for early geometers. (Colorful stories are told about Pythagoras’s reaction to the discovery of the square root of 2, geometrically the most obvious irrational number.) Infinitesimals (infinitely small numbers) also caused concern and may be the source of Zeno’s famous paradoxes about the impossibility of motion (Zeno “proved” that an arrow could not travel through the air and that the famously swift-footed Achilles could not catch up to a tortoise in a footrace). Logic and geometry developed greatly in the fourth century, as seen in the works of Eudoxus and Aristotle. A culmination of these trends is the work of Euclid, whose *Elements* provides a summary of the geometric knowledge of his day and is perhaps the single most influential textbook of all time, especially for its use of the axiomatic method, in which all conclusions are derived from a small set of simple, apparently self-evident statements (“axioms”). Euclid exhibits knowledge of algebraic geometry (showing further Babylonian influence) and devotes part of the *Elements* to number theory, including a proof that the number of primes is infinite. His other surviving works include the *Phaenomena* (an application of the geometry of spheres to astronomy) and the *Optics*, a treatise on perspective; that is, Euclid worked in what is known as both applied and pure mathematics, as did most Greek mathematicians.

An even more noteworthy example is provided by the career of Archimedes, whose work included systematic treatments of statics and hydrostatics (branches of mathematics dealing with the equilibrium of weights, in and out of water) but who also put this knowledge of mechanics to use

Painted Greek stele with metrical inscription (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

as a designer of siege engines. (He was killed when Roman troops sacked his native city of Syracuse in 212 B.C.E.) His work exhibits an originality far beyond that of any other ancient mathematician. In describing mechanical theorems, he uses a procedure of dividing figures into infinitely thin strips, which is quite similar to the procedure that led to the development of the calculus in the 17th century C.E. In his book *The Sand Reckoner* he describes a numerical system capable of dealing with extremely large numbers far superior to any system used in antiquity. Paradoxically, his influence on subsequent mathematics was relatively small: few ancient mathematicians were capable of understanding the implications of his work.

While the greatest achievements of the Greeks were in geometry, there was also important work in arithmetic and something approaching algebra. The work of Heron and Diophantus (in the first and second centuries C.E.) shows the Greek attitude toward these branches of math: their works present specific number problems (for example, “find three numbers such for which the product of any two of them plus

their sum is a square”), but their solutions lack general application or formal proof.

Mathematics came to hold tremendous symbolic importance in Greek culture. Pythagoras saw in numbers a model for the underlying harmony of the universe, and the mysticism of his worldview influenced many later philosophers, including Plato. The famous story that the entrance to Plato’s Academy bore the inscription “Let no one who is ignorant of geometry enter” may be of doubtful authenticity; nevertheless, it reflects well the Platonic attitude toward the centrality of mathematics in the education of the ideal citizen or philosopher.

ROME

BY JUSTIN CORFIELD

The system of numbers and counting used in Rome and the Roman Empire was developed from Etruscan numerals. These numerals, in turn, were adapted from the Greek Attic numerals. Although there are only a few archaeological finds that have Etruscan numerals, there are enough to show that the letter *I* represented 1, an inverted *V* represented 5, and *X* represented 10. The first two of these figures can be seen on surviving Etruscan six-sided dice, on which the opposite sides add up to seven, as in the dice of today. Several Roman dice also have survived, again with the opposite sides adding up to seven. Six small ivory dice were found at Pompeii, all the numbers denoted with small dots; the Romans often played with two dice as opposed to the Greek system, in which three dice were used.

It has been suggested that the original use of numbers possibly came from notches on a tally stick, with the Romans using a *V* for 5. Apart from the ordinary people who needed to count out money and commodities as well as tell time and work out the calendar, the Romans also had tax collectors and mathematicians who needed to use larger numbers. The Romans used the letters *I* for 1, *V* for 5, *X* for 10, *L* for 50, *C* for 100, *D* for 500, and *M* for 1,000; they also indicated large numbers by placing a bar over a numeral to indicate a numeral in the thousands. Above one million there was no standard format, with five million denoted either by placing a double bar over a letter *V* or by underlining, as in $\underline{\underline{V}}$.

There is conflicting evidence regarding the use of some Roman numerals, especially subtractive ones, whereby *IV* represents one less than 5 (that is, 4). Older Roman material tends to have *IIII* for 4, making mathematics easier. However, gradually the subtractive notion tended to be used more and more, eventually becoming the accepted form despite the fact that *IV* was also similar to initials representing the god Jupiter (the name in Latin being *IVPITER*).

It was also from Roman numerals that the number 666 became known as the devil’s number. In Roman numerals 666 was represented by the letters *DCLXVI*, using every basic numeral except the letter *M*. Those familiar with this phenomenon must have seen a bad omen when the Great Fire of London broke out in 1666 (*MDCLXVI*).

Interestingly, the Romans did not have a concept of a zero. Indeed the first Roman mathematician who is known to have used the concept was Dionysius Exiguus in 525 C.E., though it seems probable that the concept of zero was in use before then. Later the letter *N* for *nullus* (nothing) was used to denote zero.

While many Greek mathematicians are household names, there are no details about Roman mathematicians, and it seems likely that the Romans had little interest in pure mathematics. Indeed, it was said to have been a Roman soldier who killed the Greek mathematician Archimedes of Syracuse in 212 B.C.E., and most mathematicians in the Roman Empire, such as Diophantus of Alexandria, were actually Greek. However, the Romans must certainly have had people who studied applied mathematics to work out architectural plans, load bearings, astronomy, and the supervision of the raising of revenue. The poor notation of the Roman numbers did, however, handicap any major advances in mathematics. For counting, the Romans used small bronze counters on occasions, these having on them pictures of hands with a particular number of fingers raised. Cicero refers to these counters, which effectively were early “counting boards.” Gradually the Romans started using the abacus for more complicated sums, the abacus also often being called a “counting board.” Many mathematical instruments have been found in the excavations at Pompeii.

Surviving surveying manuals show the combination of arithmetic, geometry, and optics for the Romans’ work. Weights and measures followed what now appear to have been arbitrary calculations but must have had some meaning at the time. For example, the *pes*, a Roman foot (in measurement), was just over 11.5 inches, making their pace 4 feet, 10.25 inches. With a thousand of these feet making a Roman mile, the mile was 1,618 yards. Roman numerals have been used many times since the ancient world; they are regularly found in Christian ecclesiastical documents and in European accounts and are still used in calendars, clocks, and watches.

THE AMERICAS

BY PENELOPE OJEDA DE HUALA

Very little information exists regarding the function of numbers and counting in the ancient Americas. We know that the inhabitants of the Americas probably used the lunar and solar cycles to track the change of seasons, as these changes were vital to their survival. Archaeological remains show evidence of early engineering, which required forms of mathematics. However, by the time of European contact, numbering systems existed throughout the Americas.

The Archaic Period (7000–1800 B.C.E.) in North America saw a near extinction of big-game animals, forcing native groups to rely on local resources to supplement their diets. While full-scale agriculture would not be introduced until about 800 C.E., around 3000 B.C.E. some forms of early cultivation occurred throughout North America. Agricultural

developments, in turn, forced indigenous groups to pay attention to the passage of seasons and to develop systems of keeping track of those changes to procure food. Tracking change required mathematics and some form of calendrical system, but archaeological evidence for such practices does not appear until around 900 C.E.

Early architectural engineering suggests the creation of a form of mathematical measurement system. For example, in Shabik'eschee Village in New Mexico, as many as 18 pit houses were discovered. These small, sunken structures were probably household compounds. Usually round or square in floor plan and made with mud and clay, these structures were often a foot or more deep. The entryways of some of these structures have been found to be oriented toward the north-south axis, suggesting some form of astronomical observation. Pit houses were discovered throughout the Southwest and were one of the earliest permanent structures in North America.

Oral traditions of many indigenous groups indicated that certain numbers were revered. For example, among the Ojibway, an Algonquian-speaking people centered in the Lake Superior region, including the present-day areas of Michigan, Wisconsin, Minnesota, and parts of Canada, the number 4 appears in several versions of their creation and migration myths that date back to ancient times. In one version of their creation myth the Good Spirit creates four beings who will become the first people. Another version tells of the Maker, who sends four men to create the world. There are also four grandfathers and four colors of man (red, yellow, black, and white). This reverence for the number 4 is also seen in Ojibway birch bark scrollwork.

In ancient Mesoamerica the earliest evidence of a numbering system appeared in the Preclassic Period (ca. 1800 B.C.E.–150 C.E.), carved on upright stone monuments called stelae. In the present-day region of Veracruz, Mexico, at an Olmec (1200–400 C.E.) site called Tres Zapotes, a series of bars and dots appear on the back of one such monument, Stela C. These bars and dots also appear on later Maya (1000 B.C.E.–1521 C.E.) monuments. The bar-and-dot counting system was based on a vigesimal system, or a base 20 system, which corresponds to the number of digits on the hands and feet. A dot corresponds to one unit, and a bar corresponds to five units. On Stela C, the dot and bar correspond to the numbers 7.16.6.16.18, which archaeologists and epigraphists (scholars who study inscriptions) have determined to be a specific date, the third day of September in the year 32 B.C.E. Using similar numbering systems on many later Mayan monuments, it has been determined that this counting system relates to a Mesoamerican calendrical system called the Long Count; along with a ritual and solar calendar, this system was used throughout Mesoamerica.

The Long Count calendar, unlike the ritual and solar calendar, which was cyclical, was a linear count from a specific origin point. Each number corresponds to a multiple of 20, except for the last. For example, in the Long Count date on

Stela C, the 7 corresponds to the number of Bak'tuns, or the cycle of 144,000 days that have passed. In this way, the Maya and other Mesoamerican groups could configure large numbers. The Maya also invented the concept of zero, which was represented by a shell or Maltese cross. Certain numbers had specific significance in Mesoamerica, such as the number 13, which is the common number for the layers of the heavens and also important in the ritual calendar. The numbers 18 and 20 also have calendrical significance, as they are the common configuration of the solar calendar. Finally, the numbers 9 and 7 are both associated with the underworld in myth.

► occupations

INTRODUCTION

The earliest modern humans probably had only one occupation: survival. In most of the world they would have traveled and lived in groups of a dozen or so people. Even when they settled in villages, there would be only a small number of villagers. Each member of a group of people would have had to learn everything about survival: how to tell dangerous animals from safe ones; how to track animals to hunt them; how to identify edible plants; how to prepare food; how to make pottery, baskets, tools, and so on. Many anthropologists believe that early modern humans divided some occupations by gender. They base this idea mostly on observations of hunter-gathering peoples who have survived into modern times as well as on archaeological evidence that tells something about the creatures ancient people had to deal with and about the physical makeup of ancient humans. These anthropologists believe that men were probably the hunters of game, especially in areas where the game was large and dangerous. Bison, elephants, and rhinoceroses would be the kinds of animals that might require men, presumed to be physically stronger than women, to hunt.

According to many archaeologists and historians, a division of labor into occupations would not have occurred until agriculture was invented. The reasoning is that ancient hunter-gathers had to be mobile; even when they lived in small villages they had to range far over the countryside and be able to move quickly out of the way of such dangers

as floods and wildfires. Their need for mobility would have made it difficult for them to develop any settled occupations; given the dangers of their lives, everyone had to be a generalist, not a specialist in a particular craft.

With the coming of agriculture people settled in areas where crops could be planted. The work required to nurture crops would have necessitated larger groups of people than were needed for hunting and gathering. Further, a steady supply of food probably began a population boom. These may have been the two requirements for the development of occupation: cooperative work to raise crops and enough food on a steady basis to allow people to stay in one place. As people became more skilled in raising food and developed better, more nourishing varieties of crops, food surpluses would have allowed some people to spend their time on projects other than raising food. Where archaeologists find evidence of artisans, especially in the making of luxury items, they tend to assume that they have found evidence of a culture that produced surpluses of food.

It is tempting to assume that the first occupations were those that focused on products needed for survival, but ancient people were still people, and like people throughout the modern world, they seem to have wanted beauty in their lives and spiritual fulfillment. Thus, early occupations included making pottery and baskets and also making decorative ornaments for the body and artistic expressions of spiritual beliefs, such items as totems and charms. Thus, when one studies the occupations of ancient peoples, one may learn not only what they required for survival but also what they valued in their lives beyond just surviving.

AFRICA

BY LEAH A. J. COHEN

In very early times all human groups in Africa lived primarily by hunting, gathering, or fishing or a combination of these occupations. Based on studies of modern hunter-gatherer groups, it is thought that in ancient times women probably were responsible for the daily tasks of child care and gathering wild roots and seeds, while men hunted, but on a more periodic basis than gathering was done. These same studies reveal that women's gathering efforts produced most of the food consumed on a daily basis and that in general the hunter-gatherer lifestyle was less grueling than that of the early agriculturalists. These livelihoods were practiced throughout Africa from the Berbers in the far north to the San and Khoi-khoi in the far south.

Domestication of plants and animals (and the birth of farming and herding) occurred gradually, no doubt starting with hunter-gatherers' experimenting with planting while still depending on wild food sources for survival. Such experimentation may have begun as early as 6,000 to 10,000 years ago in central and northern Africa. Climatic conditions changed in northern Africa around 4,500 years ago, resulting in an environment that was less able to support the growing human population through hunting and gathering alone and providing a strong incentive for human groups to become better at farming and herding. Initially, humans broadened their livelihood activities to include hunting, gathering, herding, and agriculture. Eventually, some groups became principally farmers and others principally herders, while still others remained hunter-gatherers. In general, adoption of farming and herding moved from north to south. It is thought that herding did not become common in the southern Africa Cape until about 2,000 years ago. Specialization into farming and herding was possible only with trade among these different groups, which initiated localized trade networks throughout in ancient Africa.

Over time, better agricultural techniques throughout Africa allowed for surplus crops, which, in turn, spawned further labor specialization. Individuals and families who had skills other than farming could trade their products for food. As local trade increased, new occupations continued to emerge in the more densely populated areas, such as Nubia (eastern Africa), Axum (eastern Africa), and Jenne-Jeno (western Africa). There grew a demand for builders, woodworkers, masons, ironworkers and metalsmiths, jewelry makers, religious experts, and government officials. Some people made their living as scribes in literate societies, such as ancient Ethiopia after the fourth century B.C.E. It is thought that prior to the development of grand empires in ancient Africa, aside from hunting, gathering, farming, and fishing, people also engaged in the "part-time" occupations of healing; storytelling, from which the griot (a musician-entertainer who specialized in tribal histories) traditions emerged; and artwork.

Pottery making became desirable with the adoption of farming and more sedentary lifestyles. Many of the more rural farming human groups and villages acquired the technology to make pottery. Some of the earliest examples of pottery (though it was not necessarily made by full-time potters) are from the central Sahara (dating to about 9,500 years ago) and in Nabta Playa, just west of the Nile (dating to about 8,000 years ago). Most of the civilizations in ancient Africa employed skilled potters. Two notable examples are the Nok and the inhabitants of Jenne-jeno. The Nok, who lived in present-day Nigeria around 500 B.C.E., are known for their terra-cottas. The potters of Jenne-jeno (ca. 200 B.C.E.) also were highly skilled and left mounds of pottery fragments from various types of vessels.

Some people made their living as masons. Nubian masons made homes out of brick and also created pyramids similar to those in Egypt in the 11th century B.C.E. The most impressive stone sculptures are the tomb markers from Axum: The tallest is 79 feet high and intricately carved to resemble a multistory building, showcasing the skill of these early craftspeople and the extent of the stone-carving industry. It would have taken a team of mason months or years to create these sculptures.

The weaving industry of ancient Africa has been dated to at least as early as 3200 B.C.E. in Nubia with the Kush, a civilization that flourished from about 300 B.C.E. to 500 C.E. Weaving tools that have been uncovered in these areas include spindles and loom weights. Although evidence dates many of Africa's weaving modern weaving traditions to medieval times, they certainly have their roots in a long history of weaving in Africa. Sculptures from the ancient Nok civilization depict cloth and indicate that a weaving industry was present at the time there as well. Archaeologists have uncovered the remains of loom weights and spindle whorls at Jenne-Jeno.

The jewelry-making tradition has long been a part of culture and economic life in many places in Africa. Jewelry makers in Jenne-jeno used imported iron and Roman beads in their craft. At the very end of the ancient period (400 C.E.) copper and bronze were also used in Jenne-Jeno to create ornaments. Many of the other civilization centers, among them, Axum and Nubia, had a jewelry-making industry.

Trade flourished and local trade networks became vital during this period. By around 800 to 600 B.C.E. the trading settlement of Carthage (on the Mediterranean in northern Africa) began to bustle with the activity of importing and exporting goods to and from the Middle East, Europe, and northern Africa. Carthage's merchants were supported by farms worked either by slaves or by independent Berber farmers who sold their produce in the city. Nomadic pastoralists also came to urban areas to trade their goods. In general, trade in Africa during ancient times was based on barter and there were very few professional merchants. Later, as coinage systems developed, a merchant class emerged.

The Iron Age is often cited as beginning in Africa around the sixth to seventh centuries B.C.E., first in Nubia with the

Kush as well as Meroë and Axum. There is evidence that iron-working was present in the Nok civilization by 1200 B.C.E. Many scholars believe that this technology moved with the Bantu groups into southeastern and southern Africa. Iron ore mining followed in the footsteps of copper and bronze mining in many areas of Africa. Iron ore or other metal ores were removed from the earth either from areas already exposed (opencast mines) or from holes (shafts) dug down (sometimes as deep as 40 to 60 feet) below the surface, into which miners were lowered to chip away at the rock and send pieces of rock and ore up in baskets. In present-day Swaziland, iron ore shaft mines date to approximately 400 C.E. There is evidence that the task of mining was often done by native African slaves and by men, women, and children. Iron was forged into tools for use in farming and mining and for weapons.

With the growth of human populations and civilization centers and the adoption of sedentary lifestyles came a demand for military professionals. Ancient empires such as those of Axum and Nubia had strong armies. There were many titles within the military hierarchy, and the king or queen frequently was the leader of military conquests. Ancient Nubia, particularly after 300 B.C.E., is known for its tradition of strong queen warriors who led troops into battle. The army of Carthage (northern Africa) in the first millennium B.C.E. consisted mainly of Berbers (who themselves had become successful traders, manufacturers, and farmers); these men either were recruited or enslaved into military service from the surrounding area as a result of the expansion of the empire of Carthage.

EGYPT

BY CHARLOTTE BOOTH

Like people in all civilizations, the ancient Egyptians worked hard, and many titles have survived indicating positions held by the elite. Some titles, however, were honorary and did not have any responsibilities attached to them. Other titles described the individual responsibilities within a broader blanket title. There were three categories of occupations available to men: administration, the priesthood, and the military. One occupation that crossed all categories was the scribe. About one in 100 people in ancient Egypt could read and write, so the services of scribes were needed. Scribes were proficient in hieratic script, the cursive form of hieroglyphs that was used for administrative purposes; only temple scribes were able to read the hieroglyphic script.

A talented scribe could rise to the position of vizier, which was often a stepping-stone to the throne. The vizier was very powerful and in close daily contact with the king. The entire palace and its internal operations were under his control. The vizier also was involved in the safety of the king. In addition, the greater security of Egypt and the police force were under his control. He presided over the legal court, dealing with the daily petitions of the ordinary people, which were normally concerned with petty crimes or offenses. He acted as judge,

sentencing and administering punishments on behalf of the king.

The priesthood was open to all, men and women, whether they were literate or not, and the priestly positions reflected their skills. The temple scribes often entered the House of Life, an institution where all the religious texts were written, restored, and archived. The House of Life is reputed to have stored knowledge of medicine, geography, geometry, and astronomy, and it also produced physicians who were trained in medicine and religious incantations.

There were many priestly titles, among them, the *sem* priest, who carried out all funeral rites and prayers, including the “opening of the mouth” ceremony—a ritual in which the mummified body of the deceased was symbolically animated through the opening of the mouth so that the person could breathe in the afterlife. This priest was normally the deceased’s heir and eldest son, though from the First Dynasty (ca. 2920–ca. 2770 B.C.E.) professional *sem* priests were employed. *Ka* priests were responsible for supplying sustenance for the deceased, and they would have worked in the mortuary temples of the king and the chapels of the wealthy.

Many part-time priests worked one month in four and would return to their villages when they were not required. The lower clergy, known as *wab* priests (“pure ones”), played a supporting role by carrying the sacred bark, or boat, in which the statue of the god traveled; cleaning the temple; supervising painters and draftsmen; and engaging in other general tasks around the temple. There were also a number of subsidiary temple workers—caretakers, janitors, workmen, bakers, butchers, and florists—among them, so-called sacrificers who slaughtered sacrificial animals; all were essential to the successful running of the temple.

The third occupational avenue for men was the military, which became available at the start of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.) when the permanent army was introduced. There were many specialist units that required different abilities, including charioteers, spearmen, and infantry soldiers. Training would have started in childhood. Scribes were also an essential part of the army entourage. They accompanied the military to chronicle the events of the campaign, and they were responsible for counting the enemy dead and recording the collected booty and prisoners.

The opportunities available for women were different, though many women were housewives and remained in the home. The poorer women married to farmers would be expected to help during the busy harvest period. Winnowing grain was often carried out by women, and young girls were sent to glean. In the home women were responsible for grinding grain for bread and for baking it. The loaves could then be sold at the market along with other household produce, such as baskets, pots, beer, and linen. Even the royal women were instrumental in the manufacture of linen, and evidence suggests that the harem at Gurob was a large producer of royal linen.

Granite statue of Ankhwa, the shipbuilder, possibly from Saqqara, Egypt (ca. 2650 B.C.E.); Ankhwa holds an adze, a woodworking tool indicative of his trade. (© The Trustees of the British Museum)

Women were unable to hold bureaucratic positions except in private houses, and titles such as steward of the storehouse, steward of the food supplies, steward of cloth, and seal bearer, who would have held the official seal of the homeowner, exist from the Old Kingdom (ca. 2575–ca. 2134 B.C.E.). The titles of treasurer, major domo (“mayor of the palace”), and superintendent of the dining room have also

been discovered from the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.). Women generally worked in the service of other women and were not allowed to oversee the work of men, though there is a rare example of a female vizier in the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.). In the palace women held many titles, including overseer of the singers, overseer of amusements, and mistress of the royal harem. Titles of retail careers have also been discovered, such as overseer of the house of weavers and overseer of the wig shop, and evidence also suggests that women sold their own products at market.

The most prestigious profession for women, however, was the priesthood. Women normally functioned in the cult of Neith, the patron goddess of the city of Saïs, protector of women, and goddess of weaving and of war and hunting, and the cult of Hathor, the cow-headed goddess of childbirth, sexual love, music, and dancing. Women had lesser roles in the cults of all gods. They functioned as impersonators of the goddess and as musicians or dancers during temple rituals. Priestesses also worked one in four months on a rotation system. Some priestesses would have undergone training as midwives in the Temple of Neith at Saïs. Most midwives, however, would have learned their skills at the hands of the village women and would have received no formal training. Midwives would have been in great demand, as most women had at least five children.

Other women became wet nurses for the elite. Royal wet nurses were held in very high esteem, and children of a royal wet nurse were considered “milk siblings” to the king. It was normal for children to be nursed for three years as a safeguard against pregnancy and also a way of ensuring that they were not exposed to contaminated food.

The role of professional mourner—hired for funerals to wail, throw dust over their heads, tear their clothes, and scratch their cheeks in grief—was also available for the unskilled woman. In paintings of tomb mourning scenes, young girls can be seen standing among the women, indicating that they were taught the skill from an early age.

THE MIDDLE EAST

BY HEATHER D. BAKER

The sources for information about occupations in the ancient Near East are cuneiform tablets inscribed in a variety of languages, especially Sumerian, Akkadian, Hittite, and Old Persian. Among the earliest intelligible tablets are some bearing lists of professions. These tablets come from the site of Uruk in southern Mesopotamia, from archaeological levels dated to about 3200 B.C.E. They show that the specialization of labor was already highly developed in Sumerian cities at this early period. Not only are many different occupations listed, but there are also clear signs of hierarchical organization, with terms for various kinds of officials and administrators and also for supervisors and overseers responsible for groups of craftsmen and workers.

In addition to the lists of professions, which were kept in scholarly libraries, a no less important source of information is provided by the vast amount of archival material. This consists primarily of legal and administrative documents recorded and kept by the major economic institutions (palaces and temples) as well as by private individuals and families. These archives of cuneiform tablets shed a great deal of light on the range of craftsmen and professionals and on their social backgrounds, the conditions under which they worked, and the way in which they were organized. Lists of rations allotted to workers are particularly informative. Occasionally, archaeological evidence for specialist workshops has been found, such as the remains of potters' kilns.

The range of occupations established in the course of over 3,000 years of written history in the region is vast. Some are familiar—baker, brewer, potter—but others arose as a response to the specific needs and material conditions of the day and have no close parallel in the 21st century. Many essential crafts were passed down from father to son, but some skills were taught to apprentices by experts. Cuneiform tablets recording apprenticeship contracts have survived, and they set out the penalty to be paid by the master if he failed to teach the apprentice properly. (The possibility that the apprentice might be a poor learner does not seem to have been considered.)

The palaces and temples employed large numbers of specialized craftsmen and skilled workers. Food preparation was one of the most important areas of activity. Bakers, cooks, butchers, and brewers were needed, and setting out the tables for the meals of the gods was a skilled occupation. The grinding of flour was an onerous task often performed by prisoners. Oil pressers produced the oil (from sesame seed) needed in food preparation and for other purposes, such as treating wooden objects, making perfume, and filling oil lamps.

The production of textiles and finished garments was another important craft activity. Weavers worked in wool and linen, and a variety of garments had to be made up by specialist tailors, not just for human use but also to clothe the divine statues in the temples. The cloth that they used could be dyed by the dyers in a variety of shades made from minerals and plants. Evidence for washermen and washerwomen is also found, especially in the temple archives, since caring for the precious divine garments was vital. Leather workers had to treat the skins of dead animals and manufacture items out of them, such as sandals and various kinds of containers. Metalworkers manufactured the tools and utensils used in the everyday activities of agriculture and canal digging. Goldsmiths, silversmiths, and jewelers produced finery for members of the elite and for adorning the statues of the gods in the temples. Raw materials that were not available locally would be procured by merchants specializing in overland trade with distant regions.

Construction involved a variety of skilled occupations. The design and layout of the great monumental structures, such as the ziggurats, palaces, and temples, not to mention the

defensive walls surrounding the cities, required highly skilled architects, surveyors, and site managers. The ancient terms for these kinds of professions can be identified in the cuneiform tablets, though it is not always easy to determine the exact range of duties that went with each particular job. In much of the region mud brick was used for building, though kiln-fired bricks were preferred for the more prestigious structures of palaces and temples. Brick making was a skilled activity, but usually a seasonal one. Carpenters and joiners were needed to manufacture the doors and other fittings and to prepare the beams used in making the roof. Furniture is written about in the cuneiform tablets, and occasionally the remains of intricately made pieces have been found in excavation. Usually, however, wooden items do not survive, with the result that much information about craftsmanship has been lost.

In southern Mesopotamia, where reeds grew in abundance, they were widely used in construction and in the manufacturing of such household items as baskets and mats. Specialist reed workers had to prepare the reeds by soaking, peeling, and bleaching them before they could be used. Some structures were made from reed rather than brick, a building tradition that survived into modern times in the marshes of southern Iraq.

A great many people would have been employed in agriculture and animal husbandry. In southern Mesopotamia orchard keepers were required to look after the date palm groves. Throughout the region the cultivation of grain fields needed teams of plowmen to work with the ox-driven plows; these teams often operated in family groups, including children as young as five years old.

The occupations practiced by women are less well documented. At certain periods women are known to have figured prominently in the textile industry. Occasionally, women were employed to serve as wet nurses for children who had lost their mothers. Women from wealthier families could own property and conduct business. Priestesses are also known.

The army was vital in defending the land and conquering new territories; among the troops many specialized roles are known. Finally, there were a number of professions open only to very learned individuals. These men would have undergone lengthy training in the scribal schools before completing further, specialized training in a particular field. Scholars at the royal court, such as astronomers, exorcists, physicians, and diviners, played an important role in advising the king. This is especially well illustrated by a large group of letters from scholars to the Assyrian king Esarhaddon (r. 680–669 B.C.E.), which have been found in excavations at the city of Nineveh alongside many other documents and literary works from the royal libraries.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The number of ancient Indian occupations can seem bewildering, with occupations often having numerous subcategories

of specialists. Certain occupations were common almost everywhere in ancient India. Carpenters practiced religious rituals, perhaps the most important of which was asking the spirit in a tree to forgive him before the tree was cut down. Usually another group of workers, foresters, would chop down the tree, but when foresters were unavailable, the carpenter would do it himself. Carpenters carefully measured the fallen tree and then cut it into the number and size of planks and beams they needed for a project. The planks and beams then were loaded onto carts and taken to the workplace, either a construction site or a workshop. In addition to working on buildings, carpenters made toys, wooden sandals, chests, and furniture.

Basket makers could be men or women. They gathered their grasses themselves, mostly from the sides of lakes, ponds, and waterways. They wove matting used for walls, fences, roofs, and floor coverings. They also wove watertight umbrellas as well as watertight baskets. Some of their baskets were fashioned into strainers, allowing water to pass through while retaining solids. Every Indian home had brooms, and most had woven hampers and chests.

Blacksmiths worked long hours beside a furnace. Using pincers, they worked hot metal so that they could hammer it into shape. They made nails, hammers, axes, saws, spades, sickles, plowshares, sewing needles, razors, and knives. Copper, tin, bronze, and iron were used to make cooking pans for the home and armor for warriors. The blacksmith's work was so important to the success of other occupations that even tiny villages usually had at least one blacksmith.

A potter mixed wet clay with cow dung and ashes. He placed this mixture on a potter's wheel. After shaping the clay with his hands while the wheel spun, he set it aside to dry. Later he would put it and other shaped items into a trench piled with wood. The wood was ignited to fire the pottery. The ancient Indian potter's work was rarely highly refined because the potter made items for basic uses, such as hauling water or boiling food. A potter either owned a shop or carried his wares through the streets of his village, town, or city, while calling for people to buy his pots.

The *malakaras* were garland makers. *Malakaras* kept their own gardens, where they grew the flowers they wove. Cutting the flowers was a family affair, with sons and daughters joining in the work. To give a garland stiffness to support the flowers, *malakaras* used reeds and cotton stalks. Garlands were expected to be colorful, and *malakaras* wove into the garlands leaves, berries, feathers, shells, and ornaments carved from horn. They employed people who were out of work to hawk their wares in the streets of cities.

In China peasants were the foundation of ancient society. The Chinese themselves recognized the importance of peasants, and the work of peasants was considered more important than any occupation except warfare. Taking good care of the land he farmed was the peasant's principal duty. Peasants were expected to devote their days to laboring in fields, except when the lord conscripted them into his army for

waging a war. Husband, wife, and children were expected to spend their waking hours toiling in their fields, except when performing other tasks related to farming, such as milling grain. During the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) and most of the Zhou Dynasty (ca. 1045–ca. 256 B.C.E.), peasants worked with wooden hoes and hand plows. Sometimes the hand plows would be edged with bronze. The lords, kings, and emperors of China often took trouble to ensure the welfare of peasants, on whom their prosperity rested; during the fifth century B.C.E. some landowners provided their tenant farmers with iron plows and teams of oxen to pull the plows.

Although farming was not considered an honorable profession, it was placed higher than most occupations. Ancient Chinese writers slighted most trades and jobs, and for this reason it is not fully known what those occupations were, who performed them, and how many there were. Archaeological evidence is only just beginning to fill in bits of the large gaps in present knowledge of ancient China's workaday world.

During the Han Dynasty (202 B.C.E.–220 C.E.) the government established 20 levels of rank. The top 12 could be attained only by people of high birth, but the bottom eight were open to anyone. This system gave peasants and other laborers a chance to improve their lot and may have inspired some specialization. For instance, some peasants specialized in keeping mulberry orchards, the leaves of which fed silkworms. Women in peasant families prepared the silk from the silkworms' cocoons as part of their cycle of work. An ambitious peasant could take out a loan and purchase equipment for milling the harvested grain. This venture could result in the hiring of farmhands who ran the equipment that removed hulls from the grain and produced flour.

There was a demand for metal. The government set up factories in which ore was mined, smelted, and poured into ingots. These ingots, in turn, were sent to factories where metal objects were made. This demand seems to have created specialists in metallurgy, but their skill levels are unknown. If only one person was in charge of arranging the molds, melting the metal, pouring it into the molds, and applying finishing touches to the objects, then that person would have been highly skilled; if the tasks were divided, it is possible that unskilled labor could have been used for the tasks of melting and pouring.

Weavers often worked out of homes and were probably peasant women. They worked mostly with hemp, which provided the cloth for most garments. Silk was highly prized but also was woven in homes in the countryside. The mechanisms of the looms as yet unknown, but surviving fabrics show that during the Han Dynasty very thin to very thick fabrics were woven.

Carpentry became specialized during the last years of the Zhou Dynasty, when the tropical forests to the south were opened through conquest. Logging required teams of workers, needed more for their muscle than their skills. Using ropes, they hauled felled trees to a stream, where the trees would be loaded onto boats for transport to a city. In the city

FISHING

Many of the islands of the Pacific Ocean are small and hard, and as such offered the people who settled them little opportunity to cultivate agriculture or livestock. They do, however, offer excellent access to the ocean and to the thousands of types of fish there. As soon as humans spread out from Papua New Guinea to the smaller islands to the northeast, beginning in approximately 28,000 B.C.E., fishing became the principal source of sustenance, marking them as some of the earliest people on the planet to pursue fish. Fossils show a huge range of fish and shellfish consumed on the islands, from crab, lobster, and turtle to three species of sharks. Since there are no signs of fishhooks from the Pleistocene, the general assumption is that fishing was done either by spearing or by catching fish in motion in nets or traps.

Fishing was practiced throughout the Pacific Islands, though different islands had different species of fish, from cod in the temperate Chatham Islands to the parrotfish that were overwhelmingly common in more tropical waters. While abundance certainly had much to do with the kind of fish that were sought, there also developed over the centuries cultural traditions that imparted social preferences for some species over others. For instance, among the people of Kapingamarangi Atoll of Pohnpei, it is common to hear stories about the various methods of pursuit of the rainbow runner, even though that fish is small and its population is certainly much less significant to the islanders' eating habits than the grouper.

Of course, centuries of fishing have led to the evolution of different methods of catching fish. In lagoons and inland freshwaters, spearing and bow-and-arrow fishing eventually gave way to baited hooks. Since fishing was such a significant part of the oceanic life, it is only natural that some cultures carved ornate hooks that resemble works of sculpture. For ocean fishing, nets were the preferred method, manipulated by crews in large canoes. There is evidence that as far back as 2,000 years ago, individuals in small canoes braved the ocean to fish individually, with hooks, for larger, big-game fish, like marlin.

carpenters used saws to cut planks from the tree. From these they built furniture, beams for buildings, or coffins.

Most people in Japan, the Philippines, Indonesia, and Australia followed one occupation: survival. Each person needed to know many crafts in order to make what was needed to stay alive. It is likely that the peoples of the Japanese islands began to develop specialized occupations after about

200 B.C.E.. The numerous works of pottery and the building of wooden palisades and wooden palaces by the third century C.E. suggest that potting and carpentry may have become specialized occupations by then.

EUROPE

BY JUSTIN CORFIELD

Throughout Europe during ancient times most people were involved in farming, with the vast majority of families living in their farmhouses, which often incorporated protective walls encompassing the house as well as the shelters for livestock. In some areas a wider expanse of land was surrounded by protective walls against outsiders and invaders, incorporating some farming or grazing land and gardens.

One of the main considerations for European farmers was (and still is) the difference in climate from north to south. In the north farmers enjoyed short summers with abundant water and very fertile soil. In the south, on the other hand, long, hot summers, some water shortages, and poorer soil resulted in the need for more intensive cultivation.

On ancient farms the whole variety of agricultural pursuits would have been followed: plowing fields; planting, nurturing, and then harvesting crops; maintaining the farm; using organic fertilizers; tending the animals; and slaughtering them for eating. In addition, milking cows, churning milk, baking bread, preparing food, and maintaining herb gardens were tasks often done by women, with the children, even small children, used for scaring away birds, watching over grazing animals, or generally helping their parents and family. In addition, women were often involved in spinning, with both men and women operating weaving looms. Members of the farming household made and decorated ceramic vessels, baskets, tools, and weapons. The collection of firewood was a very time-consuming task.

Around 2000 B.C.E. we see the first evidence for craft specialization in ancient Europe; certain people minimized their role in farming or gave it up completely to specialize in making particular types of artifacts. The earliest specialists were probably metalworkers. In each village there would also have been blacksmiths and metalworkers who were capable of dealing with copper and subsequently bronze and then iron. Many of these men would have been involved in simple tasks, such as making agricultural tools or simple weapons. Especially in towns, a number, such as the mirror makers in southern Britain, became quite skilled at decorative work. Because of the need for horses for transport and war, there were many horse breeders as well as people involved in "breaking in" and then looking after the animals. There were also leather merchants who engaged in treating leather products, including saddles, reins, harnesses, and household items. Coopers, who made barrels, and wheelwrights, who made carts, were also important.

There were also tribal chiefs, their families, administrators, and people in charge of collecting taxes. Their roles

Spinning and weaving tools, Iron Age England (800 B.C.E. to 50 C.E.)
 (© The Trustees of the British Museum)

varied throughout Europe, with small tribes operating in Scandinavia and larger tribal confederations being formed in Gaul and Britain, especially to withstand the Romans. In both places the tribal chiefs Vercingetorix (d. 46 B.C.E.) and Caratacus (fl. first century C.E.), respectively, were able to rely on large war machines to try to stop the Romans invading their lands. There was only a small middle class at the time, consisting of merchants and traders, a few doctors or medical practitioners, and also those connected with religious worship—for the Celts, these included the Druids, who led the people in religious observations. The merchants varied considerably, from those who sailed long distances to those who sold goods from one village to the next. It is quite clear from the near uniformity of some of the Celtic designs that trading must have been extensive. Wine was a major commodity, with craftsmen turning out elaborate wine flagons. There was also a demand for tattoo artists, with Celts often wearing bright tattoos.

In some parts of Europe, such as around the silver mines of Spain or the tin mines of Cornwall, England, there were many who earned their pay as miners. In other parts of Europe, hunters, fishermen, or sailors predominated, depending on the locality and opportunities.

With many wars, a significant number of men were soldiers. A large number fought as or when needed and spent the rest of their time as farmers, but in some parts of Europe there were professional soldiers. The best-known examples of professional soldiers are the Balearic slingers of the Punic Wars. These were men who were trained from youth to use slings in battle. Similarly, there were professional fighters in other

parts of Europe, such as the many Spanish men who served in the Carthaginian army or the many others who served as legionnaires in the Roman army or in the auxiliary units.

The advent of Roman rule over much of Europe led to a significant change in the nature of everyday life. The large armies that the Romans maintained throughout their empire, especially on the borders, such as on the Danube River or in northern England, resulted in livelihoods for many people in supplying the soldiers with their needs. Local people built and maintained Roman military bases, provisioning them with food and water and then providing services for the soldiers. Initially, these soldiers had to be Roman citizens or men capable of becoming citizens upon their retirement after 25 years' service; with the Edict of Caracalla in 212 C.E. the army was opened up to all, and the previously established distinction between legionnaires and auxiliaries ended.

More towns were established, with a higher number of people constituting the middle class and thus becoming involved in the production of luxury goods. The Roman Empire also brought about the need for gladiators, charioteers, and other "sportsmen," and created a demand for musicians and writers. The Roman Empire was to change the nature of slavery. In Celtic Europe slaves constituted such a small part of the population as to have no real importance. By contrast, the Romans had vast numbers of slaves, many working on farms and in mines, manning galleys, looking after houses, training children, and cooking for families.

The Dacians, the Thracians, the Germans, the Goths, and the Vandals all had large numbers of warriors in their population, similar to those of the warring Celtic tribes of the Bronze Age and Iron Age. The numbers of weapons used in wars against the Romans must have led to the mass manufacture on a scale previously unknown beyond the Roman Empire. The same mass-production techniques also would have been applied to footwear, uniforms, camp equipment, and materials needed for transportation.

GREECE

BY JEFFREY S. CARNES

Farming is the most basic occupation, and the development of other occupations depends on the ability of farmers to generate surplus food, that is, the economic capital to fund the acquisition of other goods. Throughout Greek antiquity (as in most preindustrial societies) farming remained the most common occupation, and farmers were well represented in all social and economic classes. At one end of the scale were small landholders engaged in subsistence farming. Given the arid climate and poor soil of most of Greece, it was not uncommon for agricultural crises to turn landholders into sharecroppers or even slaves. By contrast, the wealthiest citizens of most Greek city-states were farmers, at least nominally. Farming was generally considered a suitable occupation for wellborn people, who tended to share a disdain for crafts and business.

The world depicted in Homer's *Odyssey* gives us insights into the development of occupations. There the *oikos*, or household, is the basic economic unit and strives insofar as possible for self-sufficiency. Agricultural labor and domestic chores are performed by family members and by slaves, with clothing production and food preparation in the hands of the female members of the *oikos*. Necessary crafts, such as carpentry, are performed by the head of the *oikos*. (Odysseus builds his own house and is capable of shipbuilding when necessary.) In ancient Greece the chief exceptions were metals (for which specialized workshops, often linked to major shrines, such as Delphi, existed from an early date) and luxury goods, which were obtained from itinerant traders. Settlement in cities led to specialization, but for nonurban dwellers of sufficient means most work was done in-house throughout the historical era. Related food-production occupations (sheepherding, goat herding, and fishing) were common in some areas, though notoriously difficult to make a living at.

In cities there was a variety of manufacturing industries, but of limited size. The largest we know of is a 120-person operation to manufacture shields; workshops of 10 or so people were much more common. Given its size and wealth, Athens gives us the most complete picture of the variety of manufacturing trades: stonemasons, carpenters, shipbuilders, shoemakers, potters, and blacksmiths. Surviving goods show that some of the work was of the highest quality. Athens was a magnet for talent, and many workers were foreigners, often slaves. Citizens were involved in the crafts as well—Socrates' father was a stonemason—but the presence of slave labor presumably drove down the profitability of most crafts, and even skilled artisans did not enjoy great prestige. Among practitioners of the other arts, poets and musicians sometimes enjoyed high status.

Given the frequency of war in the Greek world, most city-states were in a more or less permanent wartime economy, which provided many career opportunities. Armies were made up of citizen soldiers—unpaid part-timers expected to supply their own equipment, so that military service, far from being a career, was a detriment to having one. There were exceptions, however. In Athens during the fifth century B.C.E. the development of a naval empire led to increased demand for sailors and ships, and paid service in the navy became an economic cornerstone of the Athenian democracy. (The number of jobs for shipbuilders must also have been significant.) Greeks could serve as mercenaries, often in the armies of non-Greek rulers, such as the king of Persia. The historian Xenophon (ca. 431–ca. 352 B.C.E.) was one such mercenary, and Greeks were highly sought after for their discipline and their specialized fighting skills.

Trade grew in importance, along with Greek prosperity, and provided a variety of employment opportunities. Banking and insurance were of particular importance for long-distance trade. Some cities, such as Aegina, became wealthy on account of long-distance trade (especially with Egypt and

Italy), and successful merchants became the new elite. Piracy flourished alongside trade, as did robbery on land. Groups of individuals, or even whole communities, could earn their livelihoods in this way, especially given the possibility of selling captured travelers as slaves.

Retail sales of food were a common way of earning a living among the poorer classes. Vegetable and fish merchants plied their trade in the market, and purveyors of hot foods were to be found at festivals and other public gatherings. Cities also would have had hot food for sale in small shops (large, sit-down restaurants being a modern invention), and there were many bakeries as well. Most houses had cooking facilities, but ovens were rare.

Healing professions provided employment for some. Doctors were probably in short supply and often were itinerant. The surviving works of the Hippocratic corpus show a remarkable degree of sophistication but depict the status of only a small segment of the medical professions. Most doctors were probably ill trained. Surgery was performed by specialists (who often were not doctors). Midwives usually were responsible for childbirth and probably for other gynecological issues as well. Healing also came from drug specialists (sometimes called *rhizotomoi*, or “root cutters,” in reference to the source of their medicines) and from magicians. Although magic is rarely mentioned in literary sources, non-literary evidence shows that it was always popular and must have been a vocation or an avocation for many.

Education was limited to the upper classes, and the number of teachers must have been small. They included many household slaves, but at the far end of the scale were the Sophists, the great teachers of rhetoric who came to Athens in the fifth century B.C.E. Athens's status as a center of

Frieze of hydriaphoroi (water carriers) from the Parthenon (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

learning allowed teachers and rhetoricians of all stripes to flourish there throughout antiquity. Athletic trainers were also sought after, but not in large numbers.

Upper-class women were expected not to work outside the confines of the *oikos* and were kept out of public view as much as possible. Women in other classes worked from economic necessity. Certain fields, such as textile production, washing, domestic service, and midwifery, were traditionally female. Prostitution was common and legal, and the profession ranged from low-status *pornai* (prostitutes) to *hetairai* (literally, “female companions”), who served well-to-do men and often were valued for their wit, education, and musical talent. Young men also worked as prostitutes, though Greek sexual mores made male prostitution a short-term career option. Fully mature men were not considered desirable by other men.

There were relatively few lawyers in the Greek world, despite the large amount of legal activity in such cities as Athens. Citizens represented themselves in court, but they did hire speechwriters, who might have given advice about the law. Civil servants were few. Despite being the seat of an empire, Athens had no permanent bureaucracy, and most magistracies were filled on a year-by-year basis by citizens selected by lot. There were likewise few managers. Industries and commercial concerns, such as banks, were on a small scale. Nor were there many jobs in sales. Greeks had few material possessions compared with modern Western societies, and what they had was typically bought from producers.

ROME

BY KIRK H. BEETZ

Bakeries could be found in every Roman town and city as well as in almost any village. In even a modest-sized town of 12,000 or so people, there would have been a few dozen bakeries because bread was the basic food of Romans from about 200 B.C.E. onward, replacing porridge. A small bakery would have had at least two rooms, one for grinding grain and for baking and the other for displaying baked goods for purchase. A large bakery could have had several rooms, with as many as five grinding mills and with ovens that could hold more than 80 loaves of bread at a time. Bakers ground their own flour using mills shaped like hourglasses. A donkey was hitched to a mill with a simple harness. The donkey would pace in a circle, turning the hourglass stone, which ground grain on a circular stone beneath it. Flour would spill out onto a wide, circular base of stone from which the baker would gather it.

Bread and sugared pastries were prepared in the same room as the flour. The most popular shape of bread seems to have been circular with eight divisions or slices. The baker took care that his baked goods were in attractive, usually geometric, shapes. The baker did not grow his own grain but purchased it from peasants who hauled the grain to market in sacks on oxen. His workday began before sunrise so that he could be sure to have fresh bread ready for the breakfasts of

his customers. Some bakeries were busy enough for baking to continue all night after the baker's shop closed. When open for business, the baker's counter, which would have been even with the street or sidewalk, was watched by a clerk, usually the wife or child of the baker. Customers were not allowed into the bakery but had to wait outside while their purchases were fetched by the clerk or the clerk's assistant. The clerk or assistant kept track of purchases on a waxed tablet.

Butchers did a thriving business in Roman villages, towns, and cities as well. Butchers prepared different kinds of meat, but Romans favored beef over all others. The Roman government regulated weights and measures, and a butcher with faulty scales could be fined. A hunk of meat was fixed on a hook that dangled from a rod. The rod had a weight that could slide back along the rod until it balanced. Like the baker, the butcher often had to work at night because farmers were allowed to bring in animals for slaughter only at night. A butcher shop was arranged like that of the baker, with the butchering taking place in a back room behind the shop.

A butcher worked while standing up, with an assortment of cleavers of copper or iron. He set meat on a masonry table, where he hacked or sliced it. The butcher hung his roasts, chops, ribs, and steaks from hooks attached to boards on the walls. Some of these meats would have been taken to the street-side shop and hung on hooks for display. The clerk was usually the butcher's wife, who had an assistant to go into the back to fetch meats for customers. Customers were not allowed inside.

Blacksmiths worked in almost every village as well as in towns and cities. In a village the blacksmith worked with several different metals. He would not have been expected to smelt metals or to mix alloys, such as bronze. Instead, he worked from ingots either imported from abroad or made locally by a smelter. His principal products were nails, pieces for bridles and harnesses, and tools. In a town or city blacksmiths often specialized. For instance, cutlers specialized in making knives. A cutler produced several different shapes and sizes of cleavers and knives for household use or for professional use by butchers. Other smiths specialized in tools for carpenters and construction workers, such as pliers and hammers. Still others made medical instruments. In towns and cities blacksmiths would have had shops that looked much like those of bakers and butchers, but the smith himself probably would have dealt directly with customers. Against one of his walls would have been shelves that displayed the different products he could make.

Barbers were among the cutler's customers. Roman men preferred carefully trimmed hair and shaved faces, and they patronized barbers often. Barbers were either men or women, and their shops were called *tonstrinas*. They used iron scissors and razors, and they often are depicted in Roman writings as dangerous people who carelessly cut the skin of their customers. Barbers were expected to be gossips, and a visit to a barber included listening to the barber recount all the rumors he had heard. Women went to hairdressers, who were men or

women. Hairdressers worked with oils and perfumes to create the latest in hairstyle fashions. A visit to a hairdresser was a woman's chance to relax.

Important to any Roman community was the fuller, who had one of the most miserable occupations. A fuller cleaned and mended clothing and fabrics. A clothes maker sent new fabric to a fuller, who prepared it for cutting and sewing not only by cleaning it but also by softening it, shrinking it, and bleaching it. Very few people cleaned their own clothes, preferring to have a fuller do the job. For cleaning, the fuller used soda or potash. Bleaching was done by burning sulfur under cloth spread over wooden frames. To thicken cloth, the fuller treated it with urine he had collected from public lavatories. He would spend hours stamping on urine-soaked cloth. When fabric or a garment was ready, the fuller would spit a fine spray of water on it. He would also patch or stitch tears. A fuller always smelled foul, and his presence was rarely tolerated by others outside his shop, unless there was a local fuller's guild house he could visit. He suffered from skin diseases caused by the urine and chemicals he used, and his lungs were damaged by the sulfur fumes he breathed during bleaching.

The Romans often tore down buildings in order to rebuild them, and they had numerous ongoing construction projects throughout their empire. Many construction workers were unskilled laborers who were given the dangerous jobs of hoisting stone with cranes or carrying stones and bricks to where they would be used. On the other hand, stonemasons were skilled with many tools, such as drills, chisels, hammers, and saws. They not only shaped and fit together stones for building but also were expected to be able to carve images to decorate buildings and to carve tombstones. Carpenters were also skilled workers who mastered several different kinds of tools, such as planes, saws, and levels. In cities carpenters could specialize, with some working in building construction and others making furniture. Outside of cities carpenters would have been expected to be able to do both.

THE AMERICAS

BY PENELOPE OJEDA DE HUALA

Ancient American occupations revolved around subsistence. The people of the Americas varied in the jobs they performed, from primarily hunting and gathering in North America to engaging in agriculture in Mesoamerica and South America. The development of native societies can be traced through the various ways in which people labored. Archaic culture is defined by its adaptation to the environment. By 8000 B.C.E. the glacial ice that had once covered the North American continent had completely receded. As a result, the Archaic Period (ca. 8000–ca. 1000 B.C.E.) saw a spreading out of indigenous groups throughout the North American continent. At the same time, big-game animals, such as ground sloths, mammoths, giant beavers (as large as modern bears), mastodons, camels, musk oxen, and horses became extinct. The changed

environment necessitated adaptation on the part of the North American inhabitants. Because of the lack of big game, local resources had to be exploited by hunting of smaller game, gathering of wild plants, fishing, foraging, and early cultivation. The most prestigious position during the Archaic Period was that of a local ruler, who fostered such activities as intertribal ties, marriage alliances, and trade. Religious specialists were undoubtedly also honored positions.

The people of the Great Plains, an area that lies east of the Rocky Mountains and includes parts of the present-day states of Colorado, Kansas, Montana, Nebraska, New Mexico, North Dakota, Oklahoma, South Dakota, Texas, and Wyoming as well as parts of southern Canada, were predominantly occupied by hunting. People hunted rabbits, beavers, and some of the surviving big-game animals, such as bison, elk, black bear, grizzly bear, and deer. They supplemented their diet by foraging for berries and nuts. The Archaic desert people of the present-day states of Utah, Nevada, and Arizona also hunted small game and foraged for seasonal wild plants, nuts, and seeds.

For the people of the northwest coast, who resided in the present-day states of Washington, Oregon, and parts of Alaska, fishing became a major occupation. The migratory fish runs, such as the salmon spawning season, provided a livelihood that allowed for more established settlements. Hunting of big game, such as moose, elk, and deer, along with foraging of various local plants, supplemented food obtained by fishing.

The movement from large mobile resources to small fixed resources throughout North America led to fixed settlements and more sophisticated group structures. The appearance of mound building in the eastern part of North America as early as 2500 B.C.E. indicates that societies had become more stratified and that ritual specialists, probably priest-rulers, held the highest social positions. Artists also became prominent, as ritual objects for burials became highly prized. Merchants, who worked in concert with community elites, became increasingly important in the long-distance trade for luxury materials and items.

The successive cultures that prospered in Mesoamerica shared a unique set of cultural traits, including the use of a 260-day ritual calendar, a dependence on maize agriculture, the development of pictorial or hieroglyphic writing systems, and certain rituals such as the ball game. The first great agriculturally based society in Mesoamerica, the Olmec civilization, flourished in the Gulf Coast area of Mexico from around 1500 to 400 B.C.E. The success of maize-based farming led to more complex social structures. Archaeological evidence points to a cult centered on a ruler-shaman. The use of a 260-day ritual calendar and the development of hieroglyphic writing entailed the use of scribes, diviners, and specialized priests. Finely worked jade objects and ceramics found at various Olmec sites, along with the stone monumental sculptures, point to the presence of artistic specialists. Warrior imagery suggests the importance of this occupation,

and evidence of extensive trade routes indicates the existence of local and long-distance merchants.

Preclassic Period (ca. 1500 B.C.E.–ca. 150 C.E.) occupations centered on farming and craft specialization for the creation of ritual objects, monumental architecture, and historical stone monuments. In Maya culture, beginning about 600 B.C.E., the nobility were often scribes, since writing was an elite occupation. In addition to functioning as scribes, Maya elites were also artists. Rulers commissioned historical and mythological sculptural programs in the form of stelae (standing stone slabs). Specialized carvers, builders, and plaster workers were needed to create structures and their associated decoration. Like the Olmec, the Maya also employed skilled jade workers to create ritual objects as well as painters to produce elaborate murals and painted ceramics.

The rise of the first sites with monumental architectural, such as the platform mound of the Huaca de los Idolos (3000 B.C.E.), a late Preceramic Period (ca. 3000–ca. 1800 B.C.E.) site situated on the coast of present-day Peru, signals a shift from small, simple groups to more complex types of social organization. The construction of monumental architecture reflects a substantial investment of human labor along with the social structure and leadership to oversee such construction. The lack of sumptuous burials, however, also points to collective labor and communal societies. Coastal sites such as these depended on marine resources, such as fish and shellfish; agriculture; and long-distance trade. Dependence on marine resources also required textile workers to produce nets and fishing lines. This early specialization was connected to the development of a Peruvian textile tradition whose achievements would become almost unparalleled in human history.

The development of large agriculturally based societies did not begin until much later, in the Early Horizon Period (ca. 800–ca. 200 B.C.E.). The Chavín culture, the first of the great Andean civilizations, was established in the Peruvian highlands. Centered at the site of Chavín de Huántar, its distinctive style was disseminated throughout the Andean region. Chavín art drew upon various sacred sites for its religious iconography, which synthesized earlier traditions. Artistic specialists, including textile artists, gold workers (metallurgists), and ceramic artists, were employed to create Chavín's unique cultural program. Its ritual iconography indicates the importance of the shaman, an occupation that would continue to be prominent in Andean society. Burial caches provide evidence of distinct elite burials that indicate the stratification of society and give evidence of craft specialists to provide funerary offerings.

During the Early Intermediate Period (ca. 200 B.C.E.–ca. 500 C.E.) further specialization in ceramics, textiles, and gold work is apparent in the artistic production of such southern coastal cultures as Paracas (ca. 600–ca. 200 B.C.E.) and Nazca (ca. 1–ca. 700 C.E.). These coastal farmers and fishermen produced time-consuming works for burials. These exquisite funerary goods reflect their high value and an increased level of skill from fiber artists, potters, and metallurgists. The items were deposited in elaborate burials that included mummies wrapped in dozens of textiles and accompanied by numerous ceramics and gold objects. The variety of these burial caches reflects the social hierarchy of the Early Intermediate Period. The image of the shaman (a religious practitioner and healer), which becomes more prominent in Paracas and early Nazca art, probably reflects the high social status of this occupation.

► pandemics and epidemics

INTRODUCTION

Archaeologists and historians of medicine face difficulties in studying ancient pandemics and epidemics. (The words *pandemic* and *epidemic* differ in scope. An epidemic occurs when an illness occurs suddenly and spreads throughout a community, affecting many people; a pandemic spreads through a much wider geographical region.) The chief difficulty is that diseases that spread rapidly and strike down large numbers of people affect various tissues and organs and the blood, which rapidly decay and disappear, leaving behind little evidence of the diseases. Further, in prehistoric times no one produced written records of disease. Even in historical times contemporary written accounts were often inaccurate, for ancient observers may not have even known which disease was ravaging their communities.

Thus, historians often have to make inferences on the basis of whatever records exist, along with physical evidence, such as a large number of burials during a short period of time. But historians often disagree. For example, one of the most famous plagues in history, the plague of Athens, killed the Athenian statesman Pericles during the Peloponnesian Wars of the fifth century B.C.E. Some historians believe that the disease was bubonic plague, but others disagree. Similarly, in 700 B.C.E. the Assyrian army ended a siege of Jerusalem. Some historians believe that the cause was a cholera outbreak, but others think that the Assyrians were paid off. These examples show that studying ancient plagues can be fraught with uncertainty.

The diseases that afflicted ancient civilizations were often the same ones that afflicted communities in later eras. Small-

pox, malaria, typhoid, typhus, cholera, bubonic plague, and perhaps polio were common epidemic illnesses. Some were more obscure, such as schistosomiasis, a disease caused by blood parasites. In the absence of effective treatments, these diseases frequently were fatal. Worse, most were highly communicable, meaning that they could rapidly spread from one person to another, decimating entire communities. These diseases took hold principally because ancient people did not know that the source of disease was poor hygiene. Poor hygiene could be compounded during times of social upheaval and war, when people packed into towns and cities for protection. Similarly, famine could weaken a population, leaving people with little strength to survive a disease.

Ancient people were not always against epidemics. Although inoculations against disease are thought of as a relatively modern development, ancient peoples observed that they could inoculate themselves against some diseases, such as smallpox, by giving themselves a slight case of the disease. Evidence suggests that people fought smallpox in this way as early as the second or third century of the Common Era. Smallpox was such a scourge in ancient China that the Chinese had a goddess of smallpox.

Trade and travel increased the chances that epidemics would turn into pandemics. The fleas on rats, for example, carried bubonic plague, the so-called Black Death of medieval times. But evidence indicates that outbreaks of the disease occurred much earlier, before the start of the Common Era. Rats were common stowaways on ships that transported goods around the known world, carrying disease and death with them. After arriving at a port, the rats or an ill crewman could easily infect local people who had no immunity to the disease.

AFRICA

BY JULIAN M. MURCHISON

The long history of human evolution in Africa carries with it a long history of pathogens (disease-causing agents) that evolved alongside the human populations, especially in the tropical environments that characterize most of the continent. Humans evolved both biologically and culturally in response to the presence of different diseases, in ways that allowed resident populations to survive and even to flourish.

Many of the diseases that would later emerge as the cause of major epidemics and pandemics in Africa and the rest of the world seem to have existed and developed as endemic—that is, more or less permanently established in a place or among a population—during African prehistory. The presence of endemic diseases almost certainly helped determine where groups of people came to reside in different parts of ancient Africa and played an important role in shaping their lifestyles. Changes in culture and in the environment, especially associated with the domestication of plants and animals, probably contributed to the development of diseases and the likelihood that these diseases would cause debilitating epidemics.

As in other parts of the world, epidemics and pandemics in Africa have been associated most often with the relatively high population densities supported by agriculture and domesticated animals. In much of ancient Africa population densities were low and not conducive to the development of large-scale epidemics among humans. Nevertheless, historical and archaeological evidence indicates that in those areas of the continent where agriculture and the accompanying larger and denser human settlements arose in ancient times, epidemics began to occur among the residents. For instance, there is evidence that the kingdom of Axum (in the highlands of what is today Ethiopia), which had dense urban settlements two millennia ago, suffered sporadic but serious epidemics of various diseases, including smallpox.

Archaeologists and historians have identified several diseases that probably existed in Africa during the ancient period, including smallpox, trypanosomiasis (any of several blood-borne illnesses caused by infection with a certain microorganism), malaria, and schistosomiasis (a set of diseases caused by parasitic infection with a particular worm). The primary evidence for smallpox on the continent comes from Egypt, where mummified human remains have skin marks that may indicate smallpox infection. Some written records from Egypt also suggest possible smallpox outbreaks during ancient times. While these pieces of evidence are subject to interpretation and are not definitive, they are highly suggestive of smallpox's presence. If smallpox existed in Egypt, there was almost certainly enough human contact to diffuse the disease to other parts of the continent. During subsequent periods smallpox appears to have spread from Africa to neighboring areas of the world, such as the Arabian Peninsula. At the time of European contact residents of southern

Traditional healer in anti-smallpox costume, Nigeria, West Africa; smallpox epidemics arose sporadically in ancient times in Africa. (© Board of Regents of the University of Wisconsin System)

Africa utilized a form of traditional smallpox prevention involving inoculation with the smallpox virus. We do not know how long this prevention was practiced or its origins, but it is suggestive of the creative and effective ways that ancient Africans might have responded to endemic diseases and to the threat of epidemics.

One form of trypanosomiasis, often referred to as “sleeping sickness,” also seems to have a long history in Africa. The disease is transmitted by the tsetse fly, and a variety of environments on the African continent supported this fly. These environments changed as humans cleared land for agriculture and other endeavors. In humans sleeping sickness can be fatal, and a closely related form of the disease can be fatal for cattle and other animals. Therefore the presence or absence of the disease almost certainly helped determine the primary sources of food and other materials that residents of the continent could rely on in any given region. Today the herding of animals exists as a traditional lifestyle in those areas where the environment was not historically conducive to tsetse flies and trypanosomiasis.

Malaria has caused suffering and death on the African continent for a long time. Transmitted by a certain type of mosquito, malaria thrives in locations where these mosquitoes breed in shallow pools of standing water and is frequently associated with human populations that are engaged in agriculture. Malaria may very well have originated in Africa and spread to other places on the globe. It is basically a chronic, endemic disease, but it can reach epidemic proportions when environmental conditions produce large numbers of the disease-bearing mosquitoes. Written references from the Classical Period provide evidence for malaria's long history in Africa, as does modern biological research. Scientists have found that individuals who can trace their ancestry back to western Africa are more likely to have the sickle-cell trait, which carries inherited resistance to the malaria parasite. This finding suggests that over the long course of human history environmental conditions in this region helped to select for these connected traits. This sort of selection generally occurs over the course of many generations.

Like malaria, schistosomiasis, a disease caused by a parasite that lives in water, probably also has a long history on the African continent. The disease may originally have occurred in tropical forests but spread with the advent of irrigation for agricultural purposes. Thus, human cultural adaptations probably contributed to its dispersal. As with smallpox, evidence for schistosomiasis in ancient Africa comes primarily from mummified human remains that show strong indications of infection with the disease.

On the whole, large-scale epidemics and pandemics appear to have been relatively rare in ancient Africa, mainly because the demographic characteristics did not lend themselves to these sorts of outbreaks. However, there is good evidence for a number of endemic diseases with the potential for epidemic or pandemic spread under the right conditions. As domestication of plants and animals became increasingly important, the circumstances for epidemic-type outbreaks grew more common. Future archaeological research and other sources may help us to understand better the specific ways in which these diseases spread and affected the lives of people in different parts of the continent.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

Until the 19th century, modern knowledge of ancient Egyptian medicine depended mainly on the reports of the Greek authors Herodotus (ca. 484–ca. 425 B.C.E.), Strabo (ca. 64 B.C.E.–after 23 C.E.), Diodorus Siculus (first century B.C.E.), and Clement of Alexandria (ca. 150–ca. 211 C.E.). With the decipherment of hieroglyphs, Egyptian medical documents could be translated from the second half of the nineteenth century onward. Such documents were written on papyri in hieratic (cursive) hieroglyphs, and they are concerned mainly with the identification of diseases and their treatments, which often were a combination of rational and “irrational” (magi-

cal) methods. The medical papyri tell us nothing of the prevalence or the epidemiology of the diseases.

Other sources for the study of pandemics and epidemics in pharaonic times are artistic portrayals and scientific research on mummies and human remains. The process of mummification, dry weather conditions, and the location of tombs and burial grounds favored excellent preservation of human remains. Modern scientific paleopathologic research, including the use of such modern techniques as fiber-optic endoscopy, electron microscopy, and the recovery and replication of DNA, can shed light on various pandemics and epidemic diseases. Moreover, artistic representation, such as the famous statues and other images of the king Akhenaton (r. ca. 1353–ca. 1335 B.C.E.) and his family from the Eighteenth Dynasty offers clues to the causes and results of certain diseases and body deformities.

Most common epidemic diseases in ancient Egypt were caused by parasitic and bacterial or viral infections. Schistosomiasis was one such parasitic disease. According to the World Health Organization, it affects more than 12 percent of the Egyptian population today; it is acquired by infection with a certain species of worm. It can result in fever, fatigue, serious anemia, and even liver damage. Schistosomiasis has been detected in bodily remains from predynastic times up to the Roman period, though it cannot be recognized in the medical terminology of the relevant papyri.

By contrast, bacterial infections, such as leprosy, cannot be detected on mummies or skeletal remains. A few clues in medical papyri or tomb illustrations shed light on chronic progressive infections. The earliest case of nodular leprosy comes from a Christian burial in Nubia, south of Egypt in modern Ethiopia, of the sixth century C.E. The absence of material evidence on earlier mummies might have been the result of refusal to mummify victims of a disease if it was known to be infectious and required isolation from the community during life.

Evidence for leprosy in the medical papyri is tenuous because of the difficult terminology used. One helpful papyrus is the Ebers papyrus, which is said to have been found between the legs of a mummy in Thebes on the west bank of the Nile, opposite Luxor, in southern Egypt. Two cases (numbers 874 and 877) from the Ebers papyrus refer to the tumor of a certain Khonsu, which has been translated as tubercular (or nodular) leprosy: “Instructions for a tumour of Khonsu. If you examine a large tumour of Khonsu in any part of a man and it is terrible and it has made many swellings. Something has appeared in it like that in which there is air. . . . Then you shall say concerning it: it is swelling of Khonsu. You should not do anything against it.” This passage, however, could equally well relate to cancer or bubonic plague. Case 813 of the Ebers papyrus refers to an “eating” of the uterus, which might also be construed as cancer. Still, both cancer and bubonic plague are extremely rare in both mummies and skeletons of pharaonic times. In part, this may be due to relatively early deaths, but an additional factor might be low levels of carcinogens.

Another epidemic disease, malaria, must have existed in ancient Egypt, when conditions for the mosquito carrier were probably more favorable than today. No traces on mummies and no mention of relevant symptoms (such as the characteristic recurrent fever at three- to four-day intervals) in the medical papyri occur. The application of a particular test on embalmed mummies from different periods of pharaonic history has suggested that certain afflictions might have been caused by malaria.

Similarly, osteomyelitis and poliomyelitis, two well-known infections, are rare in skeletal remains. On a funerary stela from the Eighteenth or Nineteenth Dynasty (ca. 1550–ca. 1196 B.C.E.), the owner is depicted with a grossly wasted and shortened leg and deformity of the foot. He is accompanied by his wife and son. Some favor the view that this is a case of poliomyelitis contracted in childhood. It is interesting that the deformed man appears to be holding a stick, which could be used as a crutch, and that his disability had not prevented his attaining high office, marrying, and having at least one child.

Even for seriously affected patients medical treatment in an isolated environment, such as a sanatorium or healers' camp, was not done only for rational reasons. The sanatorium was a precinct where patients could be totally or partially immersed in healing holy water or practice incubation (temple sleep) in the hope of having a dream in which a deity would indicate a cure. Such practices are known mainly from the middle of the first millennium B.C.E. onward, and the only archaeologically attested example is within the temple enclosure of the Great Temple of Hathor at Dendera, a sacred site in southern Egypt. The structural remains show a number of cells around a sunken corridor. These cells are presumed to have been for incubation, and the corridor leads to a series of basins that were filled with water from the sacred lake nearby.

Healing statues with inscribed magical and medical incantations were used as mediums for the healing process. The sacred water was poured over the statue and collected in a basin, which then was used for the immersion of parts or all of the body. The influence of the inscriptions would be absorbed into the water and their effects obtained by drinking the water. Magic played a very important role in treatment of the sick. Malign influences were thought to be the cause of many diseases, and it was common to invoke the help of a benign deity to counteract the malign influence. Sometimes a spell was recited in isolation and at other times in conjunction with conventional medical therapy.

THE MIDDLE EAST

BY MARKHAM J. GELLER

Epidemics are not well documented in the ancient Near East, nor do we have any text even remotely comparable to the Greek historian Thucydides' detailed firsthand account of the great plague of Athens in 430 B.C.E. Hardly any of the scat-

tered references that exist to ancient Near Eastern plagues and epidemics can be related to any dated historical event; most merely express a general fear of epidemics or make ominous predictions of plagues. Literary accounts dealing with plague, such as the biblical 10 plagues in Egypt, are not supported by historical data that can substantiate when, or even whether, such plagues actually occurred.

The strongest evidence for epidemics in ancient Mesopotamia comes from the epistolary archives of the city of Mari on the Euphrates. Dating from about 1700 B.C.E., these texts refer to epidemics affecting various towns and cities in the vicinity. For example, they tell of a serious plague in the city of Terqa, though no remedy (such as quarantine) is mentioned. On a personal level one letter records that every member of the Bahlu-Gawum family or clan had died from a plague. We can safely suppose that plagues were considered to be manifestations of divine anger, since an epidemic is referred to as *ukulti ili*, "the devouring of a god." The only specific symptom associated with plague is fever, but we can only assume that these reports refer to a contagious pestilence. Some reports of "plague" refer to animals as well as humans being affected. Two letters from Mari refer to attacks by rabid dogs.

Terra-cotta figure of an animal thought to be a dog (ca. 700–500 B.C.E.), from Mesopotamia; figures of dogs were considered magically protective, especially against rabies, which was becoming widespread in Mesopotamia at this time. (© The Trustees of the British Museum)

The next epistolary archive containing references to epidemics is from Amarna in Egypt, though the letters were sent to Egypt from Mesopotamia and the Levant and report on events in those regions. One writer asks whether a disease affecting donkeys, which prevents them from walking, also affects people. Armies and cities were often attacked by plague during times of war, as exemplified by an Amarna letter sent from Megiddo in Palestine referring to a plague in the city as a result of its being under siege.

In later periods such contemporary reports of epidemics are rare. One Babylonian chronicle refers to an epidemic in Assyria during the reign of Merodach-baladan II (ca. 715 B.C.E.), but otherwise historical sources from the first millennium B.C.E. reveal very little about epidemics. One possible reason for this lack of information is that there was no ancient bureaucratic structure dedicated to dealing with public health, and no officials were permanently assigned to this task. Illness was treated on an ad hoc basis whenever it occurred.

The usual word for plague in the Akkadian language widely used in ancient Mesopotamia, *mutanu*, which literally means “deaths,” occurs mainly in contexts of omens and divination. Plague was often predicted based on examinations of the livers of sacrificial sheep or on omens drawn from the movements of stars and planets, but such reports provide few clues to the nature of epidemics or pandemics in the region. The information is usually general, such as “There will be constant epidemics in the land” or “An epidemic will occur in a city” or “There will be an epidemic every day.”

One clue to the nature of such epidemics, however, occurs in lists mentioning specific diseases that will affect the land following particular unfavorable omens. Babylonian planetary omens taken from sightings of Jupiter, for instance, predict plague in the land but also foretell that a type of joint disease, known as *rapadu*, will “seize” the land. Although we cannot diagnose this specific disease with any accuracy, the omen occurs with other health-related predictions, such as that a cattle epidemic will take place or that “pregnant women will die with the child in their womb.” Such phenomena, of course, were probably unrelated to each other, but these omens were intended to refer to widespread conditions affecting the entire country, not to individual cases of affliction. Another unfavorable planetary omen, associated with sightings of Venus, warns that dogs will become rabid, biting men, cattle, sheep, and donkeys, and that whatever is bitten will not recover. It is likely that many diseases besides rabies were thought to be caused by dog bites. As we learn more about the nature of the diseases mentioned in omens such as these, we will have a better chance of identifying diseases that were considered epidemics as well as illnesses attacking individual patients.

Diseases and pestilence were often considered to be the work of Nergal, the Babylonian god of pestilence and cattle disease, who was associated with the planet Mars. Diseases were considered to originate from the “evil dew of the gods” or were associated with divine spittle or even divine semen

raining down from heaven. These are all religious metaphors for the cosmic origins of disease, which was thought to have been created when the rest of creation took place; disease was often regarded as the handiwork of demons emanating from the netherworld. The technical literature of diagnosis and medicine often refers to diseases as the “hand of a god,” with the god or demon mentioned by name, but many of these labels eventually came to serve as proper names of particular diseases, without much theological importance.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Much is mysterious about the nature and frequency of epidemics in ancient Asia and the Pacific. In general, anthropologists believe that epidemics were rare or nonexistent among many peoples of the Pacific before the coming of Europeans, whose diseases killed numerous Australians and Pacific islanders. During ancient times there were migrations from the Asian mainland to Japan, the Philippines, New Guinea, and some of the islands of Indonesia, and the migrants brought their diseases—and their developed immunities—with them, which may explain why peoples of these places did not suffer from diseases later imported from Europe as severely as others did. The most prevalent ancient scourge among these islands was leprosy. Another that was common among the Indonesian islands was malaria.

Malaria, caused by a single-celled parasitic organism transmitted to humans by one particular type of mosquito, occurred throughout southern Asia. The disease—but not its cause—was well known to ancient Asian writers. Malaria was responsible for much suffering and countless deaths among both dense and sparse populations wherever pools of quiet water abounded during warm weather—conditions in which the disease-bearing mosquitoes bred prolifically. Ancient Indian physicians, in particular, tried to find treatments for malaria but in the end could do little more than attempt to reduce the fever it entailed.

In China an epidemic was taken as a sign that a ruler had lost the mandate of heaven and could be lawfully deposed. Thus it is not surprising that government officials were reluctant to record epidemics. Surviving Chinese medical writings from the Han Dynasty (202 B.C.E.–220 C.E.) indicate that epidemics occurred in various parts of the empire so frequently that they could be discussed in broad general statements rather than in descriptions of specific outbreaks.

Influenza was a common disease among pigs and ducks in Asia, and it mutated frequently into forms that could be transmitted to human beings. Archaeologists suspect that influenza began in China because early in Chinese culture pigs became an important part of everyday life. Although a new strain of influenza might begin in a rural area, it was easily carried by pigs or infected humans into towns and cities, where it took on epidemic proportions. Like modern strains of influenza, those of ancient China probably varied in severity,

but the worst strains killed thousands. Chinese physicians apparently deduced that influenza could be transmitted through the air, though this knowledge had little practical use in ancient times. Along with magic spells and potions, however, doctors devised treatments that included sensible measures, such as having patients rest and drink water.

The smallpox virus developed somewhere in Asia. Related to the cowpox virus, it seems to be a mutation of cowpox that became capable of infecting human beings. Thus some archaeologists suspect that it developed either in central Asia among nomadic cattle herders or in India, where cattle often roamed freely among people. Traders along the ancient land route known as the Silk Road may have carried smallpox eastward. In 162 C.E. a disease that was probably smallpox killed over 30 percent of the population of northwestern China.

During epidemics the Chinese often left people unburied, fearing that handling the dead could transmit the disease. Sometimes government authorities ordered the burying of the dead, but some physicians argued that burning the corpses would destroy the disease that killed them, preventing its transmission. During severe epidemics bodies lay where they had died, in fields and on roads. In 162 C.E. they would have lain everywhere in the northwest China, unmistakable evidence that the emperor had lost his mandate from heaven.

A faith healer named Zhang Jiao formed a Daoist sect popularly known as the Yellow Turbans because of their headdress. In 162 C.E. Zhang advocated the overthrow of the imperial government. By 184 C.E., when the Yellow River flooded and killed many people, followed by deaths from epidemic disease, the Yellow Turbans had followers in most of China, and they rebelled, seizing control of much of northern and eastern China. Zhang and other leaders were killed, and their armies were eventually defeated, but the Han government never fully recovered; the revolt led to the political chaos that eventually ended the Han Dynasty in 220 C.E.

In India physicians tried to learn when epidemics were most likely to occur and searched for ways to prevent them. For smallpox Indians took dried scabs of the disease from people who were recovering from it and scraped them into the skins of uninfected people—an early effort at inoculation. About 1 percent of inoculated people caught the disease, but since smallpox could virtually wipe out entire towns and rural areas, the rate of infection from inoculations seemed small.

Cholera, a deadly water-borne bacterial disease, was a common affliction in ancient India. Cities were customarily surrounded by moats into which human waste was dumped. City dwellers took their drinking water and cooking water from these moats as well as from nearby rivers or streams that were often quite polluted. Although Indian physicians believed that cholera was caused by pollution, it was apparently beyond their abilities to persuade people to find their water elsewhere, stop dumping human waste into the water supply, or discontinue building moats to help protect their cities from attack.

Annual flooding caused by monsoons was known to precede epidemics of cholera. Even so, the month of harvests, Margali, was considered to be the month that ruled epidemics. Shiva was the god of the month of Margali, and Indians prayed and made offerings to him in the hope that he would prevent epidemics. When epidemics occurred, Indians usually recited magical incantations and used charms to aid the sick and asked magicians to cast spells and mix magical potions for the afflicted.

Indians, however, had also long exhibited a practical streak in their treatment of epidemics, with medicine becoming an important profession before 500 B.C.E. There were several classifications of physicians. Two of them, general practitioners and a group that would in modern times be described as toxicologists (doctors who study and treat the effects of poisons) and epidemiologists (doctors who study the spread and control of epidemic diseases), often dealt with epidemics. Some epidemic diseases, such as tuberculosis, were considered incurable, and the physicians tried to ease patients' suffering with mixtures that included opiates similar to morphine. Cholera was classified as a "fever" disease, and the "epidemiologists" linked it to pollution of air and water. They treated it with opiates to ease the terrible pain but also with the root of a plant known today as serpentwood or Indian snakeroot. Nowadays the root is used to treat high blood pressure, but it also reduces fever; ancient Indian physicians used it to lower the fever of cholera. It was hardly a perfect treatment, but it gave patients a chance to survive the worst stages of the disease.

EUROPE

BY CARYN E. NEUMANN

Infectious diseases devastated human populations in ancient Europe, especially in later times as people began to cluster together in settlements and then towns. Epidemics and pandemics of such diseases claimed more lives than all wars and natural disasters taken together. Infectious diseases have probably been the primary agent of natural selection over the past centuries, eliminating human hosts who were more susceptible to them and sparing those who were more resistant.

Prehistoric Europeans who lived in hunter-gatherer societies were probably relatively free from the effects of epidemic diseases. The small size of these groups, their remoteness from one another, and their frequent movement would have made it difficult for airborne or crowd diseases, such as tuberculosis, influenza, and diphtheria, to become established. Diseases of the digestive tract may not have spread as rapidly as in more concentrated populations either, even though sanitation was not particularly good. When an infectious disease struck, it probably worked its way through the population and then vanished. Certain diseases, however, can flourish and be transmitted readily even among small and scattered hunter-gatherer populations. Measles and smallpox, for example, could occur in lethal epidemic outbreaks. In general, however, people in prehistoric Europe were more likely to die

of degenerative conditions or to be killed in accidents or violence than to succumb to epidemic diseases.

When humans embraced agriculture and herding, they also embraced cattle, horses, sheep, and other domesticated or semidomesticated animals that were chronic bearers of infection. In the wild, herd animals constituted large, concentrated populations of a single species—a condition that allowed numerous bacterial and viral infections to become endemic. (An endemic disease is one that is more or less permanently established in a population or an environment.) The chain of infection would never have stopped. Over time these animal populations, though they still carried the pathogens (disease-causing agents), had developed resistance to them. Thus, even though viral and bacterial infections were probably rife among wild herds of cattle, sheep, and horses, many of them provoked only mild symptoms or none at all.

The domestication of herd animals brought them and their endemic infections into close, regular contact with human populations. Many of the infectious agents, of course, did not transfer to humans, and some that did transfer caused only minor effects. Others, however, became virulent. One such disease, brucellosis (also known as contagious abortion), attacks cattle and swine. In humans, it is known as undulant fever. Brucellosis is commonly transmitted by direct contact with infected animals or with an environment that has been contaminated with discharges from infected animals. The initial symptoms in humans are fatigue and headaches, followed by high fever, chills, drenching sweats, joint pains, backache, and loss of weight and appetite.

Europeans initially lacked any acquired immunities to the new invaders and, as a result, suffered a high number of deaths from these animal-to-human diseases until human populations developed immunities. Early farming communities were also sedentary, meaning that the inhabitants lived in one place year-round, where they were in close contact with one another. As a result, a communicable disease was likely to spread quickly and with devastating effect—an effect that became even more pronounced as more and more people lived in villages and towns.

Europeans who came into close contact with the Roman Empire and large Mediterranean populations suffered exposure to parasitic disease. Until medieval times the Germanic and Slavic peoples of Europe did not suffer from these diseases. Leprosy, also known as Hansen's disease, first appeared in ancient Egypt, Africa, China, and India. It traveled to Greece from Egypt and spread throughout Europe through military movements. An infectious disease caused by a bacterium, leprosy spread easily through direct contact, by inhalation of sputum or nasal discharges, or by indirect contact with recently contaminated objects. All victims have nerve damage, and these injuries are responsible for the severe deformities that can result from leprosy.

Malaria, a disease prevalent in tropical and subtropical climates and transmitted by a particular species of mosquito, has long been one of the most widely distributed and most

severe illnesses to strike humans. The pressure of malaria on natural selection has made a much greater impact than any other pathogen on recent human evolution. Natural selection has favored the spread in many human populations of hundreds of genetic mutations that appear to give varying degrees of resistance to malaria. Ancient Europeans who lived in the warm, swampy areas that malaria-bearing mosquitoes prefer developed these mutations. They also adopted certain ways of living that helped them avoid these mosquitoes. For example, the combination of small settlements and movement to high elevations in summer served to reduce exposure to malaria. Even diet played a role. For instance, some European peoples regularly ate fava beans, which have antimalarial effects. These lifestyle adaptations were largely coincidental, since the cause of malaria was unknown until modern times, but they were nevertheless useful.

One form of response to epidemic diseases in late ancient times may have helped Christianity become established in Europe. When a serious infectious disease strikes a population, normal services often break down; some people are too sick to function, while others are too frightened of becoming infected to perform their usual tasks. In an epidemic, elementary nursing, such as cleaning and the provision of water and food, can usually greatly reduce mortality rates. Pagans had no religious duty to provide nursing to the sick. In contrast, Christians considered nursing to be a religious obligation. Moreover, those who survived with the help of such nursing were likely to feel gratitude and a sense of solidarity with those who had saved their lives. The effect of a disastrous epidemic in Europe after the advent of Christianity, therefore, was to strengthen Christian churches at a time when other institutions were being discredited. Another advantage that Christians enjoyed was that the teachings of their faith made life meaningful even amid sudden and surprising death. Moreover, even the survivors of a deadly epidemic could find comfort in the notion that their deceased loved ones were in heaven. Pagans did not receive the same sense of consolation from an afterlife. As a result, pagan survivors may have struggled with depression as an aftereffect of epidemic disease. Such emotional upset would have complicated recovery for individuals and communities.

GREECE

BY ALAIN TOUWAIDE

The concepts of pandemics (disease affecting an entire area or group of persons) and epidemics (disease affecting at the same time a large number of persons and spreading from one person to another, as a disease not normally prevalent among this group) were not theoretically formulated in Greece before the fifth century B.C.E. and the development of medical thinking, mainly (but not only) among Hippocratic physicians. Nevertheless, the existence of diseases affecting a large group of individuals was recognized as early as the development of Greek mythical and epic literature. In the mythical cycle of

Greek marble block from the frieze of the Temple of Apollo Epikourio, meaning “Apollo the Helper” (420–400 B.C.E.), from Bassae, Arcadia; the name Helper was given to Apollo by citizens of nearby Phigaleia, as thanks for their deliverance from the plague. (© The Trustees of the British Museum)

Thebes (in Boeotia, central Greece), a pestilence affects the city at the beginning of the play *Oedipus tyrannos* (Oedipus the King) by Sophocles. In the epic literature a similar affliction decimates the Greek troops besieging Troy at the beginning of the *Iliad*. The term used for such disease is *loimos*, usually improperly translated as “plague.” The cause was seen to be of a religious nature: An individual transgresses a law of the group. As a punishment, a disease affecting the group is sent by a god. Significantly, in the *Iliad* this disease takes the form of arrows falling on the warriors and killing them. The cure involves offering sacrifices to the god who provoked the disease (including a scapegoat) and compensating for the transgression by reestablishing the natural order of the group, which has been broken.

In historical times the existence of diseases affecting a large number of people is affirmed in the didactic poem *Works and Days* by Hesiod (fl. ca. 800 B.C.E.). Such disease is sent by a god (Zeus), though without reference to a transgression. It is rather the result of the human condition, submitted to work, pain, and suffering. Three major outbreaks of epidemic diseases were described in the sixth and fifth centuries B.C.E. The first is mentioned in the pseudo-Hippocratic *Embassy*. The text reveals that during the First Sacred War (ca. 590 B.C.E.), troops besieging the sacred site of Delphi suffer a *loimos*. For the first time in preserved literature a physician is called. However, he does not use any medicine: The god involved in the outbreak of the disease stops it.

The second epidemic is known through the pseudo-Hippocratic *Letters*. The troops of the Persian king Artaxerxes I (r. 465–425 B.C.E.) are suffering such a disease. Although the letter is of doubtful authenticity, it contains an

interesting statement on the origin and treatment of epidemics: Such diseases are not considered to be natural and, contrary to natural disease that nature cures, need to be treated by the art of physicians. For this reason Artaxerxes calls Hippocrates (ca. 460–ca. 377 B.C.E.).

The third major outbreak of an epidemic disease is the famous so-called plague of Athens (430 B.C.E.) described by the historian Thucydides (d. ca. 401 B.C.E.). Again, such disease affected a population during a war (the Peloponnesian War, 431–404 B.C.E.). It appeared among the besieged population of Athens. According to Thucydides’ report, the disease came from Ethiopia, passed through Libya and Egypt, and from there spread to Persia. It suddenly appeared in Athens, through the harbor of Piraeus. In the city the death toll was higher than anywhere else. Physicians were of no help, as they did not know the nature of the disease and died themselves because they were in close contact with sick patients. No therapeutic method was efficacious. The disease stopped spontaneously. The nature of the disease has been disputed for a long time. (Smallpox is among the hypotheses.) Recent archaeological and laboratory research has led to the conclusion that it might have been typhoid fever. In the late fifth century and early fourth century B.C.E. another epidemic disease was the so-called cough of Perinth described in the Hippocratic work *Epidemics 6*. It affected the city of Perinthus, on the shore of the Propontis (Sea of Marmara) sometime around 400 B.C.E. and probably was several different medical conditions, the most important of which has since been diagnosed as diphtheria.

At the time of these major outbreaks of epidemic diseases the concept of general disease was gradually formulated among Hippocratic physicians. A distinction was made be-

tween individual and general disease, including a notion of cause and, as a consequence, of treatment. These physicians concluded that individual diseases, affecting a single patient, result from the alimentary habits of the patient (even though several individuals using the same diet can suffer of the same disease). Such diseases could be cured by changing the diet and compensating for the insufficiencies or rectifying the improper diet. General diseases, affecting an entire group, are provoked, it was thought, by a corruption of the air (the so-called miasmas, that is, impurities floating in the air and resulting from any kind of pollution). They could be cured by applying a proper pharmaceutical therapy that rectified the damages caused by the disease.

There was no notion of a treatment that could eliminate the cause of the disease. The concept of the impact of the environment on the health conditions of a population is further refined in the famous Hippocratic treatise *Airs, Waters, Places*, traditionally dated to the second half of the fifth century B.C.E. and attributed to a physician from the school of Kos. A distinction was made between the constant conditions of a place (provoking the endemic diseases, that is, those peculiar to a particular population or place) and the occasional conditions, independent from the place itself, but coming from external factors and causing a general disease. The word *epidēmios* was applied to diseases affecting a large number of patients, without implying any notion of contagion. The word constitutes the title of seven books in the so-called Hippocratic collection describing the diseases present in a specific place at a moment of the year and affecting a certain number of patients.

ROME

BY ALAIN TOUWAIDE

Historical sources, including those of the Roman historian Livy (64 or 57 B.C.E.–12 or 17 C.E.), the Greek philosopher Dionysius of Halicarnassus (born ca. 60 B.C.E.), and the Greek historian Polybius (ca. 200–ca. 118 B.C.E.), report outbreaks of epidemic diseases in the Roman world shortly after the foundation of the Roman Republic (509 B.C.E.) at a higher frequency than those in the Greek world. This apparently higher frequency might be the result of better record keeping; Roman historians relied on the tradition of *Annales*, which recorded the notable events of each year. According to the descriptions by the historians who recorded the *Annales*, epidemics often were linked with military expeditions, wars, food shortages, famines, and natural calamities affecting crops. In some cases epidemic diseases also were described as coming from cattle. While some of these epidemics arose from local conditions, others were introduced into the Roman world from the west or the south. The Athenian epidemic in 430 B.C.E. might have been carried westward; Rome was struck in 428 B.C.E., according to Livy. In Sicily epidemics were said to have been introduced repeatedly by troops from the Athenian expedition of 413 B.C.E. through the outbreak in 212 B.C.E. among Roman and Carthaginian troops

The best-known epidemic in the Roman world was the so-called Antonine plague. This was a series of epidemics, including two major outbreaks, in 165 C.E. and in 180 C.E., respectively, that struck the Roman population under the Antonine emperors (138–192 C.E.). The disease was introduced into the Roman world from Mesopotamia by the troops from the expedition against the Parthians, which began in 162 C.E. and was led by Lucius Aurelius Verus (r. 161–169 C.E.). In 165 C.E. the Roman troops were affected by the disease and re-treated. They spread the disease westward to Italy and Rome. The epidemic progressed to Gaul and into Germany as far as the Rhine. The emperors Lucius Verus and Marcus Aurelius (r. 161–180 C.E.) died of the epidemic. The Greek physician Galen (129–ca. 199 C.E.), who stayed in Rome at that time, escaped from the city and did not return until 169, when he was summoned by the emperor. The death toll is thought to have been extremely high throughout the empire. Thrace, for example, supposedly lost half of its population. Such a mortality rate has been attributed to the high level of urbanization of the Roman Empire, as opposed to the fragmentation of the Greek world in smaller cities.

The nature of epidemic diseases in Rome has been addressed frequently in medical and historical literature. Because the epidemics of 428 B.C.E. in Rome supposedly came from the East, and since the so-called plague of Athens of 430 B.C.E. has been identified as smallpox, one conclusion is that the Roman epidemic represented the introduction of smallpox to the West. A similar hypothesis has been made for the Antonine plague. According to this view, this was the second attack of smallpox in the West, which proceeded according to a pattern of diffusion east to west from Mesopotamia. Another identification of the plague of Athens as typhoid fever, however, contradicts the traditional history of the diffusion of smallpox.

The categorization of diseases according to their geographical diffusion, chronological frequency, and statistical importance was initiated by Galen. He developed a threefold categorization: First, sporadic diseases are those of a single individual at a certain moment. Second, epidemic diseases affect a high number of individuals at the same time in a single place. Third, endemic diseases are those that are perpetually common in a single place. A few more general notions, probably of popular wisdom, can be found in the *Historia naturalis* (Natural History), by the Roman scholar Pliny (23–79 C.E.). They include the observation that diseases followed certain patterns; for example, epidemics moved from south to north and almost never in the opposite direction, they did not start during the winter, and they never lasted more than three months.

As in the Greek world, the cause of epidemic disease was considered to be miasmas, or particles of a corrupted nature floating in the air that people inhaled. Therapeutic methods among the Romans reproduced those of Greek medicine but were augmented with a new pharmaceutical strategy: compound medicines associating many ingredients. This strategy,

which supposedly started with the experiments of the king of Pontus, Mithridates VI Eupator (r. 120–63 B.C.E.), took root in Rome during the first century C.E., mainly with Andromachos, the chief physician of the emperor Nero (r. 54–68 C.E.).

The most significant medicine resulting from this strategy was the so-called theriac. First created as a medicine against venoms and poisons, it also was used as a broad-spectrum medicine thanks to its wide range of ingredients (among them, opium and the flesh of the viper). Many of those ingredients were credited with the properties of producing heat. The preparation resulting from their mixing purportedly had the property of burning the matter that provoked the disease (whatever the nature of the disease or the matter). Thanks to this supposed property, the use of theriac was expanded to prevention. In the case of epidemics the compound was taken to protect against contagion. The principle underlying such use led to other preventive measures, such as spreading perfumed plants and substances credited with a warming property to burn the miasmas believed to be responsible for epidemic diseases and their diffusion.

THE AMERICAS

BY CARYN E. NEUMANN

Infectious disease is one of the greatest killers in human history. But while ancient civilizations in the Americas created works that paid tribute to other aspects of life, few reports of disease have survived the passage of the centuries. Meanwhile, much of the modern literature about the Americas depicts the pre-European contact world as a disease-free paradise. It was not. Pandemic disease killed ancient Americans as it killed other ancient people.

Ancient hunter-gatherers in the Americas were relatively free from the acute, epidemic infectious diseases that later took a toll on more advanced agrarian societies. Many acute infectious diseases require large numbers of susceptible individuals to support their chains of transmission, which are characterized by brief and rapid stages of infection. In ancient food-foraging groups, populations of no more than 200 to 300 persons would not have been large enough to sustain such a chain of transmission. If introduced, these acute infections would have run their courses and then died out. From the perspective of natural selection, pathogens (disease-causing agents) that live inside the body of a host for an extended period of time (such as those that cause typhoid and amoebic dysentery) would have been favored. Infections (like measles) that spread rapidly and immunize a majority of the population in one epidemic would have been rare or absent. As populations became more sedentary, they were felled by devastating epidemics of smallpox and measles.

It is not clear whether malaria, another of the great ancient killers, was present in the New World. Malaria historically has been one of the greatest plagues of human societies. When it does not kill, it leaves a victim weakened. Malaria is found in the present-day Americas, but it is still uncertain

whether the disease existed in the Americas before the arrival of Columbus. No Native American population of the present day has elevated frequencies of any of the genetic mutations that confer degrees of resistance to malaria in so many Old World populations.

Other plagues can be clearly identified. Paleopathologists, scientists who study disease in prehistoric populations, have filled in gaps in the knowledge of the history of pandemic disease in the Americas by using various types of evidence to describe disease patterns of ancient populations. By looking at pottery, these scientists have determined that epidemic leishmaniasis (a skin disorder caused by a protozoan carried by sand flies) was present in ancient Latin America. Pottery from Peru and Ecuador, dating to about 100 B.C.E., indicates the presence of facial ulceration, scarring, and malformation of the mucous membranes among the pre-Inca. Such signs are an indication of epidemic leishmaniasis. In more severe forms the disease strikes the liver, lymphatic system, and spleen, causing lesions, anemia, and death.

Much of the evidence for the presence of disease in the New World is based on data obtained from research on archaeological human skeletal remains. One of the limitations in studying infectious disease in such samples is that acute diseases are rarely expressed in the skeleton. Almost all infectious diseases are chronic diseases, meaning that most of the great epidemics which have punctuated human history will leave, at best, nonspecific and indirect evidence in a skeletal sample. The infectious diseases that do affect the skeleton are those caused primarily by bacteria, but even these infectious organisms rarely affect the skeleton unless there is long-term survival with the disease.

Paleopathologists have examined skeletal evidence to conclude that tuberculosis, venereal syphilis, yaws (a bacterial skin infection marked by red skin eruptions and joint pain), and bejel (endemic syphilis) were present in the ancient Americas. Tuberculosis has been identified in several prehistoric Andean populations. The earliest evidence for tuberculosis in the Americas comes from Chile and dates to about 290 B.C.E. It has not been found in ancient peoples of North America. Tuberculosis is a chronic disease caused by the microorganism *Mycobacterium tuberculosis*. In cases from defined geographical areas, most people in each generation are initially infected in early childhood, typically from inhaling pathogen-laden droplets expelled by sick individuals. If general levels of health are good, more than half of those infected will never show any clinical symptoms of disease. Individuals with weakened immune systems will become visibly ill and may die. If death does not occur, the bacteria may become walled up within fibrous capsules in the body and can remain viable for decades. Severe stress in later life may prompt a recurrence of tuberculosis.

Yaws and bejel are usually acquired as childhood diseases, with transmission typically occurring in play groups. Syphilis is acquired from the mother or through sexual transmission, with an onset that usually begins after childhood.

Yaws leaves lesions on the skin and bone. Bejel affects the skin, bone, and cardiovascular system. Venereal syphilis involves skin, bone, the cardiovascular system, and the nervous system. It may severely dampen human fertility through miscarriages and stillbirths of infected fetuses. Congenital cases of yaws and nonvenereal syphilis are rare. Bones lying close underneath the skin may have lesions through spread of infection from adjacent skin lesions. Joint destruction is seen in yaws but not in syphilis. Paleopathologists have concluded that venereal disease originated in the Americas, because skeletal evidence of syphilis in the New World predates the same sort of evidence in Europe.

► religion and cosmology

INTRODUCTION

When religion began is not known, but archaeologists, paleontologists, and historians often speculate about it. Some point to early graves containing goods such as pots and jewelry as signs of a belief in an afterlife and therefore signs of religion. A significant problem with this idea is that some ancient peoples believed in gods and the supernatural but did not believe that human beings had any life after death. For them, a human being had only one life, and once it was ended the human being was gone forever.

Other researchers point to artworks as signs of religious belief. All over the world ancient peoples painted on and carved into large rocks. Some sculpted images of animals and people. For some people works of art were magical; when the works were created, reality itself changed to conform to the painting or carving. One of the problems the earliest rock art and carvings present modern observers is that they can indicate that religious belief existed but cannot show when that belief began. Early religious objects may have been made of perishable substances such as wood and leather, and early people may not have chosen to express their religious beliefs in art. For many religions the substance of religious belief and practice was not in scripture, in art, or in altars but was in everyday behavior, passed on by spoken word and examples of behavior from one generation to the next.

Some anthropologists see religion as a part of culture that developed through stages. For these researchers religious ideas would have begun in Africa before modern humans left Africa to colonize the world. Their religion would have been

a form of animism, a belief that almost everything had spiritual significance, including bodies of water, large geological formations, and any living thing.

Religions have been an expression of a fundamental aspect of being human, and it has long been thought that religion separates human beings from all other creatures. Religion is an expression of a feeling or sensation in people that there is something more to the world than can be readily observed by their senses, something that underlies the cosmos. This something is conveyed to people spiritually. It does not necessarily mean that human beings have souls, though in almost all religions people believe that they sense the supernatural nature of the universe because they have souls that are related to the supernatural. In some religions this has meant the loss of individuality, which was submerged in a universal spirit; in other cases, it has meant liberation of a person because his or her individual spirit is able to be an active participant in the great enterprises of the supernatural world.

In general, religions have required rituals on the part of people. To get in touch with the supernatural may have required waiting in a particular spot known to be a way station for traveling spirits or speaking in certain ways to invoke spirits or gods. Clapping hands could be a way to attract the attention of spirits. Kneeling could be a way to show a god that one was sincere. In the context of many religions being able to invoke the immediate presence of a god or gods was important, because their presence signified their interest in the local community. Many sculptures of gods were intended to function as places where gods could make themselves part of the living world. In ancient Egypt priestesses would bring food to statues of gods and then dance, sing, and tumble to

entertain the gods, who were present in their statues, observing all. In ancient Mesopotamia statues of gods were paraded through cities and taken to watch entertainments. Although the statues were stone, the gods could inhabit them to observe and enjoy the spectacles.

Giving spiritual life to inanimate objects may seem primitive, but most ancient peoples saw it as a sign of civilized behavior. For instance, many ancient cultures substituted inanimate objects for living ones in the confidence that in the otherworld of spirits or gods, the power of art and spoken word would make the inanimate objects real. It is an uncomfortable fact that many ancient religions practiced human sacrifice. If one studies ancient sculptures and paintings of people being sacrificed, they look miserable and frightened. In fact, for some religions, the fear and suffering of victims were important assurances of the effectiveness of the sacrifice, whether the victims were girls in the Andes or children in Burma. The Druidic cult involved bloodily torturing people to death to foretell the future or please a god. Wars sometimes were waged just to acquire prisoners for sacrifices, and those prisoners knew only terror as they were killed. The substitution of statues for people as sacrifices was for some ancient societies a sign that they had matured in their religions, that they realized spirits made their own reality and would accept symbols instead of living people because in their aspect of the universe, symbol and reality were the same.

Another aspect of ancient religion that can make modern observers uncomfortable is the seeming lack of logic. The modern world has been shaped and is constantly being reshaped by the scientific method, but in the ancient world few people approached learning via empirical research, that is, actually observing how the natural world functioned. The modern scientific method developed in the 1500s. On the basis of the logic of the scientific method, aspects of religion do not make sense. An example cited frequently is the presentation of two stories of the creation of human beings in the Bible. If a person of today were to say to someone of the ancient world—even one who was not Hebrew or Christian—that the two stories in the Bible cannot both be true, the ancient might consider such a person to be crazy. Did the authors of the Old Testament sabotage their own work by including contradictory stories? No. They believed both stories to be part of the truth. Thus it was that in ancient Egypt the gods Horus and Seth were both brothers and uncle and nephew at the same time, revealing part of the truth of their relationship and of the supernatural world. In the complexities of contradictions ancient people hoped to glimpse a little of what made the universe what it was in its wholeness.

AFRICA

BY ROBERT SHANAFELT

Religion can be difficult to define. One definition is that religion is belief and practices concerning supernatural phenomena of all sorts, from those about God to those relating

to various deities, spirit beings, and magical forces. A problem with this definition is that not everyone agrees about what is supernatural. Another approach is to emphasize special behavior in the form of prayer or other types of worship. This definition works well enough for situations where worship is clearly separated from other activities, such as in cases where people go into a special building like a mosque, a temple, or a church to pray and listen to religious leaders. But not everything that might be called religious is separated out that way from ordinary life. Is someone being religious if they attend a wedding? Visit a grave site? Paint a picture? Hope for a prosperous future? In these cases, the answer can depend on the context and details. This is true of much that is called traditional religion in Africa. What is religious is determined by the context of the case because, in much of Africa, religious life is a pervasive part of the everyday world.

Another point to keep in mind when studying religions with deep traditional roots, such as those in Africa, is that ideas do not have to be written down to be part of a complex system of religious thought. For example, Africa has a rich set of traditions about cosmology, or the nature of the universe. That is, there are rich oral accounts in various African religions of how the universe, the world, human beings, and other living things have been created and have developed through time. These sacred stories, commonly called myths but better understood as oral scriptures, often run to hundreds of pages when written down.

Examples of myths that can be traced to specific time periods in the ancient past are difficult to come by, but some hints of ancient western African images of the world are given in epic songs. Especially relevant are those described in the 19th century as being sung among the Soninke and Fula peoples. Fragments of these songs seem to be traceable to the fourth century C.E. These songs tell of heroic contests and mythic battles in ancient cities, with the legendary city of Wagadu, most prominent. The heroes in these epics are worthy of attention not only for their legendary deeds but also because they are the ancestors of great lineages of peoples.

In the epics it is also significant that Wagadu is presented as a woman with extraordinary qualities. As such, she symbolizes an ideal to be praised and honored. Wagadu, it is said, “is not of stone, not of wood, not of earth. Wagadu is the strength that lives in the hearts of men.” Epic accounts also talk of a mythic serpent to whom the people of this city made sacrifices. Some scholars have suggested that there are connections to this story and archaeological findings at the ancient city of Jenne-jeno, near Djenné, Mali. In particular, they point to serpent motifs on ceramics discovered there by archaeologists. However, as with most things where evidence is incomplete, much remains open to speculation.

The special acts of a religion are called its rituals. Rituals are like habits in that they occur regularly, but they are more than habits because they are imbued with special meaning. Common rituals in Africa as in other parts of the world in-

clude those connected to birth and naming, coming of age, marriage, agriculture, change of seasons, and death. In many parts of Africa there are also special ceremonies held to honor one's ancestors. These traditions run very deep, but it is often difficult to tell exactly how old they are.

At least one anthropologist has argued that the widespread African ritual of divination has roots traceable to Neolithic times. Divination refers to techniques used to tell the future. As practiced in contemporary times, it generally involves the casting of shells, nuts, or bones and the recitation of special phrases or poems that are associated with each particular pattern that can possibly appear. Such divination requires a prodigious memory and implies a special period of training between a master and an apprentice.

No matter what definition is used, there are many different African religions. Most of these are fully indigenous systems, developed completely in Africa. However, Africa has also long been the home of Judaism, Christianity, and Islam. In fact, one could find communities of Jews, Christians, or Muslims in Africa quite soon after these religions first began to be practiced. Islam, however, did not begin as a religion until the time of Muhammad in the seventh century after the beginning of the Christian era. Obviously, Islam could not have influenced Africa before this time.

EARLY RELIGION

One of the earliest forms of evidence about religious belief is the demonstration that the dead were intentionally buried and that valuable objects were placed into the graves of the deceased. This type of discovery suggests both that the living maintained an emotional connection with the dead and also that they may have thought there was something beyond death. Archaeologists have shown that human beings were using colorful dyes for funeral purposes tens of thousands of years ago in Africa. This is supported by excavations at Twin Rivers, Zambia, where red, yellow, and other shades of ocher have been found in abundance. Ocher is a naturally occurring, powdery compound that can be smeared onto the body directly or mixed with water or grease to form paint. The practice of using ocher and other natural pigments to paint the body for ritual and aesthetic purposes is one that continues in many parts of Africa up to contemporary times.

Art and decoration are associated with religious behavior because they help in making powerful symbolic connections. It is through such symbolic connections that feelings of the divine are linked with everyday activities. Scholars of comparative religion have shown that ocher, in its red form, was widely used throughout the ancient world as a symbol of blood and life. Other examples of apparently symbolic connections are found in much of the ancient rock art that is widely distributed throughout the continent. Many of the rock paintings have to do with the connections humans made with animals. During the days when hunting and gathering was the way of life, people all over the world developed a spiritual connection particularly with the largest and most

dramatic of the animals around them. African rock art can be divided into different phases depending on the animals that are most often represented. In one phase, for example, representations of a gigantic buffalo called *Bubalus* were commonly featured. This period extended from about 6,000 to 11,000 years ago.

There are a few cases in which connections have been established between ancient forms of art and the religions of contemporary people. For example, a hexagonally shaped jewel stone found in a prehistoric site called Tin Felki in West Africa has been shown to be identical to precious stones used by Fula women today as fertility charms. Even stronger evidence links the practices of the ancient rock artists of South Africa and the religion of the people commonly referred to as Bushmen. Most observers believe that the rock art and engravings of southern Africa were made by the ancestors of the Bushmen.

The Bushmen, or Khoisan, were hunters and gatherers who made their living off the land. A number of paintings found widely in the South African region show scenes suggestive of the trance-dances that are still practiced by some contemporary Bushmen. In these dances the dancers enter into an altered state of consciousness by evoking the spirit of powerful animals. Dancers are thus spiritually energized and often feel they have the power of healing touch in their hands. Based on his observations of such rituals, the South African rock art specialist David Lewis-Williams has developed a theory that all the early rock art in the world involved some elements of trance. Other analysts have shown how particular rock paintings reflect concerns about fertility or were expressions of hunting magic.

Two of the most important figures in the religion of the contemporary Khoisan are Mantis and Eland. Mantis is a trickster god who is capable of transforming himself into other life forms. Eland, a favorite of Mantis, is also thought to have special spiritual potency. It is the spirit of the eland antelope, in particular, that contemporary trance-dancers seek to encounter in their altered states of consciousness. Significantly, eland paintings are commonly featured in ancient South African rock art.

POLYTHEISTIC RELIGIONS

Civilizations with kings, queens, and other ranks of nobility often have a religion that is also divided into different ranks of gods and spirit beings. Religions with a hierarchy of gods and an elaborate mythology about their activities are called polytheistic religions. The complete list of the gods of a polytheistic religion is called its pantheon. The ancient Egyptians practiced a polytheistic religion with a very elaborate pantheon. Many other African peoples were also pantheistic, though their pantheons varied. In reference to contemporary times, it has been observed that those African religions that are pantheistic also have a supreme being who is all powerful, but distant from human affairs. The lesser divinities are merely manifestations of the absolute powers of the supreme

being. Not enough is known to say for sure how long this has been a general African belief.

Complex early civilization, such as that of Egypt, necessarily depended on rich agricultural production, but farming was not the only way to develop social complexity. In the African Sahel, on the southern fringe of the Sahara, at about the same time that Egyptian civilization was developing, a way of life called pastoralism began. Pastoralism is based on the herding of cattle and other livestock, and it has survived through the centuries into modern times. Cattle, because they are the key source of life, necessarily play a prominent role in the religions of pastoralists. For example, they may be sacrificed as a ritual offering or gift to the gods or to the ancestors. There is evidence of animal sacrifice from the very earliest period of pastoralism. Early pastoralists left small stone and earthen monuments in various locations across the Sahel and the Sahara, some of them associated with animal bones. (In earlier times, the Sahara was wetter and thus could support this pastoralist way of life.) In Niger and Chad archaeologists have discovered evidence of cattle sacrifices that are approximately 7,000 years old.

Not all the monuments associated with the pastoralists of this region and time period had to do simply with cattle; some clearly had other functions. One of the most notable sites of African prehistory is Nabta Playa, a ceremonial center

located in southern Egypt near the border with Sudan and Libya. Among its monuments stands a small circle of stones that was aligned to face the north and south on one axis and the axis traversed by the sun as it rose across the sky on the longest day of the year, the summer solstice. This is said to be one of the world's earliest circular astronomical monuments, predating Stonehenge by many centuries.

Burials have been found in Sudan that date from the Neolithic period, from around 7,000 years to 4,000 years before our era. The dead were buried wearing adornments such as ostrich eggshell beads, with their bodies painted with red or yellow ochre. During their lifetimes, people from this era also commonly had their teeth filed, probably as a marker of adult status or for some other ritual purpose. This custom was practiced widely in North Africa and was also known to have been practiced in Kenya.

The religion of the ancient Nubians of southern Egypt and northern Sudan appears to have some association with the religion of Sahelian peoples, as well as that of the Egyptians to their north. At Karmah, the first Nubian center and the oldest urban site yet found in Africa, there are round tumuli with cattle sacrifices that appear similar to those constructed by the pastoralists. But the people of the kingdom of Karmah elaborated upon these practices and took them in their own direction. During the height of its power (ca. 1700–1550 B.C.E.), a massive mud-brick temple with an area of some 1,700 square yards dominated the city skyline. Nearby, powerful kings were buried in huge mounds. One of the largest of these measures nearly 300 feet around. The king was accompanied in death by nearly 400 of his subjects. They appear to have been sacrificed and buried in the king's grave in order to serve him in the next world. They were not simply ordinary people, but archers interred with their bows and valuables such as semiprecious stones, bronze mirrors, and jewelry.

At the end of Egypt's New Kingdom (ca. 1550–ca. 1070 B.C.E.), in the first millennium B.C.E., the Nubian kingdom of Kush came to power. Its rulers would become the pharaohs of all Egypt, forming the Twenty-fifth Dynasty (ca. 712–ca. 657 B.C.E.). During this time their most important shrines were located in Upper Nubia in and around Napata, a town situated along the Nile to the south of old Karmah. For centuries Napata had been the southernmost outpost of Egyptian rule, and the New Kingdom pharaoh Thutmose III had constructed on the nearby sacred mountain of Jebel Barkal a temple to the mystical god Amon. This was a crucial event in Nubian religious history because it led to the spread of Egyptian religion among the Nubian people.

The Nubian pharaohs of the Twenty-fifth Dynasty looked to both Egypt and to their own traditions. To show their connection to ancient Egypt, for example, they revived the practice of pyramid building, but on a smaller scale and in a different style than had been seen during the Old Kingdom (ca. 2575–ca. 2134 B.C.E.). Still, the continued loyalty of these pharaohs to Nubia is demonstrated by the fact that all of their pyramids and the burial sites associated with them were located in their

Limestone stela with images of the goddess Tanit (first century C.E.), from Carthage (modern-day Tunisia); such stelae were set up over burial urns containing the cremated bodies of babies, small children, and animals sacrificed to the goddess. (© The Trustees of the British Museum)

homeland, not far away in Lower Egypt, where their kingdom had also to be administered. Nubians also interpreted the god Amon in their own way, particularly emphasizing his form as a powerful ram. Similarly, the Nubian lion god was emphasized as their protector. Indeed, despite the cultural influences of Egypt, Nubians retained their own distinct cultural identity and practices throughout the centuries.

After the Nubians lost control of Egypt as a result of their military defeat in the first decade of the sixth century B.C.E., their capital shifted farther to the south of Napata, to the city of Meroë. Here their beliefs and customs would survive and be transformed. Temples near Meroë that are dedicated to the Nubian lion god Apedemak still stand. It is here in the period between the fourth century B.C.E. and the first century C.E. that the brick pyramids of the Nubian kings were constructed. Archaeologists have also found large statues of rams there. Some scholars have suggested that in this period a Nubian-inspired veneration of the sacred ram spread widely across the continent, influencing religious worship among such diverse people as the Libyan Berbers, the Fon of Benin, and the Yoruba of Nigeria.

Much still remains to be learned about the early religious practices of western Africa. Undoubtedly, one important center of Iron Age culture was that around the Nigerian town of Nok. Here terra-cotta sculpture and iron goods have been found ranging across a 700-year time span starting approximately from 500 B.C.E. The most famous of the sculptures are human heads and faces that were originally part of entire bodies. While their religious or ritual meaning and use are not known, it has been suggested that they are connected to the religious practices of later peoples, possibly the Yoruba. The Yoruba people say that their city of Ife was the center of creation. Here the supreme being Oludumare (Owner of Endless Space) sent an assistant down from heaven to create land from a watery chaos. The first dry land to emerge was called Ife.

The religion of the Akan people of Ghana is also known to have very deep roots, with possible connections to a more regional pantheism. For example, there are similarities between the mother goddess Tanit of the North African city of Carthage and the Akan goddess, Mother of the High God Nyame, both of whom are said to have given birth to the universe. The Yoruba, too, have a goddess who brought order to the world through the release of *ase*, her spiritual power that activated the world's creative energy.

As mentioned previously, it is quite common for African religious traditions to depict a supreme being who is somewhat remote from everyday human affairs. While this view of God can be found prominently in kingdoms, it is also found among pastoralists such as the East African pastoralists, the Nuer and Dinka. The fact that it also typifies much of the traditional religions of southern African societies, whether kingdoms or not, also suggests that this perspective is one of considerable antiquity.

There are varieties of accounts of how the remoteness of God came to be. In one version told by the Akan of Ghana

it is said that God and humans once lived so very close together that people could stretch out their hands to touch him. This changed one day after an old woman began to pound her grain vigorously to make porridge, using a mortar and a long pestle. The problem was that, with God being so close, she hit him every time she pounded. Consequently, God was forced to move farther and farther away until he was high in the sky and no longer in reach of her pounding. While details vary, it is a common theme in African traditional religion that God was once close but was driven away by human actions.

MONOTHEISM

Archaeological evidence from the Middle East and Africa indicates that polytheistic forms of religion are associated with the most ancient civilizations. Monotheism, particularly when it means the worship of a single god to the exclusion of other gods that also exist, appears to be a more recent development. The conflicts between monotheism and polytheism are described in the Hebrew Bible. As the Bible relates it, even the faithful Jews often turned away from God to worship one or another of the gods of their neighbors.

The story that most stands out about Egypt in biblical narrative is the story given in Exodus about Moses and the liberation of Egypt's Jewish slaves. In contrast to the Bible's version of events, Egyptians circulated a different story of a rebellious man they called Moses. Although it is known only in fragmentary form, in the Egyptian account Moses is described as a heretic against the Egyptian faith and a rebel who led a revolt of outcaste lepers against the state. No mention is made of Judaism.

In Ethiopia the biblical narrative of the ancient Jewish king Solomon and the queen of Sheba (also called Makeda) has taken on great significance. According to legend, the king of Ethiopia's Amhara people is said to be the direct descendant of Menelik, a child from a liaison between the Egyptian queen and the Jewish king. Written accounts of this story date back at least to the 13th century B.C.E., but it is not known how long it may have existed in oral tradition.

Ethiopia also has been home to more ordinary people who claim deep Jewish roots; among them are the Beta Israel, most of whom emigrated from Ethiopia to Israel in the late 1980s and early 1990s of the 20th century C.E. Although there are different accounts of the details, their oral traditions suggest their ancestors were of the House of Dan, one of the Lost Tribes of Israel. Africans with Jewish links are found in other parts of Africa, as far away from the Middle East as South Africa. In South Africa claims of Jewish ancestry by the Lemba people have recently been confirmed by DNA tests.

Christianity in North Africa and Ethiopia goes back nearly to the beginning of the religion. According to traditional accounts, Egypt's first church was founded by one of the 12 disciples of Jesus—Mark. The Ethiopian kingdom of Axum adopted Christianity as a state religion in the early fourth century, and the religion continues to be Ethiopia's main religion. The city of Axum's fourth-century church,

Saint Mary of Zion, is said to house the chest that contains the original Ten Commandments, the sacred Ark of the Covenant. This city is also known for having some of the tallest and most beautiful obelisks of the ancient world.

EGYPT

BY KELLY-ANNE DIAMOND REED

Religion permeated all aspects of ancient Egyptian society, and there was no separation between church and state. The disciplines of science, magic, and what the Western world terms *religion* all functioned as one. There was no canon, nor was there any form of revelation. Because there was no set doctrine for the ancient Egyptians, there were many contrasting and contradictory ideas and concepts. This did not seem to trouble the Egyptians, who never took the time to systematize all of their beliefs. Instead, it was perceived as quite normal to consider, for example, Horus and Seth as both nephew and uncle and brothers at the same time. It seems that logic did not play a role in Egyptian religious practices.

EGYPTIAN GODS

The ancient Egyptians had a pantheon of gods. These gods could be conceived of separately or in dyads (two deities), triads (three deities), ogdoads (eight gods), or enneads (nine gods). Horus and Seth, Osiris and Isis, and Isis and Nephthys are three examples of a dyad. These pairs of divinities regularly complemented each other and are innately connected. Likewise, sometimes a god or goddess was created to form a balanced, sexually paired couple, such as Seshu and Seshat.

Triads often take the form of a family, including father, mother, and child: for example, Ptah, Sakhmet, and Nefer-tum; Amun, Mut, and Khonsu; and Osiris, Isis, and Horus. Additionally, one god could have a variety of forms. For instance, the sun god manifests in the following three forms: Khepri, Ra, and Atum. Khepri is the form of the sun god when he is the sun disk rising in the eastern sky, the dawning sun. Ra is the form of the sun god in the middle of the day. Atum is the aspect of the solar deity that appears as the evening sun.

Ra may be considered Egypt's most important deity. He was a universal god, and most of Egypt's major divinities were associated with him at one point or another. Ra played five major roles in Egyptian theology: on earth, in heaven, in the underworld, in creation myths, and as divine father and protector of the king. The cult of Ra is first seen in the Second Dynasty (ca. 2770–ca. 2649 B.C.E.), where his name is included in personal names. Likewise, in the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.) the kings took the epithet "Son of Ra." By the Fifth Dynasty (ca. 2465–ca. 2323 B.C.E.) Ra was firmly established as the state god, and Heliopolis was his cult center.

The number 8 was seen as potent in Egyptian theology. Sometimes the eight deities were not named, which demonstrates that the number was of more importance than the deity. Often the eight divinities consisted of four pairs and at other

times as two sets of four. The so-called Hermopolis Ogdoad was one of the most important ogdoads, consisting of eight primeval gods: Nun and Nunet (water), Heh and Hehet (infinity), Keku and Kekut (darkness), and Tenem and Tanemet (invisibility or wind). In the New Kingdom (ca. 1550–ca. 1070 B.C.E.) Amun and Amenet replaced the last pair.

The Egyptian ennead refers to nine gods. The Egyptians had numerous enneads, including the Great Ennead, the Lesser Ennead, and the Dual Ennead. The number 9 represented a large amount of something. The Ennead of Heliopolis was one of the more significant enneads, which consisted of Atum, Shu, Tefnut, Geb, Nut, Osiris, Isis, Seth, and Nephthys. Atum was envisaged as the father, while the rest were seen as the subsequent generations. In addition to the groupings, some gods, such as Amun and Ra, were combined to be one god, Amun-Ra, through a process of syncretism.

Each of the gods' names can be translated by either a word or a phrase. For example, Hathor means "mansion of Horus," Isis means "the seat/throne," Amun is "the hidden one," and Atum is "the complete one." The meaning of some divine names is clear, but the meaning of others remains a mystery. There were also local gods who had been connected with specific villages from time immemorial. These early associations can be seen in the examples of personal names that include the names of a divinity.

CREATION MYTHS

Different creation myths in Egypt account for the existence of the world. Unfortunately, the funerary texts do not give detailed accounts of the myths but were used to help the deceased ascend to the afterlife. Certain excerpts from the Pyramid Texts, Coffin Texts, and Book of the Dead, among other sources, reveal some of the ideas the Egyptians held about the creation of the world.

The Pyramid Texts were first inscribed on the inside walls of the pyramids of some late Old Kingdom (ca. 2575–2134 B.C.E.) kings and queens. With the democratization of religion beginning at the end of the Old Kingdom, this corpus of utterances was transferred to the private sphere. In the Middle Kingdom (ca. 2040–1640 B.C.E.) the Coffin Texts emerged, consisting of a series of spells inscribed on coffins. The Coffin Texts are directly related to the earlier Pyramid Texts. During the New Kingdom the evolution of this group of texts appears in the form of the Book of the Dead. This book was written on papyri and was included among the grave goods in private burials; there are also some royal examples. Likewise appearing during the New Kingdom are various other books concerning the afterlife, such as the *Amduat*, the *Book of Gates*, and the *Book of Caverns*. These funerary texts are laden with mythological allusions, indicating that mythic stories were culturally important and demonstrating that both royal and private persons were familiar with the mythic traditions, possibly through oral means.

Different creation myths were formed at different theological centers. For example, the ennead was the focus of the

creation myth that developed at the cult center of Heliopolis during the Old Kingdom. Atum, the “complete one,” was first created alone in the Nun, or the watery abyss. There are a variety of ways in which his progeny were spawned, including masturbation, coughing, spitting, or sweating. Atum’s successive generations make up the air (Shu), moisture (Tefnut), earth (Geb), and sky (Nut).

During the Middle Kingdom the ogdoad was the focus of the Hermopolis creation myth. The Hermopolis Ogdoad was made up of four frog-headed gods and four snake-headed goddesses. These were the primeval deities and were symbolic of the chaotic waters in which the world was created. Together they formed the original mound, lotus flower, or egg that existed prior to the sun god’s birth. In a different version of the creation myth from the New Kingdom, Ptah (the creator god) was said to have fashioned the gods and human beings on his potter’s wheel. Thebes, which was the cult center for the god Amun during the New Kingdom, embraced yet a different idea about how the world was created.

The Egyptians viewed the world as consisting of the earth and the sky. The earth was said to be the god Geb, while the sky was the goddess Nut. Funerary contexts often display the goddess Nut arching her body in imitation of the sky. Her rear was in the east and her head in the west. She would swallow the sun every evening, it would pass through her body, and she would give birth to the sun every morning. Shu was thought to hold up the sky. He also created the eight Heh gods to hold up Nut in her bovine form. Additionally, the earth was seen as masculine, while the sky was perceived as feminine. Anything that was not the earth or sky was considered the Duat, or netherworld. Many myths surround the original creator god. One version suggests that he was a great falcon who came forth from an egg; another proposes that he emerged from the great lotus flower that was in the Nun. Yet another version posits the existence of a primeval mound that appeared out of the Nun.

The Coffin Texts and the Book of Gates, among others, explain that humankind came from tears (from different gods, depending on the source). One Hymn to Amun states that Atum was responsible for the creation of everything that exists—“from whose eyes men came forth and from whose mouth gods came about.” Likewise, he distinguished them by their character, created their life, and differentiated them from one another by the color of their skin. The Hymn to Aten states that this god “created the earth according to (his) wish, when (he) was alone, consisting of mankind, cattle, and all flocks.” A document called the Instructions to Merikare explains that humankind was made in the image of god.

OTHER RELIGIOUS MYTHS

Numerous popular myths recount interactions between the gods. *The Contendings of Horus and Seth*, for example, tells of the struggle between the gods Horus and Seth for the vacant position of king of Egypt that was left by the passing of Osiris, the god of death, resurrection, and fertility. In the

end, Horus is victorious and assumes the office of his father. This story replicates the fashion in which a son would succeed his father as king of Egypt. Likewise, the living king was seen as the incarnation of Horus, while the dead king was imagined as Osiris. This story takes place entirely in the world of the gods.

Another example of a popular myth is *The Destruction of Mankind*, which also forms a portion of the *Book of the Heavenly Cow* inscribed in some New Kingdom tombs. In this myth the sun god Ra is angry with humankind for plotting rebellion against him. The major theme presented here is similar to that found in the biblical story of Noah’s Ark and the flood: human wickedness and god’s wrath. Further examples of popular myth consist of the *Secret Name of Ra*, the *Myth of Isis and Osiris*, and the *Myth of Horus at Edfu*.

PRIESTS

The ancient Egyptian priest was not at all similar to the Christian idea of a priest. He did not preach to the masses and was not responsible for the spiritual well-being of the populace. He had a very specific job, and that was to maintain the cult of the god. This was, in fact, the job of the king; however, the king delegated this duty to the priesthood. The king was the one who needed to maintain the world as the gods had defined it; this also meant keeping the gods active through the maintenance of their cults. If the gods were happy, then Egypt would flourish. The priests were responsible for clothing the god, feeding the god, anointing the god, and other physical jobs that served the deity. This is why they were called the servants of the gods. Greek authors mistakenly called them prophets.

The physical presence of the gods existed only in the temples, which were not available to the masses as places of worship. They were the homes of the gods and allowed only limited access. The ancient Egyptian temple was made up of various pylons and courts that led to the holy of holies where the cult statue stood. A well-preserved example of an ancient Egyptian temple stands at Idfu and dates to the Ptolemaic Period (ca. 304–30 B.C.E.). A large pylon stands at the front. Next one walks into the forecourt; then the pronaos, or outer entrance hall; the great pillared hall, which is flanked by auxiliary rooms; the hall of offerings; the central hall; and finally the sanctuary, or the holy of holies. Outer rooms surround the last three halls. These rooms have names like the Mansion of the Prince, Throne of the Gods, Mansion of Linen, and Chapel of Hathor. The entire temple complex was surrounded by a great wall. In general, the scenes on temple walls progress from public scenes, such as the king in battle, to scenes of the king’s private relationship with the gods and the performance of cult rituals. The priests’ job was to protect the deity who was located in the holy of holies. As one penetrated the inner rooms of the temple, the floors rose and the ceiling lowered so the focus was on the cult statue alone.

A priest had to undergo certain rites prior to being considered pure. Purifications in the form of a bath took place in

the sacred lake belonging to the temple. Certain texts suggest that this was performed twice each day and twice each night while a priest was on duty. If there was no sacred lake, then another water source was used. Additionally, priests were required to rinse their mouths with a salt solution consisting of natron (a form of salts from dried lake beds) and water. Likewise, priests had to shave their bodily hair. There is also evidence to support the shaving of eyebrows and eyelashes.

Another ritual performed for the sake of cleanliness was circumcision, but this does not seem to have been a universal practice among Egyptian men. Once a priest began his work, however, he had to undergo the procedure. In the later periods this was a characteristic mark of a priest. Ancient Egyptian priests did not have to be celibate; however, they could not copulate in the temple and had to abstain from sex for a few days prior to beginning work in the temple. Priests did take wives and have families. Some priests even took more than one wife, though this was uncommon.

According to Greek and Roman sources, there were many dietary restrictions for priests. In actuality, the prohibited foods were not quite as numerous as the later sources would have one believe. Dietary rules depended on which deity the priest served. For example, if one worked in the hare nome, or province, and the hare was the sacred animal of that area, then one would not consume that sacred animal. Ancient sources reveal that some would eat the sacred animal of the neighboring nome in order to be unpleasant.

Finally, priests could not wear wool. Since this material came from living animals it would pollute the sacred areas within the temple. This, however, was not the case with panther skin, which was the characteristic garb for the high priests. Other distinguishing outfits worn by the priests consist of a sash for the lector priests (those who spoke the ritual texts in the temples), a "skin spangled with stars" for the priests of Heliopolis, and a special collar for the priests of Memphis, who would also wear their hair in a side lock. All priests wore palm sandals. This proved to be an item of prestige in a society where people walked barefoot.

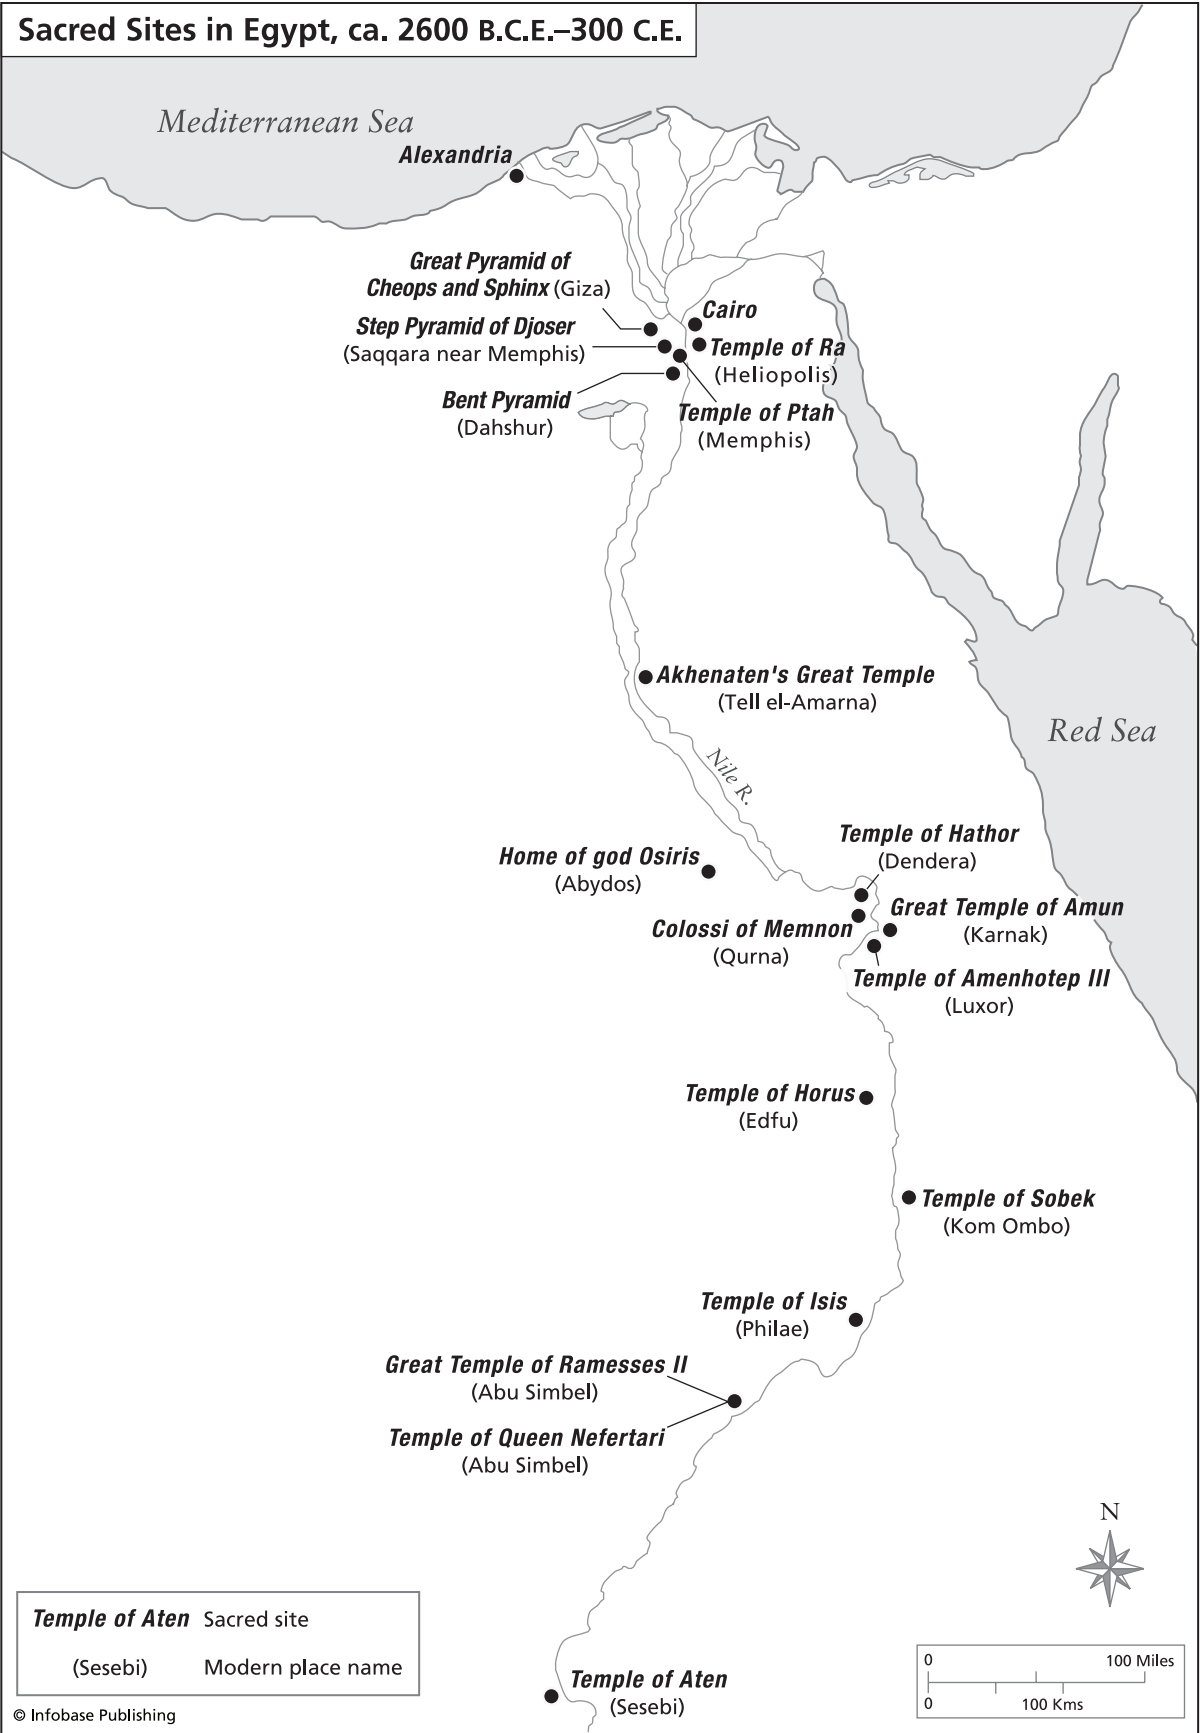

There were four ways for one to become a priest: hereditary right, royal appointment, co-optation, and purchase. It was the tradition for a son to take over his father's post. In ancient Egypt there were priestly dynasties consisting of numerous generations of priests who served the same deity. These families grew close to their god and gained significant local power. Since all priests were theoretically supposed to be royally appointed, a particular royal appointment could always trump a hereditary rite. Usually the king had far greater matters to worry about than who would fill the vacant office within a temple, especially within the smaller temples. The king would intervene in only two scenarios: when he wanted to reward a particular person with a special post or when he needed to curb the power of a particular priestly dynasty by importing an outsider to a high-ranking post. In general, the organization of the smaller temples was performed on the local level. If there was a vacant position, the committee

of clergy would nominate someone to fill it. This committee probably approved the appointing of any new priest, even when the post was passed from father to son. The last way that one could become a priest was by purchasing the office. There is much evidence for this practice in the later periods, though it is known to exist as early as the Middle Kingdom.

There were different classes of priests, but it is difficult for the modern scholar to understand the hierarchy of the priestly class. Certain types of priests were more or less important in different temples. There was probably also a variation over time. Some of the largest temples, such as the temple of Amun at Karnak, had a separate staff of administrators. In the smaller temples the administrative jobs, like counting and recording the agricultural products, were done by the same people who performed the purely ritual activities. It was possible for a temple to possess fields, gardens, and animals, all of which contributed to its wealth. The temple staff was paid through these agricultural yields. The amount of property owned by a particular temple was directly related to its income level and therefore the number of staff it could support. For example, the temple of Amun at Karnak had 81,322 personnel, the temple in Heliopolis had 12,963, and the temple of Ptah at Memphis had 3,079. These were three of the largest and most important temples in Egypt. It is thought that a modest temple would have anywhere from 10 to 25 personnel. Some temples, however, lacked a financial source of their own and had only one or two clergy members.

There were high clergy and low clergy. The high clergy, or priestly elite, consisted of four levels of "prophets" (mistranslated by the Greeks). There was also a fifth level of prophet, but these priests did not seem to have been included in the ranks of the high clergy. The first four levels of prophets were strictly servants of the god and acted in the same manner as a personal servant would act, taking care of the owner of the house—in this case, the god. The office of first prophet was the highest priestly title, especially in the case of the wealthiest temples. The first prophet was also called the high priest and had many political duties as well as religious ones. The second prophet was the second in command and often took the place of the high priest in the temple when other duties interfered. There was only one first prophet and only one second prophet in each temple. In the case of the temple of Amun, the second prophet had many workers underneath him. It was his job to manage his subordinates and oversee such tasks as making sure the administration ran smoothly, receiving tribute, and overseeing the workshops. Royal favor played a major role in advancement within the priesthood. It was possible for one to work his way up, but other factors came into play as well.

The low clergy were essentially assistants. They were called pure ones and helped the other clergy members with the cult rituals. These priests performed such functions as slaughtering animals for sacrifice, interpreting dreams, carrying sacred objects, and supervising secular workers. In addition to the clergy members, numerous lay people helped the temple function properly.

The idea of religion permeated all aspects of ancient Egyptian society.

Fitting somewhere between the high and low clergy were the specialists, those who performed specific functions with the cult. Some temples ranked their specialists in the higher class, while others ranked them in the lower class. These specialists include the stolist, who dressed the divine statue; the academics of the House of Life, who prepared the religious works necessary to the functioning of the cult; the lectors, who were not always priests but could function as funerary ritualists, learned scribes, popular magicians, or scientists; the hour priests who serve as astronomers; the horoscope priests who were calendrical specialists; and musicians and singers of both sexes.

Among the priests were permanent priests and priests who alternated in groups. The groups were called *phyles*. There were four *phyles*, each of which consisted of the same number of priests who performed the same functions in the temple. Each *phyle* worked three months a year; each month of work was separated by two months of freedom.

RELIGIOUS RITUALS

A variety of events took place in conjunction with the ancient Egyptian temple: foundation rituals, daily rituals, festivals, and oracles. Foundation rituals were performed by the king as early as the third millennium B.C.E. The scenes from the late temples at Isna and Kom Ombo show the king performing these same foundation rites. The scenes appear to depict the following events. The king leaves his palace and arrives at the temple site. The king and a goddess hammer in two posts to determine the orientation of the temple. Next a hole is dug to water level to make the structure sturdy. Then bricks are molded at the four corners of the temple, and the foundation is filled with sand. There is a presentation of plaques made of a variety of materials such as gold, silver, copper, and stone. Finally the temple is ready to be built, and chalk is sprinkled on a model temple for purification purposes. At the end there is a symbolic delivering of the temple to the god it will house.

Included in the daily rituals were the morning ritual, which comprised the morning song, the opening of the shrine, and the care of the god (divine repast and toilette). The midday ritual was shorter: The priests sprinkled water and burned incense for the other gods worshipped in the temple. The evening service was a repetition of the morning service except that the sanctuary remained closed. This service took place simultaneously in all temples in Egypt.

Numerous festivals and processions were associated with the temple. Ancient calendars indicate that the god would be taken on procession from five to 10 times each month. Sometimes the god would be in the sacred bark (a small boat), but other times it would not. Examples of some of the festivals are the Festival of the Valley, the Festival of the Nile, and the Festival of Drunkenness. Some festivals involved the public, and others were conducted in secrecy.

In the New Kingdom the consultation of oracles became popular. The priests acted as intermediaries in these matters. Oracles by statues, divine barques, prophetic voices, dreams,

and animals were some of the many ways that people accessed the divine. Divine oracles were also supposed to decide legal matters. This was done at the temple gate. The ancient texts state that the gate was the place to hear petitions and tell truth from falsehood. Unfortunately, there is not enough documentation to allow the modern scholar to understand the fine workings of this religious justice system.

THE MIDDLE EAST

BY BRADLEY SKEEN

The religions of the ancient Near East bound together their societies, creating a religious culture and patterns of thought quite unlike those of modern Western civilization. The sacred writings of the Near Eastern religions are among the oldest and greatest classics of world literature. Their interactions gave rise to Judaism and thereby also to the other two modern monotheistic faiths of Christianity and Islam.

PREHISTORY

By the end of the last ice age hunter-gatherer communities of the so-called Natufian culture (ca. 12,000–ca. 10,000 B.C.E.) in what is today Palestine and Israel already buried their dead with considerable care, accompanied by grave offerings (weaponry and personal adornments), suggesting some level of concern with an afterlife. In the Neolithic (ca. 8000 B.C.E.) the inhabitants of Near Eastern villages, such as Çatalhöyük in eastern Turkey or Jericho in Palestine, further developed a cult of the dead and the veneration of animals that were believed to embody magical or supernatural powers, such as wild aurochs, gazelles, and mountain goats. Horned head-dresses, indicating the possibility of shamanistic behavior, are illustrated in early symbolic images on painted pottery and seals.

MESOPOTAMIA

The first cities were founded in Mesopotamia. A place like Uruk was not just many times larger than a village but also had a different social organization. The agricultural surplus created by farming the land watered by the great rivers of Mesopotamia, the Tigris and Euphrates, allowed some people to stop working merely for their own food and survival and become specialists: kings and aristocrats in governance, soldiers in warfare, artisans in building, and priests in religion. Large building complexes, often called *temples* in Western literature, were, in fact, the households of individual deities, managed by stewards whom we usually denote by the term *priest* or *priestess*. Large landholdings; workshops for pottery manufacture, metallurgy, weaving, and other crafts; and enormous agricultural enterprises supported the household of each deity. The king was both the human master of the society and the intercessor with the divine on the part of its human subjects. Although ancient Mesopotamian societies were polytheistic, each city had a major god or goddess, who was worshipped alongside a host of minor ones.

Mesopotamians had no hope of any kind of reward of eternal life or paradise. During life each person was under the protection of a kind of guardian angel (personal god). It was generally believed that after death the ghost of a person journeyed to a dark place under the earth, the Land of No Return, and continued forever in a fitful slumber. There were no exceptions. Even the great king of Sumer, Gilgamesh (r. ca. 2600 B.C.E), according to the mythological epic named after him, spent much of life in quest of eternal life but discovered that all of his hopes were vain and that human beings received no reward other than the brief pleasures of life on earth. The afterlife was no paradise, but the deceased needed to be provided with various grave goods to ease the journey into the netherworld, and periodic rituals had to be performed at the grave of the deceased long after his death. The form of burial mattered little—kings received large, elaborate tombs, while commoners might be buried in a simple pit covered with a reed mat—but the proper funerary rites were necessary in all cases. If the rites were neglected, the shade of the deceased might come back to haunt the living, wandering restlessly for all eternity.

A Mesopotamian temple or “house of a god” was often grander than a royal palace. The images of the gods in the temples were dressed in the finest clothes and adorned with gold and jewels. Each day the gods went through the same kind of schedule as the king, being dressed and undressed for various activities, eating (sacrifices), enjoying entertainments (hymns), and hearing petitions (prayers). Periodic festivals saw the gods (in the form of their statues) moved around the city or even between cities, attending entertainments such as athletic competitions and festivals. One of the greatest calamities that could befall a conquered city was the removal of the cult statue of the city’s chief deity. Numerous cases are documented in ancient Near Eastern sources. Moreover, such an occurrence carried a double penalty. The fact that a deity had abandoned his or her city showed that the city and its inhabitants had fallen out of favor with the god or goddess. The absence of the deity brought ruination and desolation to the populace. The return of the cult statue—examples include the statue of Marduk, chief deity of Babylon, taken to Susa in southwestern Iran by the Elamites—offered the king responsible for such an act the opportunity to proclaim his righteousness, piety, and paternal pride in delivering its people from such a scourge.

Animal sacrifice was common. The animals offered in sacrifice had to be pure or perfect, meaning young and healthy. Typically, bulls, goats, or sheep were used, the same animals commonly eaten by people. The animals would be decorated with ribbons and ornaments and led to the god’s temple in a joyous procession, with the people singing hymns and dancing. A lock of the animal’s hair would be cut off and burned. Then the animal would be led outside to a place of sacrifice and slaughtered. The most divine organs in Mesopotamian estimation, such as the liver and gallbladder, would be returned to the god wrapped in fat, sliced, and served on

bread like a human meal. These organs would be completely burned for the enjoyment of the god. The bulk of the meat would be served as a stew to the participants in the sacrifice. Especially at a festival, when as many as a thousand animals were sacrificed, this could amount to quite an abundance of food, and its distribution would become a type of charity to the poor, who might obtain meat in no other way. The hide of the animal was given to the butcher and cooks who had performed the sacrifice on behalf of the king and other priests. In unusual circumstances, when there was a special reason to solicit the god or for great thanksgiving, the entire animal might be burned and in this way offered directly to the god.

Mesopotamians believed that nature was to be understood on the model of language. Metaphor is a figure of speech by which we say that one thing resembles another. One might say that a thunderstorm is like the raging of an angry king or that the feeling of love is like a beautiful woman. For ancient people that kind of explanation seemed a reasonable way to describe reality. So a thunderstorm is the raging of a storm god like the Babylonian Marduk, and love is a goddess like Ishtar (Semitic equivalent to the Sumerian goddess Innana). The ancients saw divinity everywhere: in the statues of the gods in the temples, in the planets in the night sky, in the signs found by examining the livers of sheep sacrificed to the gods, or wherever one sees majesty or love in the world. It did not occur to them to think of the name of a thing as arbitrary; rather they thought it was the thing itself. Hence the world and its representation in language were equivalents, and manipulating one could manipulate the other. Therefore, they believed, prayers and spells could change the way things are or what might happen in the future.

In this worldview, writing and language ought to be able to control the world; it certainly did so for the tiny literate elite who used writing to monopolize wealth and political power through access to the law courts and government denied the illiterate masses. But language, especially written language, also controlled the world in another way in Mesopotamian myth. Everything the gods accomplished was done through spells. In myths their speech creates reality. When the Israelite god creates the universe in the biblical book of Genesis, he does so through the power of language, speaking commands that become instantly real: “Let there be light! And there was light.”

Mesopotamian myth both mirrored contemporary culture on a higher plane and explained the existence of that culture. It had a tremendous impact on the beliefs of younger civilizations such as Greece or Israel. The *Enûma Elish*, or *Epic of Creation*, was sung at the New Year’s festival in Babylon. It extols the Babylonian god Marduk at the highest level of divinity. Its account of Creation as moving from an undifferentiated primal cosmos to the final order of the world we see around us populated by human beings is thought by many scholars to be the basis for the account of Creation in the first chapter of Genesis. Its description of the generations of gods fighting among themselves and against monsters for cosmic

supremacy is generally thought to have been the inspiration for the Greek creation myth in Hesiod's *Theogony*.

The epic is essentially the history of a family or royal dynasty. The preexisting universe within which the gods act is the *apsu*, or cosmic water. Nothing else exists, but when names are assigned, Creation begins to assume order. The first divinity, Tiamat (or saltwater), gives birth to the other gods, whose king is Enlil. Annoyed by her offspring, Tiamat decides to wipe them out and start again with a new race of gods. Enlil feels impotent to oppose his mother, but the young god Marduk comes forward to champion the divinities. After Marduk defeats Tiamat, he splits her body in two and uses half of it to build the vault of heaven over the waters, in which he creates the stars and orders the constellations and the zodiac, fixing the ordered progression of time. From the other half he makes the surface of the world floating above the *apsu*.

The Akkadian myth of Atrahasis, which dates to about 1750 B.C.E., describes the formation of humankind. At the beginning of the myth the great gods are served by lesser gods, who give them food and drink and dress and house them (doing for the great gods precisely what priests did for the cult statues of the gods in temples). But the lesser gods come to resent their subservient role and refuse to continue. As a result, the gods actually suffer hunger and thirst. Enki, the "wise man" among the gods, solves the problem. He produces human beings as a new race to serve the gods. Humans are made from clay (as in Genesis) and so can never hope to be divine, and yet they have a divine intelligence, because Enki sacrifices one of the lesser gods and infuses his blood into human beings.

In a passage closely echoed by the flood myth in Genesis, the gods descend to earth to found the Mesopotamian cities and to establish their own temples: to order human life by teaching all the arts of civilization. This works for a time. Because humans are so long-lived, the world soon becomes crowded with them, and their noise prevents Enlil, the king of the gods, from sleeping. So Enlil sends a great flood intended to wipe out humankind. Enki sees that the gods would suffer if humanity's service to them were ended and so instructs one, Atrahasis, to build an ark in which he and his family and pairs of all the animals would be saved from the flood. Because the gods suffer during the flood, Enlil permits humanity to exist but forces Enki to limit their numbers by creating demons to spread disease among them to shorten their lives and to kill infants. (About half of all children born in antiquity died before their fifth birthday.)

Atrahasis explains and justifies the relation between the powerful elites that ruled the ancient Near Eastern world and its masses of dependent farmers and laborers; it was like that of the gods' to humankind. It shows how myth was used to think about and solve problems in the ancient world.

The rule of the Mesopotamian gods over the world was by the power of a mythical book called the Tablets of Destiny. Because the destinies had been written down (preordained)

by the gods all at once, it was possible to foretell events in the future. Signs and traces of what the gods had written could be read in nature (through divination) by a priest wise in the ways of the gods, called the *baru* or diviner. Everything in the world was studied by the diviner, especially anything unusual that called attention to itself (an omen): Gods communicated important matters to mortals through omens.

Sacrificial animals, typically sheep, were of special concern to the gods. The main art of the *baru* was to examine the internal organs of sheep at the time of sacrifice, especially the liver. They produced clay models of livers in which something like lines and columns of script were laid out over the organ as though it were a tablet; marks in any given area were interpreted as if they were a specific word with a meaning relevant to the future. In particular, one could ask of the gods through sacrifice whether some contemplated action was favorable or unfavorable and receive guidance about what could not be found out through mere reason. This kind of divination, while it seems unlikely to modern thinking, was impressive enough that it was enthusiastically taken up by the Greeks, Romans, and Persians.

One of the places where the gods were most manifest was in the sky, their home, in the form of stars and planets. So the motions of the planets were studied carefully to see what they might reveal about the divine will. By the first millennium B.C.E., when many traditions changed because Mesopotamia was conquered by foreign peoples—the Persians (539 B.C.E.) and then the Greeks under Alexander the Great (336 B.C.E.)—the discovery that it was possible to predict the regular motions of the planets led to the belief that other kinds of prediction should be possible from observing the planets.

Since the gods were in charge of the universe, they were responsible for evil (reasonless human suffering). Disease and infant mortality were inflicted on humanity by the gods simply to keep the population down. In general, though, royal rule was used as a metaphor to explain misfortune. If someone violated the laws of a city, the king would punish him for his crime. In the same way, if someone violated any of the many divine laws that governed the universe and humanity, the gods would punish that person. The punishment was left in the hands of lesser spirits, who might well be called demons and who would inflict disease, defeat, or misfortune on human beings who had offended (sinned against) the gods. Naturally, these questions were always considered after the fact: In the midst of suffering, people would question why and would be conscious of having committed some sin or would remember the sin of a father or grandfather.

One could seek the cause of divine punishment and relief from it with the help of a special kind of priest, an exorcist. The exorcist would take something like a medical case history, ascertaining the nature of the "illness" from which the patient was suffering and what might have happened to have caused it. He would then consult manuals of exorcism (approximately 30,000 tablets of these documents survive, indicating how vast the literature and how widespread the

practice of exorcism was) and find the right ritual to pay for the particular offense.

Sometimes the immediate cause of evil was thought to be a curse put on a person by a witch. The exorcists believed that a witch might be a person the patient had met in his daily life; at the same time, a witch was more like a demon than a human being. Witches lived either in the lifeless desert or among the dead in cemeteries. They could fly across the world in the space of a single night and had supernatural bodies that allowed them to enter a house through a locked door. This image of the witch as human and not human at the same time, a member of the community and a supernatural monster, was influential not only in Greece and Rome but also among later Christian societies. Witchcraft was outlawed in Mesopotamian law codes, but there is no certain instance of anyone known to have practiced witchcraft or of the prosecution of anyone for the crime of witchcraft; it served rather as an explanation for misfortune after the fact.

THE LEVANT

The Levant (including parts of modern-day Syria, Lebanon, Jordan, and Israel-Palestine), received many cultural influences from Mesopotamia and Egypt. Libraries from cities on the border of the Levant and Mesopotamia, such as Ebla (destroyed ca. 2225 B.C.E.) and Mari (destroyed 1759 B.C.E.), tell us something about communication between the two areas. But the peoples of the Levant nevertheless made some of their own contributions as well. The Levantine storm god was a model for the Babylonian Marduk. The Levant was especially important for transmitting Near Eastern ideas and practices to Greece and to modern religions such as Judaism, Christianity, and Islam.

One distinctive feature of the religion of the Levant was the role of the storm god. While the fertility of the land in Mesopotamia came from the two great rivers, the Mediterranean coast was dependent on rain from thunderstorms coming in off the sea during the winter. Crops could then be planted and harvested in the spring. Summer was a dead time of the year when crops would not grow. As a consequence, the storm god was the most important figure in the Levantine pantheon, whether called, Hadad (Syrian), Yahweh (Israelite), by any other local name, or simply Lord (Baal).

Baal/Hadad's myth must have varied tremendously from city to city and tribe to tribe. We are fortunate to know it in detail from the version current in Ugarit, a city on the northern coast of present-day Syria. The city was destroyed about 1200 B.C.E., preserving the library of Ilimiku, the chief priest. The myth's three parts concern Baal's struggle for cosmic supremacy in succession to his grandfather El, who created the universe but no longer took a very active role in its governance. In the first part Baal defeats Yam, the god of the sea, together with his sea monsters Leviathan and Behemoth. Compare this to the winter thunderstorms to be seen at night over the Mediterranean from the Syrian coast.

The second part of the myth concerns the building of Baal's house. First, Baal must obtain permission from Asherah, El's wife. Then the house is built in the sky by the craftsman god Kothar-wa-Hasis. This "house" corresponds both to Baal's temple in Ugarit and to his dwelling place on Mount Saphon just outside the city.

In the third part of the myth Baal is dragged down to the land of the dead by its ruler Mot, but he is rescued by his sister, the virgin warrior Anat. She defeats Mot by a process identical to harvesting grain: she reaps him, winnows him, grinds him, and sows him back into the ground. Baal then returns triumphantly to heaven. It is not hard to see this episode in relation to the agriculturally dead Mediterranean summers, whose drought is defeated by the return of the winter thunderstorms.

In later times the traditional gods were worshipped under Greek and Roman names at prominent temples in the Levant, and their cults also spread throughout the Roman Empire. Local Levantine gods continued to thrive until the time of the Islamic conquest of the Near East in the seventh century C.E..

PERSIA

Persia (modern-day Iran), a country of Indo-European culture and language like Greece or Rome, conquered the Near East in the sixth century B.C.E. and, in particular, acted as the sponsor of Judaism in the return from the Babylonian captivity. The Persian religion was based on a text called the Avesta, written by the prophet Zoroaster (sometimes rendered as Zarathustra) and his disciples. The date span of Zoroaster's lifetime is unknown; while some scholars believe he lived around 1400 B.C.E., this remains speculative. Zoroastrianism is a "dualistic" religion. The prophet Zoroaster taught that the world was the scene of warfare between God (Ahura Mazda) and an evil power (Ahriman or Angra Mainyu) that wished to destroy the cosmic order. In the end god would triumph, and all the people who had ever lived would be resurrected (brought back to life) and judged with reward or punishment according to whether they had followed god or his enemy. Zoroaster also thought that the gods worshipped by other peoples were the demonic agents of Ahriman. It was believed that Zoroaster would be reborn at the end of time to play a vital role in the final triumph of good over evil.

Ahura Mazda was symbolized by light, so the main form of worship in Zoroastrianism was the maintenance of fire altars whose flames might be kept continuously burning for centuries. The priests who tended these fires and carried out other religious functions were called magi. They also kept Zoroastrian religious texts alive through memorization—these texts were written down only in later times when the very existence of the religion was threatened by the Islamic conquest of Persia in the seventh century c.e. The word magician comes from their name, because Greeks and Romans saw them as the embodiment of everything foreign and improper

in religious terms. A small portion of Zoroastrians refused to convert to Islam, and their descendents continue to live in present-day Iran; others fled to India (particularly Mumbai, formerly called Bombay). These groups (about 250,000 in number) are called Parsis.

ISRAELITE RELIGION AND JUDAISM

The Hebrew Bible is the religious scripture of Judaism, which has survived continuously from its origins in the Bronze Age (before 1000 B.C.E.) into the modern world. It is also the foundation document of Christianity and Islam, the two most widespread religions in the modern world. As a literary text it is an incomparable world classic with vast influence.

Judaism began within the matrix of Levantine religion but made a radical new interpretation of tradition. The Hebrew Bible has a great deal of mythology related to other Near Eastern myths, for example, Yahweh as a storm god living on a mountaintop, his slaying of Leviathan and Behemoth, and his creation of humankind from clay (the name *Adam* means “clay”). There is also nothing exceptional in terms of cult. Yahweh had a temple on one of his home mountains—Zion in Jerusalem—and received there the sacrifice of animals according to a fixed cultic calendar. But while Baal/Hadad had been the chief god worshipped in the Levant (polytheism) and Marduk had transcended his fellow deities to become a national god in Babylon (henotheism), the Bible introduces something quite new to Semitic religion—monotheism, the belief that there is only one god. The cult of other deities was characterized as idolatry, the worship of statues devoid of life and a terrible affront to Yahweh.

In the ancient Near East a common explanation for misfortune was that something had been done wrong in the worship of the gods: In order to counteract the misfortune, the gods must be worshipped again in the proper manner. Many scholars believe that this is how Jewish monotheism, the belief that Yahweh is the only god, developed, in reaction to the national catastrophe of the Babylonian captivity (587–537 B.C.E.), when the Israelite state was conquered by the Babylonians and its ruling elite transported to Babylon. Another factor may be the essentially monotheistic beliefs of the Persian patrons of the restoration (when the Jews were allowed to return to Israel). In any case, monotheism became the principal feature of all later Judaism and eventually of Christianity and Islam.

Part of what is new in Judaism is its moral dimension. A very clear example of this is the flood myth. In Atrahasis the gods want to destroy humankind because human beings are too loud and disturb the divine sleep, but humanity is spared because its service to the gods through cult is deemed useful. But in Genesis god destroys the human race because it has become wicked and promises not to do it again as a spontaneous act of mercy. These are concerns of a later era and can be paralleled with the development of ethical thought in Greek philosophy that was going on at the same time the Bible was being compiled during and after the Babylonian captivity.

Another new element in Judaism is eschatology. As we saw, there is almost no concern in Semitic religion about the survival of human beings in a life after death or of the end of the world as the completion of any kind of cosmic cycle. These eschatological ideas are, however, characteristic of the Zoroastrian religion of Persia. Later, Judaism and Christianity were happy to read eschatological ideas into the Hebrew Bible by allegorical interpretation (reading something manifest in the text as a symbolic representation to something that is not referred to). But eschatological themes do not become dominant in Jewish writings until the book of Daniel, the youngest biblical book (ca. 167 B.C.E.). Thereafter these topics become dominant in postbiblical Jewish religious writings, such as the Dead Sea Scrolls and the books of Enoch, and in Christian texts.

In 70 C.E. Jerusalem and its temple were again destroyed, this time by the Romans, and the Jews exiled from the land. Thereafter the cult of Yahweh ceased in its traditional form. Judaism became something new, Rabbinic Judaism, a religion of the book, whose main purpose was to read and interpret scripture. The traditional priesthood ended also, to be replaced by rabbis who led synagogues in reading and prayer.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Animism was the root religious belief in most of Asia and the Pacific during ancient times. In general animists believe that the universe has a multitude of spirits. Human beings are only a small and insignificant part of the cosmos. Some spirits are gods of various things on the earth. It is possible for animists to believe that everything has a spirit—every tree, blade of grass, animal, mountain, lake, stream, and stone—but most animistic religions do not go to this extreme.

Certain places on the earth serve as spots on paths commonly traveled by spirits. At such places a person may be able to summon a spirit or at least talk to one. Doing so is dangerous, because a human being can be driven insane or killed by a spirit passing through on business of its own. For such spirits, to kill a human who gets in the way is comparable to accidentally stepping on an ant.

OCEANIA

In what is today Oceania various versions of animism developed in ancient times. In Australia and Indonesia sacred places tended to center on large stones or rocky outcrops. People sometimes asked spiritual beings to help with hunting or to provide beneficial weather. Although individual animals had their own spirits, many animal species were represented by greater spirits. Although these spirits were usually far away and invisible, they sometimes took the form of their special animal on earth to communicate with earthly beings. Animals as diverse as kangaroos, wolves, and whales could have such spirits.

JAPAN

The ancient Japanese had a complex set of animistic religious beliefs. Many historians and archaeologists have argued that the ancient Japanese had no religion because they had no church authorities and no theology. However, the Japanese were a very spiritual people, and the fact that they had no central authorities or scriptures was actually part of their religious view, because they believed that no one person had a monopoly on spirituality. To them every human being had the potential to communicate with the numerous spirits that made up their world.

This is not to say that they did not have people with special spiritual talent. The legendary Queen Himiko (fl. 200s B.C.E.) was reputedly a sorceress whose powers helped her maintain control of her fractious, warlike people. The second monarch after her rule was a 12-year-old girl who was also a sorceress. This suggests that ancient Japanese beliefs allowed for magic and for people who were specialists in it.

The Japanese developed a concept now called *kami*. The word *kami* implies both an individual spirit and a spirituality that stems from great power or force. Thus not every tree had its own *kami*, but very big trees, by virtue of the spiritual force their size gave them, had their own individual spirits. Mountains likewise had spirits because of the power their size imparted, as did lakes, rivers, and other features of the landscape. Animals could have their own *kami*, but animal spirits often manifested themselves as much larger than the ordinary animal, showing that they had spiritual power. These special spirits could be huge wolves, pigs, or deer and were often guardians of forests. People could talk to these special animals and the animals could talk back.

The exact language spoken by the ancient Japanese is debated by archaeologists. Their names for their gods may have been different from those recorded when the Japanese became a literate people. Since each area could have its own special spirits, spiritual beliefs probably varied somewhat from place to place. In essence, the Japanese believed that the earth was special only to those who lived on it. Their gods were spirits with powers much greater than those of human beings, but they were mortal and subject to many of the inconveniences and miseries that human beings endure.

The world had an earth god and a sky goddess who were married to each other but could not embrace. The islands of Japan were created in the ocean by a husband-and-wife team later known as Izanagi no Mikoto and Izanami no Mikoto. Izanami no Mikoto died while giving birth to the god of fire, and she went to the land of the dead. Early references to the sun god indicate that he was male, though it is possible that some Japanese thought of this god as female.

Other gods represented the principal concerns of the Japanese. For example, there was a food goddess, Uke-Mochi, who was murdered and whose corpse gave rise to rice, millet, wheat, and red beans. There was a god for hunting and a god for fishing. There were also demons that could be evil or good.

The massive burial mounds of the 300s B.C.E.–200s C.E. in Japan suggest that people believed in an afterlife and may have practiced ancestor worship. Local warlords and Japanese monarchs were entombed under these mounds, atop each of which was a shrine, probably for people asking the help of the spirit of the person in the tomb. Near the end of the period during which the tombs were built, some had passages into the crypt, perhaps for people to go inside to communicate with the dead. Tombs were typically surrounded by small ceramic figures placed upright and facing outward, perhaps to ward off evil spirits.

KOREA

Two factors have hindered research into ancient Korea's religions. First, several military invasions since ancient times have resulted in the looting and destruction of ancient religious sites. Second, many of the best religious sites are in North Korea, whose government allows foreign archaeologists little access to them. The existence in Korea of burial mounds that seem to be duplicates of the massive burial mounds of Japan suggests to many archaeologists that some ancient Koreans were of the same ethnic group as the ancient Japanese and shared their religious beliefs and customs. It is possible that three distinct religious traditions held sway in ancient Korea, each animistic. One was that which was shared with the Japanese. The other two were derived from northern and central Asia.

Buddhism probably first reached Korea in 372 C.E. In 384 C.E. an Indian monk named Marananda converted the royal family of the kingdom of Paekche, which formed the western part of Korea. Paekche swiftly became a Buddhist nation, but little of the process of converting its people is known because most of Paekche's ancient sites have been destroyed. The kingdom of Silla in the southeast of Korea was introduced to Buddhism in 424 C.E., but the religion did not take hold until the 500s C.E., when the royal family converted to the new faith. Throughout the era of Buddhism's ascendancy Koreans' animistic beliefs survived, mostly in the form of magical rituals performed by shamans.

INDIA

Not much is known about the religion of the Harappan civilization (2600–1500 B.C.E.) of the Indus River area. Among the remains of that civilization are images of a man with antlers on his head, who may represent a god, and small statues of a large-breasted woman, who may have been a fertility goddess. Bulls are prominent in Harappan art and may represent a reverence for cattle that would later be continued in Hindu religious beliefs. In the rest of India animism underlay the numerous religions of peoples across the land. Animism never disappeared in ancient India, and it lay behind some of the magic and mysticism of country people. In the jungles of India were Stone Age peoples, clad only in leaves around their hips and who hunted with poisoned arrows and were said to kidnap travelers to sacrifice to their gods.

The Vedic Period lasted from about 1500 to 600 B.C.E. The Vedic culture emphasized sacrificing to its gods, but it may not have included human sacrifice. The word *Vedic* comes from the Vedas, which were stories, poems, and proverbs transmitted orally for a thousand or more years before being written down in the 300s B.C.E. They reflect the religious beliefs of the Aryans, cattle-herding nomads who spoke closely related languages and invaded the Harappan area starting in about 1500 B.C.E. The Aryans shared a belief, probably derived from animism, that all things of the world have a divine nature.

Before the Aryan migration into India, the chief god was Dyaus, god of the sky. He and Prithivi, goddess of the earth, had a son, Indra. During the Vedic Period, Indra was the most celebrated of all the gods. He was the god of storms and a great warrior. The demon Vritra had caused a worldwide drought by corralling the world's clouds; when he was born, Indra drank the mystical drink soma and then led the spirits of thunder into battle against Vritra. He released the clouds, which spread across the sky and brought rain to the earth. In a couple of accounts, after his victory over Vritra he killed

his father, symbolizing his ascendancy as the most important Vedic god.

The Vedic religion mixed with the religions of the areas the Aryans conquered, mostly in northern India, though their religious beliefs continuously moved southward to include ever more people. It is not known exactly when the Vedic religion became Brahmanism, which became Hinduism. Hinduism represented a significant break from animism, because instead of there being many spirits or gods, there was only one God and all the many gods of Hinduism were just different manifestations of the one God. The Aryans brought with them a social structure of four castes: the top caste was made up of the Brahmins, who were priests and teachers; then came the Kshatriyas, who were warriors and political leaders; after them were Vaishyas, who were farmers and tradespeople; then came the Shudras, who were laborers. Beneath them all were the Untouchables, for whom the worst jobs were reserved. Some historians believe that the Sudras and Untouchables were the native peoples of the lands the Aryans conquered.

These castes became part of Brahmanism. Brahmanism taught that there was an eternal law, Sanatana Dharma, which had always existed. The word *dharma* is often interpreted as “fate,” but it is not exactly fate. Instead it is *the way things are*, a statement asserting that there are facts about the universe that cannot be changed. When in the spring of 326 B.C.E. Alexander the Great's Macedonians defeated an Indian army led by Porus, the monarch of the Indian kingdom of Chenab, Porus was asked how he expected to be treated. He was recorded as saying, “As befits a king.” He was not expressing pride or bravado but simply his dharma, the unchangeable fact that he was a king. Thus members of the castes were living their dharmas. Each person was born into a caste because of the divine law of the universe. Each person was expected to strive to be the best he or she could be according to the rules of his or her caste.

Dharma was in part determined by karma—a form of divine energy that people acquired during their lives. It was believed that every human soul goes through cycles of death and rebirth, or reincarnation, in a new earthly body. How well a person fulfills his or her duties as a member of a caste in one life builds karma that will determine into which caste he or she will be reborn in the next life. By the 300s C.E. some Hindus believed this process included every single action a person ever took. Moment by moment what people did created positive or negative karma. In some parts of India people believed that the souls of people with too much negative karma could be reborn in animals, including insects. For some people this belief made vegetarianism a religious necessity. For others it was simply the animal's dharma if people killed and ate it.

The foremost deities of Brahmanism were Brahma, Vishnu, and Shiva. In the beginning of the universe a divine force created life-giving waters in which an egg arose. In that egg was Brahma. After a year floating on the waters of the

Limestone relief panel depicting the departure of Prince Siddhartha from his palace, to start on the spiritual journey that brings him to Buddhahood; this panel is from the dome of the Great Stupa at Amaravati, India (second century C.E.). (© The Trustees of the British Museum)

cosmos, Brahma broke out of his shell, using half of the shell to make the sky and the other half to make the earth. He then created the deities and the plants and animals of the world. Eventually he looked within himself and found the divine source of his being.

Vishnu originated during the Vedic era as a minor deity who was an ally or servant of Indra. During the first and second centuries C.E. he became a major object of veneration, deemed the protector of the earth. Whenever the earth was threatened with destruction, he would take a physical form called an “avatar.” Among his many avatars was the fish Matsya, who saved Manu, the first man, from a flood. Another was a boar that, when a demon threw the earth to bottom of the cosmic ocean, killed the demon and returned the earth to its proper place. Another two of Vishnu’s avatars were Ramacandra and Krishna, who developed their own worshippers.

Ramacandra, or simply Rama, was the son of a king who exiled him when he married Sita, a princess from another land. Ravana, the demon-king of Sri Lanka, kidnapped Sita. With the help of his brother Lakshmana and the monkey Hanuman, son of a deity and a monkey, Rama defeated Ravana and rescued Sita. Rama represented the ideal man: virtuous, courageous, a good husband, and a good leader. Krishna was the son of the sister of a wicked king in northern India. The king tried to have Krishna killed, but Krishna’s mother sneaked him to safety in the country. As a baby he killed a demon. He grew up to be entrancingly handsome, and many young women yearned for his company. Later he killed the wicked king and taught people how to live good spiritual lives.

Shiva was both creator and destroyer. His meditating generated the spiritual energy that sustained the entire universe. When his female companion, Parvati, covered his eyes for fun, the universe was almost plunged into darkness, but Shiva manifested a third eye on his forehead; as long as he could see, the universe would have light. He later turned his third eye to look inward to meditate. Shiva was also a fertility figure, as well as the deity of medicine and of dance. His worshippers used dancing as a way to express joy but also to express the chaos that could destroy the universe.

In the 500s B.C.E. a member of the Kshatriya caste, Vardhamana (ca. 599–527 B.C.E.), established Jainism. Jainism took its name from *jina*, meaning “conqueror.” Jainists were expected to swear that they would not kill, lie, have sexual relations for any purpose other than to procreate, or be greedy. Jains were supposed to be nonviolent and very strict vegetarians. They were forbidden to take any animal’s life and would place strips of gauze over their nostrils and mouths to avoid breathing in any tiny creatures. Brahmanists regarded them as heretics because they did not accept the Vedas as religious scriptures and ignored the caste system.

Siddhartha Gautama (ca. 563–ca. 483 B.C.E.) was a member of the Kshatriya caste. Through meditation he had a divine revelation that made him the Buddha, a person who achieved true enlightenment. After his revelation he spent most of his life teaching across northeastern India. The Buddha believed

that to live is to suffer, and that suffering is caused by desire. To escape suffering, a person should eliminate desire through meditation and should do what is morally right. If someone did this, his or her soul would skip reincarnation and go to Nirvana, where it would join with the universal spirit.

When Asoka (r. 265–238 or ca. 273–232 B.C.E.), king of the Maurya Empire (321–185 B.C.E.), converted, Buddhism became the state religion. Asoka followed the Buddhist doctrine of tolerance and allowed other religions to be practiced in peace. He tried to make his subjects more moral through public proclamations explaining why he was a Buddhist. During his reign Buddhism spread through most of India. It eventually reached the island of Sri Lanka, where it became the dominant religion. Buddhism began to wane in India in the 100s C.E. By then it had spread into China.

CHINA

During his reign (221–210 B.C.E.) China’s emperor Qin Shi Huangdi tried to have all documents about the past destroyed. He wanted to eliminate the possibility of imitating the errors of past governments, and he wanted world history to begin with him. He had over 40,000 Confucian scholars buried alive to eliminate their knowledge, but a few managed to survive and, in the welcoming Han Dynasty (ca. 202 B.C.E.–ca. 220 C.E.), recited what they remembered of the ancient texts. Almost everything about China’s religion before Qin Shi Huangdi’s reign was lost. What is currently thought about Chinese religion before that time comes from archaeological discoveries and inferences about past beliefs drawn from writings of the 100s B.C.E.

There were many cultures in ancient China, and each probably had its own special gods and spirits. The earliest religious beliefs were probably animistic. Animism never entirely left ancient China, and it was a source of magic among peasants. Human sacrifices were common. For instance, in the 400s B.C.E. a governor of the upper Yellow River discovered that people were still sacrificing girls to be brides of the river in springtime; he put a stop to it, but especially in the areas south of China human sacrifices to fertility goddesses continued into modern times.

Animal sacrifices were also common. In 30 B.C.E. the Yellow River was close to flooding. The local governor walked to the riverbank and offered the sacrifice of a gray horse to the river. The governor used his magical jade ornaments to cast spells to protect his people. As the river rose, all his aides fled; only he and one assistant stayed. After the waters stopped just short of breaking free to flood the land, the governor was rewarded with gold and a promotion. Such mystical practices deriving from animism continued for thousands of years.

By the time of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) ancestor worship had become prevalent not only in the Yellow River area but also in surrounding regions that would one day fall under the rule of China. People would leave offerings to their ancestors at tombs of their ancestors. Kings were expected to consult their ancestors in times of

crisis and to ask their ancestors to speak with gods to help ensure weather appropriate to each of the seasons, for good harvests, and to prevent floods. During the Shang Dynasty and most of the Zhou Dynasty (ca. 1045–ca. 256 B.C.E.) servants were sacrificed to be buried with their masters. Their heads were chopped off with special axes and buried separately from their bodies. Why they were buried separately is not known, but the practice was common enough to occur even in the burials of some ordinary peasants and soldiers. The servants were expected to serve their masters in the next life. By the end of the Zhou Dynasty human sacrifices at the burials of nobles and monarchs were rare, though they still sometimes occurred. The sacrificing of servants was replaced by the burying of ceramic sculptures of people. It is likely that the ceramic figures were magically endowed with spirits that would serve their masters and mistresses after death. The human sacrifices may have been one of the ancient practices that Qin Shi Huangdi hoped to end with his rule. His tomb has China's most spectacular collection of ceramic sculptures—thousands of life-size figures.

Most archaeologists believe that women took subordinate roles in ancient Chinese religion. Little mention is known of women divinities, although belief in a great witch whose body was carved into the lands of the earth seems to have been widespread. The most important female supernatural being was said to live in the Kunlun Mountains, a range near modern Tibet. Ancient Shang records on bamboo found in tombs mention a mother goddess to the west. By the 900s B.C.E. this goddess had become the focus of a cult. She was said to live in a mystical land that existed apart from the ordinary world, but people could find their way to it through the Kunlun. She was called Xi Wang Mu, “Queen Mother of the West,” and was said to have the secret to immortality. In about 113 B.C.E., during the Han Dynasty, an army was dispatched to northwestern China to secure the safety of the Silk Road. Another purpose of the expedition may have been to find the way to the land of the Queen Mother of the West.

During an era when the Zhou Dynasty was divided among several states the philosopher Confucius (551–479 B.C.E.) taught his belief that government should be benign. Although he insisted that he himself had no original ideas but was only reminding people of wisdom learned by ancient leaders, he and his followers tried to replace what they regarded as irrational religious views with rational ones. This did not mean that Confucianism opposed religion; Confucius insisted on following religious rituals, arguing that in them people could find ways to communicate properly with gods and their ancestors. What Confucians opposed were the practices of folk magic, including witchcraft and human sacrifice. In religious rituals was rationality; in magic spells and the invocation of demons was nonsense. Although the Han Dynasty adopted Confucianism as its philosophy of government and Confucius became a venerated figure, Confucianism itself was never a religion.

Another teacher of the same era, Laozi (ca. 604–521 B.C.E.), did found a religion, called Daoism. Credited with writing *Dao de jing* (The Way and Its Virtue), he advocated self-control as a way to preserve the body and live long. His followers created rituals that were supposed to bring the body under control and subdue the forces within it that made it grow old. The chief god of Daoism was Yu Huang, the Jade Emperor. The Queen Mother of the West was his wife. He was assisted by many gods. Each year he summoned them to his palace and gave each god new duties based on how well the god had performed his work during the previous year. When there were troubles such as droughts, floods, or plagues, Daoist priests told the god in charge that he was performing poorly, and Yu Huang took note. The offending god could be dismissed from his post during the annual review of his work.

The parallel between Yu Huang and the Chinese emperor was intentional. The emperor ruled because he was appointed by the gods, and he had to maintain a good relationship with them if he was to remain in their favor. Should he fall out of favor, religious doctrine dating all the way back to the Shang Dynasty said he should be replaced by someone the gods had blessed. It thus was the custom for usurpers of the throne to declare that they were only acting on behalf of the gods. During the second half of the Zhou Dynasty emperors had little political power but were treated with respect by the rulers of the various Chinese provinces, because without the emperors they would have little to justify their own rule. The emperor maintained the fiction that he appointed the rulers of the Chinese states on the basis of divine authority: He was emperor because of divine favor, and divine favor passed through him to the various warlords, chiefs, and kings of China's provinces.

During the 300s B.C.E. the concept of yin and yang developed. Yin and yang represented the universe as a duality of opposing forces. Yin was dark, soft, receptive, and “female,” while yang was hard, bright, active, and “male.” Without yin and yang in constant opposition, the world would not be possible. Much folk magic depended on mediating between yin and yang to find the proper balance between them, and much that was wrong in the world was attributed to an imbalance of the two.

During the Han Dynasty an entire department of government was devoted to religious matters. There was much for the officials to keep track of. For instance, the emperor had to wear particular kinds of clothing at particular times of year because his clothes were a reminder to the gods to change seasons at the appropriate times. If he wore the wrong clothing, disaster could follow, with the seasons becoming mixed up. There were rituals for him to perform—probably more than any one person could remember—which meant the government needed priests who could keep track of what was needed.

During the second half of the Han Dynasty two things occurred that would shape Chinese religion for centuries. First, in about 142 C.E. the mystic Zhang Daoling declared that he had had a revelation from Laozi telling him to start a

new religion. By then Daoism had fragmented into different sects. Zhang Daoling created the Way of the Heavenly Masters, which provided a model for earthly as well as heavenly rule. He established a religious government in the province of Sichuan, with himself and his heirs ruling a bureaucracy intended to imitate that of Yu Huang. Thus renewed, Daoism became a central feature of Chinese religion.

The second important religious occurrence was the spread, beginning about 50 C.E., of Buddhism into China. By about 65 C.E. it was known to the emperor's court. During the 100s C.E. it became the most prominent religion in the capital city, Luoyang. In 166 C.E. Chinese emperors began holding rituals in which they sacrificed to both Laozi and the Buddha. For common people in China, Buddhism held the promise of salvation, of a chance to go to heaven. Early Buddhist translators of scriptures into Chinese often used images from Daoism to explain their faith to people, and the way of Daoism and the pious way to Nirvana of Buddhism often blended. For centuries most Chinese saw little difference between the two and venerated both religions even while continuing to worship their ancestors and believe in magic.

EUROPE

BY KIRK H. BEETZ

Some of the earliest artworks from Europe may also be the earliest signs of religion there: cave paintings from France and Spain dating to about 32,000–30,000 B.C.E. and small stone carvings of large-breasted women, such as the so-called Venus of Willendorf found in Austria, dating from roughly 28,000 to 23,000 B.C.E. The principal subjects of the paintings are animals, richly detailed by the prehistoric artists. Also found in caves are sculptures, mostly relief carvings, of animals and of women. Archaeologists have long debated the significance of the ancient cave art, but most speculate that the depictions of animals were intended to give people power over them in order to make hunts successful. Human figures often are portrayed hunting the animals, and perhaps by painting or sculpting these scenes the artists believed they were making the animals and the hunts real.

Statuettes like the Venus of Willendorf may represent a fertility cult or an earth-mother cult. Whether the carvings were intended to be worshipped or were totems representing a goddess is not known. Some archaeologists suspect that they represent a matriarchal religion or society, meaning that women were the dominant priests or social leaders. However, there is considerable debate over the purpose of these figurines.

Ancient religion often is connected with death and burial. Burying the dead goes back at least to the last great ice age, and many archaeologists believe that the practice is a sign of belief in an afterlife. On the other hand, burying the dead might be merely a sanitary measure—corpses bring disease and attract predators, and burying them covers both decay and odor.

By 3500 B.C.E. Europeans were building monuments of huge stones, or megaliths (from the Greek *mega*, meaning “large,” and *lithos*, meaning “stone”). Usually these people placed corpses within the stone chambers and then covered the structures with large earthen mounds, termed *tumuli* by archaeologists. In a few places the megalith builders took more elaborate measures, such as building stairs down into chambers and constructing several niches for the dead, making it clear that more than one person was interred inside a single tumulus.

Even such large and laboriously built burial structures as these, however, are not necessarily evidence of belief in an afterlife. The imposing megaliths might, for example, have been intended to announce that a particular village or clan owned the surrounding land. The tumuli, some of them visible for miles, might have carried the same message. On the other hand, there are indications that mourners left burial goods in the stony chambers of some tumuli, which would suggest a belief that the dead needed supplies for an afterlife.

In Ireland, England, and western Europe many megalithic complexes took centuries to build. Some are merely enigmatic rows of upright stones weighing tons each, their purpose unknown. Others provide hints to their ritual significance. The most famous of these is Stonehenge in England. Stonehenge was erected in an on-and-off fashion over hundreds of years, and periodically people, presumably individuals with high social status, were buried among the stones. This and many similar monuments were situated so as to line up with astronomical events. At Stonehenge the sunrise on the summer solstice aligns with the axis of the main passage between the exterior of the circle and the interior. The significance of this arrangement is unclear, but it must have had some symbolic or ceremonial meaning.

CELTIC RELIGION

The Celts appear to have developed in east-central Europe, perhaps in the area of today's southern Germany and Czech Republic, though they may have migrated there from central Asia. They begin appearing in the historical record about 500 B.C.E., at which time their culture was flourishing. Greek and Roman writers tried to fit Celtic religious beliefs into their own understanding of religion, sometimes doing as Julius Caesar did and giving Celtic gods and goddesses the names of their Greek or Roman counterparts to make things easier for their reading audiences.

However, Celtic beliefs were too complicated to fit comfortably with the sorts of gods and goddesses the Greeks and Romans worshipped. Some archaeologists believe that ancient European religions sprang from a core religion (perhaps belonging to the megalith builders) that once existed in central Europe. In Greece and Rome the gods and goddesses of this core religion each gained preeminence over some special realm, such as war, agriculture, or the sea. When the Greeks and Romans ventured into the rest of Europe, they brought their specialized gods with them. But the people they met, the

Celts, had taken another direction in their religion. The Celts believed there were gods and goddesses everywhere. Bodies of water, even small ones, had their own individual spirits, as did particular pieces of land. Dark parts of forests could harbor spirits of great power.

By the first century B.C.E. the Celts inhabited almost all of northern Europe, and they had become a diverse group of peoples with diverse religious beliefs. For instance, the Celts of the Iberian Peninsula (present-day Portugal and Spain) held somewhat different beliefs from Celts in Britain, Gaul, and the Balkans. Ideas about life after death, an afterworld, and the human soul had variations depending on which group of Celts one studies. These differences defied Greek and Roman efforts to describe a single set of Celtic beliefs.

For example, one aspect of Celtic belief mentioned by Caesar involved the transmigration of souls. The word *transmigration* is here chosen with care, because it is not the same as *reincarnation*. Celts did not believe in reincarnation—the rebirth of the soul into a new human being—but some believed that the soul of a dead person could migrate to the body of another living person. Thus the souls of the dead were dangerous. One way of dealing with the danger was to decapitate an enemy and carry the head home to be placed in a chest or in a shrine. Because the head was believed to be the seat of life, control of it imparted control of the dead person's spirit, which could be used for protection from other spirits.

Other Celts, however, believed that the souls of the dead went to an afterlife. They envisioned a special land where no one ever lied, where good fruit abounded, and where hunting was always successful. It seems to have been universal among the Celts that they did not believe in sin or in good deeds as having effects after death. Everyone, good and evil, went to the afterlife and shared in it. For those who believed in this afterworld, it was ruled by the first man who ever lived, who when he died became the first person in the afterlife and made the land of the dead his own.

The land of the afterlife was not a well-defined place, partly because the living could visit it and even live there. In parts of western Europe, Britain, and Ireland a person could walk through a supernatural mist and emerge in a strange land with amazingly beautiful and imposing fortresses inhabited by people who were courteous and kind. Elsewhere people believed that crossing a lake or spring or walking through a sacred grove or among old stone megaliths could bring a person into the otherworld, which could have been the land of the dead or a mystical alternate dimension to the earth. The Celts themselves seem to have been vague about the nature of the otherworld, regarding it as something removed from the laws of the ordinary world and therefore something that ordinary people could not fully comprehend. During the festivals of Beltane (May 1) and Samhain (November 1) the borders between the everyday world and the otherworld disappeared, and both humans and supernatural beings could cross from one to the other without trouble.

The roles of the priests, shamans, seers, and magicians of the Celts are almost as unclear to scholars today as they were to ancient observers. The Druids are the best known of these figures, but they did not have influence much beyond the British Isles and western Europe. When Caesar wrote of them, he noted that they had probably originated in Britain, because those who studied to be Druids usually went there for their education. Archaeologists and historians have speculated that what Caesar actually saw was a dying cult, with the Druids already disappearing from the Continent but holding out in parts of Britain. This notion implies that the Druids flourished for only a few hundred years. Whatever the period of their existence, they were certainly among the best organized of Celtic religious groups. They met annually in the land of the Carnutes (the area around modern-day French cities of Chartres, Orléans, and Blois), where they discussed political, theological, and legal business. They had a leader who was elected at this assembly, when necessary, and who served for life.

Druids seem to have been exclusively male. A woman could be executed for witnessing any part of certain sacred rites. The Druids resisted the use of a written language. Each priest was expected to spend 20 years memorizing laws and rituals, and no outsider was allowed to learn them. Druids served as judges in legal matters, as priests in worship, and as seers who through ritual could foretell the future. The Greeks and Romans depicted the Druids and Celtic priests in general as very murderous and bloody, and the archaeological record supports their claims. For instance, the Druids foretold the future by cutting out a living human being's intestines and studying their configuration. Another approach to telling the future was to stab a person in the diaphragm and observe where the blood spurted and how the victim writhed in agony. Torturing, maiming, and mangling human sacrifices occurred at festivals and during efforts to win the favor of certain gods. Sometimes horses were sacrificed. Wars sometimes have been waged for the purpose of taking prisoners to be used in ritual sacrifices.

Although the Druids tried to make themselves the exclusive intermediaries between human beings and the supernatural, most Celts believed that anyone could have contact with the supernatural. One way to achieve this kind of individual contact was by making sacrifices during public rituals. This practice was taken very seriously, as evidenced by the very rich sacrifices given to spirits of rivers and lakes. The river Thames in England has yielded numerous artifacts, such as finely cast bronze armor and gold jewelry. Some armor, shields, and swords are extraordinarily ornate, as if made specifically for sacrifice to the river god, perhaps in the hope of future military victories. (When a Celtic war party led by Brennus looted the temple at Delphi in Greece in 279 B.C.E., much of the booty seems to have been deposited in a lake in eastern Europe.) Sometimes the sacrifices were deposited on sacred sites on land, and people did not touch the gold and other valuables for fear of retribution from gods and other Celts.

Iron Age horned helmet (150–50 B.C.E.), from the river Thames at Waterloo Bridge, London, England; horns were often a symbol of the gods in different parts of the ancient world, suggesting that this was a ceremonial helmet made for a god. (© The Trustees of the British Museum)

Magicians had a strong hold on many Celts. Even long after being absorbed into the Roman Empire, Celtic peasants practiced the old magic of their ancestors. The Romans regarded magical practices as dangerous because a magician might develop a cult following that could cause trouble. The rebellion of 53 B.C.E. may have been sparked in part by shamans or magicians stirring up notions of freedom among the Celts. In (probably) 60 C.E. a Roman army attacked the island of Anglesey, off the coast of Wales, and annihilated the Druids living there. The island was perhaps the last remaining center for Druidic education and had been the scene of numerous human sacrifices; the Druids seem to have made themselves troublesome by encouraging revolt against the Romans. At that moment Queen Boudicca of the Icenians of Britain led a revolt that nearly drove the Romans out of England. The source of her power among the Britons seems to have been her status as a sorceress.

Over 200 names of Celtic gods have been discovered, and historians are far from sorting them out. Some gods seem to have had several names, while other names seem to belong to individual local gods. For the Celts religion was a matter of locality, because each area had its own gods of the land and water. These gods sometimes reappear in medieval tales—for example, the Lady of the Lake and Lancelot du Lac (Lancelot of the Lake) in the legends of King Arthur—revealing their powerful long-term hold on people's imaginations.

It is likely that sun gods and earth goddesses were worshipped throughout the lands of the Celts. The sun god was often represented by wheels, and carts in eastern Europe seem to have become symbols of the sun's movement through the sky. Spoked wheels appear to have been included in sacrifices to the gods. Domestic goods were sacrificed to the earth goddess, who seems to have been in charge of the fertility of

the soil. She was sometimes celebrated in spring festivals. Sky gods were common and tended to be represented by a hammer, which was associated with thunder.

Associating other gods with specific aspects of the world is difficult, because Celtic gods and goddesses tended to be good at doing everything. For instance, the god Lenus of northern Gaul was associated with the Roman war god Mars by Caesar, but Lenus was a healing god as well as a warrior. Lugos of Gaul and Ireland was associated with the Roman messenger god Mercury by Caesar, but Lugos was also a good warrior. His mate, Rosmeta, represented abundance and was symbolized by buckets of wine. Danu was celebrated by many Celts as a fertility goddess. A goddess known throughout Gaul and among southern European Celts was Badhbh, perhaps the most terrifying of Celtic gods. Many Celtic gods were shape-shifters—that is, they could change into animals or even human beings—and Badhbh could change into a crow. In that form she flew over battlefields, waiting to feast on the souls of the dead; she could carry souls from life to the otherworld. Celtic warriors were mindful of her and took care not to offend her. She waited at river crossings for warriors to pass by and knew which ones would die that day.

Regional gods and goddesses of note include Sequana, the goddess of the Seine River. At the headwaters of the Seine, her water could heal people. Sulis was a goddess at the site of present-day Bath, England. Another deity who was good at almost everything, she offered healing and retribution.

GERMANIC AND SCANDINAVIAN RELIGIONS

Even less is known of the religions of the Germanic and Scandinavian peoples before the era of the Vikings than is known of Celtic religion, mostly because literate observers such as Greeks and Romans had far fewer contacts with them than with the Celts. The early Scandinavians may have had an earth goddess or a fertility goddess at the center of their religious beliefs. She granted her followers prosperity that was represented by displays of wealth. The peoples of northern Europe may have had a war god at the center of their beliefs. When they and the Scandinavians mixed, creating the Germanic peoples known to history, they may have had a fundamental conflict between their religious views, with the worshippers of the war god regarding the lavish wealth of the earth goddess as immoral and wasteful.

Over time the diverse Germanic peoples evolved a compromise religion that became the foundation for the Norse beliefs known from Viking sagas. The gods of the worshippers of the earth goddess became known as the Vanir, whereas the gods of the worshippers of the war god became known as the Aesir. Their compromise manifested itself in a myth about a war among the gods. The war god and his followers tried to kill a giantess who could not die, and she endured terrible tortures because of their efforts. Perhaps taking pity on her, the Vanir came to her rescue and fought the Aesir. The Vanir possibly represented healing and mercy. The gods reached a stalemate in their battle and then made a treaty.

They exchanged hostages, with one of the hostages being the earth goddess herself, who went to live with the war god. If she was the basis for the Norse goddess Freyja, it would explain Freyja's sexual promiscuity, which would represent her exceptionally fruitful powers. It may be significant that the earth goddess ended up as a hostage to the forces of the war god, making him the chief of all gods.

This war god would have become Odin, perhaps by the 400s C.E. It worth noting that an early Christian writer, known as the Venerable Bede (673–735 C.E.), wrote that Odin had been a great Germanic king who was deified. Although Bede was biased against the pagan religion of the Germans, he may have touched on a truth, because sometimes historical figures become gods or goddesses in their cultures. For instance, two of the avatars of Vishnu—Rama and Krishna—in the Hindu faith may have been important leaders during the preliterate era of the Vedic religion.

If in fact a core European religion once existed that was transformed into the pantheons of Greece and Rome and into the elaborate and contradictory beliefs of the Celts, then it took another interesting turn among the Germanic peoples. Where the Celts had gods all over the landscape, the Germanic peoples developed supernatural beings that were usually mortal. They had dragons, dwarfs, light elves, dark elves, trolls, and giants. Dragons were frightful creatures who loved wealth and hoarded treasure that they fiercely guarded. The dwarfs lived in the ground. If exposed to light, they turned to stone. Light elves were beautiful and airy. They may have inhabited the sky. Dark elves lived underground and were sullen and unfriendly. Trolls were monsters, perhaps associated with specific spots of land. They served the giants, who inhabited mountains and lands of frigid cold. (All these different beings seem to have been part of a creation-of-the-world myth in which all appeared at about the same time, with human beings inhabiting a realm between the sky and the ground. Thus the ancient Germanic religion had a world of three parts, with humanity in the middle.)

The mortality of these and other supernatural beings is perhaps the most unusual aspect of the Germanic belief system. Only rarely does any being have immunity from being killed. Even the gods can die. This mortality even for gods is part of a dark view of existence that all the Germanic peoples seem to have shared by the first century B.C.E. Everything was temporary in their faith. The gods would perish, and the world would end. Even those who had gone into the afterlife would eventually be snuffed out. The later Vikings viewed the end as a great battle between good and evil, full of betrayal and futile heroism. The war god himself would perish. The earth would be destroyed, taking the earth goddess with it.

It is not known for sure when runes began to be used in Germanic rituals. A form of writing made up of straight lines set at various angles, ideal for engraving into stone, runes may have been a late development, but they may have predated the onset of Christianity in the 100s C.E. They were considered sacred, and most people were not allowed to know

their meaning. It seems that just as Druids wanted to keep their supernatural knowledge to themselves, the priests of the Germanic peoples wanted exclusive knowledge of how to write. Part of the importance they attached to writing was that it could reshape reality. To them the written word had a supernatural creative power. A written word could kill, could create an animal, could change the weather, or could change much else.

The Germans may have shared with the Celts a belief that the spoken word had the power to alter reality. This belief was wrapped in mysticism. Common in the German culture were women seers and sorceresses. The Germans did not have temples, so their ceremonies often took place in homes. Female seers traveled the countryside, perhaps making annual rounds, and they held ceremonies in people's houses. They could tell women whether they would become pregnant in the near future and tell farmers whether they would have good or bad crops. During early medieval times the female seers wore cloaks made of many different animal skins, and they probably did so in ancient times too. Archaeologists have found bronze caps, dating to the last few centuries B.C.E., that were attached to staffs the female seers carried with them. Perhaps they served as signs of a woman's status as a magician. The staffs themselves may have served to focus their owners' supernatural powers.

It is possible that these female seers sacrificed animals on occasion to help them foretell the future. They may have claimed certain powers over the dead, such as being able to bring them back to life for a short time to speak with the living and even take action. The female seers' powers were to be used only by women. Men who practiced the magic of the female seers were put to death; apparently they represented a danger to the community because the magic could get out of their control.

The ancient Germanic peoples practiced human sacrifice extensively, but this does not seem to have been associated with the female seers. Animals were often sacrificed by chiefs or kings. The blood of the animal could consecrate a building or meeting place. The animals were cooked and eaten by the chief and his guests, symbolically uniting them in mutual obligation. Those assembled were expected to aid the chief in his rule, and the chief was expected to guide his followers to prosperity. In Sweden and Denmark special gathering places existed where tribes made sacrifices to mark the seasons. Human beings were killed on such occasions, probably nine or 99 at a time, as was the practice of the Norse. Hanging, strangling, cutting the throat, and drowning were among the methods employed. The corpses were hung from trees in a sacred part of a wood or sometimes dumped in bogs. Even in Denmark's sacred groves of Nerthus, the goddess of peace, prisoners were drowned as sacrifices to her in the first century C.E.

Some ceremonies were practiced by all Germanic people. For example, they made sure to leave food as offerings to the elves, took care not to offend the easily insulted dwarfs, and used charms to ward off evil spirits. That they buried their

dead with goods such as food suggests that they believed in an afterlife in which the dead would need or want the goods. They seem to have believed that deceased family members could be good influences for their living kin. Historians and archaeologists disagree about exactly where the Germanic peoples thought people went after death. Many argue that the notion of Valhalla, the home in the afterlife for those slain in battle, came late to the Germanic peoples, the ancient peoples believing only in a dark place in the earth governed by a goddess of the dead.

EARLY EUROPEAN CHRISTIANITY

Christianity was making itself felt in Europe by the end of the first century C.E. It was one of several religions circulating at the time, especially in central Europe. One competing faith was Mithraism, an exclusively male religion especially popular among soldiers. Mithras was a warrior god, and dead soldiers could hope to join him after death in a battle against evil. Perhaps the key to the growth of Christianity in Europe in these early years was that it welcomed women in its religious rites. Roman men often served decades in the army, leaving women at home to raise the children. It is a tiny logical step to imagine many women taking their sons and daughters to a church that treated women with greater respect than did other European religions. By the time the Roman emperor Constantine the Great converted to Christianity (ca. 312 C.E.), the faith already had a strong European following. Thereafter, Christian priests often became secular as well as spiritual leaders—for example, as bishops who governed towns and regions around towns.

During this same period, however, Christians themselves were embroiled in bitter theological disputes with one another. The main issues concerned the divinity of Christ and particularly whether, if divine, he was of the same substance as God. Conflict over such questions, resulting often in executions and sometimes in wholesale massacres of “heretics,” continued in Europe long after the fall of the Western Roman Empire in 476 C.E.

GREECE

BY BRADLEY SKEEN

Religion was the main binding force in ancient Greek culture. Greek religion gave birth to philosophical speculation that in time not only led to the development of science but also provided the theological language of Rabbinic Judaism, Christianity, and Islam. It formed the basis for the creation of the first modern literature, which is still among the most important ever produced. Greek religion has remained a source of inspiration for artists, writers, and composers as well as theologians and philosophers down to the present day.

MINOAN RELIGION

The Minoan civilization on the island of Crete (ca. 2000–ca. 1400 B.C.E.) was the beginning of Greek civilization, though

its people did not speak Greek. Minoan culture centered on a number of palace complexes; the most important was Knossos. The agricultural produce of the surrounding countryside was dedicated to various gods in the palace storehouses; obviously religion was very important.

We know about the religion of Minoan Greeks from their art and from myths that were written down centuries later. For example, frescoes in the palace at Knossos make it clear that one of the most important activities of Minoan culture was an athletic festival in which young male and female athletes leaped over bulls. Meanwhile, the classical myth of Theseus (a legendary king of Athens) tells that each year every city in Greece had to send young men and women to Knossos, where they were sacrificed by being killed by the Minotaur—a monster with a human body and the head of a bull. No definite connection between the historical evidence and the myth can be made, however. The Minoans left extensive records written in an alphabet known as Linear A, but these texts have never been deciphered.

Minoans did not build temples like later Greeks but instead worshipped the gods on hilltops and in caves. Perhaps they thought these locations were nearest the gods of the sky and the gods below the earth, respectively. These shrines were generally located near palaces, and their service was one of the chief duties of the kings. The most important form of worship was animal sacrifice, especially of bulls. Cave shrines sometimes contained a statue of the goddess honored in them, but shrines also held many offerings of double-headed axes and swords that suggest important male deities. Private houses generally had small shrines. Many statuettes of a woman have been found, wearing the clothing of a Minoan aristocrat and holding her arms above her head with a writhing snake in each hand. Undoubtedly, the statuettes depict goddesses.

Invaders from the north—the first people we know of who spoke the historical Greek language—eventually overwhelmed the Minoan civilization. They founded many new cities, especially on mainland Greece; the most important was Mycenae, so their culture is called Mycenaean (1400–1100 B.C.E.). They wrote a form of Greek in a Minoan alphabet later than Linear A and known as Linear B, generally inventories of the royal palaces of the cities. Many of the listed items were dedicated to various gods, the same as those worshipped by later Greeks, such as Zeus, Poseidon, Athena, and Dionysus.

The Homeric epics of the *Iliad* and the *Odyssey* are another source of information about the Mycenaean. The most important works of Greek literature, they were written down around the sixth century B.C.E. but are both set in Mycenaean times (as was the narrative of much Greek myth) and were based on oral traditions that went back to that era. These texts suggest that many institutions of historical Greek religion, such as priesthood and sacrifice, were already formed in the Mycenaean culture. But as in the case of the Minoans, the sparse evidence provides more questions than answers.

Between 1200 and 1000 B.C.E. the whole eastern Mediterranean world, including Greece, underwent a terrible collapse.

Larger governmental structures and the economy failed. Several waves of barbarians raided at will throughout the area. Every major Greek city was destroyed. Greece entered a dark age lasting many centuries, with no social organization above the level of the village and no contact with the outside world. The ability to read and write was completely lost.

THE RELIGION OF THE GREEK CITIES

During the Archaic Period (600–480 B.C.E.), Greece recovered politically and economically and once again had extensive overseas contacts with the Near East, not only through merchants but also through the many Greek mercenaries who served foreign kings. Greeks reacquired literacy and developed their own alphabet, modified from Phoenician writing, which was also the ultimate basis for the Latin, Hebrew, and Arabic alphabets still used today. They borrowed many religious ideas and forms from the Near East, such as the idea of the temple as a house of a god, the ritual of animal sacrifice, and myths that were incorporated into literary works like the poet Hesiod's *Theogony* (Generation of the Gods). The Archaic Period established the conditions for

the flourishing of Greek culture and religion in the Classical Age (480–323 B.C.E.), a period admired as an ideal by many later cultures.

By the eighth century B.C.E. Greek cities (or city-states, since each city in Greece was an independent country) began to be established or reestablished, often by bringing together all the villages in a given locale under one government and even relocating the population to a central point. New religious institutions had to be created for the benefit of the cities. Each city established temples for its particular gods—places where people gathered to pray and sacrifice to a god and where property dedicated as offerings to the god was stored. The temples were controlled by the city and administered by priests chosen from among the aristocratic classes. The city also fixed a calendar of festivals and sacrifices for the gods it honored. The official religion, with all of its public rituals carried out by the citizens all together in great public ceremonies, was the most important factor in unifying the city and providing it with a national identity. By the same token the religion of the city was the chief form of religious experience of the Greeks.

Frieze of the gods Poseidon and Apollo and the goddess Artemis from the Parthenon (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

The private religion of the family continued as earlier at household shrines. Cemeteries became centers of family religion also. Traditionally the dead were believed to sleep peacefully, and families brought wine and food to graves to keep their dead ancestors content and prevent troublesome ghosts from returning.

The principal form of worship in civic religion was animal sacrifice, nearly identical to the practice of the Near East and certainly imported into Greece from the older civilization. Descriptions of sacrificial practice in Homer indicate that Eastern rituals were adopted by Greeks of the Mycenaean era and remained almost unchanged through classical and later times. The purposes of sacrifice were to honor the god who received it, to give a gift in exchange for the many gifts the god had bestowed on humanity (such as rain, peace, or justice), and to ask for more benefactions. Since everyone who attended a sacrifice shared equally in the following meal, the ritual was often also a gift from the wealthy to the poor (who might otherwise rarely have meat in their diets).

Sacrifice usually took place after a procession through the city with hymn singing and dancing, leading the animals to the temple. A Greek temple was meant for housing the cult statue of a god, but its dark interior was rarely entered. The outside of the building was the important part, ringed by a row of columns to act as a backdrop, its facade topped by a frieze illustrating a well-known myth of the god. The ritual centered on an altar in front of the temple. The sacrificial animal, preferably a bull, had to be perfect, free from illness or deformity. A girl carrying a basket of grain on her head led the procession. When it reached the altar, the priest and the professional butchers who would actually kill the animal purified their hands by washing them with water. The animal was asked if it was willing to be sacrificed; it could be induced to nod its head by giving it water or food in a bowl on the ground.

The participants in the sacrifice threw the grain from the basket over the animal and the altar. The priest used a knife hidden in the grain to cut off three hairs from the animal's back and threw them onto a fire built on the altar; this was the sacrifice in symbolic form. A single blow from an ax then cut the bull's spine. At the moment this deadly blow fell, the women present made a shrill cry. Two attendants held up the animal's limp head, while a third used the knife to slit its throat. The blood was caught in a basin and splashed on the altar to purify it. Then the animal was butchered. If the sacrifice was made in order to perform divination—that is, to learn whether the will of the gods was favorable or unfavorable to a particular action—the diviners examined the animal's liver for special indications. The liver, certain other organs, and the thighbones were wrapped in a sheet of fat cut from the carcass and burned on the altar. The remaining meat was usually cut into chunks, roasted on sticks over fires, and eaten. The hide became the property of the temple or priests. If the person who initiated the sacrifice had a special reason to do great honor to the god, all the meat was burned.

PANHELLENIC SHRINES AND GAMES

All Greeks recognized themselves as a people bound together by common culture and language. Organization above the level of the city-state was of a religious rather than a political character. When the city-states were established in the Archaic Period, national religious institutions also came into existence at what modern scholars call Panhellenic shrines. Available to all Greeks (*pan* means “all,” and *Hellenes* was the Greeks' name for themselves), these shrines helped form a Greek identity and dealt with issues whose importance went beyond individual cities.

The most important shrine was Delphi, founded in the ninth century B.C.E., where a priestess known as the Pythia gave oracles from the god Apollo. Delphi, as the most prestigious source of divination in Greece, was especially important, and its oracle often adjudicated disputes between cities where no ordinary legal recourse was possible. The Delphic Amphictyony, a league of Greek states organized to administer and protect Delphi, could also act as an embryonic federal body for Greece. For example, in 334 B.C.E. the league declared war on Persia in retaliation for the Persian sacking of Delphi in 480 B.C.E.; this was the legal pretext for Alexander the Great's conquest of Persia.

Other Panhellenic shrines also pointed toward ideas of national unity. At the temples of Zeus at Olympia and Nemea and that of Poseidon at Corinth as well as at Delphi, athletic and artistic contests were held in an annual rotation, with competitors from all of Greece. These games had a political dimension, since during them a general truce was enforced on all Greek cities at war with each other (as many often were). Other temples of Panhellenic importance included the temple of Demeter at Eleusis (near Athens), where initiates into the goddess's mysteries received a kind of personal salvation, and that of the hero Asklepios at Epidaurus, famed for healing the sick and disabled through the interpretation of dreams.

MAGIC

Many rituals that had existed in early Greece were not suited to the religion of the new cities because they served private rather than public interests. These were mostly of two kinds: purifications meant to cure disease or remove guilt from personal or ancestral sin, or initiations into secret mysteries that were supposed to bring salvation of the soul after death. These ceremonies were performed by ritualists, especially priests of the god Dionysus or the hero Orpheus, who wandered from city to city and thus were not part of the religious hierarchy of any city. Since these initiates stood apart from the city in some way, they were thought of as alien and hostile and their rituals characterized as foreign. After the Persian invasion of Greece in 480 B.C.E. they began to be called “magicians” and their practices denounced as magic. A magician, or *magus*, was, properly speaking, a priest of the Persian national religion, but the term came to be used in condemnation of Greek

religious figures whom the city found subversive or threatening. Many of the practices denounced as magic and therefore foreign were, in fact, based on old Greek traditions, while many elements of civic religion—such as the temple and animal sacrifice—had been borrowed from the Near East. The point of using a loaded term like *magic* was ideological, not historical. For all these same reasons Christians were also later accused of magic.

The attack on these old-fashioned Greek practices as magic was led by such philosophers as Heraclitus (ca. 540–ca. 480 B.C.E.) and Plato (ca. 428–348 or 347 B.C.E.) and by the Hippocratic physicians, who, beginning in the fifth century B.C.E., wished to establish a new sort of medical practice based on reason. These groups were most hostile to magic precisely because they were themselves trying to make the betterment of the soul and the healing of the body a respectable part of civic culture and felt they had to distinguish themselves from what the city rejected. Other philosophers, however, like Pythagoras (ca. 580–ca. 500 B.C.E.) and Empedocles (ca. 490–430 B.C.E.), embraced the image of the magician because of its aura of mystery and subversive power.

Magic was a sort of phantom of religion, one that worked for the individual against the city. Even members of the elites who ruled cities found certain situations in which their own interest conflicted with the interest of the city as a whole. By the mid-fifth century, the very period that is often considered the golden age of Greece and the high point of Greek rationalism, some people saw an advantage in fulfilling the role of a magician who could use the mysterious powers of secret rituals to advance private interests against that of the city—in return for a fee. They began to practice new rituals, especially those involving so-called curse tablets. Such a tablet consisted of a letter written on a sheet of lead under the name of a god or the ghost of a dead man. The tablet, deposited in the man's grave or in a cave or well, commanded the ghost to carry out certain orders. For example, it might tell the ghost to change the outcome of a lawsuit (and so prevent the working of justice in the city). Another common command was to make a woman want to commit adultery with a certain man (which also attacked the city because citizenship was tied to membership in certain clans and thus the whole fabric of the city would be undermined by uncertainty about the paternity of children). Other tablets sought to damage the business of some businessmen in favor of a rival (which would subvert the economic structure of the city). Still other tablets tried to “fix” the outcome of sporting events (which in Greece were religious festivals and part of civic religion).

While we might think of this kind of “magic” as naive, the archaeological discovery of thousands of curse tablets from all over the Greek world (and later the whole Roman Empire, which readily accepted this kind of ritual) shows that it was very common. The formation of the Greek cities had many benefits for their citizens, but at the price of limits on individual freedom and subordination to the collective. Indi-

viduals trying to maintain a balance between duty to the city and their personal desires released the emotional pressure through agencies like magic and secret initiations, attacking the city in a symbolic way, as they would not do in more direct action. Magic was a protest against the city.

MYTH

A myth is an attempt to explain something that is not understood, using linguistic models such as metaphor or analogy. Myths interpret the world in the way the mind most easily understands, through the structure of language itself. An example is to say that the world is like a human being with its many interconnected parts ruled by a mind or that a storm is like the anger of a great king. This might seem simplistic compared with modern scientific explanations, but it is not intended to be the same kind of answer to questions about the world. Myth begins in oral tradition and ritual, but in Greece it became the basis of one of the greatest world literatures, especially in the Homeric epics and in the first plays in the modern sense, the dramas of Aeschylus (525–456 B.C.E.), Sophocles (ca. 496–406 B.C.E.), and Euripides (ca. 484–406 B.C.E.) and the comedies of Aristophanes (448–385 B.C.E.), and the first poems in the modern sense, by Sappho (fl. ca. 610–580 B.C.E.), Pindar (ca. 522–ca. 438 B.C.E.), and others. These authors are among our best sources for understanding Greek religion.

Perhaps the most important Greek myth is told by Hesiod in his *Theogony*. Drawing on older Near Eastern mythology, Hesiod describes the creation of the world through successive generations of the divine family. The Greek word for world is *cosmos*, which means “order.” The universe moves from an undifferentiated state toward the order we see around us today. Hesiod imagines first an emptiness or gap (*chaos*). Creation begins when love (*Eros*) binds together whatever is separated by chaos. This calls into being the first two gods, Gaia (the earth) and Uranus (the sky). They give birth to the Titans, a race of wild and cruel gods. The chief of these is Kronos, who is incited by his mother to castrate and dethrone his father and become the ruler of the universe. He then marries his sister Rhea but devours their children as they are born so that he will not suffer the same fate as his father. Finally, Rhea hides one of her children, Zeus, from Kronos. Once he reaches adulthood, Zeus indeed attacks his father and frees his brothers and sisters from their father's belly. These siblings are the first Olympian gods. They defeat the Titans and bind them under the earth. Zeus and the Olympians go on to finish the process of creation, giving the world its final form, destroying various monsters, and creating humankind. This myth explains the creation of the world in terms that anyone can understand, as the genealogy of a family. With each generation the gods (and therefore the world) become less abstract, less terrible, and more human. At the same time, we see that Greek gods were free to do the very things that were most forbidden in Greek society, such as attacking their parents or committing incest.

The 12 Olympian gods were honored as a distinct group in Greek religion and figure prominently in Greek literature. The original children of Kronos and Rhea were Zeus, Poseidon, and Hades and their sisters Hera, Demeter, and Hestia. The three brothers cast lots to see which part of the world each would control: Zeus receives the sky, Poseidon the sea, and Hades the underworld, where he rules over the dead. Hera takes charge of marriage, Demeter of agriculture, and Hestia of the hearth, the life of individual homes. Aphrodite, the goddess of love and desire, comes into existence from the foam generated when Uranus's castrated genitals fell into the sea. The other Olympians are the offspring of Zeus. Zeus fathers the twins Apollo and Artemis (the sun and the moon) with the Titan Leto. Zeus engenders a son by Metis ("thought"), who is prophesied to supplant him just as Zeus did his own father. So Zeus swallows up the pregnant mother and, in due course, gives birth himself to the child, miraculously changed in gender: Athena, the mistress of warfare, who becomes his most powerful and most loyal ally.

Zeus marries his sister Hera and fathers Hephaestus, the craftsman of the gods, and Ares, the god of battle. Hermes is another son of Zeus and his messenger in charge of conveying the dead to the underworld and of everything in human life that concerns mediation (such as speech) as well as of merchants and thieves (who each transfer goods from one to another). Finally, Dionysus usually is considered an Olympian (though he exceeds the number 12, he is counted in alternation with Hestia). He is the god of wine and the offspring of Zeus and the mortal woman Semele. When her body is destroyed on beholding Zeus's true divine form (jealous Hera tricks her into asking for this), Zeus carries Dionysus in his thigh and gives birth to his son.

COSMOLOGY

The Homeric poems imagined the earth as a flat disc like a warrior's shield, because if one stands in an open place and surveys the horizon in all directions, it appears to be a circle. Delphi, the sacred center of Greece, was thought to be at the center of this circle. The sky appears to be a solid dome arching over this disc, making it also easy to imagine a corresponding hemisphere under the earth, the underworld. This worldview is inherent in all Greek myth and probably goes back to the earliest times.

In the sixth century B.C.E. the first philosophers—called the "pre-Socratics" because they wrote before the great flowering of Greek philosophy with Socrates (ca. 470–399 B.C.E.) and his successors—began to question the mythic conception of the world. Their questions led to the new idea that the nature of the world could be investigated through reason rather than through the creation of myth. Philosophers did not deny the presence of divinity in the world—they affirmed it—but it was a divinity deduced from the observation of the world rather than the traditional anthropomorphic gods of Homer. Philosophical investigations eventually led

to a geocentric model of the solar system, in which the earth was at the center and orbited by the sun, moon, and planets. Some speculations by philosophers, however, anticipated important discoveries of modern science: Aristarchus (ca. 310–ca. 220 B.C.E.) suggested a heliocentric solar system (with the sun orbited by the planets, including the earth), and Democritus (ca. 460–ca. 370 B.C.E.) posited the atomic nature of matter—although neither idea gained wide acceptance in antiquity. The achievement of philosophy was to replace tradition with reason as a way of knowing the truth, if only for a small elite group.

At the same time, the abstraction of their conceptions about the heavenly bodies (as opposed to the older anthropomorphic gods) led Greeks to invent the pseudoscience of astrology (based on older Mesopotamian ideas). Its essential idea is that the stars and planets influence events on earth and that astronomical calculation can therefore predict people's personalities and future events. The view became very widespread, though it was countered to an extent both by traditional philosophical ideas about the freedom of the individual and by skepticism that such detailed knowledge of the future was possible.

THE LATE CLASSICAL AND HELLENISTIC PERIODS

Alexander the Great of Macedon (356–323 B.C.E.) conquered first Greece and then the whole of the Persian Empire from Egypt to India and central Asia. This brought Greek culture into an entirely new world, exposing Greeks to new influences as they colonized this vast area. Religion underwent many changes. One result of this extraordinary achievement was that Alexander became worshipped as a god in his own lifetime. The spirits of the exceptional men of past ages had always been worshipped as heroes, but Alexander demanded and received this worship for himself (a legend circulated that Alexander was actually the son of Zeus, who had mated with his mother in the form of a serpent). Thereafter, during the Hellenistic Period (323–31 B.C.E.), his successors in the various Greek kingdoms carved out of Alexander's empire were routinely worshipped as saviors and protectors by their subjects.

Another feature of Hellenistic religion was the re-creation of native religions as Greek mystery cults. The worship of the goddess Isis in Egypt was only the most prominent of many foreign religions that were given a Greek interpretation and exported to cities throughout the Greek and later the Roman world. Greek philosophers like Pythagoras and Plato interpreted the belief that the dead were reborn like new plants from harvested seed to mean that they were reincarnated into new life determined by the moral judgments of the gods. These phenomena helped pave the way for Christianity, which eventually replaced Greek religion and incorporated many of its features. The Greek world was gradually conquered by Rome, and the Roman emperor Constantine announced toleration of Christianity within the empire in the Edict of Milan (313 C.E.). The emperor Justinian finally outlawed traditional Greek and Roman religion in 529 C.E.

ROME

BY MICHAEL J. O'NEAL

The complex religious beliefs of the ancient Romans are difficult to describe for at least three reasons. First, they changed over time, often radically so. Second, the Romans incorporated the beliefs of numerous cultures that lived within their vast empire. Finally, the Romans tended to be tolerant of divergent religious beliefs within their borders as long as these religions did not disrupt the social order.

The chief generalization that can be made is that Romans were pagans, meaning they practiced a polytheistic religion. The word *paganism* comes from the Latin *paganus*, meaning “country dweller,” and was a term Roman city dwellers often used as something of an insult directed against less-sophisticated people in the countryside. *Polytheism* means belief in more than one god. Even people who are not students of Roman life are likely to be familiar with the names of some of the many Roman gods, if only because planets in the solar system are named after them, including Mercury, Venus, Mars, Jupiter, Saturn, and Neptune. The term *pantheon*, which originated in Greece, is used to refer to a set of officially recognized gods such as these. The makeup of the Roman pantheon, particularly as it was recognized by the state, changed over time.

The polytheism of the Roman Empire did not endure until the empire's end. In the early years of the Common Era, Christianity was spreading throughout many parts of the Roman Empire, particularly in the east. In the fourth century C.E. Christianity became the official religion of the empire, and pagan beliefs and practices were officially outlawed.

EARLY ROMAN RELIGION

Rome borrowed a number of its gods from the ancient Greeks, often simply giving a Greek god a Roman name. Thus, the Greek god Zeus became the Roman god Jupiter; the Greek Hermes became the Roman Mercury. However, historians of religion note a peculiar difference between the Greek and Roman pantheons of gods. The Greeks developed an elaborate mythology, or set of narratives, surrounding the activities of their gods. Many of these narratives remain foundational narratives in Western life. For example, the Greeks originated the story of Narcissus, a handsome youth who fell in love with his own reflection in the water. His name is still used to refer to narcissistic people, or those who are vain and overly concerned with their appearance. The story of Icarus, who plunged to his death when he flew too close to the sun and caused his wax wings to melt, survives as a warning against arrogantly setting aspirations that are too high.

The Romans, in contrast, attached little in the way of narrative to their early gods, identifying them by name and function only. The earliest Romans saw their gods in animistic terms, which meant they believed in gods who ruled over or influenced places and aspects of their daily lives, but they did not create stories about them or their relationships with

other gods. In time, genealogies and a complex system of mythology grew up around these gods. The earliest Romans, however, saw these gods in simple terms, referring to them as *numina*; this word that is difficult to translate, though “presence” or “power” comes close. Early Romans believed that these gods were present everywhere in life. Many were adopted from the Etruscans, who predated the Romans on the Italian peninsula. Roman theologians referred to these gods and goddesses as *di indigetes*, from which the modern word *indigenous* comes. These were the native Roman deities, in contrast to the *di novensides*, or “newcomer gods” imported from other cultures, especially in later centuries. A list of *di indigetes* runs to at least 180 names.

An important early Roman goddess was Ceres, the goddess of growing plants, especially grains, and motherly love (and the source of the modern word *cereal*). Ceres is an example of the way Roman communities adopted gods and goddesses as patrons, particularly in times of crisis. Ceres was the patron of the Mediterranean island of Sicily, but in 496 B.C.E. the Italian peninsula suffered a famine, so Ceres was absorbed as part of the Roman pantheon as a way to overcome crop failure.

Additionally, Ceres is a good example of how sets of minor gods and goddesses served as assistants to look over particular human affairs. Thus, Ceres was attended by numerous other minor gods and goddesses who oversaw various aspects of agriculture. A few examples include Insitor, the sower; Obarator, the plower; Occator, the harrower; and Sarritor, who weeded. Thus, when a farmer was about to sow his crop, he invoked the name of Ceres and her attendant Insitor. But Ceres and her attendants were only a few of the many gods and goddesses of archaic Rome. January, for example, is named after Janus, the god depicted with two faces facing in opposite directions. Janus was the god of doors, gates, and beginnings and endings. Again, in the early Roman cosmology these spirits, or presences, were considered part of the fabric of the world and human endeavor, to be honored and appeared in response to circumstances.

In the ancient Roman home the senior male, often called the *paterfamilias*, was regarded as the chief priest of his family, perhaps of his larger clan. He supervised worship in his family and headed his family's cult, which included its ancestors. With regard to public religious activity, the king was the nation's religious leader, but religion was very much a local affair, conducted primarily within the family. Each family worshipped its own cult, or favored gods.

Over time, though, a system of public observances and practices evolved. A class of priests, called *flamens*, ensured that proper observances and sacrifices were made to the gods. Just as the gods were ranked in order of importance, so too were the priests. The highest rank included those responsible for the most important gods. These were Jupiter (the chief god, equivalent to the Greek Zeus and responsible for rainfall, thunder, and the sky), Mars (originally the god of agriculture but later the god of war), and Quirinus (the god

of the state, or the people, and of the army during times of peace). These gods were called the Capitoline Triad because they were worshipped in a temple on Capitoline Hill in Rome. Historians call this particular group of gods the Archaic Triad because a later Capitoline Triad emerged, consisting of Jupiter, Juno (the queen of the gods), and Minerva (the goddess of wisdom).

Just below these more prestigious flamines were those associated with less important gods and goddesses, such as Janus and Vesta. Vesta was the goddess of the hearth, and in the ancient Roman Forum a fire, the “hearth” of the state, was kept perpetually burning. It was attended by a group of women called the vestal virgins, who were obligated to maintain the site for a period of 30 years and whose chief duty was to keep the fire burning. In the home, wives and mothers honored Vesta, prayers to Vesta were offered before and after meals, and every town had a perpetual fire in honor of her. When the Romans established a new colony, coals from the “mother fire” in Rome were carried to the vestal hearth in the new location.

Some of the other major gods and goddesses of the Roman pantheon included Apollo, the god of the sun, festivities, music, and dancing; Bacchus, the god of orgies and drinking; Cupid, the god of romance and love; Diana, the goddess of the moon and hunting; Mercury, the messenger god; Neptune, the god of the sea; Venus, the goddess of sex and beauty; Pluto, the king of the underworld; Saturn, the god of agriculture; and Vulcan, the god of smithing.

RELIGION IN THE ROMAN REPUBLIC

Religion during the early monarchical period of Rome (the period from the founding of Rome up to 509 B.C.E., when the Roman Republic was created) was therefore fairly simple. It was based on a belief in animistic spirits that influenced human activities, particularly those associated with the home and the farm. While public worship was conducted under the auspices of the king, religious belief was centered in the home. A small class of priests was responsible for ensuring that the major gods were honored, but in rural Rome a family’s senior male was responsible for maintaining religious observances in the home. Much of early Rome’s religion was inherited from other nations, blending native Etruscan religious beliefs with those of the Greeks.

Religious matters became remarkably more complex during the period of the Roman Republic and beyond. The early founders of the republic were the first to give thought to the modern doctrine of the separation of church and state. During the earlier monarchical period the king was Rome’s chief religious figure. Under the republic religious duties were separated from political duties, though religion continued to affect political decisions. The founders of the republic created a priesthood called *rex sacrorum*, meaning “king of rites.” Priests carried out the duties of the earlier kings, but, to prevent them from abusing their authority, they could not hold public office or become members of the Senate.

Several classes of priests existed to carry out various duties. The most important of these classes was the College of Pontiffs, led by the pontifex maximus, the chief religious figure in Rome. Until the third century B.C.E. the pontifex maximus was chosen by members of the college. Later the position became a publicly elected one. The pontifex maximus supervised the *rex sacrorum*, the vestal virgins, and the major flamines. As noted earlier, each flamen was associated with an individual god and carried out the rituals performed to honor that god.

Throughout the late Roman Republic the requirements for becoming a pontiff changed. At first only members of the patrician class could become pontiffs. In about 300 B.C.E., however, membership was opened to the lower class of plebeians. Although the office of pontifex maximus came to be publicly elected, not anyone could be a candidate. A candidate had to be a member of the College of Pontiffs and be nominated by members of the college. Members were appointed to the college by existing members, so the entire process remained somewhat closed. Not until 104 B.C.E. were pontiffs elected by the public.

Despite this opening of the process, most members of the College of Pontiffs were members of the social elite. Many were also prominent ambassadors, politicians, and generals. Perhaps the best example is Julius Caesar (100–44 B.C.E.), one of Rome’s most famous emperors, who served as pontifex maximus early in his career. Evidence suggests, however, that these prominent people did not abuse their religious authority. For example, no single prominent family ever had more than one member in the College of Pontiffs.

The College of Pontiffs had a number of duties. In many respects, the college could be said to have assumed any duties that were not fulfilled by other colleges. Thus, members of the College of Pontiffs were experts in Roman law. They knew, for example, the exact wording of legal documents that had to be used to gain access to courts of law. The college also maintained the calendar and records of public events. Members supervised such legal matters as burials, wills, adoptions, and inheritances. It also supervised the vestal virgins, public rituals, and rituals having to do with sacrifices and vows. Finally, the College of Pontiffs supervised the *ludi Romani*, or Roman Games, held annually in September in honor of the god Jupiter beginning in 366 B.C.E.

While the College of Pontiffs was the principal administrative arm of Roman religion, the College of Augurs represented the efforts of Romans to communicate with their gods. The chief duty of the augurs was to interpret the will of the gods through various rituals and omens. The word *augur* survives in modern English in such expressions as “that augurs well,” meaning that something promises to turn out well.

To understand the position of the augur, it is necessary to understand how Romans conceived their relationship with their gods. In modern life religious devotion generally suggests that believers submit themselves to God’s will and that

the deity is a loving one who cares for the welfare of the people he created. The ancient Romans saw their relationship with the gods in somewhat different terms. A god was to be honored, but the relationship was often one of bargaining. Public vows, for example, were made to form a legal contract with a god, in which the person making the vow promised to perform an act to honor the god in exchange for the god's favor. Thus, for example, armies vowed publicly to build a temple to a god in exchange for a victory in war. The god might or might not choose to grant the person's wish, but the person still owed a duty of loyalty to the god.

The notion of bargaining required a way for people to communicate wishes to the gods and for the gods to communicate their intentions to humans. The ancient Romans believed that the gods communicated their wishes through omens that had to be read by a class of priests. This was the role of the College of Augurs. To carry out their function the augurs took part in two types of activities; the activities were supervised by civil magistrates, but the augur was present to interpret the results and report his conclusions.

One activity was to read the intention of the gods by interpreting patterns in the flights of birds in a *templum*, or sacred space. The magistrate and augur marked out the sacred space and then waited for birds to fly overhead. Alternatively, augurs interpreted the behavior of specially selected sacred chickens. For example, grain would be fed to the chickens by a *pullarius*, or "chicken man," and whether they ate the grain or how enthusiastically they did so was taken as an omen. These kinds of omens were read in connection with virtually any sort of political activity: an election, a war, the passage of a statute, and so on. The rules for conducting these rituals were extremely detailed and complex. If even the smallest detail was overlooked or conducted improperly, the ritual was deemed invalid and had to be redone. Often the Roman Senate reviewed the conclusions of the augurs and, if they determined that the ritual was improperly conducted, ruled that it had to be conducted again.

The other ritual activity the augurs supervised was divination through animal sacrifice. An animal such as a goat was ritually sacrificed and its *exta*, or entrails, especially the gallbladder and liver, were examined. The augurs who conducted this ritual were a suborder of the augurs called haruspices—literally, "men who look at guts." There were 60 official haruspices, though others practiced this type of divination unofficially. It is believed that this type of divination was an Etruscan practice that the Romans absorbed. Again, the requirements were very specific. A particular animal had to be selected, including size, gender, age, and color, depending on the god whose will was being questioned. The animal was blessed, carried to an altar in procession, and killed with a single blow. If the animal struggled or if the haruspex tripped or slipped, it boded ill. The haruspex then examined the entrails. If there was anything wrong with them, such as gallstones or spots, it was a sign that the gods had rejected the sacrifice and a new animal had to be slaughtered. If the en-

tails were flawless, that was a sign that the gods approved the course of action being proposed.

The Romans believed that they could read the will of the gods in at least three additional ways. One consisted of *monstra*, or prodigies, from which the modern word *monster* comes. *Monstra* could consist of any natural but strange occurrence, such as the birth of a calf with two heads or severe lightning. When such an event occurred, the Senate called in haruspices to inquire into the prodigy and interpret the gods' will. The *monstra* were not necessarily punishments or prophecies of doom; rather, they were warnings that the gods felt neglected, giving the Romans a chance to respond and perhaps mend their ways.

A second additional way the Romans read the will of the gods was through the Sibylline Books. These books date back to the monarchical period in Rome and the reign of Lucius Tarquinius Superbus (r. 534–510 B.C.E.), or Tarquin the Elder. This was a period in Roman history that remains shrouded in legend. It is known that the Sibyls were priestesses and prophets in ancient Greece. One of these, who lived in Cumae, a Greek colony northwest of Naples, Italy, was the most famous and has been known to history as *the Sibyl*. According to the legend, she arrived in Rome to sell Tarquin nine books that, she claimed, foretold the history of Rome. Initially Tarquin rejected her offer, so she burned three of the books and renewed her offer. Again Tarquin refused, so she burned three more. Tarquin relented and purchased the remaining three.

The Sibylline books were not prophetic, but they did include advice on what Romans should do when signs from the gods were inauspicious, or unfavorable. The books were housed in the Temple of Jupiter on Capitoline Hill in Rome until the temple and its contents were destroyed by fire in 83 B.C.E. In charge of the books were the *duoviri sacris faciundis*, or "the two men for sacred actions," yet another order of priests, albeit a small one. Later the number of priests in charge of the books increased to 10 and then to 15. Normally the Senate ordered the *duoviri* or haruspices to consult the books in cases of crisis or emergency or when they had observed *monstra*. The usual recommendation that came from consulting the books was for Rome to import a new god or cult, often from Greece. The *duoviri* played some role in establishing the new cult, at which point their role ended.

A final additional way the Romans believed they could learn the will of the gods was in the interpretation of dreams. According to the Roman historian Livy (59 B.C.E.–17 C.E.), in 293 B.C.E. an epidemic broke out on the Italian peninsula. After the Sibylline Books were consulted, it was concluded that they directed the Romans to build a cult site and temple for the Greek god of medicine, Aesculapius, on an island in the Tiber River. This temple became a hospital of sorts, where ill or troubled Romans went to recover by making sacrifices to Aesculapius. Patients slept in the temple and asked the god to explain what was wrong with them in a dream. The temple priests then interpreted the dream.

The priests in the College of Fetiales had a single job: to ensure that when Rome declared war, it did so properly. The procedure for declaring war was complex. Four of the 20 members of the College of Fetiales were dispatched to the foreign nation with demands for restitution and threats of war. If a month passed with no response, the *fetiales* declared war. The *fetiales* then sacrificed a pig, returned to the border of the country's land, and hurled a spear over the border into the land. It was believed that in this way, Rome's wars would be just. Beginning in 280 B.C.E. Rome thought it was impractical for the *fetiales* to hurl a spear into a far-flung foreign land, so the ritual was conducted at the temple of Bellona, a goddess of war, which the Romans thought of as "enemy" territory.

RELIGION IN THE ROMAN EMPIRE

The period modern historians refer to as the Roman Empire began in the first century B.C.E. In the early centuries of the empire a number of changes took place in Roman religion. One was the greater popularity of foreign cults from such countries as Iran and Egypt. The second was the growth of the Imperial Cult. The third was a growing trend toward monotheism (belief in one supreme God) and the eventual conversion of the Roman Empire to Christianity.

The Romans ruled a vast empire that contained many different cultures and traditions. Accordingly, Romans were exposed to a variety of religious beliefs. Many of these were absorbed into the Roman belief system. In particular, cults from such places as Iran, India, the Iberian Peninsula (Spain and Portugal), Britain, and Egypt became popular.

Several examples could be cited. One was the cult of Cybele, referring to a Phrygian goddess regarded as an earth mother and the goddess of fertility, caves, mountains, wild animals, and nature in general. (Phrygia was an ancient country in Asia Minor.) In Rome she became Magna Mater, or "great mother." Many of Cybele's followers took part in ecstatic ceremonies that included dancing, drumming, and drinking. She was officially adopted by Rome in 203 B.C.E. A second major cult was that of Isis, a goddess from Egyptian mythology. Throughout Egypt and in many places outside Egypt, Isis was the center of a mystery cult—that is, a cult that believed it had secret, mystic knowledge and wisdom that could be known only impartially and intuitively. Many Romans regarded Isis as an aspect of Cybele. The emperor Caligula (r. 37–41 C.E.) was an enthusiastic follower of the Isis cult and established a festival in her honor. Another foreign mystery cult that gained popularity in Rome was the cult of Mithras, a Persian god associated with the practice of astrology. Finally, Sol Invictus, meaning "the undefeated sun," was a pagan nature cult adopted by a succession of Roman emperors to emphasize their relationship with the sun god.

One of the most important cults during the Roman Empire, however, was native. It is generally referred to as the Imperial Cult and refers to the belief that the emperor was divine. The purpose of this cult was to strengthen the loyalty of the Roman people and Rome's many colonies to their

emperor. Among the emperors who were deified in this way were Augustus (r. 27 B.C.E.–14 C.E.), Claudius I (r. 41–54 C.E.), Vespasian (r. 69–79 C.E.), and Titus (r. 79–81 C.E.). The deification of these emperors was declared by the Roman Senate after the emperor's death. Although the practice seems strange in modern life, ancient peoples, particularly those in the eastern half of the Roman Empire, had a long tradition of regarding their kings and emperors as having a special relationship with the gods, and many prominent Romans during the empire began to claim descent from the gods. Many Roman public buildings, including temples, baths, theaters, and arenas, were built as monuments to the Imperial Cult.

CHRISTIANITY IN THE ROMAN EMPIRE

For a period of some three centuries Christians were cruelly persecuted by the Roman Empire. Rome regarded the new religion as a threat to its power. Emperor Nero (r. 54–68 C.E.) claimed that the Great Fire of Rome in July 64 C.E. was the work of Christians, though some historians believe that he started the fire because he wanted to rebuild Rome in his own image. Under the emperor Diocletian (r. 284–305 C.E.) the persecution of Christians was particularly severe.

Despite this persecution, Christian missionaries won converts and created Christian communities throughout the empire. The persecution of Christians ended abruptly in 313 C.E. when the emperor Constantine I (r. 306–337 C.E.) converted to Christianity. Some historians believe that his conversion was sincere; others argue that he converted only because he could see the growing influence of Christianity and wanted to preserve his power. In any event, he established religious freedom in the empire in 313 C.E. with the Edict of Milan. In 325 C.E. he called the Council of Nicea, the Catholic Church's first ecumenical council, which established some of the bedrock doctrines of the church. Then in 380 C.E. the emperor Theodosius I (r. 379–395 C.E.) issued an edict that made Christianity the official religion of the empire. In 391 C.E. Theodosius outlawed all other religious cults, and many ancient Roman temples were either destroyed or rededicated to Christian saints. The Pantheon, for example, had been a temple dedicated to all the Roman gods but became a Christian church dedicated to all the Christian saints. In the fifth century the Roman Empire fractured, the western portion coming to an end with the abdication of the emperor Romulus Augustulus (r. 475–476 C.E.) in 476 C.E. Although the empire came to an end, Christianity survived. The most dominant Christian figure in Europe was the bishop of Rome, which remained the seat of the Catholic Church.

THE AMERICAS

BY KEITH JORDAN

Reconstructing the religious beliefs, cosmologies, and ritual practices of the ancient peoples of the New World is a difficult and uncertain task because of the nature of the surviving evidence. The majority of early Native American cultures did

not develop systems of writing, so they left no religious texts or mythic epics. In Mesoamerica several ancient civilizations employed hieroglyphic scripts to record information. However, in some cases, like the early Olmec culture (ca. 1500–ca. 400 B.C.E.), we are not yet able to decipher these writing systems. Advances in the decipherment of Maya glyphs (symbolic characters used in writing) have opened new windows into the mythic cosmology and royal religious rituals of this culture. However, Maya inscriptions do not become plentiful until the Early Classic Period (ca. 150–ca. 550 C.E.), and earlier examples are more difficult to read and interpret.

For other Mesoamerican groups and for all of the peoples of ancient North and South America, scholars must make inferences about their beliefs from archaeological evidence. Finding objects buried with the dead, for example, allows archaeologists to infer belief in an afterlife where the deceased would have need of such items. Excavated artifacts or arrangements of objects that appear to have served no practical purpose may yield information on religious rituals—or such an interpretation might simply reflect our own lack of knowledge of ancient behavior. Large, elaborate, or specialized buildings lacking traces of domestic activities often are best interpreted as shrines or temples. Human and animal images carved in stone, modeled in clay, or painted on rock faces, ceramics, or architecture provide glimpses of gods, spirits, and ritual practitioners, though in the absence of written texts, interpretation of these works of art necessarily involves speculation.

All of these archaeological finds require considerable interpretation. In some areas and cases, archaeologists use the religious beliefs of much later historical Native American peoples from the same geographic region as a framework to understand the ancient material. This practice can be risky guesswork—we rarely can be sure whether later peoples were truly related to ancient cultures in the same areas or represent relative newcomers. In any case, religion and cosmological ideas can change drastically over millennia, as the documented history of Old World religions clearly show. A more cautious approach uses the behavior of later Native Americans as well as other peoples at similar levels of social organization as possible analogies for understanding ancient religion, without suggesting direct historical connections.

BEGINNINGS

We possess very little information to help us understand the religious beliefs of the first settlers of the Americas from Asia at the end of the last ice age 10,000 to 12,000 or more years ago. Their deliberate burial of the dead, accompanied by tools and weapons, and evidence of funerary rituals, like cremation, indicate a belief in an afterlife. Some scholars attempt to reconstruct the basic ideas of the religion of the earliest Native Americans by comparing the beliefs and practices of much later Native American groups across the Americas. Certain ideas about the universe and patterns of ritual behavior are shared by many indigenous peoples throughout

North, South, and Central America, suggesting that these concepts were introduced by the ancient common ancestors of all of these diverse cultures. For example, many Native American cosmologies view the earth as the middle level of a multilayered universe, with a watery underworld beneath and the sky realm of sun, moon, and other celestial spirits above. Often a mythical central axis or pathway, seen as a giant tree, unites all three levels and passes through the center of the earth, allowing spirits and humans to cross from the earth to other levels of the universe. Frequently, the four cardinal directions—north, south, east, and west—are also sacred and determine the plan of the universe, and each is equated with a symbolic color.

Closely related to these widespread beliefs among Native Americans is a common type of religious specialist, the shaman. Modern shamans are ritual practitioners who are believed to be able to travel to the spirit worlds above and below the earth, often along the central axis of the cosmos, while in trance states induced by fasting, repeatedly drumming and dancing, using hallucinogens, or employing other means. They use their abilities to contact and control nature spirits, spirits of the dead, or deities in order to cure illnesses, predict the future, and obtain good hunting results or harvests for their clients. Shamans throughout the Americas are believed to ally themselves with guardian spirits, often in animal form, who help them perform magic. In a trance state the shaman may experience being transformed into an animal and may do battle against evil spirits and other shamans in this form. Because shamanism is common along the Pacific coast of Asia from Vietnam north to Siberia as well as in the Americas and because the ice age ancestors of Native Americans came from northeast Asia, some anthropologists see shamanism as part of the cultural “baggage” brought into the New World by the first settlers.

We also have little evidence for religion among the archaic hunting and collecting peoples who succeeded the first Native Americans (ca. 7000–ca. 1800 B.C.E.). Burial practices in some areas, like eastern North America, grew more elaborate, suggesting more complex ideas of a hereafter. Rock paintings across the New World show human and animal figures. Some rock art in the American West shows strangely costumed figures, who may be shamans, and geometric patterns that some anthropologists equate with visual patterns experienced in hallucinatory trances. In Oaxaca in southern Mexico, remains of dismembered bodies at a cave site hint at the beginnings of human sacrifice some 7,000 years ago.

EASTERN NORTH AMERICA

A striking increase in the complexity of burial and other rituals took place in the North American Midwest and Southeast during the Early and Middle Woodland Periods (ca. 1000 B.C.E.–ca. 500 C.E.). The Adena culture of southern Ohio erected large burial mounds over burials with elaborate grave goods. Among these objects are stone tubes used as pipes for smoking wild tobacco, a plant still used by native South

American shamans as a hallucinogen. Comparing these pipes to similar objects produced by recent Native North American groups suggests that the pipes might also have been “sucking tubes” employed by shamans to suck spirits of disease out of a patient’s body. One pipe was sculpted into a figure of a man whose strange body shape suggests dwarfism or a goiter. In historic Native American groups deformed individuals were sometimes viewed as having special connections to the spirit world. One man buried in an Ohio Adena mound had his upper front teeth removed so that he could insert the upper jaw and fangs of a wolf into the space. Was he a shaman thought to transform into a wolf during his trances?

The Hopewell cultures of Ohio and Illinois (ca. 200 B.C.E.–ca. 400 C.E.) created massive square and circular enclosures bounded by earthen mounds and ditches. These sites are free from domestic trash and objects associated with daily life, suggesting that they had a ceremonial use. They are frequently located near springs, caves, mountains, and other landscape features regarded as sacred by later Native Americans, and some are aligned to permit observation of the solstices and equinoxes as well as other astronomical events. Small wooden buildings associated with these earthworks may have been shrines or lodging for pilgrims visiting the sacred site from distant regions.

We do not know what sorts of spirits were worshipped in these enclosures. Human forms do not show up frequently in Hopewell sculpture, but animals are shown in a realistic fashion on carved stone effigy pipes. These sculptures face the smoker when the pipe is in use and could represent the animal spirit allies of shamans. Stone and clay sculptures of men with single horns protruding from their foreheads hint that such ritual specialists were present in this culture. Ancient West Mexican and 19th-century C.E. Plains Indian shamans wore their hair in a similar fashion. In one Hopewell sculpture a possible shaman is shown wearing a bearskin. Among many later Native North American groups, bears are strongly associated with healing. Hopewell burials yield bone tubes that may have been sucking tubes and copper headdresses in the form of deer antlers, possibly used by shamans in hunting magic. At one Ohio Hopewell site, a face mask made out of a human skull could have been part of the costume of a shaman, perhaps for burial rites.

The Hopewell peoples buried their dead under mounds, frequently after keeping the bodies above ground in a shrine or charnel (a building or chamber in which the dead are kept) that was then ritually destroyed and buried. They may have envisioned such events as releasing the spirits of the dead into the afterlife and renewing the world and the community in symbolic parallel to cycles of life and death in nature.

MESOAMERICA

During the Early Formative (ca. 1800–ca. 1200 B.C.E.) in Mexico, village farmers produced and buried thousands of small clay figurines. Most of these images represent women, sometimes with exaggerated breasts and hips. Religious spe-

cialists might have used such objects as part of curing rituals, perhaps aimed at correcting infertility in both land and humans. Other figures from central Mexico show masked and costumed males—perhaps the religious specialists themselves.

On the Gulf Coast of Mexico in the modern states of Tabasco and Veracruz, the Olmec civilization (ca. 1500–ca. 400 B.C.E.) constructed large sites with monumental architecture that served as both political capitals and religious centers. Many archaeologists interpret Olmec religion as a kind of shamanism, but with the Olmec kings taking on the duties and traits of shamans as a way of justifying their claims to power. Some small Olmec stone carvings show male figures apparently transforming into jaguars, the most common guardians or alter egos for Mesoamerican shamans. Figures showing varying mixtures of human and feline features may represent different stages of the transformation. The hallucinogenic “fuel” for this process might be indicated on one

Jade votive ax of a figure combining human and animal traits and thought to represent a supernatural being, Olmec, from Mexico (1200–400 B.C.E.); the flaming eyebrows mimic the crest of an eagle, and the cleft in the head compares with the groove in the head of a jaguar. (© The Trustees of the British Museum)

of these images where an engraving of a toad appears on its head. The venom of the toad species *Bufo marinus* has hallucinogenic properties, and toad bones discarded in trash heaps at the Olmec ceremonial site of San Lorenzo support its religious use by the Olmec. Some small stone and ceramic Olmec figures also portray individuals in strangely contorted positions resembling yoga and other postures that some scholars interpret as facilitating altered states of consciousness by comparison to spiritual practices from other cultures. Other images seem to show the king identified with the World Tree, the center of the shamanic universe, representing his ability to mediate between this world and the supernatural realms above and below.

Colossal Olmec stone sculptures and a cave painting show rulers emerging from the mouths of fanged reptilian or jaguarlike monsters. Some wear bird costumes, perhaps representing “flying” in a hallucinatory trance. Based on the beliefs of the later Maya, many archaeologists interpret these monster mouths as symbolizing caves, seen by many Mesoamerican peoples as entrances to the underworld. These sculptures may represent Olmec kings journeying to the world of ancestral spirits magically to assist their subjects. Since raindrops and corn plants are also shown in these scenes, their goal was probably to bring rain and maintain agricultural fertility.

The architecture of the Olmec ritual centers seems to symbolize a multitiered concept of the cosmos similar to later Native American cosmologies. At La Venta (ca. 900–ca. 400 B.C.E.) a colossal clay pyramid may represent the central axis of the world. It may also symbolize the first mountain of later Maya and Aztec myth, which emerged from watery chaos at the beginning of time. Huge mosaic pavements of serpentine, a mottled green stone, deliberately buried under a plaza at the site could signify the waters of the underworld upon which the earth floats in later Mesoamerican cosmologies. Another mosaic and a stone sarcophagus in the form of a crocodile-like dragon buried at higher levels might symbolize the reptilian earth monster of later Aztec myth, representing the earth floating on the underworld sea. The court itself, bounded on the north end by tombs, may have been intended to represent the world of ancestors. The Olmec may have designed the site as a model of the cosmos that, with the proper performance of rituals, not only represented but also magically sustained the universe. We must be cautious and skeptical, of course, in assessing models of what the Olmec thought or intended based on the beliefs of other Mesoamerican cultures documented up to more than 2,000 years after these sites were constructed.

Similar problems make it difficult to identify which deities the Olmec conceived as inhabiting their universe. Olmec sculpture shows a range of strange mythical beings that combine the features of humans with animals, including jaguars, crocodiles, and eagles. Interpretations of what these creatures might have represented range from nature spirits to a pantheon of distinct deities. For those scholars who believe in the second model, several theories attempt to distinguish dif-

ferent gods in Olmec art by their distinctive features. Some art historians agree that the crocodilian monster depicted on the La Venta sarcophagus was an important mythic being, now referred to as the Olmec Dragon. The creature combines reptilian with toad, jaguar, and bird features, like harpy eagle feathers above its eyes. It represented the earth—plants are shown growing from its back on the sarcophagus—and its mouth formed the entrance to the underworld. The same or another dragonlike deity may have symbolized the sky and might also be the earliest version of the famous Feathered Serpent of later Mexican mythology. According to an alternative theory, an eaglelike bird deity was the Olmec god of the sky and sun. A sharklike monster may represent an underworld god. The most common figure in Olmec art, the “werejaguar,” is a strange, childlike creature with a cleft forehead and a snarling, downturned mouth and seems to have portrayed a rain god. A similar being with vegetation growing out of his head is commonly interpreted as a corn god.

Olmec ritual included human sacrifice. The bones of infants are among the offerings deposited in a sacred spring at El Manati near San Lorenzo, and images of rulers carrying baby rain gods in their arms may also represent child sacrifice. Dwarfs and fetuses appear in Olmec sculpture, and it is possible the Olmec equated deformities in children with their deities. Olmec rulers apparently used stingray spines and jade awls to let their own blood as offerings and perhaps to help induce trance, like the later Maya. Not surprisingly for a farming society, many of their rituals centered on water. They tossed offerings into springs and at San Lorenzo built an elaborate system of drains, pools, and fountains, apparently for religious purposes. Artistic images and actual rubber balls indicate that the Mesoamerican ritual ball game had been developed by Olmec times.

Mayan kings followed in the path of their Olmec predecessors, taking on the role of chief ritual specialists for their subjects. Despite older theories about Mayan theocracies, there is no evidence for priests outside the ruling family among the ancient Maya. Mayan gods known from much later inscriptions and sources, like the maize god, Itzamna, and Chaak, appear as giant plaster masks adorning royal pyramid temples from the Late Formative (ca. 400 B.C.E.–ca. 150 C.E.). The maize god figures in an ancient version of the epic Popol Vuh, dating to the 16th century C.E. In this saga he is defeated in the ritual ball game and killed by the gods of death, rulers of the underworld. His sons, the Hero Twins, later defeat and destroy the underworld gods in turn and resurrect their father, who then creates the world in its present form by erecting the World Tree, the axis of the universe. The story reflects the life cycle of corn and the hoped-for rebirth of the king as a god after death. By the Late Formative, the Mayan rulers were already identified with the maize god, and recently discovered murals at San Bartolo, Guatemala, show a king enacting the rebirth of this deity. Itzamna, a sky and creator deity, was closely associated with the king’s shamanic role. A related entity, the so-called Principal Bird Deity, also makes his appearance on

Late Formative monuments. He can be understood as both the shamanic alter ego of Itzamna and as the false sun, the monster Vucub-Caquix, defeated by the Hero Twins. Chaak, a long-nosed god, presided over rain and thunder.

The Mayan version of the multilevel universe also seems to have been established by the Late Formative. Buried offerings of jade and pottery at Cival, Guatemala, were laid out in the shape of a cross with jade axes and a wooden post at the center, representing the four cardinal directions and central axis. Pyramid temples at Uaxaktún and Calakmul, Guatemala, represent the sacred mountain, rising out of the water at creation and bridging the levels of the universe. Masks on the Calakmul pyramid represent the earth and sun, while the entrance depicts a monster mouth, the cave entrance into the underworld.

At Teotihuacán near modern Mexico City, a number of deities were worshipped during the city's heyday (ca. 1 B.C.E.–ca. 650 C.E.). As is the case with the Olmec, our ideas about the nature and number of these gods are based only on artistic evidence and represent points of disagreement among anthropologists and art historians. A male deity with goggle-like rings around his eyes, a moustache, and fangs resembles the later Aztec storm god Tlaloc and probably had the same function, presiding over rain, storms, and perhaps warfare. At least one major goddess, also associated with the earth, water, and fertility, is known from mural paintings and stone sculpture. Recent work suggests that this "Great Goddess" may be in fact several deities confused with each other by earlier interpreters. The Feathered Serpent appears as a border in paintings of elite figures and may have been a patron of royalty here, as he was later among the Aztecs. At the Temple of the Feathered Serpent, stone images of this deity alternate with heads of another reptilian creature, who may be the War Serpent, associated with war and fire, or Cipactli, the later Aztec crocodilian earth monster.

Water and symbols of life and preciousness emanate from the storm god and goddess's hands and the Feathered Serpent's mouth, but if these gods brought plenty, they demanded blood in return. Over 100 victims were sacrificed and buried in the Temple of the Feathered Serpent. While Teotihuacán art is not explicit in its depiction of human sacrifice, warriors or priests in frescos carry impaled human hearts, and the symbolism of a painted image of coyotes tearing a deer to shreds is obvious. Rulers or priests are also shown drawing their own blood as penance with spines of the maguey cactus and inserting the spines into balls of fiber as offerings. Butterfly and owl gods may be associated with conquest and sacrifice, and a fertility god who looks like the later Aztec Xipe Totec, dressed in the flayed skin of a sacrificial victim, makes his first appearance in the city's art.

PERU

Evidence of organized religion and large temple construction in Peru dates back to the Late Preceramic Period (ca. 2700 B.C.E.). On the coast Preceramic peoples built huge

adobe ritual platforms arranged in U-shaped configurations, perhaps symbolizing a balance of opposing forces in the cosmos. They deposited groups of unbaked clay sculptures of humans, textiles, and shell and stone jewelry in these structures, presumably as gifts to the gods. At the same time, the inhabitants of the Peruvian highlands built small chambers for use as shrines, where they burned foodstuffs and textiles in sacrifice to unknown deities. These respective styles of temple and cult persisted in both areas through the second millennium B.C.E. Shamanism may have played an important part in these early religions. At Garagay in the central highlands, modeled adobe building decorations show strange beings that combine jaguar and spider features. Forms hanging from their mouths may be fangs or a mucous discharge—a known side effect of using hallucinogenic snuff. At Mina Perdida on the coast a clay effigy of a creature with jaguar fangs and vulture features was buried wrapped in cloth. Did it represent a shaman in transformation, a god, or an ancestral spirit? At another highland religious center there is evidence of human sacrifice in the form of reliefs of dismembered prisoners—or are these also images of experiences in trance states?

The great ritual center of Chavín de Huántar flourished in the Andean highlands between 900 and 200 B.C.E. The site was constructed near a confluence of rivers and may embody an idea like the later Inca *tinkuy*—a sacred juncture or transition point between parts of the cosmos. By analogy between the finds here and those of later Peruvian cultures, Chavín may have been the home of an oracle, visited and consulted by pilgrims from distant regions. Its central temple was riddled with dark galleries and unusual acoustic properties that priests could manipulate to create dramatic "supernatural" effects for the faithful. Attendants left offerings of food and the remains of human sacrifices in its labyrinthine corridors.

The decoration of the main shrine during its first, or Old Temple, phase (ca. 900–ca. 500 B.C.E.) shows themes probably related to shamanism. Stone heads attached to the walls of the temple seem to show humans transforming into jaguars, with mucous from snuffing hallucinogenic plants pouring from their noses. Other reliefs portray jaguars with harpy eagle claws and fanged humans carrying hallucinogenic cacti. Like the Olmec, the builders of Chavín viewed powerful predators as sacred animals. The principal deity seems to be represented by a human figure with jaguar mouth and fangs, the so-called snarling or "smiling" god. During the New Temple Period (ca. 400–ca. 200 B.C.E.) sculpture at the temple depicts mythic beings, combining human features with those of birds of prey and caimans bearing plants. Perhaps the caiman was thought to have taught the builders about agriculture in their mythology. The snarling god now carried a rod or wand in each hand, and archaeologists call this image the staff god.

The influence of Chavín spread from the highlands to the Pacific coast, as evidenced by the distribution of images of supernatural beings in Chavín style. Based on comparison with later Peruvian oracles, the Chavín cult might have been

adopted by local peoples as a kind of “franchise,” with local versions of the original shrine built and staffed by priests from Chavín in return for gifts and tribute paid to the main center. Textiles from the coastal site of Karwa show a figure like the Chavín staff god, but female—perhaps related to the understanding of later Peruvian local versions of oracle centers as “daughters” or “wives” of the original.

At Paracas (ca. 600–ca. 175 B.C.E.) on the south coast, painted ceramics and embroidered textiles show a creature with large, round eyes, called the Oculate Being, apparently an important deity. The textile designs also depict flying humans with bird wings and dancing humans in contorted positions, with their heads thrown back. Some scholars interpret

these figures as shamans transforming into birds or dancing themselves into a trance. Perhaps the most important aspect of religious life for the Paracas culture was the cult of ancestors. The textiles came from large tombs holding hundreds of mummies.

Egypt

~ The Egyptian Legend of the Creation,
excerpt, ca. 311 B.C.E. ~

The Book of Knowing the Evolutions of Ra, and of Overthrowing Apep

[These are] the words which the god Neb-er-tcher spake after he had, come into being:—“I am he who came into being in the form of the god Khepera, and I am the creator of that which came into being, that is to say, I am the creator of everything which came into being: now the things which I created, and which came forth out of my mouth after that I had come into being myself were exceedingly many. The sky (or heaven) had not come into being, the earth did not exist, and the children of the earth, and the creeping, things, had not been made at that time. I myself raised them up from out of Nu, from a state of helpless inertness. I found no place whereon I could stand. I worked a charm upon my own heart (or, will), I laid the foundation [of things] by Maat, and I made everything which had form. I was [then] one by myself, for I had not emitted from myself the god Shu, and I had not spit out from myself the goddess Tefnut; and there existed no other who could work with me. I laid the foundations [of things] in my own heart, and there came into being multitudes of created things, which came into being from the created things which were born from the created things which arose from what they brought forth. I had union with my closed hand, and I embraced my shadow as a wife, and I poured seed into my own mouth, and I sent forth from myself issue in the form of the gods Shu and Tefnut. Saith my father Nu:—My Eye was covered up

behind them [i.e., Shu. and Tefnut], but after two *hen* periods had passed from the time when they departed from me, from being one god I became three gods, and I came into being in the earth. Then Shu and Tefnut rejoiced from out of the inert watery mass wherein they were, and they brought to me my Eye [i.e., the Sun]. Now after these things I gathered together my members, and I wept over them, and men and women sprang into being from the tears which came forth from my Eye. And when my Eye came to me, and found that I had made another [Eye] in place where it was [i.e., the Moon], it was wroth with me, whereupon I endowed it [i.e., the second Eye] with [some of] the splendour which I had made for the first [Eye], and I made it to occupy its place in my Face, and henceforth it ruled throughout all this earth.

When there fell on them their moment through plant-like clouds, I restored what had been taken away from them, and I appeared from out of the plant-like clouds. I created creeping things of every kind, and everything which came into being from them. Shu and Tefnut brought forth [Seb and] Nut; and Seb and Nut brought forth Osiris, and Heru-khent-an-maati, and Set, and Isis, and Nephthys at one birth, one after the other, and they produced their multitudinous offspring in this earth.

Asia and the Pacific

~ The Rig-Veda, excerpt (ca. 1700–1100 B.C.E.) ~

HYMN CXXIX: CREATION

1. THEN was not non-existent nor existent: there was no realm of air, no sky beyond it.

What covered in, and where? and what gave shelter?
Was water there, unfathomed depth of water?

2 Death was not then, nor was there aught immortal: no sign was there, the day's and night's divider.

That One Thing, breathless, breathed by its own nature:
apart from it was nothing whatsoever.

3 Darkness there was: at first concealed in darkness this
All was indiscriminated chaos.

All that existed then was void and formless: by the great
power of Warmth was born that Unit.

4 Thereafter rose Desire in the beginning, Desire, the
primal seed and germ of Spirit.

Sages who searched with their heart's thought
discovered the existent's kinship in the non-existent.

5 Transversely was their severing line extended: what
was above it then, and what below it?

There were begetters, there were mighty forces, free
action here and energy up yonder

6 Who verily knows and who can here declare it,
whence it was born and whence comes this creation?

The Gods are later than this world's production. Who
knows then whence it first came into being?

7 He, the first origin of this creation, whether he formed
it all or did not form it,

Whose eye controls this world in highest heaven, he
verily knows it, or perhaps he knows not. . . .

HYMN CXXX: CREATION

1. THE sacrifice drawn out with threads on every
side, stretched by a hundred sacred ministers and
one,—

This do these Fathers weave who hitherward are come:
they sit beside the warp and cry, Weave forth, weave
back.

2 The Man extends it and the Man unbinds it: even to
this vault of heaven hath he outspun, it.

These pegs are fastened to the seat of worship: they
made the Sama-hymns their weaving shuttles.

3 What were the rule, the order and the model? What
were the wooden fender and the butter?

What were the hymn, the chant, the recitation, when to
the God all Deities paid worship?

4 Closely was Gayatri conjoined with Agni, and closely
Savitar combined with Usnih.

Brilliant with Ukthas, Soma joined Anustup: Brhaspati's
voice by Brhati was aided.

5 Viraj adhered to Varuna and Mitra: here Tristup day
by day was Indra's portion.

Jagati entered all the Gods together: so by this
knowledge men were raised to Rsis.

6 So by this knowledge men were raised to Rsis, when
ancient sacrifice sprang up, our Fathers.

With the mind's eye I think that I behold them who first
performed this sacrificial worship.

7 They who were versed in ritual and metre, in hymns
and rules, were the Seven Godlike Rsis.

Viewing the path of those of old, the sages have taken
up the reins like chariot-drivers. . . .

HYMN CXC: CREATION

1. FROM Fervour kindled to its height Eternal Law and
Truth were born:

Thence was the Night produced, and thence the billowy
flood of sea arose.

2 From that same billowy flood of sea the Year was
afterwards produced,

Ordainer of the days, nights, Lord over all who close the
eye.

3 Dhatar, the great Creator, then formed in due order
Sun and Moon.

He formed in order Heaven and Earth, the regions of
the air, and light.

► resistance and dissent

INTRODUCTION

People can resist and dissent from government, religion, or society. The degree to which a culture tolerates dissent tells about what was important to the culture's people. Studying what resistance and dissent means can be a tricky business. For example, India's Emperor Asoka (r. 268–233 B.C.E.) was tolerant of religious faiths other than his own, even building places of worship for them, but this did not mean he cared little about his religion. To the contrary, he was a very devout Buddhist, but his faith included the principal of tolerance of others. Thus, when trying to learn about a culture, both the motives for resistance and dissent and the motives for repressing resistance and dissent need to be examined carefully.

In general, ancient governments reacted to dissent brutally. Dissenters were seen as enemies just as foreign armies were, and both dissenters and prisoners of war were primary candidates for torture, humiliation, and sacrifice to gods. Often, governments did not need to react forcefully to dissent because society would take care of the problem for them. In cultures, there is a strong impulse among ordinary people to see to it that everyone conforms to the rules. It may seem to them to be just a matter of fairness—no one should be allowed special privileges—or it may be out of fear of government or religion. Many an ancient government reacted to dissent or rebellion by killing not only the dissenters but also the entire families of dissenters and even complete villages, towns, or cities. Few people would wish to risk their families' lives by dissenting, and both family and community would put pressure on dissenters to shut up and conform to the rules. Indeed, the community might take it upon itself to kill or exile a dissenter.

Many mythologies have accounts of dissenters. In mythologies in general, the fates of dissenters are horrible. People who dissent from religious customs bring down the wrath of capricious gods or make a mess of the natural world. Floods, droughts, seasons that fail to come or to leave, earthquakes, wildfires, and other afflictions of the natural world are blamed on dissenters. Thus, dissenters are afflicted with boils and diseases or die in horrible ways. The end of their dissent can bring the world back to an orderly existence, or the mythology may say that an entire nation or

city disappeared because of a permanent disruption of the way life had been.

It was for these reasons that resistance and dissent were serious matters in ancient cultures. Dissenters who rebelled for only their own desire for power tended to be resented by most people, unless they actually won political or religious power, in which case they would style themselves saviors or as divinely favored. Sometimes by example, dissenters could change society. Dissenters could inspire new religions or political movements, as did the Buddha and Confucius. People who bore persecution with dignity could attract sympathy and converts to their point of view. Occasionally, society was changed for the better. On the other hand, many dissenters won by killing those who opposed their point of view, and the history of resistance and dissent has many cases in which the dissenters became the rulers and were themselves opposed by dissenters.

AFRICA

BY MICHAEL J. O'NEAL

It is difficult for modern historians to re-create patterns of resistance and dissent in ancient Africa, primarily because of the absence of written records and the nomadic nature of many early African communities. The social organization of most ancient African societies was based on the tribe, with the clan and the family being other vital components of the community. This social structure was combined with an ethic that bound people to the community, including its community of ancestor spirits. This ethic, which was instilled from an early age through legends, fables, and social training, discouraged the kind of power struggles, factionalism, and dissent characteristic of more complex, but less integrated societies. In general, ancient African communities found ways to quell dissent and achieve social harmony.

One way in which this goal was achieved was through orature. *Orature* means roughly the same thing as *oratory*, or "making speeches," but *orature* generally refers more specifically to the rhetoric employed by indigenous African peoples in sermons and, particularly, for social protest. Again, no instances of orature from ancient Africa were recorded, so there were none to survive. However, the tradition of orature has been passed down through many generations, and historians are confident in their belief that the roots of more modern traditions of orature extend deep into the African past.

The purpose of orature was to bind people to the community. It was a way for prominent people in the community, usually those with the best speaking skills, to raise issues that were of concern to the community, protest matters that were causing dissent and divisions in the community, and find a way to quell dissent and reforge the bonds that held the community together. The basic structure of orature consisted, first, of a "caller," the person who invoked the ancestral and

creator spirits and raised the issue of concern for the community. The caller had to be a person of high moral character who could stir the spiritual forces of the community. Because there was very little distinction between the spiritual realm and the secular (or nonspiritual) realm, the caller drew on the spiritual beliefs of the people to create a sense of harmony and inclusiveness. In response, the community functioned as a "chorus," commenting on and validating the caller's words. In the traditions of orature the community did not sit and listen politely and quietly; rather, the community interjected its own commentary, thus forming a community with the speaker. In some cases these responders were people specifically assigned to that role. In many cases, though, the responders included the larger community.

Rebellion and dissent may have been a marked feature of life in the ancient Nubian kingdom of Kush. (Nubia was the name of the region, roughly modern-day Sudan; Kush was the name of the civilization.) Again, the historical record is sparse, and historians have had to piece it together from fragments of evidence, including surviving records from the Egyptian Empire to the north. Further, historians are not always in agreement about the meaning of the available evidence.

Egypt had long had its eye on Kush territory. As the Egyptian Empire spread, it expanded southward into the region occupied by the Kush people. In about 1500 B.C.E. Egypt began a major push southward, but it encountered stiff resistance from the Kush, though whether from their own organized kingdom or from a confederation of city-states is unclear. The reason that Kush opposition can be considered a form of rebellion rather than simply war between two states is that for over three millennia the ever-changing and constantly shifting relationship between Egypt and Kush had been close. During some periods Kush was an Egyptian colony. During others Kush was powerful in its own right, and Kush rulers actually ruled Egypt as that nation's Twenty-fifth Dynasty in the eighth century B.C.E. The shifting power relationship between Kush and Egypt continued, and the Kushite state survived into the Common Era. But about 350 C.E. Kush collapsed. In large part the state disappeared because it was taken over by the kingdom of Axum. However, the Kush state had been weakened by internal politics and skirmishes with tribal factions on its borders. Few details are known about these events.

The empire of Carthage, on Africa's northern coast, also faced rebellion and dissent. Throughout its history, Carthage and Rome were major rivals in the Mediterranean Sea. Carthage had a large navy, which it used to protect its merchant fleet. Because of its trading prowess, Carthage was a threat to Rome's interests on the African continent. Their rivalry erupted into three wars, called the Punic Wars, which extended from 264 to 146 B.C.E. It was during the interlude between the First and Second Punic Wars that Carthage faced dissent from its army. The outcome of the First Punic War,

from 264 to 241 B.C.E., was indecisive. However, to put an end to the war, Carthage had had to pay a great deal of tribute to Rome. These payments exhausted Carthage's treasury, with the result that it was unable to pay its army, particularly the mercenary soldiers it had hired to fight in the war. (Carthage relied for its power almost entirely on its navy, hiring mercenaries to fight its land battles.) Some unpaid mercenary rebels seized control of one of Carthage's main assets in the Mediterranean, the island of Sardinia. Armed conflict between the rebels and the main force of Carthage's mercenary army erupted in 240 B.C.E. Carthage won, and the conflict ended in 237 B.C.E. after brutal fighting. The so-called Mercenary Revolt further weakened Carthage, laying the groundwork for its eventual defeat at the hands of the Romans.

Although Carthage as a major military and trading empire was crushed by the Romans in 146 B.C.E., Carthage continued to exist as a political unit into the Christian era. As the Christian church grew and spread, it expanded into Africa, and Carthage became the home of a major diocese of the church. In 397 C.E., for example, a church council met at Carthage, and it was there that the accepted canon of books of the Bible was established. However, many African Christians were disaffected. Not only did they disagree with one another over church doctrine but they also rebelled from the authority of Rome, which was still under the control of the Roman Empire. In the eyes of some historians this religious dissent weakened the region, making it ripe for conquest by the Vandals from the north in the fifth century.

EGYPT

BY EDWARD M. W. A. ROWLANDS

Ancient Egypt was a very centralized and conservative state, where the ability to influence the direction of the government was restricted to a privileged few. Even so, throughout ancient Egyptian history dynasties of pharaohs could rise and fall owing to the impact of political factions. The priesthood, high officials of the kingdom, members of the royal family, and army generals all at various times achieved and exercised significant influence on the pharaoh.

The political history of Egypt before its unification is unclear, but the success of the first ruling families probably came from a combination of war and dynastic marriage. Early regional monarchs in the Naqâda III Period (ca. 3300–ca. 3100 B.C.E.), such as the ruler known only as “King Scorpion” of Hierakonpolis, would undoubtedly have been driven by their own desire for glory and craving for power. As the number of kingdoms in Egypt decreased, the successful ruling families grew powerful enough to be taken very seriously by any king. Evidence of this power appears in the concentrated wealth of small groups of people in burials found at Buto, Abydos, and Hierakonpolis. The ability to distribute luxury items to the aristocracy was important, and as kings came to dominate

commercial routes and ever-increasing territory, they were able to meet these leading families' demands.

After the unification of the country around 3100 B.C.E., Egypt was dominated from Memphis in Lower Egypt. The pharaoh, considered divine and omnipotent, held absolute power, as can be seen especially in the Old Kingdom (ca. 2575–2134 B.C.E.). Snefru (r. ca. 2575–2551 B.C.E.) was able to build three pyramids. His successor, Khufu (r. ca. 2551–2528 B.C.E.) built the Great Pyramid, a structure so enormous that it was the tallest man-made object on earth for several millennia. Any sort of political protest to a regime this strong and centralized could have come only from the very top of society. Public expressions of defiance would have been crushed.

The vizier, the official who headed the pharaoh's administration, was essentially second in command in the kingdom. Imhotep, vizier to the pharaoh Djoser (r. ca. 2630–2611 B.C.E.), was the genius who designed the Step Pyramid at Saqqara. He was showered with titles by the pharaoh and is likely to have wielded considerable influence at court. The holder of the viziership had a variety of important roles, from collecting taxes to leading military campaigns, and this power sometimes led a vizier to challenge the authority of the pharaoh. Amenemhet I (r. ca. 1991–1962 B.C.E.), for example, is thought to have been the vizier of a previous monarch and used his position to gain the throne. In the New Kingdom (ca. 1550–1070 B.C.E.) the power of the viziership was split, with one vizier for Lower Egypt and another for Upper Egypt.

In the transition from the Old to the Middle Kingdom (ca. 2140–1640 B.C.E.) the power of the pharaoh crumbled. Egypt was administered by nomarchs, officials who controlled the nomes (provincial administrative centers) of the kingdom. In the Old Kingdom the pharaoh appointed the nomarchs, usually choosing members of his own family. By the end of the Old Kingdom these officials had become a power to rival his own. Their positions became hereditary as the pharaoh gradually lost his control over them. During the Old Kingdom the nomarchs had raised armed forces when the pharaoh demanded it. By the end of this era and into the First Intermediate Period (2134–2040 B.C.E.) nomarchs had caused strife and decentralization by their control of local forces and taxation. Their independence from the pharaoh can be seen by the growth of their statuary and the size of their tombs. The country was united again in the Middle Kingdom by Amenemhet I, but the nomarchs' threat to the pharaoh did not end until Sesostri III (r. ca. 1878–1841? B.C.E.) established a royal army that was no longer levied by the nomarchs.

The successful military campaigns of the Eighteenth Dynasty (1550–1307 B.C.E.) and long-running wars in Syria-Palestine, first against the Hurrians and then against the Hittites, brought the army into a very powerful position. Before the New Kingdom the military had not been as powerful as the

priesthood or the bureaucracy, but this changed after the Hyksos invasion of Egypt that ended the Middle Kingdom. After the Hyksos occupation ended, Egyptian pharaohs attacked areas outside Egypt's traditional boundaries in an attempt to make sure that there would be no repeat foreign invasion. These foreign campaigns started to bring in vast wealth and gradually moved to the acquisition of an empire. The army was now needed not only to defend Egypt's borders but also to maintain an empire that kept Egypt prosperous and strong. As a result, over time certain elements of the military were able to threaten the power of the pharaoh, and army officers such as Horemheb (r. ca. 1319–1307 B.C.E.), and Ramses I (r. ca. 1307–1306 B.C.E.) became pharaohs themselves.

Priests of the great temples gained enormous power and influence on the back of successful military campaigns into Nubia and Asia Minor. Pharaohs proudly embellished the main cult center of the god Amon at Karnak with successive extensions. Temples employed large numbers of workers and possessed vast estates. By the reign of Amenhotep III (r. ca. 1391–1353 B.C.E.) the priests of Amon had such power and wealth that they may even have begun rivaling the pharaoh himself. The monotheistic pharaoh Akhenaton (r. ca. 1353–1335 B.C.E.), with his cult of the sun god Aton, attempted to curtail the threat from the priests, even ordering the name of Amon obliterated from temples. However, after Akhenaton's death the cult of Amon regained its original position, its priests a powerful political faction whom pharaohs had to heed and respect.

Pharaohs throughout ancient Egyptian history had large families. Ramses II (r. ca. 1290–1224 B.C.E.), for example, is said to have had more than 50 sons. Political factions developed within these large families and strove to influence the pharaoh and his succession. Some members of the royal family were involved in the attempt to assassinate the last great pharaoh of the New Kingdom, Ramses III (r. ca. 1194–1163 B.C.E.). The conspiracy was led by one his principal wives, Queen Tey, in an attempt to change the line of succession and place her son Pentawere on the throne. It is clear that the coup failed, as it was Ramses IV (r. ca. 1163–1156 B.C.E.), his father's chosen successor, who ascended.

After the New Kingdom declined, Egypt would never be as powerful again. The Twenty-first Dynasty (1070–945 B.C.E.) saw the high priests of Amon come to rule Middle and Upper Egypt at the expense of the pharaoh. The last ruler of the Twentieth Dynasty, Ramses XI (r. ca. 1100–1070 B.C.E.), had to tolerate an army officer and self-anointed high priest named Herihor taking the royal title and ruling beside him. Foreigners—from Libya, Nubia, Assyria, Persia, and Greece—then came to dominate the country. From 30 B.C.E. the Romans held Egypt as a province with a Roman governor. Even then, however, the priesthood remained a powerful faction. Foreign rulers wanted to maintain the idea that the pharaoh had divine sanction, and with this goal in mind temples such as those at Luxor and Karnak were restored and even expanded.

THE MIDDLE EAST

BY FRANS VAN KOPPEN

Royal monuments are omnipresent in the archaeological heritage of Mesopotamia, Persia, and other ancient Near Eastern cultures. The first modern explorations of these monuments reinforced the concept of the local monarchy as an unopposed hierarchical system where the welfare of the nation depended on the whims of brutal kings, a notion that was inspired by classical and Old Testament writings and was fueled by 19th-century political concerns. The understanding of ancient Near Eastern rulership changed considerably once indigenous sources, in particular cuneiform records from ancient Mesopotamia, were taken into account. These sources shed light on the ideological underpinning of the royal office and illustrate how kings could at times apply decisive power but often were limited in the exercise of their authority. Royal power was founded on the force of tradition, but long-established values also prescribed how this authority should be put into effect. In practice kings were able, with varying success, to impose their will on the top levels of government but had limited direct control over lower tiers of the system. Ancient states therefore knew more autonomy at the bottom of the hierarchy than the rhetoric from the top would lead one to believe.

The literature of the ancient Near East embodies the views of the ruling elite, expressed in royal inscriptions and poetic compositions that were disseminated outside the court as part of the educational curriculum familiar to all who had learned how to read. This literature celebrates the magnificence of kingship, including the victorious confrontation with foreign enemies, but internal opposition against the king was here obviously out of place. Tendentious works criticizing affairs of state are rare, and most of them cannot be dated exactly, precluding the opportunity to confirm whether they circulated at the time of the events they condemn or afterward and in support of a different regime. The search for protest and dissent thus requires one to read between the lines of the official propaganda or depends on the availability of incidental explicit sources. One textual genre reveals how ancient scholars thought about the topic: Mesopotamian handbooks of divination dealing with the significance of ominous signs include among their predictions scenarios of doom for the king and his dynasty.

Royal ideology is culturally embedded, and no single profile can do justice to the long history and vast areas of the ancient Near Eastern world. All societies, however, seem to have agreed on one thing: Kingship was established by the gods, originally “descended from heaven,” according to the Sumerian King List, and was therefore an essential requisite for the proper working of society. (The Sumerian King List is an ancient text listing the kings of Sumer, including foreign dynasties.) Whereas the institution of kingship was thus never questioned, the human occupant of the throne certainly was if he failed to adhere to the traditional values of his

culture: being of proper descent, enjoying the approval of the gods, taking the leading role in the cult, and promoting the economic well-being and security of his subjects.

Historical writings frequently condemn past kings for failure in these domains, and public support of a ruler waned if his performance was considered inadequate. A case in point is the Babylonian king Nabonidus (r. 556–539 B.C.E.), who promoted the moon god Sin at the expense of other gods. He stayed in Arabia for a number of years, and this resulted in an interruption of the annual festival in honor of Marduk, the head of the Babylonian pantheon, for which the king had to lead the ceremonies in person. This resulted in popular disaffection, particularly in the circles of the Marduk clergy, and Nabonidus himself refers to the animosity of the residents of Babylon as one of his reasons for leaving the capital. Open criticism of his religious politics, however, first appears under his successor, the Persian king Cyrus II (r. 539–ca. 529 B.C.E.), and it is possible that the extent of popular discontent was deliberately exaggerated to defend the legitimacy of the new dynasty.

While good rulership was thought to promote the well-being of society, national setbacks cast a shadow over the suitability of the king. Public dissatisfaction could even culminate in his disposal, as is suggested by such omen predictions of the diviners as “his own city will rebel against the king” and “the eldest of his city will dismiss the king”—though incidents of this kind did not often come to pass. Most dynasties, however, were stable because the king could rely on the continuous support of powerful servants whose fortunes were tied closely to their lord. They owed him absolute obedience, backed by oaths of loyalty, and in return enjoyed the king’s favors and the material benefits that derived from it. Given the very personal nature of this relationship, members of the top tiers of the administrative hierarchy were at risk of losing their positions and having their rewards revoked if a rival king ascended the throne, and it was their collective intent to support their ruler through periods of adversity.

Paradoxically, the most dangerous forms of internal opposition arose from the same class of royal servants. Essential functions at the court and the provincial administrative centers were fulfilled by powerful dignitaries who were eager to increase their share of royal favors, influence, and wealth at the expense of other members of the elite. They typically allied together to attain these goals. Now and then dignitaries were able to build up sufficient support to assassinate the king and claim the throne, but normally they chose to promote their preferred candidate among the king’s potential heirs. Some political systems, such that of the Neo-Assyrian Dynasty (ca. 1000–626 B.C.E.), did not adhere to the principle of succession by the firstborn son but allowed the king to select his heir or even change his mind more than once during the course of his reign. Court factions threw in their lot with a particular candidate in expectation of future rewards, and the presence of more than one contender with sufficient support led to internal struggle or even civil war.

A particularly fierce episode started toward the end of the reign of the Assyrian king Shalmaneser III (r. 858–824 B.C.E.), when prince Assur-da’in-aplu, who had been passed over for succession, led the heartland of the Assyrian state in a rebellion against the designated crown prince, Shamshi-Adad V (r. 824–811 B.C.E.). After five years of civil war the crown prince managed, with the support of the outer provinces, to defeat his rival and reunite the realm. That both contenders depended on separate domains indicates that members of the old aristocracy supported their respective candidates for the throne.

Given the potentially devastating consequences of factional struggle, kings dealt carefully with powerful clans among their servants. They tried to break up interest groups by cautionary punishments of disloyal servants and rewards to those who reported the culpable acts of others; some kings did not hesitate to have large numbers of their highest servants executed. Powerful kings were in this way able to enforce the personal dependence of their direct entourage, and they depended on the top of the state apparatus to enforce loyalty at the lower tiers of the system.

ASIA AND THE PACIFIC

BY UFFE BERGETON AND MICHAEL J. O’NEAL

Just as political power and state control are inextricably intertwined with ideology, so also are the ways in which resistance and dissent can be conceived and expressed. From the earliest period of Chinese history for which we have extensive written documents, that is, the Western Zhou (1045–771 B.C.E.), the world was thought of as a hierarchical pyramid with the highest deity, Heaven (*Tian*), at the top, followed by his human counterpart, the king as the son of Heaven (*Tian Zi*); the royal vassals; and the lower ranks of nobility down to the common people. Some of the earliest expressions of social protest are found in the *Shi jing* (Book of Songs), a collection of anonymous poems from the Western Zhou and Spring and Autumn Periods (722–481 B.C.E.).

At the time of Confucius (551–479 B.C.E.) rulers were still born into power, but whether they retained it depended on whether they could keep the mandate of Heaven, which was bestowed or taken away by Heaven based on their moral virtue (*de*). In the Spring and Autumn Periods increasingly large state administrations demanding specialized administrative skills gave rise to a relatively independent class of scholar-officials (*shi*). Before Confucius, moral authority and charismatic power (*de*) had been concentrated in the hands of the son of Heaven, who had the most direct access to divine powers. Confucius’s most important innovation was to shift the locus of moral and religious authority from being an exclusive royal prerogative to being accessible to any individual, regardless of birth, who was able to purify his charismatic virtue through self-cultivation.

Thus, in the emerging *shi* class, engaging in self-cultivation, the ground was laid for a class of political “dissenters,”

of which Confucius and his follower Mencius (ca. 371–ca. 289 B.C.E.) were themselves prime examples. While still adhering to a hierarchical aristocratic worldview, the *shi* often remonstrated with rulers whose misguided policies and moral behavior put them in danger of losing the mandate of Heaven. When remonstrations failed, they would sometimes leave their home states in search of a more virtuous ruler elsewhere. In a sense, by thus “hiding” from a ruler through self-imposed exile to avoid moral pollution through forced collaboration, such traveling *shi* can be classified as moral-political recluses, demonstrating their dissent by resigning from office.

A more desperate form of protest is exemplified in the person and legend of Qu Yuan (ca. 340–278 B.C.E.), a government official of noble birth who committed suicide to make a political statement and to vent his frustration over the destruction of his home state of Chu through the slander and pernicious influence of sycophants. Before drowning himself in the Mi Luo River, Qu Yuan wrote the *Li Sao* (On Encountering Trouble), a long, allegorical poem in which he casts himself as a beautiful concubine neglected by the king. Ever since, Chinese statesmen have often used similar metaphorical poetry—involving frustrated women, symbolically referring to the ignored voices of wise ministers—as veiled political statements of dissent.

While different in other respects, the Warring States philosophies of Laozi and Zhuangzi (fourth century B.C.E.) agreed that their age was so chaotic that whole-scale rejection of contemporary forms of government and social values through reclusive withdrawal was the only meaningful course of action. In contrast, being firmly rooted in social philosophy, Confucius and his followers were unable to accept these radical forms of political protest, which to them amounted to “living with the birds and beasts.”

In legalism, a Machiavellian political philosophy associated with the late Warring States thinker Han Fei (d. 233 B.C.E.), dissent was no longer an option, and anyone showing resistance to the government would be ruthlessly suppressed. The *Han feizi*, a philosophical work attributed to Han Fei, mentions a case of two sagelike retired recluses who were executed simply for wanting to live independently of the state. By placing themselves outside the jurisdiction of the government and by being immune to the lure of monetary compensation and the fear of punishment, they were seen as subverting the authority of the ruler and thereby endangering the foundation of state control. Legalist-inspired policies were adopted by the ruthless Qin Dynasty (221–207 B.C.E.), which consequently strove to discourage all forms of resistance, as exemplified in the infamous incidents of the burning of books and the killing of scholars to preempt dissension.

These examples of resistance illustrate how politically engaged individuals expressed dissent in isolation, through remonstrations, reclusion, suicide, or allegorical poetry. In other cases individuals grouped together to voice political disagreement. Two such cases from the late Han Dynasty (202 B.C.E.–

220 C.E.) have often been linked to the fall of the empire: the party proscription and the Yellow Turban Rebellion.

The party proscriptions arose in the bitter feuds between the palace and the reformist officials of the imperial administration. In his successful coup d'état in 159 C.E., the emperor Huan relied on eunuch (castrated) officials, whom he subsequently awarded with noble titles and political influence. As the wealth and political clout of the eunuchs grew, the local elites and powerful officials came to view them as inefficient parasites sucking the lifeblood out of the empire through lavish spending. University students joined the reformists in turning public opinion against the eunuchs through the use (one of the first in historical records) of critical essays, pamphlets, rhymed political slogans, and student demonstrations.

In 167 C.E., when the eunuchs responded by accusing the reformist movement of forming a faction and conspiring against the emperor, the reformist leaders were imprisoned and barred from office. However, the death of the emperor Huan dealt a heavy blow to the eunuchs, and by 168 C.E. some of the formerly imprisoned reformists were again occupying important government offices. In 168 C.E. the tide turned in favor of the eunuch who in 169 C.E. launched the second great proscription, which lasted until the Yellow Turban Rebellion in 184 C.E. and during which the accusation of factionalism was repeatedly used to discredit, imprison, proscribe, and even execute the enemies of the eunuchs. Since in the Han Dynasty the classics were part of the repertoire of the educated, political elite, the discussion of factions in the *Analects* of Confucius greatly influenced Han conceptions of dissent: “The gentleman . . . is sociable, but does not form factions.” The eunuch thus could shrewdly exploit the terminology of Confucius, one of the cultural heroes of the reformist tradition, against the reformist officials themselves.

The reformist movement used the pen to express opposition to the Han government, and the Daoist-inspired Yellow Turban peasant uprising resorted to armed revolt. Together they contributed to the destabilization of the Han Dynasty, eventually leading to the disintegration of the empire under various warlords and many short-lived simultaneous courts during the Six Dynasties Period (220–589 C.E.).

While the historical record for ancient China is relatively complete, the corresponding record for most of the rest of Asia is not. Much of this history is shrouded in myth, legend, and conflicting accounts, usually by Chinese writers, including both contemporaries and those who wrote in later centuries.

A good example is provided by Japan. The history of ancient Japan is conventionally divided into three major periods. The earliest was the Jōmon Period, which extended from about 13,000 B.C.E. to about 300 B.C.E. During this period Japan was not a unified nation but a tribal society. Following the Jōmon Period was the Yayoi Period, which extended from 300 B.C.E. to about 300 C.E., though some historians believe that the Yayoi culture may have begun as early as 900 or 800 B.C.E. A main distinction between the two cultures is that the

population increased dramatically, and social organization became more complex. Following the Yayoi Period was the Kofun Period, which extended to 539.

Japan, though, continued to remain largely a tribal society. One major effort to unite the tribes was the work of a woman named Himiko, who lived from about 175 to 248 C.E. Himiko was a shaman, or a priestess, who organized a number of Japanese tribes into a state called Yamataikoku, located in either the Yamato or the Kyushu region of present-day Japan (the archaeological evidence is ambiguous). The historical record about Himiko is thin. She is mentioned in an ancient Chinese text titled *Sanguo zhi* (Records of Three Kingdoms), written in about 297 C.E. She is also mentioned in an ancient Japanese history titled *Nihon shoki* (Chronicles of Japan) and a later Korean text called *Samguk sagi* (Chronicles of the Three Kingdoms). According to these accounts, Himiko unified up to 100 tribes primarily through sorcery and shamanism. She lived in a palace, attended by a thousand women and one man. She never married or appeared in public, and her younger brother served as her political adviser.

According to historical accounts, after Himiko's death, her position was assumed by a female relative, perhaps a niece. Rebellion broke out, however, when a tribal king named Shujin (a name that means "Lord-person") led a military force against Himiko's successor. He and his force overthrew the ruling house. He then proclaimed himself emperor of that part of Japan, establishing the tradition of male rule. Few details are known about this rebellion.

Japan, though, was on its way to becoming a unified state. Beginning in about 300 C.E., tribes and clans began to coalesce. A strong, military aristocracy began to emerge. The rulers that replaced Himiko are referred to as the Yamato rulers, and sometimes the period itself is called the Yamato Period. Rivalry and dissent, though, by no means disappeared. As the Yamato Dynasty tried to expand its domains, it met with resistance from nearby rival tribal confederations. One figure at the center of the effort to subdue these rebellious provinces was Yamato Takeru, a half-historical, half-legendary prince who was said to have been dispatched in the fourth century to crush a rebellion in eastern Honshu, where rebels were judged guilty of refusing to submit to the Yamato emperor's authority.

The history of ancient India followed a similar arc. Through much of the subcontinent's prehistory, shifting portions were ruled by separate kings; no unified Indian state existed. That state of affairs changed, however, in the third century B.C.E. under the Maurya Dynasty, and particularly under the rule of Asoka the Great (304–232 B.C.E.). Historians regard Asoka as one of the greatest kings who has ever lived. Early in life he subdued portions of India through military conquest. Later in life he renounced violence and ruled over a vast kingdom that corresponded with modern-day India.

Asoka was the son of the emperor Bindusara and a low-ranking member of Bindusara's harem. Thus, he had numerous

half-brothers who shared a father but had different mothers. By all historical accounts the brothers were extremely competitive, and they began to look with suspicion on Asoka because he excelled at military arts and at his studies. The oldest of these brothers, Prince Susima, would in the normal course of events have inherited the throne, but he saw Asoka as a rival, so he persuaded their father to send Asoka to quell a rebellion in Takshashila in northwest India. Susima's belief was that Asoka would be killed, especially since Takshashila was an extremely warlike region, where the population was bullied by militias and military clans that wreaked havoc. Asoka ended the rebellion without a fight. Later, Susima tried the same tactic when a rebellion erupted in Ujjain in central India. Again, Bindusara dispatched Asoka, except that this time fighting took place between Asoka's forces and the rebels. Asoka was injured, but his generals quelled the rebellion. Later, after he ascended the throne in 273 B.C.E., Asoka led the largest army in Indian history up to that time to quell rebellion in the Kalinga Province, whose rulers refused to submit and who, in fact, gave refuge to one of Asoka's rebellious half-brothers.

Political unrest continued after Asoka's death. The Sunga Dynasty assumed control in 185 B.C.E. when the last of the Mauryan rulers, Brihadratha, was assassinated by the commander in chief of his armed forces. The Sunga Dynasty was overthrown in 73 B.C.E. by Vasudeva, who established the Kanva Dynasty in 71 B.C.E. Even during the so-called middle period, which extended to about the middle of the first millennium C.E. and has been described as India's "golden age," this type of power struggle and rebellion remained commonplace. The nation again fragmented into warring kingdoms and states, with feudal lords establishing power over various regions of the country. Further destabilizing the country were invasions from various tribes from the north and west, which themselves established dominance over the regions they conquered. The Gupta Dynasty of the fourth and fifth centuries reasserted control over large portions of India, particularly in the north. Like their predecessors, the Gupta emperors had to unify their realm by quelling rebellious provinces and feudal states by armed force.

Korea, like China and India, consisted of city-states. During the first millennium B.C.E. the three city-states that dominated were Koguryo, Paekche, and Silla, though other minor city-states existed as well. Within each of these city-states were many tribes. Historically, these city-states have been called the Three Kingdoms, and the Three Kingdoms Period, when they reached the height of their influence, extended from the first century B.C.E. to 668, when Silla defeated Koguryo.

Militarily, the most powerful and dominant of the kingdoms was the Koguryo (the name from which "Korea" evolved). Beginning in 37 B.C.E. and into the first centuries of the Common Era, a succession of monarchs overcame resistance to unite the kingdom's tribes and extend the kingdom's boundaries. Resistance, though, often focused on Chinese

invaders. During the reign of Taejo (53–146 C.E.), for example, the Koreans mounted a number of attacks on the Chinese garrisons at Lolang, Xiantu, and Liaodong. Their efforts were successful, and Koguryo became entirely independent. The regime also launched attacks against smaller states to absorb them. Later, under King Gwanggaeto the Great, who reigned from 391 to 412 C.E., the kingdom further expanded its territories through military conquest, overcoming resistance from the feudal lords who controlled various regions of the peninsula. His army conquered at least 64 walled cities and 1,400 villages against a tribe called the Buyeo. He subdued additional tribes, annexed portions of the peninsula, conquered Silla, and waged war against Japan. The result of his efforts and those of his son was to turn Korea into a unified country for some 50 years.

EUROPE

BY BRADLEY SKEEN

The ancient Mediterranean civilizations of Greece, Macedonia, and Rome approached the rest of Europe with a desire to control events there for their own advantage. The response to this imperialistic interference was violence: among different tribes fighting each other on behalf of or against the outsiders, in devastating raids on the homelands of the great powers themselves, and finally in the conquest of the Western Roman Empire once political and economic circumstances had radically changed.

The ancient Greeks and Romans built upon older cultures (Etruscan, Minoan, Egyptian, and Assyrian) around the Mediterranean to establish cities and develop the sophisticated economic and political structures that mark civilization. But their neighbors in Europe—Gauls or Celts in present-day Spain, France, the British Isles, and northern Italy; Germans in modern-day Germany and Czech Republic; and Iranian peoples around the Black Sea—maintained a more traditional way of life as farmers or nomadic herdsman. The primary units of social organization were the household and clan, while chiefs exerted loose control over limited areas. Larger political structures that the Romans called “tribes” theoretically united larger areas populated by speakers of a common dialect, but in practice kings and chiefs had little way to enforce their rule, precisely because they lacked such tools of more complex societies as taxation and standing armies.

An extensive commercial trade conditioned relations between northern and Mediterranean Europe. The northerners had access to raw materials, including furs, amber, tin, and gold, which they were eager to exchange for luxury goods, especially wine, from the southern societies. Because of the prestige they would gain from possessing the trappings of those societies, northern rulers were keenly interested in obtaining items such as sets of ornamental gold and silver dinnerware and dies to strike their own coins. Greeks and Romans attempted to exert control over leaders in the

north by granting or denying them access to such goods. Alternatively, Greeks and Romans occasionally launched military expeditions against groups who were hostile to their interests.

Resistance to imperial control could take only a military form. Although leaders in northern Europe had little actual power through their office, they were sometimes able to attract a large following through a personal charisma that made them seem destined for victory, a quality called *rede* in the Germanic languages. Endorsement by religious authorities—for example, the pagan priesthood of the Druids—certainly helped build such a reputation. Favored leaders could attract large war bands not only from their own tribes but also from more diverse groups. Sometimes bands of as many as 50,000 warriors raided Greek or Roman territories with devastating effect. About 390 B.C.E. a band of Gauls sacked Rome itself. In 281 B.C.E. another band of Gauls attacked Greece, getting as far as the shrine of Delphi (279 B.C.E.). Turned away, they crossed over into Asia and were defeated in 277 B.C.E. by the Macedonian king of Syria, Antiochus I, though he could not prevent them from settling in what is now Turkey and founding the new kingdom of Galatia, named after them. After 113 B.C.E. a force composed of two German tribes and many Celts ravaged Italy and Spain until it was defeated by the Romans in 101 B.C.E.

As Rome consolidated its political organization and military power in the Mediterranean, however, the situation changed. Roman leaders increasingly had to develop a charismatic reputation through military victory and build up a military apparatus personally loyal to them as civil war became common at the end of the republic. At the beginning of the empire prestige was still an important concern of the emperors, as was the assurance of security for the empire by acquiring defensible borders. Accordingly, Roman generals undertook the conquest of much of northern Europe around the turn of the era.

Julius Caesar conquered Gaul (modern-day France and the Low Countries) between 58 and 51 B.C.E. Although local peoples tended to ignore invaders of this kind unless they were directly threatened, once the scope of Caesar’s ambitions became clear, the Gallic chieftain Vercingetorix (d. 46 B.C.E.) managed in 52 B.C.E. to attract a large war band of various tribal groups to make a concerted defense of the fortified hill town of Alesia (in present-day France). His efforts were ultimately unsuccessful.

Once his position was secure at the beginning of the empire, the emperor Augustus (r. 27 B.C.E.–14 C.E.) decided to conquer Germany. In 9 C.E., after initial campaigns by his stepsons, Augustus sent an army of three legions (30,000 men) to pacify the area. Under the command of Varus, a bureaucrat rather than a military specialist, this force was opposed by a large band of Germans led by Arminius (also known as “Armin” or “Hermann,” 18 B.C.E.–19 C.E.), who had led German warriors as auxiliaries fighting for the Romans in previous campaigns. He caught the Roman force in an ambush in

the Teutoburg Forest (near modern-day Bremen) and annihilated it; the victors dedicated the slaughtered legions' battle standards to the Germanic gods in sacred groves. This stunning victory effectively ended Roman ambitions in Germany, though renewed Roman military actions and diplomacy among Germanic rulers eventually broke up Arminius's alliance, which depended on nothing more than the magic of his name. The emperor Claudius (r. 41–54 C.E.) conquered Britain (43 C.E.). After years of occupation a local queen, Boudicca (d. 60 C.E.), managed to stage a revolt against Roman rule, but her efforts were quickly suppressed. Thereafter the Romans reverted to the traditional policy of controlling events in Europe through diplomacy and bribery of local leaders, with only occasional limited military interventions.

In late antiquity (third to fifth centuries C.E.) the situation in Europe changed dramatically. Because of the richer economic prospects available in Roman territory and because of pressure from new migrations from the east of such peoples as the Huns and Slavs, Germanic tribes, who had been partially romanized through centuries of contact, wanted into the empire, not to plunder but to live. Now huge war bands of Goths, Vandals, and Franks penetrated especially into the western part of the empire, ranging as far as North Africa, establishing independent kingdoms.

Because of population changes brought about by the migrations themselves, as well as the inability of central governments based in Rome and Constantinople to provide security despite an ever-increasing burden of taxation, local people in its western provinces ceased to support the empire as a unified political entity, and it collapsed. The last western emperor, Romulus Augustulus (b. 463 C.E.), was deposed by the Goths in 476 C.E. The Eastern Roman Empire (now called by historians the Byzantine Empire), secure for the time being, no longer had reason to intervene to try and impose its authority in the West.

GREECE

BY JEFFREY S. CARNES

The Greeks thought of themselves as a free people, particularly in contrast to the Persian Empire. This encompassed not only freedom from political domination but also the positive freedom to engage in open debate about political matters and to live as one pleased with a minimum of interference from the state. This was particularly true in democratic states, but oligarchies as well valued freedom, albeit for a much more restricted class of citizens. This attitude is evident in two works of the Greek poet Homer (eighth or ninth century B.C.E.), the *Iliad* and the *Odyssey*, where kings regularly hold councils to receive advice from other nobles. The limits on this sort of speech are evident as well: There is an open acknowledgment at the start of the *Iliad* that angering a great king is dangerous; when a common soldier named Thersites speaks out against Agamemnon, he is publicly humiliated by Odysseus, with the approval of the entire army.

Although many *tyrannoi* were good rulers, the Greeks made the figure of the *tyrannos*—a term that describes a sole ruler without hereditary claim to the throne—a sort of bogeyman, emblematic of the ways in which a sole ruler might exercise power capriciously and quash dissent. The Greek historian Herodotus (ca. 484–ca. 425 B.C.E.) tells the story of Periander (r. ca. 627–586 B.C.E.), tyrant of Corinth, taking to heart the metaphoric advice of a fellow tyrant to cut down the stalks of wheat that stood higher than the others, that is, to kill the most powerful people in the state, who might pose a threat to his rule. The king of Persia was seen in a similar light, and all Greek cities, even the most repressive, viewed themselves as bastions of liberty and were proud of their ability to be self-governing and open to debate, whether the deliberative body was a small council of elders or an assembly of the entire people. “Slaves to none, nor are they subject” marvels the chorus of Persian elders in *Persai*, a drama by the Greek dramatist Aeschylus (525–456 B.C.E.).

Political factions existed everywhere and at all times in the Greek world, a culture in which dozens of independent and frequently warring states existed in an area the size of Iowa, less than 60,000 square miles. The word *stasis* (literally, “standing”) was used for a faction that took a stand in a political dispute and also for the political unrest caused by such groups. Sometimes these stands were based on class or regional antagonisms. Sixth-century Athens, for example, experienced civil strife between those who lived in city, seaside, and hillside districts. By the sixth century it was common for a faction to present itself as the champion of an economic or social class (such as landowners, debtors, or the poor) even where the connection was tenuous. Larger states also were ready to offer aid to factions elsewhere as a way of extending their spheres of influence: By the time of the Peloponnesian War between Athens and Sparta, virtually every polis (or city-state) in Greece had oligarchic and democratic factions. The extremely bloody *stasis* on Corfu in 427 B.C.E. was the first of many. The Greek historian Thucydides (d. ca. 410 B.C.E.) paints a grim picture of the extent to which factionalism led to revenge, paranoia, and the utter breakdown of Greek civic life.

Apart from the more violent forms of *stasis*, political disagreement and dissent were tolerated to varying degrees throughout the Greek world. As is often the case, the best evidence comes from Athens. This is not only because of the relative abundance of Athenian sources compared with those from other cities but also because Athens was the freest and most open of the cities now known; if Athens failed to tolerate certain types of dissent, it is therefore likely that other cities also failed to do so.

The Athenian democracy was based on the principle of *isonomia* (equal protection of the laws); closely related to this was the principle of *isegoria* (equal right to speak, such as in the Assembly and other political fora). Later in the fifth century B.C.E. the term *parrhesia* (frankness or freedom of speech) appears as a quality in which the Athenians prided

Head of Greek philosopher Socrates (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

themselves, as was their ability to be “free and tolerant in their private lives,” according to the funeral oration by the Athenian statesman Pericles (r. ca. 460–429 B.C.E.) as recorded by Thucydides. There was a striking degree of frank speech, particularly in the theater.

The comedies of the Athenian playwright Aristophanes (ca. 450–ca. 388 B.C.E.) are full of scurrilous attacks on politicians; their competence, honesty, physical characteristics, and sexual proclivities are all fair game. Further, Aristophanes mercilessly criticizes state policy even in wartime. In his *Lysistrata*, produced in 411 B.C.E., he shows the women of Greece taking power (by means of a sex strike) to end the unpopular war the men had created. The play is unstinting in assigning blame to politicians, military leaders, and the people of Athens, and it jokes about the pro-Spartan factions within the city. Yet Athens was in serious danger at the time: The disastrous Sicilian expedition four years earlier had cost the lives of thousands of its citizens, and the oligarchic conspirators Aristophanes mocks overthrew the democracy within a matter of months. It is hard to imagine a modern democracy under similar circumstances tolerating this degree of dissent.

Alongside this openness were times in which citizens were punished for exceeding the limits of tolerance. Despite

the extreme freedom of speech usually granted to the theater, the tragic poet Phrynichus (fl. ca. 500 B.C.E.) was fined 1,000 drachmas for “reminding the audience of their own troubles” by putting on a play about the Persian sack of Miletus at a time when the Athenians themselves feared the Persian threat. Aristophanes, too, was prosecuted (apparently unsuccessfully) in the 420s B.C.E. by the Athenian politician Cleon (d. 422 B.C.E.) for making fun of the city’s magistrates.

For religious issues there was a similar alternation between freedom and intolerance. Athens in the fifth century B.C.E. included several philosophers who challenged traditional notions of morality and religion; in addition, cults such as Orphism and Pythagoreanism were popular. At the same time there were several high-profile prosecutions for impiety. In 437 B.C.E. the philosopher Anaxagoras (ca. 500–ca. 428 B.C.E.) fled the city in the wake of such a charge; in 415 B.C.E. Alcibiades (ca. 450–404 B.C.E.) and others were charged with mutilating statues of the god Hermes and holding mock versions of the Eleusinian Mysteries (initiation ceremonies in the cult of the goddesses Demeter and Persephone); and in 399 B.C.E. the charge of “believing in strange new gods” was one of the accusations against the philosopher Socrates (ca. 470–399 B.C.E.), for which he was sentenced to death. In a sense these prosecutions actually were about religion: Religion was a state matter, and to offend religious sensibilities was to threaten the state. For the most part, however, the religious prosecutions were motivated by politics: Anaxagoras and Alcibiades had powerful enemies, and Socrates was associated with many notoriously antidemocratic characters (including Alcibiades), some of whom had played a role in the brutal dictatorship of the Thirty Tyrants in the aftermath of Athens’s defeat in the Peloponnesian War.

Some conclusions may be drawn from this information. First, the Athenians tolerated a great deal of free speech as long as it did not seem immediately threatening to their physical safety or to their sense of well-being. The comedies of Aristophanes probably did not normally pose such a threat but were instead a type of contained dissent: He poses revolutionary ideas in a circumscribed, well-defined space but does not argue for revolution or even serious change. (It is noteworthy that *Lysistrata*, like many of his other comedies, ends with a return to a kinder, gentler version of the status quo.)

Second, the principle of *parrhesia* was a tradition, not a constitutionally guaranteed right. Pericles speaks of the unwritten laws that govern conduct; Socrates recognized at his trial that the unwritten accusations against him were more damaging than the actual charges. Popular opinion and prejudice could be worth more than the force of law; Pericles’ idealized vision of the city notwithstanding, Athens was full of petty jealousies. The law was extremely flexible: Irrelevant charges could be used to punish political enemies, and courtroom procedure was ill defined and very much subject to the immediate will of the people. Cleon’s prosecution of Aristophanes

phanes may have been technically without merit, yet it may well have stood a chance of success.

Third, freedom of speech did not protect the speaker from retaliation at the hands of his enemies. Greek culture honored the values of competitiveness and aggression, and Athens, in particular, was known for being wordy and litigious. One should perhaps be surprised that the punishment of dissenters by their enemies was apparently so rare.

ROME

BY KIRK H. BEETZ

Perhaps the most successful dissenter in Rome was one of the first, Lucius Junius Brutus (sixth century B.C.E.). King Tarquinius Superbus (r. 534–510 B.C.E.), meaning “Tarquin the Proud,” apparently murdered Brutus’s brother. This event motivated Brutus to conspire against Tarquinius Superbus. Brutus had help in this conspiracy from members of the social elite who belonged to the Senate. They had been accustomed to being consulted by Rome’s kings on matters of public policy, but King Tarquinius Superbus ruled by edict, without consulting the Senate, a practice that probably angered senators. In addition, Brutus’s brother had been a senator, making it clear that the king was a threat even to members of the Senate.

Brutus’s opportunity came in about 510 B.C.E. Tarquinius Superbus was expanding Rome’s dominance of its area through wars against local cities, and that year the Romans were laying siege to the city of Ardea. While her husband, Lucius Tarquinius Collatinus, was at the siege, Lucretia was raped by Tarquinius Superbus’s son, Sextus. She wrote to her husband about what had happened. When he and his fellow officers rushed back to Rome, she told them what had happened and then stabbed herself to death. Brutus seized the moment and persuaded his companions to rebel against the king. According to tradition, he became one of Rome’s first two consuls, Lucretia’s husband being the other, but he fell in battle soon thereafter when Etruscans tried to reinstate Tarquinius Superbus as Rome’s king.

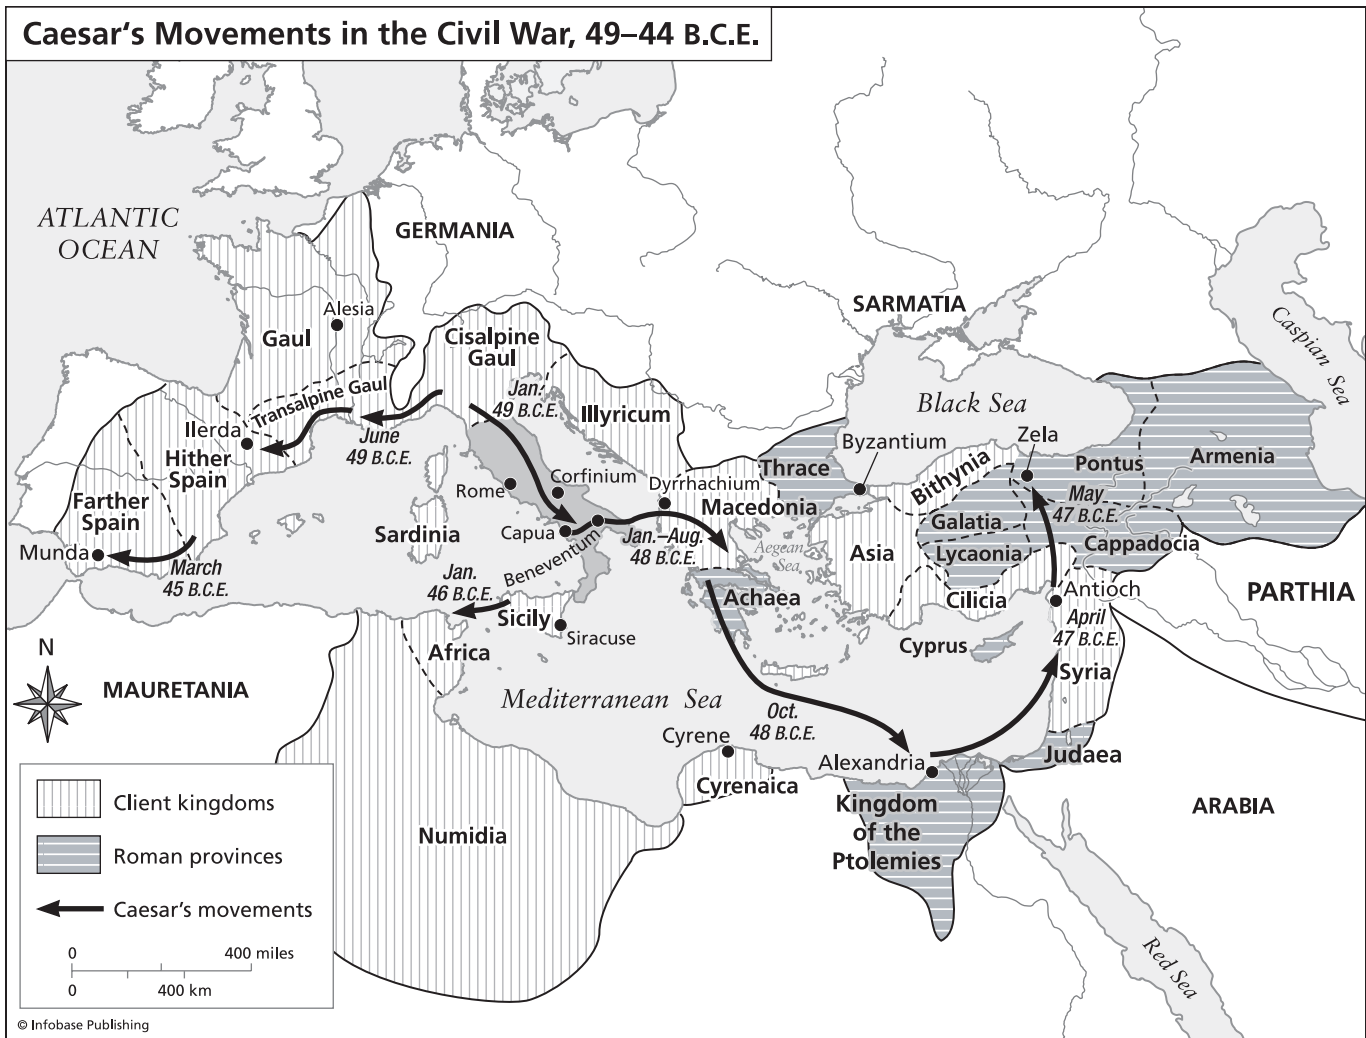

As the Roman Republic expanded its territories through warfare, the difference in wealth between the aristocrats, called patricians, and the commoners, called plebeians, widened, creating broad discontent among plebeians. Three important champions for their cause arose: Tiberius Gracchus (163–133 B.C.E.), his brother Gaius Gracchus (153–121 B.C.E.), and Gaius Marius (ca. 157–86 B.C.E.). Tiberius Gracchus came from a wealthy family but was not an aristocrat. He saw that common soldiers, who were required to come from landed families, were losing their farms to wealthy patricians, and he tried to reform the laws by requiring that retired soldiers be given public lands. The Senate opposed this action, but Tiberius Gracchus persuaded the Plebeian Council, the assembly that represented the plebeians, to pass the reform. He then urged other reforms, including one that would give Roman citizenship to Rome’s Italian allies—something even some

plebeians opposed because they feared it would dilute their own privileges as Roman citizens. Tiberius Gracchus ran for reelection as tribune, and on election day he and hundreds of his supporters were attacked by a mob led by senators and were slaughtered.

Gaius Gracchus emerged as the new leader of the reform movement. Like his brother, he served in the army. In spite of his brother’s murder, he chose to advocate some of the same reforms his brother had advocated. He was elected to two terms as tribune (123–122 B.C.E.) During his terms he managed to have laws passed that took public lands out of the hands of the wealthy and redistributed them among the poor. He advocated Roman citizenship for Italian allies, and he undertook a more comprehensive reform of Roman government than had his brother. He lost his race for a third term as tribune when rival candidates pretended to favor his reforms, and thereafter the new tribunes dismantled his work. Gracchus’s supporters began carrying weapons for protection, and their enemies pretended that Gracchus’s supporters were in rebellion. As a consequence, the Roman army slaughtered over 3,000 of the supporters, and Gracchus was stabbed to death by one of his slaves. One of the enduring legacies of the Gracchus brothers was the development of two opposing political views: the popular, called *Populares*, and the elite, called *Optimates*.

Gaius Marius served as consul seven times between 107 and 86 B.C.E. He was a highly successful general with a large following of active and retired soldiers. He eliminated the requirement that soldiers be landowners, allowing tens of thousands of poor and out-of-work Romans to join the army—something that alarmed some senators because such men had little to lose and everything to gain from political reform. In 91 B.C.E. the tribune Marcus Livius Drusus was assassinated for advocating the Gracchus brothers’ reforms. Rome’s Italian allies rebelled, demanding citizenship. This conflict became the Social War (90–89 B.C.E.). During that war the Roman general Lucius Cornelius Sulla (138–78 B.C.E.) attacked Rome with his army and forced Marius to flee. Sulla belonged to the *Optimates* faction, but his actions were viewed as illegal. Marius himself led troops into Rome in 87 B.C.E. and ordered the murders of members of the *Optimates* faction, including patricians. About a month after becoming consul for the seventh time, he died unexpectedly.

In 49 B.C.E. Julius Caesar became dictator of Rome. He was a populist reformer and was despised by the *Optimates* faction. A prominent member of the *Optimates* was Marcus Junius Brutus (85–42 B.C.E.). During the civil war between Caesar and Pompey, Brutus joined Pompey’s army because Pompey represented the *Optimates* faction. After the war Brutus wrote to Caesar, asking to be forgiven, and in 48 B.C.E. Caesar pardoned him. He and other *Optimates* members conspired to assassinate Caesar, on the ground that they would be protecting the republic and civil liberties. They murdered Caesar in 44 B.C.E. but were defeated by Octavian in the war that followed. Brutus committed suicide.

During the Roman Civil War of the first century B.C.E. Marcus Junius Brutus and others conspired to assassinate the dictator Julius Caesar, which they accomplished in 44 B.C.E.

The competition between the Optimates and the Populares continued, with Tullius Cicero (106–43 B.C.E.) championing the Optimates against Octavian. As a consequence, he was murdered.

After the transformation of the republic into the Roman Empire, there were many conspiracies to assassinate emperors and other political leaders, but the most notorious faction of dissent was a religious organization. Eastern religions had made their way into Rome and Roman Europe. One of these religions was Christianity. The Christians came to political prominence in 64 C.E., when most of Rome was consumed by fire. Rumors circulated that the emperor Nero (r. 54–68 C.E.) had started the fire to clear land for a palace and gardens he wished to build. He made scapegoats of the pacifistic Christians, who were regarded as anti-Roman. The cruelty of torture and murder to which Christians were subjected won for them sympathy among many Romans. The emperor Diocletian (r. 284–305 C.E.) renewed the persecution of Christians

with vigor, but in some Roman provinces the local governments did not press the persecutions. In 312 C.E. there was a dramatic reversal in fortune because the emperor Constantine I (r. 306–337 C.E.) converted to Christianity.

With Constantine's conversion, pagans became the dissenters. Prominent among them was Quintus Aurelius Symmachus (ca. 345–ca. 402 C.E.). In 382 C.E. he protested the removal of the Altar of Victory from the Senate, and the emperor Gratian (r. 367–383 C.E.) sent him into exile. Gratian was assassinated in 383 C.E., and Symmachus was allowed to return to Rome. In 391 C.E. he became a consul. In 391 C.E. Emperor Theodosius I (r. 379–395) issued edicts suppressing Rome's traditional religion, and Symmachus protested. His written arguments for tolerance of differing religions survive, as does a large collection of his letters. He was one of the last supporters of the traditional Roman religion to engage Christians in debates about religion and its place in Roman culture.

THE AMERICAS

BY KIRK H. BEETZ

In the ancient Americas people who openly disagreed with or resisted those in power tended to be treated harshly. Dissent was seen as a threat to the entire community for its risk of upsetting the social structure or incurring the wrath of the supernatural world. The mythology of North Americans suggests that dissenters were ejected from their tribes or villages. Sometimes these outcasts founded a new home and became celebrated as persecuted people who began a new and glorious village or culture. Behind the mythology is the implication that people needed to be in groups to survive, and outcasts usually did not survive expulsion.

More is known about the effects of resistance and dissent in the societies of ancient Mesoamerica than in those from lands farther north. Perhaps the greatest city of the ancient Americas was Teotihuacán, which reached its peak from before 100 C.E. to about the mid-500s C.E. It had a highly regimented society. Its commoners lived in apartments that were organized into gridlike blocks. Each apartment housed three families, with sleeping, cooking, and working areas for each family. Archaeologists speculate that the housing was intended to keep commoners well organized. One effect would be that an individual family would have little privacy in which to conspire against the government. For those people who did resist the rulers of Teotihuacán, appalling fates awaited. They would be tortured and executed, perhaps sacrificed to a god.

Despite the government's efforts to keep its people in line, dissent seems to have become a problem. During the 400s C.E. the commoners may have become restive, perhaps even rebelling on occasion. Their grievances may have included the conspicuous and ever-widening gap between their welfare and that of the social elite. Eventually, much of the center of the city was burned during either an attack from outside or a revolt of the residents of the city. Because there seems to have been no one outside the city powerful enough to challenge it, archaeologists are inclined to believe that the destruction was caused by residents fighting against their rulers. The revolts marked the decline of Teotihuacán. Most of the people of the city moved away to join Mayan city-states or to found agricultural communities in Mexico.

When the Olmec flourished is debated among archaeologists, but the culture seems to have lasted about a thousand years, from about 1500 to 500 B.C.E. The Olmec developed a complex culture and built some large monuments. They are now best known for their huge carvings of stone heads. They did not develop large cities and presumably did not have city cultures. Dissent among the Olmec may have taken the form of religious protest, and one reason they did not build big cities may have been resistance by commoners to being organized in large groups separated from the life of the land—agriculture, hunting, and gathering.

The Maya drew some of their culture from the Olmec, though many archaeologists believe that the Maya were not necessarily descendants of the Olmec. Near the end of their era the Olmec developed writing, something the Maya used to organize their society. Writing allowed rulers to extend the reach of their laws and traditions through written documents, much as other literate cultures have done in other parts of the world.

The Maya worked at creating a society in which every person knew his or her role in the community. Each person was supposed to have a place and a duty within society from birth and was expected to focus on that place and duty throughout his or her life. This became a social contract between commoners and their lords in which the elite had obligations to the commoners just as binding as those the commoners had to the elite. The Maya may have escaped some of the problems

experienced by Teotihuacán by having even their kings endure the same privations as the poor. Kings and nobles wore better clothes, had better housing, and had their pick of the best food, but they lived among their people and starved when their community starved and suffered from war when their people suffered from war. Indeed, kings and nobles were expected to be among the first to risk their lives when they waged war.

Even so, people sometimes became angry with their government. Mayan culture provided an outlet for this: Groups of people could shift their allegiance to another city or just pick up their belongings and move away. When they shifted allegiance to another city, they did so as groups. Probably under the leadership of local elders or a local governor, they would reallocate whole villages or community farmlands to a neighboring city-state, making its king their king and sending their taxes to their new government. This would have made them subject to raiding for slaves and human sacrifices by their old government, so they would have needed to join a city-state that was willing and able to protect them. In the absence of such a government, entire villages or groups of villages would sometimes abandon their homes and carry what they could to a new place out of reach of their former government. Such movements may explain why certain styles of pottery would mix with another style from a region far away, resulting in the creation of a new style or the loss of one style as the other became dominant.

Violence arose when cities tried to throw off the dominance of another city. Both Tikal and Calakmul experienced repeated revolts as the nobility of smaller cities tried to end the paying of tribute to those cities. Such revolts were very risky; if the rebels were captured, they would be tortured for days and then ritually sacrificed. If the commoners of the rebel cities believed they endured too much misery because of the revolt, they could shift allegiances or pick up and leave, which they sometimes did. Further, when a city's monarch was replaced by force, people might resist his orders. In 378 C.E. a noble from Teotihuacán, Siyaj K'ak', killed the king of Tikal and made himself king of the city. Depictions of Siyaj K'ak' show him in Teotihuacán clothing and armor, but his successors are pointedly in Tikal garb; in one depiction a later king's Mayan clothing contrasts with Siyaj K'ak's Teotihuacán clothing, a public effort to distance the monarch from his ancestor by showing that he was committed to Tikal's traditions.

For South America little is known about dissent and resistance of the ancient era, except that resistance could bring terrifying consequences. The Moche (ca. 100–ca. 600 C.E.) of Peru left murals that show the cost of resisting its rulers. Whether rebels or prisoners of war, the fate was torture and then mass bloodlettings, during which a priest sliced open the throats one at a time of hundreds of prisoners, all in a public display during which the prisoners had to watch what was happening. To risk such a fate, people had to be highly motivated and prepared to die rather than be captured. Perhaps dissidents among the Moche did as the Maya sometimes did and, if they could, moved away.

► roads and bridges

INTRODUCTION

The earliest roads in the ancient world consisted of tracks made by game animals and migrating herds. Ancient hunter-gatherers followed these tracks in pursuit of game and used them to travel from one place to another. In time, however, more sophisticated roadways were built, and the extent and quality of some of these roads might come as a surprise to

modern people accustomed to traveling at high speeds on interstate highways. The first paved streets were built probably in about 4000 B.C.E. in the Indus Valley of India. The first engineered road was built in England in about 3800 B.C.E., primarily to span marshland. In about 3000 B.C.E. the ancient Egyptians constructed a road paved with stones to aid in the construction of the Great Pyramid. Between about 1100 and 20 B.C.E. the Chinese constructed a road network of some 25,000 miles, and the Silk Road from China through central Asia to the Mediterranean Seas became a major trade route. Couriers through the Andes Mountains in South America relied on roads for travel, and Darius the Great's Royal Road in Persia, built around 500 B.C.E., was of such high quality that postal couriers could travel almost 250 miles per day on it. The Greeks and Mesoamericans also built extensive road systems, along with bridges to span rivers and marshes.

The most sophisticated ancient road system, however, was built by the ancient Romans, attested to in part by the word *pavement*, from the Latin word *pavimentum*, referring to the layer of concrete at the base of Roman roads. Many Roman roads were so well constructed that they survive in modern times to be seen by tourists in France (Gaul), Italy, England, and other parts of the old Roman Empire. Roman road building began in about the sixth through the fourth centuries B.C.E., but it was not until the Roman Republic, from the fourth through the first centuries B.C.E., that major engineered roads were constructed. In time, these roads would link every part of the Roman Empire. A person could travel from the far reaches of the empire to the center of ancient Rome, the Forum, using constructed roads nearly the entire way. Perhaps the most famous of these roads is the Via Appia, or Appian Way, which extended over 300 miles. Some of the earlier roads followed the natural contours of the land, but later roads represented massive excavation projects, because the builders modified those contours. To match the sophistication of their roads, the Romans also built bridges, some of which extended for hundreds of yards.

Ancient roads and bridges were often constructed primarily for the purpose of military conquest and the movement of troops and provisions. Later, they facilitated the administration of an empire, as officials, inspectors, couriers, tax collectors, and the like could travel relatively rapidly and safely. In time, roads and bridges also came to facilitate trade and commerce. While boats and ships were used extensively in the movement of goods, many communities were inaccessible by water, so roads had to be constructed to enable goods to be transported. Some of these roads were even named for their trade purposes. Perhaps the best example is the Via Salaria, a Roman road built primarily for the transportation of salt.

AFRICA

BY MICHAEL J. O'NEAL

A system of roads and bridges was crucial to the development of ancient civilizations, including those of Africa. Roads

served a number of key purposes: They enabled central authorities to communicate with far-flung regions; they allowed people from the countryside to engage in trade and exchange with people in the larger towns and cities, putting them on a more equal footing socially and economically; they enabled nations to trade with other nations, expanding the range of products available to their people; and perhaps most important, they allowed people to overcome the limitations of geography and come in contact with one another, trading ideas, information, and beliefs. A strong, vibrant empire or state was almost impossible without a system of roads.

The earliest roads in Africa probably were game trails people used to travel from place to place as they searched for food and water. Of course, none of these trails survives, but little imagination is needed to envision people following paths through the forest or over the savanna that animals had beaten down in their movements. While game trails were probably the earliest roads the world over, in Africa the wide, packed-down trails made by elephants no doubt were of particular use. Like these ancient trails, no prehistoric bridges survive for the simple reason that such bridges would have been crudely constructed of logs, though evidence exists of later suspension bridges built with vines.

The first true roads probably developed with the advent of agriculture. As ancient farmers and herders moved about with their livestock, they beat down more permanent paths over the terrain linking parts of their community with others nearby. In some instances these paths, hardened by centuries of use, can still be found in Africa. They are observable because grasses and other vegetation still have difficulty taking root in the densely compacted soil. Further, these ancient roadways probably were forged on higher ground; low-lying ground was more likely to be boggy or thick with vegetation. On higher ground the action of human and animal feet, and later carts and wagons, wore down the ground into the bedrock over a period of thousands of years.

As far as archaeologists know, none of these ancient roads was improved or engineered in any way; primitive peoples lacked the tools and time for making such improvements. Further, trying to improve roads in the shifting sands of the Sahara would have been fruitless. Nonetheless, trade routes between western Africa and the Middle East took at least four clearly defined routes. Caravan leaders led traders over the routes, which required about 40 days of travel between Arabia and such West African nations as Mali and Ghana. These routes were not established until about the third century C.E., when the camel was domesticated. Camels were necessary in the Sahara because they can go without food or water for long stretches of time. Some of these caravans consisted of as many as 12,000 camels, though 1,000 was a more common number. The route was marked by a sequence of oases that provided water.

Among the earliest improved roads of Africa were those built in the kingdom of Nubia, the region to the south of Egypt. Archaeologists discovered some of these roads in

the 1960s during salvage operations in connection with the construction of the Aswān Dam on the Nile River. Archaeologists discovered two types of roads. One type consisted of stretches where all of the rock was removed and placed in low mounds at the edge of the roadway to form a border. The sand was smoothed after the rocks were removed. The width of the roads varied depending on the terrain, but generally these roads were about 30 feet wide. In some places, such as a 4-mile stretch of road that ran west from the Nile River at the city of Denduz, this type of road was built on sandstone bedrock. It is clear that the rock borders were deliberately placed to mark the route, for they are found in places where there is no loose rock, so they had to have been carried into position over some distance.

The other type of road, an example of which was found running from the city of Dakkah to Kalabsha, is marked not by lines or piles of loose rock but by pairs of stone markers. These markers are roughly 1 foot in diameter and up to 3 feet tall, but in nearly every instance one of the markers is taller than its pair. Pairs of markers occur at roughly even intervals of a mile.

These roads, however, were not constructed in the modern sense of the word. Rather, they were more in the nature of clearings, with loose rock and other obstacles moved away. The first engineered roads in Africa were built by the Roman Empire, which required a complex system of roads and bridges for trade, administration, and military transport. These roads were built using methods that were surprisingly modern, with packed underlayments and crowning to allow water to run off. One of the most important Roman roads in Africa was the coastal highway that ran from Alexandria in Egypt all the way west to the coast off Gibraltar in Spain. While the road no longer exists, its existence is documented in itineraries from the time. Stretches of the highway were constructed in the centuries prior to the Common Era; the road was completed at about the end of the first century C.E. Although these roads were built by the Romans, they were used by Africans, even after the Romans withdrew, for trade and travel.

One of the signal achievements of the Roman Empire was bridge construction. While many of Rome's bridges in North Africa and elsewhere were constructed of timber (and thus do not survive), others were constructed with stone and concrete. With the exception of crude log bridges and perhaps suspension-type bridges made with vines, the bridge did not arrive in Africa until the Romans expanded into the continent.

EGYPT

BY MARK ANTHONY PHELPS

Roads, in the sense of paths that have been cleared by humans to facilitate travel and transport, arrive with of urban living. Footpaths existed from the moment that humans discovered other humans. With the advent of agriculture and the rise of urban areas, larger paths were needed to transport larger

loads of goods longer distances. These early paths would follow the terrain that offered the least difficulty for travel. Often these ancient paths have become modern roads. The function of roads has remained constant throughout history. Goods are transported, salesmen carry their wares, people visit family members and others, pilgrimages are made, diplomatic embassies travel, official messengers bear royal documents and goods, and armies move from place to place. The bulk of transport in the Nile Valley was naturally done by means of the river. Given the annual inundations, or periods of flooding, the paths were generally buried every year. Dried canals served as pathways and roadways. There are a number of roads outside the valley that have been preserved.

The best-explored road system in Egypt is that which connects the oases of the Western Desert. This road was the subject of intense study from 1992 to 1997, under the auspices of the Luxor-Farshut Desert Road Survey. This road system connects a number of oasis sites, which in turn connect to more distant oases and to the Nile Valley. Human activity along these roads is known from Paleolithic times (up to 7000 B.C.E.). Given that there were no wheeled vehicles until the Twelfth Dynasty (ca. 1991–ca. 1783 B.C.E.), the traffic for most of the history of this road was by foot or by donkey. Later inscriptions and artwork point to the use of horses on the route, probably as part of a royal courier service.

Like any road of its nature, this road had a number of forts. The forts served two purposes. First, they were there to collect taxes for the royal treasury, presumably at nome, or province, boundaries. Second, they were there to provide security, both for individuals and for the kingdom. The presence of soldiers would discourage travelers from avoiding the tolls. Also, soldiers could keep some sense of order in the region by protecting against desert raiders and by guarding access to the oasis wells. Further, they could serve as watchmen on the alert for the movement of rebels and other hostile groups. Towers became employed more frequently by later Hellenistic and Roman armies.

Likewise like any road of its nature, this route preserves both the graffiti of the literate segment of the population and stelae and inscriptions that date from the advent of writing to modern scribbles. Among these writings is a significant inscription from the time of the unification of Upper and Lower Egypt. It is written on behalf of the ruler known as the Scorpion (end of the fourth millennium B.C.E.). The inscription seems to record the use of the road to outflank the armies of Naqāda by the Scorpion's army from Abydene.

The Wadi Hammamat forms a natural pathway from the Nile to the Red Sea and has long served as a way for trade between Upper Egypt and points south in the Nile Valley. A road dating to the Predynastic Period (ca. 5300–ca. 3000 B.C.E.) connected the port of Sawaw to the Nile at Coptos (present-day Qift). The presence of quarries and gold mines created a demand for the roadway as well. Road systems grew up around Nile cataracts, generally consisting of roads at least 16 feet wide. These roads enabled cargoes of any size to be

GRAFFITI

The graffiti along the Luxor-Farshut Road in the Western Desert is typical of what is found along ancient roadways. What follows are samples of what individuals wanted to proclaim to the world. Some of these proclamations are more than 5,000 years old. One can find a traveler at leisure, writing, “Regnal Year 17, first month of the Shemu season, day 17: Spending the day by the scribe Monthuhotep beneath this mountain on holiday.” Another traveler was not feeling so relaxed. He inscribes a letter on a rock wall requesting that the priest pray to a number of gods for his safety on the journey.

Pilgrimages are a common reason to travel, and pilgrims often left graffiti behind them that served as reminders to the god and proclamations to fellow travelers in the mundane world that this pious act was being performed. One example: “He has made [it] as his monument at the time of his coming from the Abydene nome in order to perform rites for king Mentuhotep.” Priests also reminded both divine and mundane observers that they were present: “Made by the second prophet of Amun, Roma.” It so happens that Roma was already well known before this graffiti was discovered. He became the high priest of Amon (the most significant and most powerful priest in the empire) under the pharaoh Ramses II (r. ca. 1290–ca. 1224 B.C.E.). Roma was by no means the only official to leave his mark, nor was he the most significant one. That would have been “the son of the king of Upper and Lower Egypt, Mentuhotep.” He would later become pharaoh himself.

The first five lines of an otherwise lost literary work were inscribed along this roadside. It was in praise of an unnamed Theban ruler of the Second Intermediate Period (ca. 1640–ca. 1532 B.C.E.). It begins, “Oh people great and small, and the army in its entirety—behold, a man is in the City [Thebes], whose like has not been known!” Finally, a happy text greets the literate traveler, “As for the one who will read these writings, he will arrive [home] in peace.”

moved from ship to ship on the river. In urban areas, processional ways to temples were often paved. The stones were laid directly upon the soil. Typically the processional way would be from a river quay to the entrance of a temple.

The Ways of Horus, the royal road that led from the Nile Valley northeast through the Sinai to Palestine was the main overland route connecting Egypt to most of the significant commercial centers of the ancient world. The route brought in goods from Anatolia, the Arabian Peninsula, Mesopota-

mia, and all points east. Networks grew up connecting the main road to cities and villages throughout the inhabitable regions of the area. The roadway had forts, which in addition to the normal duties also protected wells for travelers. Way stations also dotted the route.

Open roads were basically areas that were cleared of rocks, which were then piled along the edges. Roads to quarries were often hewn out of solid rock for some portion of the trip to the river. The Egyptians had the technology to level rock surfaces, which they often used for building roads. Quarry roads were typically at least 16 feet wide and occasionally were paved. The need for paving was determined by the soil, which often was too sandy to haul blocks weighing multiple tons. The longest quarry road was located in Lower Nubia and was some 50 miles long. The oldest surviving quarry road with paving stones terminated on a quay in what used to be Lake Moeris. The construction of this road consisted of virtually no leveling prior to the laying of the stones, which were placed in the soil with the largest slabs laid on the outside of the road, while smaller stones were used in the center. This road was uniformly four cubits wide (ca. 7.3 feet). In addition to clearing surfaces or laying paving stones on the ground, Egyptians also would make log roads, which they lubricated with mud so that sledges could be dragged along them. There were officials with the titles “master of the roads” and “overseer of the masters of the roads.” An important task for these officials was the creation and maintenance of quarry roads.

There is virtually no mention of bridges prior to Roman domination. Seti I (ca. 1306–ca. 1290 B.C.E.) is depicted as crossing a bridge on his way back from a Syrian campaign. The Greek historian Diodorus Siculus (first century B.C.E.) writes that there was a fort at each mouth of the Nile. These forts were situated on both sides of the river with a bridge that had defensive installations straddling the river, but it is a claim found nowhere else.

THE MIDDLE EAST

BY MARK ANTHONY PHELPS

Routes followed by ancient peoples to traverse the land—whether for hunting or herding or some other purpose—began as simple footpaths. Roads smoothed or otherwise specially prepared for transport and transit came later, typically with settled living in villages, towns, and cities. No paved open roads have been discovered in the ancient Near East from the period prior to Roman domination. They are described as being “dusty” in a number of sources. The Gutians, invaders of Mesopotamia from modern Iran during the 22nd century B.C.E., were accused of allowing roads to be covered with weeds. The Egyptian work known as the “Satirical Letter” describes roads in coastal Syria-Palestine as being covered with pebbles, weeds, and briars. In the Bible roads are a place where one can hide snares, ropes, and traps. Old Assyrian texts mention that trade resumes in the spring after the “opening of roads” in Anatolia, a process necessary

after winter rains would have washed boulders and other debris into pathways. This event is also mentioned in the Jewish text the Talmud. The Greek historian Xenophon (ca. 431–ca. 352 B.C.E.) also refers to the necessity of clearing the Persian Royal Road and the problem of mud in the spring.

Thanks to the Assyrians, the Iron Age was a period of expansion in road construction throughout the region. Paved processional routes cropped up in cities. Campaign accounts recount the frustration of Assyrian kings in encountering narrow roads in mountainous terrain. Many accounts describe engineers with picks widening routes through stone so that the army could pass. Mention is also made of roads being so narrow that the king's horse could not fit on the path and of terrain that was too treacherous for horses to pass. The widened roads were still of use to the Persians, who seem to have followed the Assyrian roads through the area. The Persian army was employed in road building. According to Xenophon, Persian spearmen carried axes, bowmen carried mattocks, and slingers carried shovels.

Evidence of urban paved roads has been found on occasion. Cobble streets appeared in towns in the Halaf Period in Mesopotamia (ca. 5500–ca. 4500 B.C.E.). An Early Bronze Age (ca. 3800–ca. 2000 B.C.E.) paved street has been discovered at Beth Yerah in Israel, and a Middle Bronze Age (ca. 2000–ca. 1500 B.C.E.) street has been found at Nābulus in Israel. Typically, urban paving was restricted to processional ways to temples, areas around gates, and occasionally other major streets. Few have been preserved. During the Neo-Assyrian Period (ca. 1000–ca. 626 B.C.E.) a number of paved roads were built in Assyrian cities. The royal road ran through Ninevah on its way to points west. The best-known paved road in Mesopotamia was Aiburshabum, the processional street of Marduk in Babylon, built in the Neo-Babylonia Period (625–539 B.C.E.). It has been unearthed. For the bulk of its length, the street is approximately 22 yards wide, narrowing to under 7 yards as it approaches the temple.

The method of construction of paved streets varied. A number of different styles are evidenced in Iron Age Israel. These methods included paving consisting of reeds and clay, shards and pebbles, rubble and plaster, and wedge-shaped cobbles, with the point of the wedge inserted in plaster. In Mesopotamia the preferred method of construction consisted of setting bricks in a layer of asphalt and then topping the roads with limestone slabs, which were sealed with asphalt. Maintenance of the roads was a function of governments. Local governments were responsible for roads in their territory, while the overall road network was the product of the central government.

The width of roads naturally was determined by their function and usage. Roads were at their widest in cities, evidenced by Aiburshabum street in Babylon. Other recovered streets in Babylon were from 2 to 11 yards wide, usually in the range of 3 to 6 yards. The royal road through Ninevah widened by Sennacherib (r. 704–681 B.C.E.) was 33 yards wide. Archaeologists assert that a road needed to be at least 2.6

yards wide for two small two-wheeled carts to pass. Mountain roads often were narrower.

There is evidence of way stations beginning with the reign of Shulgi (ca. 2094–ca. 2047 B.C.E.) throughout the ancient Near East. Some of them may have been private capitalist ventures, especially those closer to urban centers. In open areas these stations provided protection from raiders, gathered intelligence on both traveling parties and locals, and helped the government collect duties and tolls. They also provided lodging, food, drink, and prostitutes for travelers.

Bridges in the ancient Near East were rare prior to Roman rule. A number are mentioned in the Neo-Assyrian Period. Sennacherib built one of bricks and limestone in Ninevah. Bridges are mentioned in a number of places in Neo-Assyrian texts. The remains of a bridge in the city of Babylon have been uncovered, presumably built by Nebuchadnezzar II (r. 605–562 B.C.E.), consisting of five to seven piers. It is cited by the Greek historian Herodotus (ca. 484–between 430 and 420 B.C.E.). Nebuchadnezzar claimed to have built a bridge of wood over the East Canal in Babylon, in turn covered with bricks supporting Aiburshabum street.

Most bridges in the ancient Near East were pontoons rather than permanent structures. Ownership of a bridge was the source of serious income, as tolls would be charged for access. There are Neo-Babylonian contracts preserved concerning bridge ownership. The surface of these bridges often consisted of logs or dirt, occasionally having guide ropes. The pontoon bridge built across the Hellespont (the strait that separates Anatolia from Greece) by the Persian king Xerxes (r. 486–465 B.C.E.) had not only dirt over logs and guide ropes but also a fence.

With the coming of the Romans and then the Byzantines, bridges became a more common sight. Syria and Palestine were fully integrated into these societies, as is evidenced by the wide network of roads. Roads further had a symbolic value, as Roman engineering conquered nature, evidenced in paving and bridge building. They demonstrated that Roman rule brought tangible benefits, a key hurdle in trying to maintain control over a conquered region.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

In looking at the history of roads and bridges in Asia and the Pacific it is important to understand the distinction some archaeologists make between paths and roads. Paths are ways that are worn by foot traffic, but roads are the products of construction. They may follow an old path, or they may, through human effort, create new avenues for traffic. They may even be intended to send traffic in new directions. The Silk Road, contradicting its name, consisted of several interconnected paths that led in a general east-to-west direction from northwestern China through central Asia to northern India or through the Persian Empire to the Mediterranean world, followed for the purposes of trade. Trade along the Silk Road was a signifi-

cant factor in the development of many ancient civilizations. When the paths became eroded from use, travelers created new paths by walking, riding, or hauling carts over untrodden terrain. Thus, archaeologists tend to prefer to call the Silk Road a “route” or a collection of “routes,” rather than a road.

Rivers have functioned as highways for the Chinese ever since the Shang Dynasty (1500–1045 B.C.E.), when the Chinese culture was focused on the Huang River. During the Zhou Dynasty (1045–256 B.C.E.) the capitals Xi’an and Luoyang were far away from the most productive farms of the empire, which were on the eastern reaches of the Huang River and the Yangtze River. The rivers and their tributaries meandered in loops and turns, making shipping on them slow. Food from the east could spoil by the time it reached the capital. The response to this problem was to build roads that were as straight as possible from the lower rivers to the capital.

Often, soldiers were given the task of building roads, but peasants were frequently drafted also. They were unpaid. Convicted criminals might be sentenced to hard labor working on roads. Sometimes rich convicts paid poor people to serve their sentences. Many road-building tasks required tens of thousands of workers. The workers were expected to carry all that they would need, including their own food.

Some roads were constructed following old trails. Others were built to be as straight as possible, especially if they were to connect with the capital city. There were roads built for use by the military to move troops and supplies. Others were built for commerce, especially the transport of grain from rural areas to city markets. There were even roads built for postal carriers. During the Han Dynasty (202 B.C.E.–220 C.E.) roads were built for the use of the emperor and his officials. Many roads had three lanes. The two outer lanes were for the carts and carriages of commoners, allowing them to pass oncoming traffic without having to leave the roads. The middle lane was higher and flatter than the outer lanes and was reserved for use by the emperor.

Among the most remarkable roads of China are those built in the western mountains, beginning about 500 B.C.E. Roads were often carved out of mountainsides and were often very narrow and dangerous to use. On some cliff sides, wooden roads several miles long were built. Workers would carve out deep holes in the rock and then fit a large log into each hole. Exactly how this was done is not known. Ancient Chinese records tell of messengers and government officials riding horses at a gallop across these wooden roadways, often cantilevered out thousands of feet above a sheer drop.

Ancient Chinese bridges tended to be made of wood. Although records occasionally mention stone bridges, it seems that only a few from the Han and the Six Dynasties (220–589 C.E.) survive. For the ancient Chinese, bridges served two purposes. One was practical, with bridges allowing traffic to move over a river or gorge without trouble. The other was decorative. Practical bridges included ones made of stone over the Wei and other rivers. Posts were sunk into riverbeds, and long, heavy stones were laid across them to form road-

ways. These stones often weighed several tons. Some wooden bridges, which were built much the same way as stone bridges, had roofs. Decorative bridges were often placed in gardens or ponds. One popular form was the cross bridge. It was shaped like a cross, with four bridges converging on a central point. These bridges were designed to give people good views of gardens or ponds. Another form of bridge was the moon bridge, which was a semicircle over a stream or moat. Its very high arch made it difficult to use in a practical way, but it was usually intended for ceremonial use.

The ancient Indians built few bridges. They reserved their bridge construction for spanning the moats of cities and perhaps they built rope bridges high in mountain ranges. Whenever travelers met a stream they could either cross it at a shallow ford, fell trees that spanned the water, or build rafts from nearby trees.

By the time of the Maurya Empire (ca. 321–ca. 185 B.C.E.) road building had become complex. A road was laid out by an architect and, to help the road’s designers decide which materials to use during construction, the soil was studied along which the road would pass. Trees and bushes would be cleared from the path of the road. The surface of the road would be raised higher than the surrounding land and would be flat and level. Ditches were dug along each side of the road to carry the runoff from rain. Local towns were often given the responsibility of maintaining nearby roads. Some roads were very important to the economy of India, and central governments would take charge of maintaining those roads. To pay for maintenance, the governments charged merchants about 1/20th of their goods when they used a road.

Rest stops were built alongside roads, providing travelers with protection from sun and rain. They were maintained by workers who kept them clean. Artificial ponds were built near rest stops so that travelers could replenish their water supplies and bathe. Wide-spreading banyan trees were planted about every mile to provide shade.

Most historians date road building in Japan from about 576 C.E., because medieval records mention roads being built on the island of Honshū at that time. Many archaeologists do not look past that date. One of the problems archaeologists have is that Japan is densely populated and roads have been built over or reconstructed many times as the nation’s population has grown. Archaeologists have found evidence for some ancient road building on Honshū, perhaps before the 100s C.E. These were roads running straight north-south; they were imposed on the land to create straight lines in eastern Honshū. Their north-south orientation was probably influenced by the Chinese custom of orienting structures according to the points of the compass. Japanese of later generations built palaces and even cities next to or between these roads, indicating that they were spiritually important. The purposes the ancient Japanese had for building the roads was to make trade easier, to allow for the government to stay in touch easily with its provinces, and to allow its armies to move quickly.

EUROPE

BY JUSTIN CORFIELD AND MICHAEL J. O'NEAL

During the Mesolithic (ca. 10,000–ca. 4,000 B.C.E.) and Neolithic (ca. 7000–ca. 2000 B.C.E.), the emergence of sedentary settlements led to their connection by trails and pathways through the forested landscape and along major rivers. The earliest-known constructed pathway is the wooden causeway across marshy terrain in southwestern England called the Sweet Track. The wood used in the construction of the Sweet Track has been determined by tree-ring dating to have been cut in the spring of 3806 B.C.E. Throughout Europe in the Bronze Age (ca. 2800–ca. 700 B.C.E.) and Iron Age (ca. 1000 B.C.E.–ca. 500 C.E.), increased trade led to the establishment of well-traveled routes between settlements, and wheeled vehicles and draft animals came into use. An increasing number of trackways and causeways were built across marshy ground and shallow water, where the damp conditions have led to their preservation. Open bodies of deep water, such as rivers and straits, still posed obstacles, however, and crossing them required watercraft, since true bridge-building techniques had not yet been developed.

The Celts formalized the process of building roads in many areas, especially around larger settlements. Groups of

people were involved in building specific roads, which often were covered with timber, brushwood, or stones so they would not turn into quagmires when it rained. This was especially important in marshy areas such as The Fens in England. Many Celts in Gaul and Britain traveled long distances by chariot, and pathways that were wide enough for a horseman or person on foot eventually were widened for ox-pulled wagons or horse-drawn chariots. The Roman general Julius Caesar (100–44 B.C.E.), in his *Gallic Wars*, refers to this use, noting that his main opponent during the second invasion of Britain in 54 B.C.E. was planning to wait for the Romans to send out their cavalry before using the chariots to attack “out of the woods by well-known lanes and pathways.”

Some of the Celts’ most heavily used roads were extensive. One coastal road began in modern-day Genoa, Italy, and traveled along the Mediterranean coast through Marseilles and Narbonne in France to Cadiz in southern Spain. Another important road in England was the Ridgeway, which followed the crest of the Wessex Downs and had operated as a trade route beginning in Neolithic times. A number of important paths and passes crossed mountains, especially the Pyrenees and the Alps. They were eventually expanded and used by large armed convoys, perhaps the most famous being that of the Carthaginian general Hannibal (247–183 B.C.E.), along with his elephants, in 218 B.C.E.

Many of the Bronze Age and Iron Age roads and pathways became major roads used by the Romans and subsequent civilizations. In addition, many roads that fell into disuse have been unearthed or can be seen by aerial archaeology. Entrances to Iron Age forts were particularly important, and the roads were often lined with flint, giving an impression similar to that of cobblestones, which allowed carts and chariots to cross the ground easily.

One road that existed before the Romans but that was later used by the Romans is the so-called Amber Road. No one knows when the Amber Road was constructed—although “constructed” is the wrong word, for the Amber Road was essentially a network of paths or routes that were carved out over time primarily for the transport of amber. The roads were not developed in the sense of having been constructed using principles of road technology. However, generations of foot travelers, beasts of burden, and carts created the roadways. In this respect, it was like the Silk Road that ran through Asia or the Salt Road of southern Europe, especially Italy. Amber, a fossil resin, was a valued resource in ancient Europe and around the Mediterranean region, used in many ornamental objects, such as beads and even in coins, primarily because it could be brought to a high polish. Long before the Romans arrived, Europeans had conducted an active trade in amber, transporting it over these routes.

The Amber Road comprised a number of stretches that connected various portions of Europe. Much of the Amber Road consisted of overland routes, but to the extent that it was a trade route, it also included stretches of rivers. One main route extended east-west and connected Europe with

Section of the Sweet Track, the oldest prehistoric timber trackway in Britain (Neolithic, 3807/3806 B.C.E.), from Somerset, England (© The Trustees of the British Museum)

Asia. The other main routes ran north-south and connected northern Europe and the Baltic region with southern Europe and the Mediterranean region. Perhaps the oldest of these stretches ran from the Baltic coastline down through present-day Poland, the Czech Republic, and Austria to the Adriatic Sea. Another ran from the North Sea through the Brenner Pass through the Alps into Italy and Greece. A number of routes ran through portions of modern-day Switzerland, the Netherlands, Belgium, France, and as far south as Spain. Later, another north-south route ran from northern Prussia through Bohemia to the Adriatic Sea.

The Amber Road contributed significantly to the development of European culture. The Egyptian pharaohs traded for amber with people from the north, as did the later Romans. The Amber Road was an important link between the cultural centers of the Mediterranean and northern Europe during the Nordic Bronze Age, roughly from 1800 to 600 B.C.E. In modern times archaeologists and historians have devoted considerable resources to locating these ancient routes. In particular, the Old World Trade Route Project has traced an entire network of such routes throughout Europe (and Asia), such that a map shows a thicket of them that differs little from a modern road map. They note that these routes were not used exclusively for trade. They were also used as postal routes, routes for pilgrims, administrative links, routes for the movement of troops, and even routes followed by nomadic peoples.

The Celts built many bridges over rivers they could not ford easily. These would have been made of wood, and their ability to build them quickly before sieges and battles indicates that such bridges would have existed throughout Europe for everyday trade and communication. It also seems likely that the Celts specifically did not build bridges in some places to make a settlement harder to attack or to make an invading army less likely to use a particular route. When Hannibal crossed through southern France, he encountered fewer bridges than one might expect. Perhaps the Celts, for strategic purposes, had refrained from building bridges there, or perhaps they had destroyed existing bridges to delay Hannibal's passage.

GREECE

BY SPYROS SIROPOULOS

Roads became a necessary aspect of social life from the moment human communities became organized and exchanging goods and traveling became common. Travel was not always easy or safe in antiquity. The myth of Theseus, who journeyed from Troezen to Athens, killing a number of thieves and murderers on the way, indicates the difficulty of journeying in the ancient world and the need for establishing safe passage for travelers and tradesmen alike.

Since walking was the usual means of transportation in antiquity, the first roads were nothing but clear-cut paths in the countryside. Religious and commercial purposes led to

the construction of more carefully designed routes. Opposite the strategically located island of Salamis and on the cross-road between Athens, northern Greece, and the Peloponnese lay the city of Eleusis. During the time of the Athenian statesman Solon (ca. 630–560 B.C.E.), Salamis and Eleusis were attached to Athens. A biennial celebration in honor of the goddesses Artemis and Persephone was established. A road leading from Athens to Eleusis was constructed, called *Ierá Hodós* (Sacred Way). Some stretches of this road survive. On the roadbed, paving was undertaken. Traces of retaining walls and the roadbed cut in limestone rock survive in some areas. This road is perhaps the most impressive finding of ancient country or interstate roads from antiquity.

Another impressive discovery is the 3-yard-wide road from the Peloponnese to central Greece. Since it was mainly a road used by merchants, provision for places where carts could pull and pass one another is visible today. A different kind of road was the *Diolkos*, constructed along the Isthmus of Corinth. Beginning in the eighth century B.C.E. the Greeks' colonization of the West made the transportation of goods imperative. The Greeks tried to avoid the dangerous circumnavigation of the Peloponnese. The Corinthians pulled the smaller ships traveling from east to west over the isthmus, earning money from payments of toll. Later, in the sixth century B.C.E., the Corinthian tyrant Periander (d. 586 B.C.E.) constructed over the narrowest part of the isthmus (3.7 miles long) a paved road, with two parallel channels cut for the wheels of specially designed transporters, on which ships were loaded.

Ancient sources do not give details of the *Diolkos*'s function. Systematic excavations from 1956 until 1962 brought to light many parts of the road, allowing archaeologists to determine its route and the starting point at the Corinthian gulf. Although it was initially thought that the road was wooden, excavations have proved that it was 3.2 to 6 yards wide, paved with limestone cubes. The parallel channels for the transporters, about 1.6 yards apart, were curved alongside the road, but specially designed gutters were constructed around curves for added security. The ships were pulled by slaves who walked along the sides of the road in wide paths. Letters of the Corinthian alphabet were carved on various points of the *Diolkos*; these, with some fragments of broken pottery found there, help to date the road, which was used until at least 833 C.E.

Road planning in cities was not always easy, especially for great centers such as Athens or Piraeus, where community life from years ago had already formed small, narrow roads before the civic way of life's explosion in the Archaic and Classical Periods (600–323 B.C.E.). To an extent, natural topology determined the planning of roads. Consequently, two kinds of street layouts developed: the regular, with straight, parallel, and rectilinear streets, and the irregular, where roads did not follow straight lines but sometimes led in a radial fashion to the same spot. Aristotle suggested that the second style of street layout was better for the defense of the city. According to the second-century C.E. writer Philostratus, it seems that

this irregular style was named Attic because of its establishment in various demes (small political divisions) of Attica, though it is found in other cities, too.

The main road in the city of Athens was the road of the Panathenaia, named after a festival for all Athenian citizens. This road originated from the central place of Agorá (“marketplace”) or Kerameikós (the area where potters, called *kerameis* in Greek, lived). This road not only ran through Athens; it also connected Athens with all the demes of Attica and the rest of Greece.

Hippodamus from Miletus (fifth century B.C.E.) is often falsely considered the inventor of a street planning that bears his name. Hippodamus did not come up with the specific way of town planning, but he adapted elements of the Greek city to fit roughly the following ideal: rectangular divisions of town areas, with roads that were 6.2 yards wide and blocks of 94.26 by 39.04 yards, divided in 10 square building sites of 18.81 yards—that is, five properties on each side divided by a narrow street 1.31 yards wide. Excavations at the town of Olynthus, built in 432 B.C.E. according to this Hippodameian plan, brought to light a part of it that fits this description.

Even since the Bronze Age bridges have been constructed out of wood for passage over streams and rivers. Stone bridges were common in the fifth century B.C.E. The style is usually the same: Pillars with lintels, or horizontal beams, on top support the bridge. The space between the pillars serves as water passage, in order to lessen the impact of water on the bridge and ease the construction process. A wooden passage with planks was constructed on top of the stones. We have examples of arched water passages on solid bridges, too, from the Classical Period, although it is uncertain whether any bridges with true arches date from before the Roman Period.

A famous bridge of the Classical Period was that over the river Cephissus at Athens. On the way to Eleusis people would stand on the bridge, singing rude or befooling limericks to passersby, thus giving a new meaning to the verb *gefyryzein* (from the Greek word *gefyra*, meaning “bridge”), which meant to mock someone from a bridge.

In war, too, bridge making was essential for the carriage of troops over water. During his invasion of Greece in 480 B.C.E., the Persian king Xerxes I (r. 486–465 B.C.E.) is said to have crossed the Hellespont by a bridge of boats tied side by side for nearly a mile in length. According to the tragedian Aeschylus (525–456 B.C.E.), this event was an act of *hybris* (an act that went beyond established moral codes), partly responsible for Xerxes’ defeat by the Greeks. Alexander the Great had specialized mechanics in his army, one of their tasks being the construction of bridges. During the Hellenistic Period many bridges were built, some of them over 325 yards long.

ROME

BY KATIE PARLA

The maxim “all roads lead to Rome” describes Rome as the nucleus from which major routes for conquest, trade, and

communication originated. The adage, while accurate, does not adequately describe the complexity and organization of the Roman road system, which stretched far beyond the capital city and the Italian peninsula for a total of more than 50,000 miles of paved roadways across Europe, Asia, and Africa.

During the earliest periods of Rome’s urban development, in the seventh and eighth centuries B.C.E., the necessity for road construction was minimal, as Rome had limited contact with its neighboring regions. Many routes were unpaved paths in the countryside created by foot and wagon traffic over short distances linking minor settlements.

During the early to middle Roman Republic, of the sixth through fourth centuries B.C.E., preexisting roads from the Bronze and Iron ages, as well as conquest and trade routes established by Etruscan and Sabine tribes, were adapted and extended. The Via Latina began as a series of dirt trails that the Etruscans transformed into fixed routes for their conquest of Campania in Italy. Later the Romans paved and extended the Via Latina. The Via Salaria was another pre-Roman road that was later transformed by the Romans. The Sabines established this unpaved road to reach the salt marshes along the Tiber River. These and other pre-Roman roads typically followed the natural topography of the land, winding around mountains and avoiding valleys and other natural obstacles.

During the middle to late Roman Republic, in the fourth through first centuries B.C.E., the Romans began building major paved highways known as consular roads. These courses were built by censors, elected officials of the Roman government who were responsible for building and maintaining roads and aqueducts, and they began in Rome and radiated outward to other parts of the Italian peninsula. Rather than avoiding natural obstacles like their archaic predecessors, the Roman roads often took the most direct routes, which required the manipulation of topographical elements by cutting through mountains, leveling out elevation irregularities, and building bridges over valleys, rivers, and swamps.

The first major consular highway was begun in 312 B.C.E. by the censors Appius Claudius and Caius Plautius and was called the Via Appia after Appius Claudius. The first-century poet Statius (ca. 45–96 C.E.) praised the Via Appia as the *Regina viarum*, queen of all roads, for the vital role it played in Rome’s conquest, communication, trade, and travel. The road was built in stages over the course of more than a century, and the first segment reached Capua, 132 miles southeast of Rome. It was later extended as Rome conquered more territory approaching the Adriatic Sea, and it eventually reached the Italian cities of Benevento, Taranto, and ultimately the port city of Brindisi, for a total length of 364 miles.

Most of Rome’s roads were originally built for purpose of conquests. Roads were built to move troops and conquer territories as well as to transport slaves and war booty back to Rome from these areas. The roads later took on other

Iron hipposandal from Roman Britain (first to second century C.E.), found in London; hipposandals were a form of temporary shoe that could be fastened to the horse's hoof for use on metal roads. (© The Trustees of the British Museum)

functions, serving as administrative and commercial links between the capital city and its distant territories and connecting other cities and ports.

To help the Roman republican or imperial government control conquered lands, provincial governments were established to communicate and enforce the Roman laws. Roads linked the capital city of Rome to the distant provinces, thereby allowing the central government to communicate with its bureaucrats abroad. Provincial governors could carry out the decrees of the Roman government based on messages delivered along the routes.

Roman roads were a critical component of the infrastructure that allowed the economy to grow rapidly from the middle republic to the high empire. Raw materials, manufactured goods, building materials, and commodities could be imported and exported along these routes, fueling economic growth. The provincial governments in Roman territories were also responsible for protecting Roman business interests abroad, which was possible due to the communication facilitated by the road network.

Roads were built by soldiers, slaves, and local workers under the direction of engineers. Local materials and conditions determined the depth of a road's foundations, its width, and the technique used to build it. Road foundations were not flat but featured an *agger*, a ridge in the center sloping downward toward the edges of the roadway to facilitate drainage.

The construction process was begun by clearing the land of trees and other major obstacles along a straight route. Then a trench was dug, the earth at its bottom was packed down, and a layer of concrete, or *pavimentum*, was poured. The next stratum was the *statumen*, a mixture of stones, followed by the *rudus*, a mixture of sand or soil with clay or concrete. Durable, flat paving stones were cut to fit together to create a smooth road surface. Sidewalks for pedestrian traffic flanked

many roads, and milestones on the roadside reported the distance from the road's origin.

For routes over marshy land the approach was different. Pavements were laid over wooden rather than concrete foundations. Steep inclines and natural obstacles also required the builders to deviate from standard building practices. Roads sometimes followed a zigzag course to minimize the human effort in climbing an incline once the roadway was paved. While tunnels could be cut through mountains and bridges could be constructed over rivers, valleys, and marshy land, sometimes it was necessary to avoid these obstacles altogether, causing the road to curve or change its straight course.

The materials and techniques used to construct Roman bridges developed over time. Some of the first bridges were made with wood and rope to connect commercial and residential areas on opposite sides of the Tiber River. Rome's first stone bridge, the Pons Aemilius, was constructed from 181 to 179 B.C.E. to connect the city's cattle market to the opposite side of the Tiber.

By using the arch, the Romans were able to build stone and concrete bridges with one or more spans across valleys and rivers. Local materials determined the method of construction. In one common method, concrete piers were built on riverbanks or through ravines to serve as the supporting columns for the arches. A wooden framework was built and concrete arches poured onto it, linking the piers. Stone veneer was then used to cover the bridge's concrete core. A pulley system, operated by slaves or animals and possibly driven by a treadmill, was used to lower huge pieces of stone into place. When concrete was not readily available, stone was used to build both the piers and the spans. Bridges that had to be built quickly or were temporary were made out of wood that was harvested locally. During military campaigns troops carried small boats for making pontoon bridges to allow speedy transportation across bodies of water.

The legacy of Rome's network of roads and bridges can be witnessed to this day from Great Britain to the Middle East. The permanence of the materials and expert engineering employed in their construction makes these wonders as impressive today as they must have been in antiquity.

THE AMERICAS

BY PENNY MORRILL

It is helpful to start by defining the different types of roadways in the Americas. A path or trail normally follows the most efficient route between two points. Paths avoid major geographic obstacles and usually do not follow a straight line. Paths are the result of the wear of traffic and are maintained by tradition.

Roads are constructed by a labor force. They are intentionally prepared surfaces of the landscape that attempt to provide the most direct route, usually between two points. Formal road systems have a definable width and can incorporate bridges, roadbeds and pavement, curbs, side walls, drainage culverts,

and other architectural elements. Causeways are raised roadbeds. In many cases, formal roads are ceremonial. Over time, a road can be abandoned as a formal route but possibly be retained as a path. North American roads dating to the ancient period have not been uncovered by archaeologists.

Before the Spanish conquest in Mesoamerica in 1521 there were no pack animals or wheeled vehicles. All movement of agricultural products and trade goods was by human carriers across land or by canoe. For this reason, finding physical evidence of early roadways is difficult and, in some cases, impossible. This is particularly true at the center of Olmec civilization (1500–400 B.C.E.) in Tabasco and Veracruz, a low-lying coastal area of bogs, marshes, and rivers.

The Olmec ceremonial and political centers at San Lorenzo (1200–900 B.C.E.) and later at La Venta (900–400 B.C.E.) provide evidence that there were local routes, probably paths, for transportation from subordinate villages to the center of each of these chiefdoms. In addition, regional trade routes existed for the large-scale export of materials that were produced in the extensive workshops discovered in the Olmec heartland. The Olmec also imported from great distances. For example, the major sources of the highly prized greenstone were in Guerrero and the Montagua valley of Guatemala. For the large portrait heads and other major sculpted works found at San Lorenzo and later Olmec sites, huge basalt boulders were brought by land and water routes from the Tuxtla Mountains, 60 miles from San Lorenzo. In this early trade and exchange network, human carriers walked across land or used canoes along the river systems, leaving behind very little physical evidence, even though their routes were later used by other chiefdoms.

Farther afield there is evidence of interaction among the Olmec and the peoples of central Mexico, Oaxaca, and the Maya region. While this points to the possibility of formal roadways extending from the Olmec center, other trade relationships existed beyond the Olmec sphere, for example among elite families in the Tehuacán and Oaxaca valleys. Archaeological investigations have provided evidence that elite families of the Tehuacán and Oaxaca valleys were importing goods from other regions. The pottery styles of these two areas were similar, also an indicator of contact. The relationship between these valleys gained importance because of the obsidian trade through the Cuicatlan Cañada. Obsidian, used to make tools and weapons, was being brought from Otumba, at a great distance from this region. Archaeologists now believe that Cuicatlan Cañada, a long river canyon running north-south between the valleys of Tehuacán and Oaxaca, remained a critical trade route into the Spanish colonial period. After the end of Olmec domination, widespread dispersion of Zapotec pottery in the Tehuacán and Nochistlán valleys and in the Cuicatlan Cañada reflect trade expansion by the Zapotec (600 B.C.E.–900 C.E.) into these regions, probably using the roads that were already in existence.

In many regions of the Americas archaeological evidence of trade is all that remains to prove the existence of ancient

roads and bridges. The Chavín people (after 1000 B.C.E.) on Peru's northern coast traded actively. At Chavín de Huántar ceramics of various stylistic traditions came from areas far away. Chavín-style gold work has been found at Chongoyape, far up the northern coast. Chavín textiles were used in a southern coast burial at Karwa, some 300 miles from Chavín de Huántar. As in early cultures of Mesoamerica, stylistic elements become the markers for trade and indicators of the existence of roadways. Also on the southern coast the burials of the Paracas people (after 600 B.C.E.) indicate that the members of the elite were trading over long distances for luxury goods.

A survey of the Virú, Moche and Chicama valleys along the northern coast of Peru has brought to light more than 150 ancient roads. The identity and dating of both formal and informal routes were verified by analyzing cross-cutting through older roadbeds and by taking note of related ancient structures, canals, and walls. Over the span of 2,500 years roads in the Moche valley were cleared and graded, with roads cut through small hills and with stone-faced ramps. For certain distances the roads were curbed with debris from road construction, or they were walled. Early in the history of this area the Cuspisnique (500 B.C.E.) built roads exclusively with walls.

The most intriguing of all the roadways throughout the Americas are the Nazca Lines. The Nazca people occupied the Ica and Nazca valleys on the southern coast, and their civilization reached its height in the centuries after the birth of Christ. The Nazca built a pilgrimage center at Cahuachi on the southern bank of the Nazca River facing the Pampas, where the lines were inscribed. It also can be surmised that the Nazca people approached Cahuachi along ceremonial roads. The Pampas cover a large area (130 square miles) that is unique geologically. Light-colored stone is covered by a thin layer of dark stone, allowing for subtractive drawing onto the landscape. The Nazca Lines were created by removing the dark stones to reveal the light ones.

Archaeological investigations at Cahuachi indicate that perishable houses were constructed, perhaps tents. From this it can be surmised that Cahuachi was not a permanent community but a place where ceremonial roads intersected. Archaeologists believe that entire communities of Nasca people walked in processions along these sacred roads. The sacred roads seem to have served ritual purposes and were not always thought of in a utilitarian sense.

CONTRIBUTORS

Saheed Aderinto is a Ph.D. student at the Department of History, University of Texas at Austin. Some of his most recent publications include “Prostitution and Urban Social Relations” and “Policing Urban Prostitution: Prostitutes, Crime, Law and Reformers in Colonial Nigeria” in *Nigeria’s Urban History: Past and Present* (2006) and “Discrimination in an Urban Setting: The Experience of Ijebu Settlers in Colonial Ibadan, 1893–1960” in *Inter-group Relations in Nigeria during the 19th & 20th Centuries* (2006). His writings have also appeared in *IFRA Special Research Issue*, *Ethnic and Third World Review of Books*, *African and Asian Studies Journal*, and *The Encyclopedia of Prostitution and Sex Work* (2006).

Olutayo Charles Adesina, Ph.D., teaches at the Department of History, University of Ibadan, Nigeria. He is the author of “The Underground Foreign Exchange Market in Ibadan during Devaluation” in *Money Struggles and City Life: Devaluation in Ibadan and Other Urban Centres in Southern Nigeria, 1986–96* (2002) and “Teaching History in Twentieth Century Nigeria: The Challenges of Change” in *History in Africa: A Journal of Method*, vol. 33 (2006).

David Otieno Akombo, Ph.D., teaches music education and world music at Wabash College of Indiana. He is the author of *Music and Healing across Cultures* (2006).

Francis Allard, Ph.D., teaches in the Department of Anthropology at Indiana University of Pennsylvania. His research interests include the archaeology of early China and Mongolia. He has contributed articles to *Archaeology of Asia* (2005) and *Beyond the Steppe and the Sown: Proceedings of the 2002 University of Chicago Conference on Eurasian Archaeology* (2006).

Miguel Arisa is finishing his doctoral studies in art history at the Graduate Center, City University of New York. He teaches at Technical Career Institutes and is a regular lecturer at the

Cloisters and a docent at the Metropolitan Museum of Art, New York.

Mariam F. Ayad, Ph.D., teaches graduate-level classes on Egyptian language and literature at the University of Memphis, where she is the assistant director of its Institute of Egyptian Art and Archaeology. Her main research interests focus on the role of women in ancient Egyptian temple ritual and the selection and transmission of funerary texts in post-New Kingdom Egypt. Her book on the God's Wife of Amun is under contract with Routledge.

Heather D. Baker, D.Phil., is a researcher at the University of Vienna, Austria, specializing in Babylonian history, society, and culture. She has published widely on Babylonian and Assyrian history and is writing a book to be titled *The Urban Landscape of First Millennium BC Babylonia*.

Robin Barrow, Ph.D., FRSC, is professor of philosophy of education at Simon Fraser University, Canada. His most recent books include *Plato* (2007) and *An Introduction to Moral Philosophy and Moral Education* (2007). He is the author of *Athenian Democracy* (2001) and *Greek and Roman Education* (1996).

László Bartosiewicz, Ph.D., D.sc., teaches archaeozoology at the Loránd Eötvös University in Budapest (Hungary) and the University of Edinburgh (United Kingdom). He is the author of *Animals in the Urban Landscape in the Wake of the Middle Ages* (1995) and principal author of *Draught Cattle: Their Osteological Identification and History* (1997) and has published more than 200 scholarly articles.

Kirk H. Beetz, Ph.D., emeritus, has published over two dozen books and more than 900 articles. His books span topics from endangered mammal species to children's literature, including *Exploring C. S. Lewis' "The Chronicles of Narnia"* (2000). His recent writings have focused on the history and culture of ancient Japan.

Craig G. R. Benjamin, Ph.D., teaches world and ancient Eurasian history at Grand Valley State University. He is the coeditor of vols. 2 (1998), 4 (2000), and 6 (2002) in the Brepols Silk Roads Studies series and the author of *The Yuezhi: Origin, Migration and the Conquest of Northern Bactria* (2007).

Uffe Bergeton, Ph.D., is in the Ph.D. program in the Department of Asian Languages and Cultures at the University of Michigan. He is the author of *The Independence of Binding and Intensification* (Ph.D. dissertation, University of Southern California) and various articles on theoretical phonology and syntax.

Amy Hackney Blackwell has degrees in history from Duke University and Vanderbilt University and a J.D. from the Uni-

versity of Virginia. Her books include *Mythology for Dummies* (2002), *LSAT for Dummies* (2004), *The Everything Irish History and Heritage Book* (2004), and *Essential Dictionary of Law* (2004). She has contributed to the *Encyclopedia of World Nations and Cultures* (2006), *Alternative Energy* (2006), and *Chemical Compounds* (2006).

Christopher Blackwell, Ph.D., teaches classics at Furman University. He is the author of *In the Absence of Alexander: Harpalus and the Failure of Macedonian Hegemony* (1999) and various protocols and software applications for building digital libraries, and he serves as technical editor for the Center for Hellenic Studies of Harvard University.

Amy Bogaard, Ph.D., teaches prehistory and archaeobotany at the Department of Archaeology, University of Nottingham, United Kingdom. She is the author of *Neolithic Farming in Central Europe* (2004).

Peter Bogucki, Ph.D., is an archaeologist who is associate dean for undergraduate affairs of the School of Engineering and Applied Science at Princeton University. He has studied prehistoric settlements in Poland and has a particular interest in the spread of farming in Europe. He is the author of *The Origins of Human Society* (1999) and the editor (with Pam J. Crabtree) of *Ancient Europe 8000 B.C.–A.D. 1000: An Encyclopedia of the Barbarian World* (2004).

Larissa Bonfante, Ph.D., professor of classics at New York University, is the author of several books on Etruscan and early Roman culture as well as publications on ancient dress and nudity, including *The World of Roman Costume*, co-edited with Judith Sebesta (1994).

Charlotte Booth is a Ph.D. student at the University of Wales, Swansea, and teaches Egyptology for Birkbeck College and other institutions in the United Kingdom. She is the author of *People of Ancient Egypt* (2007), *The Hyksos Period in Egypt* (2005), and *The Role of Foreigners in Ancient Egypt* (2005).

Lisa R. Brody, Ph.D., teaches Greek and Roman art history at Queens College, City University of New York. Her research interests include Greek iconography and cult, ancient lamps and their decoration, children in antiquity, and representation of ethnicity in Greco-Roman art. She compiled the revised edition of David Sacks's *Encyclopedia of the Ancient Greek World* (2005) and is author of *Aphrodisias III: The Aphrodite of Aphrodisias* (2007).

David Brown, Ph.D., is researching the interactions of the pre-Islamic astral sciences of Mesopotamia, Greece, India, Egypt, Iran, the western Semitic world, and China at the Free University of Berlin. He is the author of *Mesopotamian Planetary Astronomy-Astrology* (2000) and *The Interactions of Ancient Astral Science* (forthcoming).

Deborah N. Carlson, Ph.D., teaches in the Nautical Archaeology Program of the Department of Anthropology at Texas A&M University. She also directs the Institute of Nautical Archaeology's shipwreck excavation of a Roman marble carrier off the Aegean coast of Turkey at Kizilburun and is preparing the final publication of the Classical Greek ship excavated by the Institute of Nautical Archaeology at nearby Tektas Burnu.

Jeffrey S. Carnes is associate professor of classics at Syracuse University. He is the author of *The Uses of Aiakos: Pindar and the Aiginetan Imaginary* (forthcoming) as well as articles on Greek lyric poetry, gender studies, literary theory, and Plato.

Julia Marta Clapp is pursuing her doctorate in art history at the Graduate Center, City University of New York. Her research interests include modern and pre-Columbian Latin American art.

Wendy E. Closterman, Ph.D., teaches ancient history and Greek at Bryn Athyn College. Her research focuses on Athenian burial and funerary ritual. She is the author of "Family Members and Citizens: Athenian Identity and the Peribolos Tomb Setting" in *Antigone's Answer: Essays on Death and Burial, Family and State in Classical Athens*, edited by C. Patterson (forthcoming).

Leah A. J. Cohen is an independent writer and editorial consultant with a master's degree in geography from the University of Florida. She specializes in Africa area studies and food security. She was a senior author for the *Encyclopedia of African History and Culture*, volumes 4 and 5 (2005).

John Collis is professor emeritus in the Department of Archaeology, University of Sheffield, where he taught for over 30 years. He has had a major role in the development of university and professional training in archaeology in Britain, and is secretary of the European Association of Archaeologists' Committee on Training and Education. He is author of several books and excavation monographs, including *Digging Up the Past* (2004) and *The Celts: Origins, Myths and Inventions* (2004).

Constance A. Cook, Ph.D., directs the Asian Studies program and teaches Chinese language and literature courses at Lehigh University. She is the author of *Death in Ancient China: The Tale of One Man's Journey* (2006) and coeditor of *Defining Chu: Image and Reality in Ancient China* (1999).

Susan Cooksey, Ph.D., is the curator of African art, Harn Museum of Art, University of Florida.

Justin Corfield, Ph.D., teaches history and international relations at Geelong Grammar School, Australia. He is the co-author of *Historical Dictionary of Cambodia* (2003) and

has written extensively on Asia, Australia, and European colonial history.

James A. Corrick, Ph.D., is a full-time editor and writer with 25 books to his credit. His most recent titles are *The Early Middle Ages* (2006), *The Byzantine Empire* (2006), and *The Renaissance* (2007).

Arden Decker is a Ph.D. candidate in the history of art at the Graduate Center, City University of New York. Her research interests include Mesoamerican art as well as modern and contemporary art of Mexico.

Leo Depuydt, Ph.D., teaches Egyptology at Brown University and is curious about everything relating to ancient Egypt in its Near Eastern and Mediterranean context, especially the area's languages and history. He wrote *Civil Calendar and Lunar Calendar in Ancient Egypt* (1997) and *The Other Mathematics: Language and Logic in Egyptian and in General* (2007).

Haig Der-Houssikian, Ph.D., is professor emeritus (2003), linguistics, at the University of Florida, Gainesville. His research and publication interests are in morphology, Creolization, and sub-Saharan Africa.

Christine End, M.A., works on the Giza Archives Project at the Museum of Fine Arts, Boston. Her main interests of research are Middle Kingdom funerary iconography, material culture, burial practices, and mummification. As a researcher and illustrator, her work has appeared in Egyptological publications and documentaries.

Linda Evans, Ph.D., specializes in ancient Egyptian art at Macquarie University, Sydney, Australia. She recently completed her doctoral dissertation on the representation of animal behavior in Egyptian tomb paintings and has published several papers on the role and depiction of animals in the ancient world. She has also contributed chapters to *Egyptian Art: Principles and Themes in Wall Scenes* (2000), *The Encyclopedia of Animal Behavior* (2004), *Egypt: The Land and Lives of the Pharaohs Revealed* (2005), and *Historica* (2006).

Stephen M. Fabian, Ph.D., is an anthropologist and currently teaches seminars on religion, myth, and ritual at Princeton University. He is the author of *Space-Time of the Bororo of Brazil* (1992), *Clearing Away Clouds: Nine Lessons for Life from the Martial Arts* (1999), and *Patterns in the Sky: An Introduction to Ethnoastronomy* (2001).

Erin Fairburn is a graduate student in the Department of Egyptology and Western Asian Studies at Brown University. She has contributed to *The City and Urban Life* (forthcoming).

Alessia Frassani is a Ph.D. candidate at the Graduate Center of the City University of New York. Her research interests in-

clude the art and civilizations of ancient Oaxaca and issues surrounding the cultural interaction between the Old and New Worlds.

Markham J. Geller is professor of Semitic languages at University College London, in the Department of Hebrew and Jewish Studies. He has recently published a text edition of cuneiform medical texts, *Renal and Rectal Disease Texts, Babylonisch-assyrische Medizin VII* (2005).

J. J. George is working on his Ph.D. at the Graduate Center, City University of New York. His research area is pre-Columbian art and architecture.

Wolfram Grajetzki, Ph.D., wrote his dissertation at the Humboldt University of Berlin and has taught Egyptology there. He has excavated in Egypt and Pakistan and was principal archaeologist and author for the online learning project Digital Egypt for Universities (University College London). He is preparing the catalogue of Egyptian coffins in the Fitzwilliam Museum, Cambridge. His publications include *Burial Customs in Ancient Egypt* (2003) and *The Middle Kingdom in Ancient Egypt* (2006).

Lyn Green, Ph.D., has taught at several Canadian universities and for the Royal Ontario Museum. She has contributed to several encyclopedias, including *The Oxford Encyclopedia of Ancient Egypt* (2000) and the *Encyclopedia of the Archaeology of Ancient Egypt* (1999) as well as *The Royal Women of Amarna* (1996). Currently she is devoting her time to her duties as president of the Society for the Study of Egyptian Antiquities, which has over 400 members and subscribers internationally, and to writing.

Angela Herren, Ph.D., teaches pre-Columbian art and architecture as an assistant professor in the Department of Art and Latin American Studies at the University of North Carolina at Charlotte. A specialist on painted manuscripts from central Mexico, she completed a 2005 dissertation entitled "Portraying the Mexica Past: A Comparative Study of Accounts of Origin in Codex Azcatitlan, Codex Boturni, and Codex Aubin."

David B. Hollander, Ph.D., teaches ancient history at Iowa State University. He is the author of *Money in the Late Roman Republic* (2007).

Brooke Holmes, Ph.D., is an assistant professor of classics at the University of North Carolina, Chapel Hill. She is at work on a book about the symptom in early Greek medicine and classical Greek literature.

Michael Allen Holmes is a freelance editor and writer who recently contributed to *Shakespeare for Students*, 2nd edition (2007). He has also written an unpublished novel.

John W. Humphrey, Ph.D., is professor of Greek and Roman studies at the University of Calgary. A veteran of many seasons of archaeological excavation in Turkey and Greece, he is the author of *Greek and Roman Technology: A Sourcebook* (1998, with J. P. Oleson and A. N. Sherwood) and *Ancient Technology* (2006).

Keith Jordan, M.Phil., is a Ph.D. candidate in pre-Columbian art history at the Graduate Center of the City University of New York. He is currently finishing his doctoral dissertation, entitled "Stone Trees Transplanted? Central Mexican Stelae of the Epiclassic and Early Postclassic and the Question of Maya 'Influence.'"

Amr Kamel is an Egyptologist in the Rare Books and Special Collections Library at the American University in Cairo, Egypt.

David Kelly is an instructor of English writing and literature at Oakton Community College in Illinois. He has written over 100 published literary analyses and wrote the instructor's manual for the *Exploring Poetry* computer program. His short fiction has been published in *The Rockford Review*, *Grub Street*, and *The Iconoclast*, among other places.

Panagiotis I. M. Kousoulis, Ph.D., is a lecturer in Egyptology at the Department of Mediterranean Studies of the University of the Aegean. He is the author of *Moving across Borders: Foreign Relations, Religion and Cultural Interactions in the Ancient Mediterranean* (2007) and *Ancient Egyptian Demonology: Studies on the Boundaries between the Demonic and the Divine in Egyptian Magic* (2007).

Philippa Lang teaches ancient science and related subjects, with research interests in ancient medicine and philosophy, in the Classics Department of Emory University, Atlanta. She is the editor of *Re-Inventions: Essays on Hellenistic and Early Roman Science*, *Apeiron* special issue vol. 37 (2004).

Russell M. Lawson, Ph.D., is associate professor of history and chair of the Division of General Studies at Bacone College in Oklahoma. He is the author of *Science in the Ancient World* (2004), *The Land between the Rivers: Thomas Nuttall's Ascent of the Arkansas, 1819* (2004), and *Passaconaway's Realm: John Evans and the Exploration of Mount Washington* (2002, 2004).

Anne Mahoney, Ph.D., teaches Greek and Latin linguistics and literature at Tufts University. She is the author of *Plautus: Amphitryo* (2004) and *Roman Sports and Spectacles: A Sourcebook* (2001). She is also the editor of revised editions of *Allen and Greenough's New Latin Grammar* (2001), *Morice's Stories in Attic Greek* (2005), and *Bennett's Essentials* (2007).

Susan Malin-Boyce, Ph.D., serves as deputy director of the Regime Crimes Liaison Office, Mass Graves Investigation

Team, in Baghdad, Iraq. She has contributed to *Ancient Europe 8000 B.C.–A.D. 1000: Encyclopedia of the Barbarian World* (2004) and to publications addressing Early and Late La Tène settlement in Bavaria, Germany.

Renee McGarry is a student in the Ph.D. program in art history at the City University of New York Graduate Center. Her research interests include Aztec sculpture of the natural world and religious manuscripts from the post-Conquest period.

Paul McKechnie, D.Phil., is a senior lecturer in classics and ancient history at the University of Auckland, New Zealand. He is the author of *First Christian Centuries: Perspectives on the Early Church* (2002) and *Outsiders in the Greek Cities in the Fourth Century B.C.* (1989).

John M. McMahon, Ph.D., teaches at Le Moyne College in Syracuse, New York, where he directs the classics program. He is author of *Cave Paralysis: Impotence, Perception and Text in the Satyricon of Petronius* (1998) and numerous articles on the intersection of ancient literature and natural history. His most recent work includes nine entries in the forthcoming *Biographical Encyclopedia of Astronomers* (2006).

Jianjun Mei, Ph.D., teaches the history of science and technology at the University of Science and Technology Beijing. He is the author of *Copper and Bronze Metallurgy in Late Prehistoric Xinjiang: Its Cultural Context and Relationship with Neighbouring Regions* (2000).

James E. Meier, Ph.D., is assistant professor in the Department of Humanities and Social Sciences at Central Florida Community College. He is a contributor to the *Encyclopedia of African History and Culture* (2005).

Francesco Menotti, Ph.D., is a lecturer in European prehistory at the Institute of Prehistory and Archaeological Science, Basel University, Switzerland. He is the author of *Living on the Lake in Prehistoric Europe* (2004).

Melissa Moore Morison is associate professor of classics and classical archaeology at Grand Valley State University. She has extensive experience in archaeological fieldwork in Greece, Turkey, and the United States. Her research interests include Roman provincial archaeology, Greek and Roman pottery, and ceramic technology.

Penny Morrill, Ph.D., teaches pre-Columbian and early colonial Mesoamerican art at Hood College, Frederick, Maryland. She has an essay, "The Queen of Heaven Reigns in New Spain: The Triumph of Eternity in the Casa del Deán Murals," in a Brill anthology, *Woman and Art in Early Modern Latin America* (2006). She has authored several books on modern Mexican silver: *Mexican Silver: 20th Century Hand-*

wrought Silver Jewelry and Metalwork (4th ed., 2007), *Silver Masters of Mexico: Héctor Aguilar and the Taller Borda* (1996), and *Maestros de Plata: William Spratling and the Mexican Silver Renaissance*, a catalog for a traveling exhibit (2002–2004).

Julian M. Murchison, Ph.D., teaches in the Department of Sociology and Anthropology at Millsaps College. His work in cultural anthropology examines the intersections of medicine and religion in East Africa. He recently published a chapter examining stories about a cure for HIV/AIDS in *Borders and Healers* (2005).

Caryn E. Neumann, Ph.D., teaches history in Ohio Wesleyan University's Black World Studies Department. She is a former managing editor of the *Journal of Women's History*.

Emily Jane O'Dell, is a Ph.D. candidate at Brown University and has taught at Brown University in both the Department of Egyptology and Ancient Western Asian Studies and the Department of Literary Arts. She has been the chief epigrapher of the Cairo-Brown University Abu Bakr Epigraphic Survey in the western cemetery of the Great Pyramids in Giza, Egypt, for the past five years.

Simon O'Dwyer is founder and researcher for Prehistoric Music Ireland, author of *Prehistoric Music of Ireland* and prehistoricmusic.com, and contributor to *The Encyclopedia of Music in Ireland* and *The Encyclopedia of Ireland*. He has published four papers for the International Study Group on Music Archaeology.

Penelope Ojeda de Huala is a Ph.D. candidate in art history at the Graduate Center of the City University of New York, where she studies pre-Columbian to contemporary art of Latin America. Her research focus is Guatemala and Peru, particularly the enduring thoughts and practices of indigenous cultures as manifested in art.

Michael J. O'Neal, Ph.D., is a writer who lives in Moscow, Idaho. He is a frequent contributor to reference and educational books, including *Lives and Works: Young Adult Authors* (1999), *The Crusades* (2005), and *America in the 1920s* (2006).

Dianne White Oyler, Ph.D., teaches African history at Fayetteville State University. She is the author of *The History of the N'ko Alphabet and Its Role in Mande Transnational Identity: Words as Weapons* (2005) as well as articles in the refereed journals *Research in African Literature*, *the Mande Studies Journal*, and the *International Journal of African Historical Studies*.

Katie Parla is an art historian and archaeological speleologist working in Rome and Naples as a docent leading didactic seminars of archaeological sites. She consults for the History

Channel and will appear in their 2007 series *Cities of the Underworld* as an expert on underground Rome and Naples.

Marie Passanante is a doctoral candidate in the Department of Egyptology and Ancient Western Asian Studies at Brown University.

William H. Peck teaches at the College for Creative Studies, Detroit, and the University of Michigan, Dearborn. He was for many years the curator of ancient art at the Detroit Institute of Arts and is at present a member of the Brooklyn Museum excavations in Egypt at Karnak. He is the author of *Drawings from Ancient Egypt* (1987) and numerous contributions to reference books and encyclopedias on the ancient world.

David Petechuk is a freelance writer specializing in educational texts focusing on the sciences, literature, and history. The former director of publications for the health sciences at the University of Pittsburgh, he is the author of *The Respiratory System* (2004), *LSD* (2005), and *Health & Medical Issues Today: Organ Transplantation* (2006).

Mark Anthony Phelps is taking a leave after teaching continuously since 1994 (primarily at Drury University, in five different departments) to finish his dissertation at the University of Arkansas entitled “Sewage from the Orontes: Roman Elite Attitudes toward Ecstatic Religion in the 3rd and 4th centuries C.E.” This degree in ancient Mediterranean history augments his graduate degrees from Harvard and Johns Hopkins in Hebrew Bible and ancient Near Eastern languages and cultures. His research interests reflected in his writings are widely eclectic, spanning Paleolithic to contemporary society and including the disciplines of archaeology, linguistics, cultural anthropology, physical geography, historical geography, classical history, ancient Near Eastern history, medieval history, modern history, religion, and biblical history.

Jen Piro is a Ph.D. candidate in anthropological archaeology at New York University. Her dissertation research focuses on the development of pastoral economies in Early Bronze Age Transcaucasia.

Karen Radner, Ph.D., is lecturer in ancient Near Eastern history at University College, London. She specializes in the Assyrian Empire and is the author of *Die neuassyrischen Texte aus Tall Seh Hamad* (2002), *Das mittelassyrische Tontafelarchiv von Giricano/Dunnu-sa-Uzibi* (2004) and *Die Macht des Namens: Altorientalische Strategien zur Selbsterhaltung* (2005).

Judith A. Rasson, Ph.D., teaches in the Department of Medieval Studies, Central European University, Budapest (a post-graduate American-accredited university). Her research interests lie in southeastern Europe (especially the countries

of the former Yugoslavia) and focus on Neolithic and historic archaeology and ethnographic material culture.

Kelly-Anne Diamond Reed, Ph.D., teaches ancient Egyptian history and archaeology at Villanova University’s Department of History. She is investigating early Egyptian funerary rituals and burial customs.

Duane W. Roller is professor of Greek and Latin at Ohio State University. Trained as an archaeologist, he has over 30 years’ experience in field archaeology in numerous Mediterranean countries. He is the author of *The Building Program of Herod the Great* (1998), *The World of Juba II and Kleopatra Selene* (2003), and *Through the Pillars of Herakles* (2006) as well as many other publications in history, classics, and archaeology.

Kelley L. Ross, Ph.D., teaches philosophy at Los Angeles Valley College. He specializes in Kantian epistemology, metaphysics, and ethics, with emphasis on members of the Friesian tradition—Jakob Fries, Leonard Nelson, Rudolf Otto, Sir Karl Popper, and others. Since 1996 he has been the publisher and editor of the online philosophy journal *Proceedings of the Friesian School, Fourth Series*.

Edward M. W. A. Rowlands, M.Phil., has research interests in Mycenaean political geography, trade, and religion.

Lucas G. Rubin, Ph.D., develops master of science programs for Columbia University. He was previously administrator of the university’s Center for Archaeology, where he managed multiple excavations and projects. His research and scholarship have focused on fires and firefighters in ancient Rome.

Michael M. Sage, Ph.D., teaches classics and ancient history in the Classics Department at the University of Cincinnati. His main areas of study are historiography and military history. He is the author of *Cyprian: A Biography* (1975) and *Warfare in Ancient Greece: A Sourcebook* (1996).

Rick Schulting, Ph.D., is a lecturer in scientific and prehistoric archaeology at the University of Oxford. His current research interests lie in understanding the Mesolithic-Neolithic transition in western Europe, emphasizing the use of radiometric dating and stable isotope analysis, and in skeletal evidence for interpersonal violence in earlier prehistoric Europe.

David R. Sear, a fellow of the Royal Numismatic Society in London and the American Numismatic Society in New York, has authored an extensive range of numismatic books over the past four decades, aimed at collectors and students of ancient Greek, Roman and Byzantine coinage. He has been a resident of Los Angeles for the past 25 years and operates a research service authenticating ancient coinage. His

numerous publications include *Roman Coins and Their Values* (1964; rev. ed., 2000–2005), *Byzantine Coins and Their Values* (1974, rev. ed., 1987), *Greek Coins and Their Values* (1978–1979), and *The History and Coinage of the Roman Emperors, 49–27 B.C.* (1998).

Robert Shanafelt, Ph.D., teaches courses in anthropology, religion, and Africana studies at Georgia Southern University. He has published a number of articles on different aspects of life in southern Africa, among them, “Crime, Power, and Policing in South Africa” in *Democratic Policing in Transitional and Developing Countries* (2006).

Alison Sheridan, Ph.D., is head of early prehistory in the National Museums Scotland, Edinburgh, specializing in the British and Irish Neolithic and Bronze Age. Exhibition work includes *Heaven and Hell—and Other Worlds of the Dead* (2000), for which she was lead curator and book editor. Other books include *From Sickles to Circles* (with A. M. Gibson, 2004) and *Vessels for the Ancestors* (with N. M. Sharples, 1992).

Spyros Siropoulos is senior lecturer of Greek philology and history at the Department of Mediterranean Studies, University of the Aegean, Greece. He has published various articles in three books: *Unlike a Woman: Gender and the Social Function of the Athenian Tragedy* (2003), *The Goat’s Skin: The Other Side of Alexander the Great’s Power* (2003; in Greek with English summary), and *The Things after Alexander: The Centrifugal Potencies of the Hellenistic Kingdoms* (2005, in Greek).

Bradley Skeen, M.A., has taught at the University of Minnesota, Webster University, and Washington University. He is a specialist in magic, religion, and philosophy in late antiquity and has contributed to research in that field in *Die Zeitschrift für Papyrologie und Epigraphik*, among other journals.

Christopher Smith, D.Phil., is professor of ancient history at the University of Saint Andrews in Scotland. He is the author of *Early Rome and Latium: Economy and Society c 100–500 B.C.* (1996) and *The Roman Clan: From Ancient Ideology to Modern Anthropology* (2006) as well as editor of several collections of essays, including *Trade, Traders and the Ancient City* (with Helen Parkins, 1998); *Sicily from Aeneas to Augustus* (with John Serrati, 2000), and *Religion in Archaic and Republican Rome and Italy: Evidence and Experience* (with Edward Bispham, 2000). He is engaged in work on Roman historiography and oratory.

Nancy Shatzman Steinhardt is professor of East Asian art and curator of Chinese art at the University of Pennsylvania. She is author of *Chinese Traditional Architecture* (1984), *Chinese Imperial City Planning* (1990), *Liao Architecture* (1997), and *Chinese Architecture* (2002) and more than 60 scholarly articles.

Tom Streissguth is a freelance author, editor, and journalist who has published more than 70 nonfiction and reference books. His most recent titles include *Clay v. United States*, *Genghis Khan’s Mongol Empire*, *Library in a Book: Hate Crimes*, *Eyewitness History: The Roaring Twenties*, and the *Greenhaven Encyclopedia of the Middle Ages*.

Ananda Cohen Suarez is a Ph.D. student at the Graduate Center of the City University of New York, specializing in pre-Columbian and colonial Latin American art history. She is particularly interested in cross-cultural encounters, vernacular religious art, and manuscript production in the early colonial Americas.

Frank J. Swetz, D.Ed., is professor emeritus of mathematics and education, Pennsylvania State University. His research interests focus on cultural and societal impact on mathematics learning and teaching. Among his recent books are *Legacy of the Luoshu: The 4000 Year Search for the Meaning of the Magic Square of Order Three* (2002) and *Teaching Mathematics to Children* (2003).

John Thorburn, Ph.D., is associate professor of classics at Baylor University, where he teaches a variety of subjects dealing with the classical world. He has published on Greek tragedy, Greek comedy, Greek and Roman history, and a variety of ancient subjects. He is the author of *The Alcestis of Euripides* (2002) and the *Facts on File Companion to Classical Drama* (2005).

Alain Touwaide, Ph.D., is a historian of sciences in the Department of Botany of the National Museum of Natural History at the Smithsonian Institution (Washington, D.C.). He has extensively published on the history of medicine in the Mediterranean world from antiquity to the Renaissance. Recently, he coedited the volume *Visualizing Medieval Medicine and Natural History, 1200–1550* (2006).

Francesca C. Tronchin, Ph.D., teaches Greek and Roman art and archaeology at Ohio State University. Her primary area of research is Roman domestic decor and issues of eclecticism in ancient sculptural displays.

David K. Underwood, Ph.D., teaches Western humanities, art history, philosophy, and Latin American studies at the University of South Florida in Tampa and at Saint Petersburg College in Clearwater, Florida. He is the author of two books and several articles and essays on Iberian and Latin American art and architecture.

David Vallilee is an independent scholar.

Frans van Koppen, M.A., teaches Akkadian at the School of Oriental and African Studies, London. He contributed to *The*

Ancient Near East: Historical Sources in Translation (2006) and *The Babylonian World* (forthcoming).

Lawrence Waldron, M.F.A., is an associate professor and doctoral candidate at the City University of New York, specializing in non-Western fields of art history and culture. He has presented and published various articles on the art and culture of the pre-Columbian Caribbean and Southeast Asia.

Ezekiel A. Walker, Ph.D., teaches African and world history at the University of Central Florida. His forthcoming book is entitled *Growth, Crisis and Transformation in the Cocoa-Farming Economy of Southwestern Nigeria* (2007).

Peter S. Wells is professor of anthropology at the University of Minnesota. His publications include *The Barbarians Speak: How the Conquered Peoples Shaped Roman Europe* (1999), *Beyond Celts, Germans and Scythians: Archaeology and Identity in Iron Age Europe* (2001), and *The Battle That Stopped Rome: Emperor Augustus, Arminius, and the Slaughter of the Legions in the Teutoburg Forest* (2003).

Jacqui Wood is an archaeologist and authority on prehistoric cooking and the lifestyles of prehistoric Europeans. She runs her own excavation in Cornwall, England.

Ronald Young, Ph.D., teaches in the Social Sciences Department at Canterbury School in Fort Myers, Florida. His teaching and research interests are in the area of Latin American Studies. In addition to numerous reference articles, he is presently working on a general history of Colombia to be published by Greenwood Press.

Katharina Zinn, M.A., is writing her Ph.D. dissertation on ancient Egyptian libraries and archives at the University of Leipzig, Germany. She works in a project on scarabs in the Fitzwilliam Museum, Cambridge (United Kingdom) and a project on Middle Kingdom Reliefs from Lisht in the Princeton University Art Museum. She has published articles on the organization of collective wisdom as well as multilingualism in ancient Egypt.

List of Illustrations

VOLUME I

Glass kohl tube in the form of a palm column, from Egypt	5	Marble statue of the Greek goddess of fertility, Demeter	37
Gold lion, used as a fabric ornament and found at Persepolis, Persia (modern-day Iran)	7	Section of the facade of a Roman aisled, barnlike building on a villa estate in the parish of Meonstoke, Hampshire, England	44
Jade ornament of four discs carved from a single jade pebble, from China	8	Facade of the Great Temple of Abu Simbel, Egypt	59
Toiletry implements from Roman Britain	10	The ruins of Persepolis (in modern-day Iran), the seat of the Achaemenian Empire of Darius I	63
Greek marble head, showing headdress of snail-shell curls	11	Panoramic view of West Lake in Lin'an (modern Hangzhou), China	66
Gold coin of the Roman emperor Marcus Aurelius, set in a gold ring	12	The theater at Epidaurus, Greece	76
Jade pectoral of the Olmec culture (Mexico), showing large holes in the earlobes, where earplugs would be placed	13	Engraving of the Roman Colosseum by Antoine Lafréry	80
View of rice fields in the Malagasy Republic of southern Africa	17	Petroglyph of animals and people at Tassili, Algeria, in North Africa	90
Wooden model of a man plowing with oxen, from Egypt	21	Banquet scene, fragment of wall painting from the tomb of Nebamun, Thebes, Egypt	95
Cuneiform tablet recording barley rations given to workers and their families at the temple of the goddess Bau, from Tello (ancient Girsu), southern Iraq	25	Human-headed winged bull from the palace of King Sargon II at the Assyrian capital Dur-Sharrukin (modern-day Khorsabad, Iraq)	99
Ritual spear blade from Japan	31	Schist head of the fasting Buddha, from Rawalpindi District, Gandhara, Pakistan	101
Iron Age farming tools, from Stantonbury Hill, Somerset, England	35		

Bird bone engraved with animal heads from the cave of Courbet, Penne-Tarn, France	106	Terra-cotta statuette of a lady in a swing, from Agia Triada, Herakleion	182
Hermes with the Infant Dionysus, by the Greek sculptor Praxiteles	111	Amphora from Pompeii, Italy	184
Roman terra-cotta relief showing an Egyptian scene set on the Nile	117	Feline-head ceramic bottle from Peru	185
Inner coffin of the priest Hornedjitef, Thebes, Egypt	125	Boys kept in seclusion in an initiation camp in Angola, southern Africa	188
Cuneiform tablet with observations of Venus, Nineveh, northern Iraq	126	Game of Senet from Egypt	190
Chinese covered jar	128	Terra-cotta figurine of a woman with a child, Cyprus	191
The Semna dispatches, administrative documents from an Egyptian outpost, from Thebes, Egypt	141	Profile of a Greek boy	195
Babylonian boundary marker, Sippar, southern Iraq	143	Roman rag doll made of linen, rags, and papyrus	196
Dedication by Alexander the Great to Athena Polias, from Priene, Asia Minor	146	Olmec figure of a baby (ceramic, cinnabar, and red ochre), Mexico	197
Wattle framework being filled with red mud, a construction technique used in ancient times, from Zambia	151	Ancient Egyptian city of Sesebi	206
Clay foundation peg from Bad-tibira, southern Iraq	154	Panels with striding lions, Neo-Babylonian, during the reign of Nebuchadnezzar II	211
Dolphin fresco in the queen's megaron (reception hall) at Knossos, the capital of Minoan Crete	159	Jade ritual reaping knife, from Henan, northern China	215
Iron window grill, Roman Britain	160	Roman silver coins depicting the founding twins of the city of Rome, Romulus and Remus	227
View of the royal tombs at Meroë, ancient city of northeastern Africa in present-day Sudan	164	Pottery vessel of the storm god, Teotihuacán, Mexico	232
Fragment of a basalt water clock, from Tell el-Yahudiya, Egypt	166	Grass, sand, and volcanic formation in the Sahara, southern Algeria	236
Kerma ware pottery beaker, from Kerma, Sudan	175	The Great Temple at Abu Simbel on the banks of the Nile	243
Painted pottery group of cattle, from el-Amra, Egypt	177	Ax made from reindeer antler found at Earls Barton, Northamptonshire, England	254
Ceramic bowl with abstract decoration, from Tall-i-Bakun in modern-day Iran	178	Petroglyph of a human figure wearing a loincloth, from the Sahara Desert at Tassili, Algeria, North Africa	273
Pottery jar with dragon handles, from China	180	Pair of child's leather sandals from Thebes, Egypt	275
Buccero ware water jug, from Chiusi, Tuscany, Italy	181	Two Assyrian court officials from the reign of Sargon II	276
		Caryatids from the Porch of the Maidens at Erechtheion, a temple on the north side of the Acropolis at Athens	280

Pottery figures of a drummer and a woman and child, Tala-Tonalá style, Jalisco, Mexico	283	Roman gold bars with assayers' stamps	368
Group of bronze tools for woodworking from Thebes, Egypt	287	Granite statue of Senmut holding Princess Neferure, the temple of Amun, Karnak, Thebes, Egypt	378
Stone bowl from Khafajeh, Iraq	288	Cuneiform tablet with schoolwork, probably from southern Iraq	379
Bird head made of stone, Papua, New Guinea	290	Yue ware water dropper in the shape of a frog drinking from a cup, from Zhejiang, southern China	381
Steatite vase from Greece	293	Fragments of painted plaster, Roman Britain, from Otford, Kent, England	385
Papyrus with part of the "Tale of the Eloquent Peasant" from Egypt	298	Colossi of Egyptian pharaoh Ramses II and his wife at entrance to Karnak Temple	395
Drawing by Michelangelo of the Crucifixion of Christ and two thieves	304	Portion of a relief in the tomb of Darius I, king of Persia, showing his throne bearers	400
VOLUME II			
Pyramid of a king, thought to be Adikhalamani Tabirqa, in Meroë, Sudan	312	Cowrie shells, the earliest form of money in China	429
A reconstructed Egyptian grave pit	314	Roman marble relief of Jason, the physician and patient	433
Jade eye plaques from China	316	Stucco head of a monk, said to be from Hadda, Gandhara	440
Iron Age pottery cinerary urn shaped like a hut, from Italy	318	<i>The Dream of Scipio</i> , by Raphael	444
Stele of Aristion, a philosopher of Athens	319	Papyrus marriage contract between the priest Pagosh and Teteimhotep, from Assiut, Egypt	449
Gold diadem, found in the Camaná valley, Peru	321	Scarab stamp seal and impressions, in lapis lazuli, depicting Ishtar, the Assyrian and Babylonian goddess of love, fertility, marriage, and childbirth	451
Bronze figure of Isis and Horus, from North Saqqara, Egypt	329	Fragment of an archaic Greek stele, with the heads of a mother and child	455
Babylonian lapis lazuli cylinder seal of Sin-ishmeanni	331	Ethiopian Orthodox priests at festival of Timkat	463
A 19th-century Indian painting depicting the climax of the epic the Ramayana	332	Roman hand of Sabazius, found at Tournai, Belgium	469
The figure of Silenus, the mentor of Dionysus, Greek god of plays	334	Pottery dog, from Colima, Mexico	471
Marble relief with two Roman theater masks	337	Fineware cup decorated with frogs and lotus flowers painted in black, from Faras, Sudan	473
The Great Harris Papyrus, from Thebes, probably Deir el-Medina, Egypt	347		
Mesopotamian stone vase depicting animals of the first city dwellers of Mesopotamia	351		
Indian bronze cast coin	355		
Mesolithic perforated part skull and antlers of red deer, from Star Carr, Vale of Pickering, North Yorkshire, England	359		

“Empress” pepper pot, from the Hoxne hoard in Suffolk, Roman Britain	478	Stone weight carved in the form of the head of an aquatic bird and thought to have been used in fishing, from Orange County, Florida	582
Terra-cotta utensil with six receptacles, thought to be an egg dish or cup holder	480	A bronze lamp found at the palace of Persepolis, Persia	586
Detail of an Ethiopian tribute bearer, from a relief in stairway of the palace at Persepolis, Persia (modern-day Iran)	486	Broken limestone lamp from the cave of Courbet, Penne-Tarn, France	589
Greek terra-cotta statuettes: woman holding pancake and woman kneading dough	500	Roman lamp showing a chariot race	591
Spout and bridge vessel in the shape of a woman, holding what is thought to be a spindle wrapped in cloth, from the Nasca culture of Peru	503	Paleolithic stone hand ax from Olduvai Gorge, Tanzania	593
Olmec jade perforator, from Mexico	536	Papyrus from the Book of the Dead of Nakht with agricultural scenes, from Thebes, Egypt	595
Coffin with skeleton of a child, from Speos Artemidos, Egypt	547	An administrative text in cuneiform (the world’s earliest form of writing), recording food supplies, probably from southern Iraq	597
Terra-cotta votive womb, Italy	551	Pair of fragments of silk, from Cave 17, Mogao, near Dunhuang, China	599
Hellenistic ivory figure of a hunchback thought to show signs of Pott’s disease	553	Roman aqueduct in Tunis	602
Altar from Roman Britain dedicated to the goddess Fortuna, the healing god Aesculapius, and Salus, goddess of health	554	VOLUME III	
Paleolithic stone chopping tools from Olduvai Gorge, Tanzania	562	Sandstone offering table with Meroitic cursive inscription around the edges, from Faras, Sudan	610
A folding wooden headrest, from Akhmin, Egypt	563	Clay tablet with Elamite inscription found in the treasury of the palace at Persepolis, Persia (modern-day Iran)	613
Stone bowl and pitcher from Greece	567	Jade disc inscribed with a poem by the Qianlong emperor, from China	614
Roman jug, two-handled cup (the handles now missing), strainer, ladle, and stirrer, from Arcisate, near Como, northern Italy	569	Linear A tablets, from Agia Triada, Heraklion	617
Archery case painted with a hunting scene, from Thebes, Egypt	574	The Rosetta Stone, from Fort St. Julien, el-Rashid (Rosetta), Egypt	623
Impressions of cylinder seals on clay, depicting hunting scenes and found in the treasury of the palace at Persepolis	575	Jade cicada, China	626
Harpoon tips made of antler from the cave of Courbet, Penne-Tarn, France	578	Page from the Book of the Dead of Hunefer, Thebes, Egypt	644
Fragments of a fresco from Tiryns, Greece, showing hunter and dog	579	Sculpted panel depicting Vishnu Trivikrama, eastern India	650
		Frieze of three Greek muses	657

Copper vessel with silver wire, from Ur, southern Iraq	680	Whistling vessel in the form of a macaw, Peru, Moche culture	773
Gold cup of the Bronze Age, beaten out of a single lump of gold and found in Rillaton, Cornwall, England	683	Rock inscription at Seheil, Egypt, recording a seven-year famine	777
Gold mask from Mycenae	684	Roman wall painting showing a coastal landscape, from Boscoreale, Campania, Italy	782
Hammered gold standing figure, Colombia or Ecuador	687	Petroglyph showing herders and cows, from Sahara Desert at Tassili, Algeria, North Africa	787
Granite statue of Senwosret III, from Deir el-Bahari, Thebes, Egypt	694	The Rhind Mathematical Papyrus, showing mathematical problems and solutions, from Thebes, Egypt	799
Albert Bierstadt, The Rocky Mountains, Lander's Peak	719	Painted Greek stele with metrical inscription	804
Detail of a Persian soldier from the stairway of the palace of Darius, king of Persia, at Persepolis (modern-day Iran)	728	Granite statue of Ankhwa, the shipbuilder, possibly from Saqqara, Egypt	810
The fortifications of Eleutherae, a city in the northern part of Attica, bordering the country of Boeotia	733	Spinning and weaving tools from Iron Age England	814
Roman marble statue of a youth on horseback and wearing a military cloak	735	Frieze of <i>hydriaphoroi</i> (water carriers) from the Greek Parthenon	815
Linen bag of salt for mummification, from Deir el-Bahari, Egypt, New Kingdom	743	Traditional healer in anti-smallpox costume, Nigeria, West Africa	820
Stone panel from the palace of Sennacherib, Nineveh, northern Iraq	744	Mesopotamian terra-cotta figure of an animal thought to be a dog	822
Lead pig (ingot), Roman Britain, from Hints Common, Staffordshire	749	Greek marble block from the frieze of the Temple of Apollo Epikourio (Apollo, the Helper), Bassae, Arcadia	826
The el-Amarna Hoard, from el-Amarna, Egypt	754	Limestone stela with images of the goddess Tanit, from Carthage (modern-day Tunisia)	834
Silver coins of various cultures found at Persepolis, Persia (modern-day Iran)	756	Limestone relief panel depicting the departure of Prince Siddhartha from his palace, to start on the spiritual journey that brings him to Buddhahood	846
Fragments of a stone mould and bronze knife money, from northeastern China	757	Iron Age horned helmet, from the River Thames at Waterloo Bridge, London, England	851
Cast ingots of bronze used as money in Rome before the invention of silver coinage	761	Frieze of the gods Greek gods Poseidon and Apollo and the goddess Artemis from the Parthenon	854
Babylonian relief plaque of harpist	766		
Red sandstone railing pillar in the form of a flute player, Mathura, northern India	767		
The Greek god Apollo with kithara, a stringed instrument similar to a lyre	770		

Jade votive ax of a figure combining human and animal traits and thought to represent a supernatural being, Olmec, from Mexico	863	Painted wooden model of a boat, from Meir, Egypt	977
Head of the Greek philosopher Socrates	878	Terra-cotta model of a merchant ship, Amathus, Cyprus	978
Ivory panel commemorating Quintus Aurelius Symmachus, an orator and figure in Roman government and a prominent pagan	881	Wall painting of Ulysses and the Sirens, Roman, from Pompeii	983
Section of the Neolithic Sweet Track, the oldest prehistoric timber trackway in Britain, from Somerset, England	888	A Scythian slave and the satyr Marsyas	992
Iron hipposandal, Roman Britain, found in London	891	Image of Psyche on a lead coffin lid, Roman, made in Lebanon	994
VOLUME IV			
Deep gorge in the Atlas Mountains of Africa	898	Sarcophagus of Nectanebo II, the last native ruler of Egypt, from Alexandria	1001
Limestone stela of Heqaib, from Abydos, Egypt	900	Basalt relief of a gazelle, Neo-Hittite, from Carchemish, southeastern Anatolia (modern Turkey)	1002
Iron Age Lindow Man, found in Lindow Moss, Cheshire, England	903	A Neolithic burial jade carved with faces, from southern China, Liangzhu culture	1004
View of Mount Olympus, in Attica	905	Coins from the Hoxne hoard, Roman Britain, found in Hoxne, Suffolk	1007
Gold ring bought by a pilgrim and showing the Roman Temple of Aphrodite at Palaepaphos	906	Servants carrying food for the king's tables, palace of Xerxes, Persepolis, Persia (modern-day Iran)	1019
Neo-Assyrian stone panel from the palace of Sennacherib, Nineveh, northern Iraq	912	Pottery, Japan	1026
Base-silver radiate of Carausius, with the emperors Diocletian and Maximian, Roman Britain	914	Double spout and bridge vessel with pelican and fish, Nasca culture of Peru	1041
Unwrapped mummy of a woman, perhaps from Thebes, Egypt, Late Period	926	Game of 58 Holes, made of ivory inlaid with gold and blue paste, from Megiddo, Palestine	1050
Bust of Pseudo-Seneca by Peter Paul Rubens	942	Ceramic Liubo players, from China	1052
Altar to the sea god Neptune, an offering from the Roman admiral of the British fleet, from Lympne, Kent, England	959	Bronze group of a bull and acrobat, Minoan, from Crete	1053
Aerial view of the Niger River and surrounding savanna during the rainy season	963	Hockey game, found in the Themistoclean wall, Athens	1054
Relief fragment showing Assyrian soldiers towing a boat through shallow water	967	Roman terra-cotta sculpture of two gladiators fighting	1056
		Stone <i>hacha</i> (ax), Veracruz, Mexico	1057
		Painted wooden model of a granary, from Aswan, Egypt	1063
		Amphora, a ceramic vessel used for storing and carrying oil and wine and other commodities, from Athens	1068
		Ugandan woman wearing a bark cloth dress	1074

Tapestry made of multicolored wool on linen showing Artemis and Actaeon, Egypt	1076	Bust of a Greek warrior known as Leonidas	1145
Wool textile fragment from Persepolis, Persia (modern-day Iran)	1078	Bronze statuette of the Mars, Roman god of war, Earith, Cambridgeshire, England	1151
Bone needles from the cave of Courbet, Penne-Tarn, France	1081	Stone ball found in Olduvai Gorge, Tanzania	1162
Greek utensil used for unwinding balls of wool, called Ariadne's clew box	1081	Short sword of steel, bronze, and gold from eastern Central Asia	1165
Mantle border fragment made of cotton and camelid hair, Peru	1084	Spear thrower carved in the shape of a mammoth, from the rock shelter of Montastruc, Tarn-et-Garonne, France	1167
Site of ancient walled town, Cameroon, Central Africa	1087	Vase from Mycenae portraying warriors in battle gear	1168
Gold bracelet or diadem, from the Phoenician trading center of Tharros, Sardinia	1099	Sixteenth-century shield depicting Roman battle scene	1170
Steatite seals from the Indus Valley	1100	Bronze duck weight, found in the treasury at Persepolis, Persia (modern-day Iran)	1175
Iron Age luxury imports from Italy, Rome, and the Near East, found at Hertfordshire, England	1102	Bronze steelyard with lead weights from Roman Britain	1178
The Crawford Cup, Roman, found on the border between Syria and Turkey	1105	Red porphyry one talent weight, from Knossos	1179
Petroglyph of camel and horse, from the Sahara Desert at Tassili, Algeria, North Africa	1111	Roman cup or bowl depicting a man carving the number 7 on a nilometer, a device used to measure the water level of the Nile's annual flood	1181
Achaemenid Persian gold model chariot from the region of Takht-i Kuwad, Tadjikistan	1114	Abu Simbel—hymn in praise of the Egyptian pharaoh Ramses II	1185
Horse harness fittings from Iron Age Britain	1116	Clay tablet with Babylonian inscription, found in the treasury of Persepolis, Persia (modern-day Iran)	1186
Chariot with horse and rider, from a sarcophagus at Heraklion	1119	Pillar edict of the emperor Asoka from Uttar Pradesh, India	1188
Frieze in the temple of the Egyptian pharaoh Ramses II, showing a listing of captured cities in Nubia	1127	Painted pebbles from cave of Mas d'Azil, Ariège, France	1188
Clay prism of King Sennacherib	1132	Bilingual milestone marker	1190
Stone figure of the war god Skanda, from eastern India	1139	Pottery inkwell from Roman Britain, inscribed with its owner's name, Iucundus	1191

Entries S to Z

► sacred sites

INTRODUCTION

Probably the first sacred sites were aspects of the natural world that people identified with the supernatural. Large formations, such as big rock outcrops, mountains, lakes, and rivers, all could serve as impressive sources of spiritual power. Mountains are imposing not only because of their size but also because they seem closer to the sky. Many cultures have placed shrines or altars atop mountains in the belief that people could be better heard by gods when they were nearer the sky than when they were at the bases of mountains. Rock outcrops often have the advantage of having faces on which sacred images could be painted or carved, allowing people to show in their images what is special about the sacred place. Lakes and rivers frequently are associated with the life force, because water is believed to be part of the life force; after all, people quickly die without water. Lakes and rivers were thought to have gods dwelling in them, and many ancient peoples made sacrifices to lakes and rivers in the hope of making the gods there happy or to persuade the gods to help with crops or wars.

A place in a dense forest where light cannot penetrate past the branches and leaves of trees could be construed as a place where forest spirits would gather or dwell. Shrines in such places might not have survived if they were wooden or consisted of no more than the space among the trees, but historical records suggest that ancient cultures in Europe, Africa, Asia, and America had such places, where good and evil spirits were thought to dwell.

Sacred places can be associated with historical events or important people. Where a special person received enlight-

enment about the supernatural or spoke with spirits can become a holy place to which the faithful will make pilgrimages. Shrines could be built to mark locations where a single religious leader received or proclaimed divine knowledge over his or her lifetime, with the shrines marking stations for religious pilgrimages of the followers of the religious leader or of the religion of which the religious leader's revelations became a part. The locations of great battles that were important sites in mythology sometimes were commemorated with altars, shrines, temples, or tombs. There were so many such places that some ancient people wrote tour guides to the sacred sites.

Otherwise ordinary places could be made sacred by people. One way was to deposit a sacred relic, such as a fragment of hair, bones, fingernail clippings, or a personal item worn or used by a sacred or holy person. Great mounds could be built over the relics, or temples could be erected to house them. Another way to make a place sacred was through ritual. Sometimes ancient cities were made sacred and even objects of worship by depositing icons of gods in central temples or through ritual blessings of the cities. Sometimes the ground on which a city was to be built was consecrated through rituals, making the new city a sacred place that was set apart from the ordinary world.

AFRICA

BY ROBERT SHANAFELT

Sacred sites in ancient Africa include special areas of the natural landscape such as mountains, caves, forests, and springs and human constructions such as mounds, tombs, and pyramids. The continent contains some of the oldest sites in the

world that seem to have had ritual significance for human beings. By 10,000 years ago religious symbolism was well established in art, body decoration, burial, and monument building. One substance very widely associated with burial was the red pigment ocher. Ocher is further connected with the land and with sacred sites in that it was painted or smeared on rock surfaces or onto artifacts left in the ground. Studies of ancient religions from around the world suggest that this pigment was a common symbol for blood and life.

A substantial number of ancient engravings on stone and paintings on rock walls have been discovered in many regions of Africa, including the region that is now the Sahara. In very early times graphic images of animals and abstract geometric forms made on rock faces probably were meant to establish supernatural connections among people, animals, spirit beings, and the landscape. Southern Africa provides some of the very earliest examples of rock art with undoubted religious connections, dating back to perhaps 30,000 years ago but continuing into the time of European colonialism.

There appears to be a direct relationship between the religion of the so-called Bushmen (the San) and the ancient rock art sites found in southern Africa. For example, some paintings depict ritual dances similar to those still practiced by Bushmen today. The modern-day Tswana also claim an ancient religious connection. According to one oral tradition a set of engraved footprints in southeastern Botswana marks the spot where the first Tswana man emerged from the underworld. In North Africa the Atlas Mountains of Morocco were favored locations for ritual activities. Here rock engravings made between 5,000 and 7,000 years ago depict otherworldly images such as horned women and men with animal heads.

The impressive megaliths (large standing stones) and pyramids that often mark the sacred sites of the ancient world are usually associated with civilizations that had substantial populations and productive farming. While this is also true for the sites in Africa with the largest monuments and pyramids, in some cases pastoralists (groups who herd animals as their principal occupation) or other societies with relatively small populations constructed megaliths. Herders and early farmers in what are today Niger, the Central African Republic, and Chad built stone monuments to cover the graves of their revered leaders. Ritual cattle sacrifices also occurred in many of these locations. Stone circles and other megalithic monuments are especially pronounced in the region around the present-day town of Bouar in the Central African Republic.

Nabta Playa, a site bordering on what is today Libya, Sudan, and Egypt, served as a ceremonial center for pastoral nomads between 6,000 and 7,000 years ago. In addition numerous tombs, the site has five rows of megaliths that radiate out from a center point. It also has an important stone circle. This stone circle is particularly significant because it is one of the earliest examples of an astronomical observatory in the world, predating England's Stonehenge by some 1,000 years. Although it is quite small compared with Stonehenge, being only about 12 feet in diameter, it is still impressive given

Deep gorge in the Atlas Mountains; these mountains were a favored site for ritual activities in ancient times. (© Board of Regents of the University of Wisconsin System)

its early date. It consists of four sets of upright slabs, with one set aligned in a north-south direction and the second set aligned eastward to face the sun as it arises during the summer solstice.

The Egypt-Sudanese border area that in ancient times was known as Upper Nubia is also the location of a mountain called Jebel Barkal that was sacred for both Egyptians and Nubians. This site became especially important during the Twenty-fifth Dynasty (ca. 712–ca. 657 B.C.E.), when Nubian pharaohs ruled all Egypt. Later Nubian pharaohs built pyramids for themselves and their queens and were laid to rest at nearby Meroë. Another example of a sacred mountain in Africa is Makade Egzi in Ethiopia, near the ancient city-state of Axum. Axum itself is famous for impressive stone gravesites and obelisks. In a much earlier time, around 3000 B.C.E., many stone dolmens (upright stones across which lies a stone slab) were erected in what is now the eastern region of the country.

As mentioned earlier, features of the land and the landscape are sacred in many traditional African religions.

Among the hunting-and-gathering peoples who inhabit the forests of central Africa—so-called Pygmy peoples such as the Mbuti of Congo and the Aka of the Central African Republic—the forest is thought to be a divine being or spiritual force. Many peoples of West Africa also consider portions of the forest sacred, while other groups, like the Tswana, consider the homeland of their ancestors to be the most sacred ground. The elders and keepers of traditional knowledge among the Mijikenda of Kenya also work to protect special areas of forests that they associate with their ancestors. Here it is difficult to tease apart today's spiritual inspiration and imagination from the realities of the past. For example, while oral tradition suggests the Mijikenda sacred forests were inhabited by their ancestors for at least the past 10 generations, some archaeologists think they were occupied more recently. On the other hand, other experts think the occupation goes back to antiquity, much further than oral tradition suggests. Similarly, while it is known that people have inhabited the forests of central Africa for thousands of years, it is not known at what point people began to consider the forest itself as sacred.

Finally, it should not be forgotten that both Christianity and Judaism established early roots in North Africa and in Ethiopia. Today a special treasure house near the Church of Saint Mary at Axum is said by many followers of the Ethiopian Orthodox Church to house the Ark of the Covenant, the chest that contains the original Ten Commandments.

EGYPT

BY CHRISTINE END

The ancient Egyptian worldview was embodied in the concept of *maat*, or divine order. Under *maat*, Egypt was at the center of the universe; night, day, and the seasons were perfectly governed, and the cosmos was harmoniously balanced. Appeasing the gods who presided over every aspect of the Egyptian world was necessary to perpetuate *maat*. A goddess, also named Maat, personified the concept. Kings frequently included “beloved of Maat” in their titles to show their devotion, and surviving reliefs show kings offering small Maat figures to a variety of gods. By giving a figure of Maat, the king was ensuring that the deity would uphold *maat* and therefore Egypt's position in the universe.

The king was not the only one to appeal to the gods; offerings were a part of life for the ancient Egyptians. Excavations revealing abundant offerings indicate an especially sacred site. Individuals left gifts at specific locations to venerate a particular god, to ask for help, or to mark a pilgrimage to a revered place. These offerings could have been amulets, statues, mummified animals, notes or spells written on pottery, foodstuffs, offering tables, or poured unguents or pure sand. Some offerings were much larger, such as shrines, stelae, or even temples. These places were considered sacred because of mythological or religious connotations, the presence of exploitable resources (such as water or metal) in the area,

or symbolic natural or man-made landforms. There are many overlaps within these categories. For example, sometimes a temple was built on a natural sacred mound, or a building's design might have imitated a natural sacred land formation.

The Egyptian perception of the sacred often combined the mythological and tangible worlds. Some myths include descriptions of the beginning of the universe. One popular Egyptian creation story begins with chaotic primordial waters, called *nun* (sometimes represented by a god of the same name). *Nun* was the first thing in the universe out of which the primeval mound, or *benben*, emerged. This mound was the first thing the sun's rays fell upon. Bodies or sources of water were sacred because water symbolized mythological creation and also, in the tangible world, was an essential resource, particularly in the desert. The Nile River was the most important body of water; it was the source of agriculture, transportation, and sustenance for Egypt's people and wildlife. This river was so sacred and boat travel was so engrained in the ancient Egyptian consciousness that some royal burials included boats so that the deceased could navigate the waters of the afterlife.

Sacred bodies of water could also be man-made. Artificial lakes were frequently created at temples if a natural water source was not available. The temples of Amon and Mut at Karnak, Hathor at Dendera, Osiris at Abydos, and other temples and temple complexes at Medinet Habu, Armant, and Tanis all incorporated man-made lakes into their environment. These lakes were used for daily washing, ritual libations, watering sacred animals, and sailing sacred barks during festivals. Wells, a natural water source accessed in a man-made fashion, were another way to exploit water. On desert roads or in towns far from lakes or the Nile, wells were of life-sustaining importance.

Water was not the only exploitable natural resource for the Egyptians. Mines and quarries were considered sacred places where the riches of the earth were accessible. Certain gods were associated with particular types of metal or stone. For example, Hathor was deemed the lady of turquoise, and Ra, the sun god, was said to possess bones of silver, skin of gold, and hair of lapis lazuli. Shrines and stelae dedicated to gods were frequently erected at their mine sites.

Man-made mound structures were sometimes incorporated into sacred sites such as tombs, symbolically associating them with creation myths. In ancient Egyptian creation mythology, the primeval mound was the first thing to emerge out of the turbulent waters. Papyrus was the first thing to grow on the newly emerged mound. This mimicked the agricultural cycle of the emergence of fertile silt-covered land after the Nile flood. Therefore, including a mound at a site would connect it with both the tangible and mythological worlds.

A different type of man-made mound is found at Abydos on the west bank of the Nile. Abydos was considered the mythical burial place of Osiris, god of the dead and the afterlife. Pilgrimages to Abydos honoring Osiris began in early

dynastic times. A mound created from the accumulation of centuries of small offerings brought to this sacred site is still visible today. Offerings at Abydos also included structures such as temples and cenotaphs.

Temples were extremely sacred places to the Egyptians. Commoners were not permitted inside the boundaries of the temple. Interaction between the common person and the gods occurred only when shrines were carried out of the temple precincts. Important precincts included the temple of Amon and Mut at Karnak, Luxor Temple in the south, the temple of Ptah at Memphis, and the sun temple of Heliopolis in the north. Architectural elements of the Egyptian temple appear to refer back to the primeval mound and the waters of *nun*. The hall that led into the temple contained columns topped with papyrus (representing its growth on the mound) and sometimes lotus, thus creating an artificial marshland. Papyrus and lotus plants additionally symbolized Lower and Upper Egypt, respectively. In the most sacred area at the back of the temple, the ground rose and the star-painted ceiling became lower, leading into the highest, darkest area representing the primeval mound. The temple therefore stood as a mythological microcosm within which the priests ritually duplicated the creation of the universe.

Natural land formations may have been the sign of a sacred area. Some scholars believe that the choice of the Valley of the Kings for New Kingdom (ca. 1550–1070 B.C.E.) royal burials was made because of a pyramid-shaped hill at the site, echoing the shape of pyramids used for Old Kingdom (2575–2134 B.C.E.) royal burials. If true, this is an example of a natural site chosen for a sacred purpose because it resembled a man-made structure. Further, there is some argument as to whether the pyramid shape itself derives from a natural mound formation or is a logical progression in the evolution of man-made structures. Areas surrounding pyramids were considered sacred places in which to be buried. In the Old Kingdom it appears that the king was thought to be the only one with the ability to rise from the dead, but individuals buried around his tomb might have a chance at the afterlife because of their location near him.

The sun was also revered, inspiring the building of many sacred structures. The Egyptians identified several solar deities, each representing the sun at various times of the day. Solar worship, especially of the sun god Ra, was an important part of Egyptian religious belief from the time of the Old Kingdom. Obelisks and *benben* stones (the predecessor of the obelisk that represented the primeval mound) were erected at several sites sacred to Ra. Additionally, kings deemed themselves *sa Ra*, or “son of the sun.”

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

The people of Mesopotamia believed that temples functioned as physical homes for their gods and goddesses. Accordingly, Mesopotamians built their temples specifically to accommodate deities and not as a place for worshippers to gather. A temple would contain a statue of the resident god and a repository to store votive offerings given by the faithful. Priests and priestesses lived next to the sanctuary and performed daily rituals, including furnishing large meals for the gods. Workshops for the manufacture of everything from tools to till the deity's fields to pottery to hold the deity's beer were associated with each temple.

Each city had numerous temples dedicated to different gods and goddesses, but typically one deity would function as the city's patron and inhabit the city's largest and richest temple. The city of Babylon was considered sacred to the god Marduk and his son Nabu. Nabu also had a shrine in the neighboring city of Borsippa. Nippur, another Babylonian city, was sacred to the god Enlil. Assur, the capital of Assyria, was the home of the god Assur, the chief god of the Assyrian pantheon and a counterpart of the Babylonian god Marduk. Nineveh was another important Assyrian city; its most important temple was that of the goddess Ishtar. The city of Ur, near the mouth of the Tigris and the Euphrates, was the sacred city of the god Nanna. In some cities a pair of temples housed a divine husband and wife; for example, in Babylon, the temple to Marduk was next to the temple dedicated to his wife, Sarpanitum.

Limestone stela of Heqaib, from Abydos, Egypt (1990–1750 B.C.E.); Abydos was the principal cult center of Osiris and a place of pilgrimage for Egyptians. (© The Trustees of the British Museum)

Israel was home to several sacred sites important to Jews and Christians. Jerusalem has been the holy city of the Jews since about 1000 B.C.E. and has been a destination for religious pilgrimages since that time. The Temple Mount was the site of the Jewish temple, the center of organized worship, and the holiest place in Judaism. Two temples succeeded each other there in ancient times. The first one, Solomon's Temple, was built in the 10th century B.C.E. and was destroyed by the Babylonians around 587 B.C.E. The second temple was built in 515 B.C.E. and was destroyed by the Romans in 70 C.E. The Western Wall, or Wailing Wall, is the retaining wall that supports the western side of the Temple Mount. It was built along with the second temple and survived when the Romans destroyed the temple. According to Jewish tradition, the emperor Titus (r. 79–81 C.E.) left it standing to remind the Jews that Rome had conquered them, but the Jews regarded it as a sign of God's promise that they were his chosen people. The wall has been a popular site for prayer since ancient times.

The tomb of the biblical Jewish woman Rachel (wife of Jacob) was traditionally believed to be on the outskirts of Bethlehem. The town of Bethlehem also contained a grotto where the Roman Church father Jerome (ca. 347–419 or 420 C.E.) translated the Bible into Latin—a translation known as the Vulgate—around 400 C.E. Bethlehem's Church of the Nativity was built by the emperor Constantine the Great (r. 306–337 C.E.) in 330 C.E. over a holy cave where Jesus was believed to have been born. Constantine also built the Church of the Holy Sepulchre over the spot in Jerusalem where Jesus was said to have been crucified.

Ancient Persian worshippers of Zarathustra, or Zoroaster, centered their worship on fires. Each home had its own sacred fire at which family members worshipped daily. In the fourth century B.C.E. Persians began building fire temples that became centers of community worship. Cities and towns had their own temples; famous temples were located in the cities of Shiz, Baku, and Kabulistan. Zoroastrians disposed of dead bodies by leaving them on mountaintops inside stone-walled enclosures called towers of silence, where the bodies were eaten by vultures and dried by the sun. This was considered the cleanest way of dealing with the dead because it prevented decaying flesh from polluting the ground.

Many sacred sites were located in Asia Minor. Mount Ararat, in the mountains of Armenia, was a sacred site for millennia. The Asklepion in Pergamum was a hospital built in honor of the god of health, Asklepios; it was famed for a sleeping cure in which the god was supposed to visit patients in their dreams. The Temple of Artemis at Ephesus was one of the Seven Wonders of the Ancient World. Christian sites included the Cave of the Seven Sleepers in Ephesus, a cave in which seven Christian boys pursued by persecuting Romans hid themselves; the soldiers walled them up inside, and they were said to have fallen asleep until the fifth century C.E., when they were released by an earthquake and learned that Christianity was now prevalent.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

For many in the ancient Asia and Pacific region, unusual or impressive geological features carried spiritual power. For example, in ancient Japan a mountain would have *kami*, a spiritual power, just because it was massive. Mount Fuji, which stands tall over eastern Honshū, was especially sacred not only for its size but also for its individuality, standing separate, as it does, from the main mountain chain of the island.

Ayers Rock in Australia is another example. Called Uluru by the ancient Australians, it fell from the sky during the dreaming time, the era of the Creation. It was also the site of a great battle between the lizard men and the snake men, before human beings appeared. Uluru is impressive: made of sandstone, it stands 1,143 feet high and is a mile and a half long. It seems to glow red as the sun sets. The rock was said to be "owned" by a single person at a time. This person controlled who visited the rock. Many ancient sacred sites in Australia were "owned" by someone. The owner also owned all the stories associated with the sacred place. He or she could tell others the stories, but they were not supposed to repeat the stories unless they themselves became "owners" of the sacred place. This custom continued through the 20th century for Uluru, with owners taking people into special meeting areas, usually just outside caves, to tell them the stories about the sacred site. As is the case with many ancient sacred rocks, Uluru was painted with symbols. Some of them tell the story of Creation. They were painted with ocher shades and blood drawn from the arm of the painter, which emphasized the artist's spiritual connection to the rock and what he was depicting. Caves that were painted often served as places for initiation rites for children moving toward adulthood, where they would learn some of the sacred lore of their people.

The Chinese had many sacred places. During the Shang Dynasty (ca. 1500–1045 B.C.E.) there were many cultures outside the Shang Empire, and they had numerous different beliefs about their sacred places. Most of these beliefs have been lost. One site that was sacred throughout ancient times was Mount Tai Shan. It is about 5,000 feet high, and its summit is a huge crag of rock that seems to thrust out into the sky, giving those who stand on it a breathtaking view of the rocky, lumpy countryside in Shandong Province. The route up to the summit is marked by shrines. A pilgrim in ancient times was expected to leave offerings at each shrine, and even today people leave gifts of fruit and flowers as they scale the mountain. Confucius climbed the mountain and was recorded as saying, "I feel the world is much smaller," as he gazed at the world from the summit. The emperor Liu Ch'e (r. 141–87 B.C.E.) of the Han Dynasty (202 B.C.E.–220 C.E.), climbed Mount Tai Shan to speak with the gods. He made his climb a proper pilgrimage by stopping at every shrine to pray and leave offerings. By his era Mount Tai Shan had become a symbol of Chinese culture, and Liu Ch'e's climbing the mountain displayed his commitment to Chinese civilization as well as his

own important place in Chinese religion. He was expected to speak with the gods on behalf of the Chinese.

In addition to building shrines on already-sacred sites, people made some sites sacred through rituals and the building of religious structures. In India people built stupas, originally tombs of dirt piled in the shape of hemispheres. Stupas took on great importance after the death of Siddhartha Gautama (ca. 563–ca. 483 B.C.E.), who was the Buddha. Parts of his body were entombed in several stupas. Emperor Asoka (r. 268–233 B.C.E.) of India had seven of these stupas opened and their contents divided among 84,000 stupas scattered through India. The most important was the Great Stupa in Sanchi, north of the Narmada River in Madhya Pradesh in central India. Over hundreds of years, people added to it, coating it in brick, surrounding it with a wall, and building ornate gates alive with sculptures of gods and goddesses.

A stupa typically had a circular crown projecting around its top. The one for the Great Stupa looks like many fingers thrusting out horizontal to the ground. The crown was called *chatra*, meaning “umbrella.” The dome of the stupa was the *garbha*, meaning “womb.” *Garbha* referred not to a physical birth but to the Buddha’s passing out of the cycle of birth and rebirth into nirvana, a blissful spiritual state in which the soul escapes the pain of life in the physical world. The dome was also sometimes called an *anda*, meaning “egg,” because it symbolized the first egg from which the universe emerged.

Hindus used the concept of the *garbha* to create the *garbhagriha*, a shrine where a person might be seen by a god. Hindu shrines and temples often had images of gods inside them, but the Hindus did not believe that the statues were gods, and they did not believe that gods ever actually entered the statues. The statues frequently were placed in a shadowy part of a shrine, because it was intended to set an observer’s mind to thinking about the mysteries of spirituality. It was this train of thought that could bring a person into touch with a supernatural being. This encounter with a supernatural being was *darshana*, meaning “viewing.”

Sacred sites were also built with the intention of inspiring awe in visitors. In India, during Asoka’s reign, people began carving sacred sites into large stones. At first these were just caves where a monk could sit by himself and meditate. Eventually, they became huge temples that are amazing even today. The best may be at Ajanta in western India. From the 100s B.C.E. to the 600s C.E. temples were carved into immense rocky cliffs. Some temples began in natural caves, but others were carved either from the side of a cliff or from the top down into a cliff. Cracks were hammered into the rocks and filled with wood that was then doused with water, which slowly widened the cracks as the wood swelled. Rock masons carved openings into spaces that became rooms and corridors, with columns and statues. The detail work was done by artisans using tools as fine as those of jewelers. Walls were then painted with religious scenes. The central shrines were often in shadows, with openings allowing light to highlight

statues representing the Buddha or gods. Both Hindus and Buddhists carved such temples.

EUROPE

BY AMY HACKNEY BLACKWELL

Long before the Celtic peoples arrived, prehistoric Europeans created sacred sites by arranging giant stones, or megaliths, in ways that were to them spiritually significant. These stones remained standing during Celtic times, and the Celts adopted some of them as their own sacred sites. Celts and Germans also found spiritual power in many natural formations, such as groves of trees, mountains, caves, and islands.

Hundreds of megalithic sites remain throughout Europe, from Ireland to the eastern Baltic area, containing stone structures and graves erected between 4500 and 2000 B.C.E. Many megalithic sites were tombs, and human remains have been found in some of them. Others reveal no obvious purpose, consisting only of upright stones arranged in a pattern but without burials. The most accepted explanation is that megaliths had religious or ceremonial significance. Many of them are aligned in such a way that they catch the sun on specific days of the year, which may be evidence that prehistoric peoples used them in sun worship.

There are several common types of megalithic structures. A menhir is a single standing stone. Some standing stones are arranged in circles or rows, called alignments. A dolmen is a tomb made of several large upright stones supporting a flat stone roof, while a passage grave consists of a corridor lined and roofed with large stones leading to a stone burial chamber. Many megalithic tombs were once covered with mounds either of earth or of small stones. The earthen mounds are known as tumuli; the stone mounds are called cairns.

Most surviving megalithic sites are in northwestern France, Britain, and Ireland. The largest known menhir, the so-called *grand menhir brisé* (“great broken stone”) in Brittany, France, stood about 67 feet high before it was broken in an earthquake in 1722. Carnac, another site in Brittany, contains over 3,000 standing stones arranged in straight lines, all erected between 4500 and 3300 B.C.E. Carnac also has several tumuli and several dolmens. Gavrinis Island off the coast of Brittany holds a huge megalithic cairn that dates to about 3500 B.C.E. Inside the cairn a passage leads to a grave chamber constructed of large granite stones. The walls of the passage and chamber are elaborately carved with spiral decorations. Ireland is home to several similar tombs, the most famous of which is Newgrange, built about 3200 B.C.E. Newgrange is especially notable for the way the rising sun of the winter solstice shines directly on a design in the main chamber.

Perhaps the most famous sacred site in prehistoric Europe is Stonehenge in England, which was built in several stages between 3100 and 1600 B.C.E. Stonehenge is a complex monument, and the standing stones that are visible today are only the most recent version of it. Moreover, it was at the center of a landscape of monuments that all had some sort

of symbolic or sacred purpose. Barrows dot the surrounding countryside, while a roadway lined with ditches and banks leads the way to the nearby river Avon. Debate rages as to Stonehenge's purpose, but it may have had a calendrical or ceremonial function.

Bronze Age rock art chiseled on rocky outcrops in many parts of Scandinavia as well as in the Alps includes images of animals, people, and boats, as well as abstract spirals and suns. These carvings clearly conveyed some sort of spiritual significance. Some of the scenes found in Sweden show rituals and processions.

Celts adopted ancient megalithic sites as their own; historians believe that the Celts created legends of fairies and other supernatural beings to explain the existence of these mysterious structures. The Hill of Tara in County Meath, Ireland, was a particularly sacred site in Celtic times. The Celts believed that the hill had been the capital of the mythical people who lived in Ireland before them. On top of the hill was a fort built during the Iron Age, perhaps around 1000 B.C.E.; this fort contained a standing stone called the Lia Fáil, or Stone of Destiny. Celtic kings were crowned next to the Lia Fáil, which was supposed to shriek out loud if the feet of the rightful king rested on it.

Most ancient Europeans believed that trees had spiritual significance. The Roman historian Tacitus observed that ancient Germanic peoples worshipped sacred groves of trees, especially oak trees. He described a ritual in which Germans performed annual human sacrifices in the sacred groves. In Denmark and Scandinavia people selected particular ash trees as sacred objects. Oddly shaped trees often gained particular spiritual significance and were believed to be the homes of spirits.

Celtic people throughout Europe believed that certain groves of trees were sacred. Forests sacred to the Celts of France included the Forest of Paimpont near Rennes, the grove in the Greek colony of Massilia (modern-day Marseilles), the Augustonemeton in the Auvergne region of central France, the Memetacum in the Artois region of northern France, and the Forest of Huelgoat in Brittany. The Roman historian Pliny mentioned a Spanish people called the Nemetatae, named after a sacred grove in northern Spain. (One Celtic word for a "sacred grove" was *nemeton*.) A Celtic group in Germany called themselves the Nemetes, or "people of the sacred grove." Sacred groves left their mark on some modern place names, such as Nemetostatio in Devon and Vernemetum in Nottinghamshire, England.

Many rivers, wells, springs, bogs, and hot springs were sacred to ancient European peoples. Archaeologists have found religious artifacts at many watery locations, such as the river Shannon in Ireland and the Seine in France. At Flag Fen in England, Bronze Age and Iron Age people deposited hundreds of bronze objects, as well as animal sacrifices, in the bog. Across northern Europe bogs and marshes have yielded thousands of objects that could only have been thrown in deliberately as offerings. The famous Iron Age bog bodies,

Lindow Man (Iron Age, mid-first century C.E.), found in Lindow Moss, Cheshire, England, and thought to have been ritually murdered; Germanic and Celtic human sacrifice took place at the site of peat bogs, where the bodies were then thrown. (© The Trustees of the British Museum)

of which Tollund Man and Grauballe Man in Denmark and Lindow Man in England are but three examples, were probably individuals who were sacrificed ritually (or perhaps executed for crimes) and then cast into the bogs, where the soil's unusual chemistry preserved the bodies remarkably well.

Hot springs were especially attractive to ancient peoples. The natural hot mineral springs at Bath, in southwestern England, were first frequented by hunter-gatherers around 8000 B.C.E. Celts built a shrine to the water goddess Sulis there around 700 B.C.E. This shrine became a major religious center for Celts in the area. Romans took over the shrine around 65 C.E. Although their name for the town was *Aquae Sulis* (Waters of Sulis), they replaced Sulis with the Roman goddess Minerva as the focus of worship. Among her many other roles, Minerva was the goddess of medicine, and the shrine became a destination for people hoping to regain their health. Over the next four centuries the townspeople improved the facilities, constructing temples and bathhouses. Other well-known sacred hot springs existed (and still exist) at Baden-Baden in Germany, Perrier in France, and Evian-les-Bains on Lake Geneva.

Ancient Europeans often considered mountains sacred. Celts believed that their gods lived on top of high mountains. Islands were also sacred. The island of Anglesey in northern Wales was believed to be the home and power base of Druids. In about 60 C.E. Romans attacked the island, slaughtered the

defenders, and burned the Druids' sacred oak groves in an effort to end their power and influence.

GREECE

BY BRADLEY SKEEN

Pausanias, a Greek of the second century C.E., wrote a tourist guide to his homeland. A modern book of this kind might concentrate on art galleries and battlefields, but Pausanias's main interest was in religious practices and religious places. For the Greeks the sacred was the most important part of life and found its expression in the hearts of cities, in villages, in the wild places of the countryside, and beside the hearth of every Greek home.

The earliest Greeks, the Minoan civilization of Crete (2000–1400 B.C.E.), carried out religious rituals in rural places whose nature seemed connected to the divine. Mountaintops were the closest places to the gods of the sky, while caves seemed connected to the deities of the dead who lived under the earth. Other gods were worshipped within sacred enclosures set off around large trees.

Household shrines also existed in Minoan times and continued throughout Greek history. Each house had its own altar dedicated to the family's ancestors and to whatever gods protected the home according to family tradition. Frequently, such shrines had small statues of divine figures. A ceramic tube usually hung on the wall above the shrine; the tube contained a live snake, the *agathos daimon* ("good spirit") that represented the powers watching over the family.

Greece experienced a cultural collapse or dark age (1100–800 B.C.E.) during which many religious traditions were lost. When Greek cities were established or reestablished in the Archaic Age (after 600 B.C.E.), the sacred had to be brought into them (though many rural shrines had kept their sacred character and maintained their rituals even through the time of collapse). The idea of the temple was imported from the older civilization of the Near East. Because of the central importance of religion to the creation and existence of cities, the temples were built in the very hearts of the cities—either on the agora (business district) or the acropolis (fortress), the places that in modern society would be reserved for government or commercial buildings as the most important public structures.

When a temple was built, its sacred precinct was cut off from ordinary space, usually by a wall, and purified through ritual. The space was further sanctified by a foundation deposit of holy objects buried under the floor of the new temple. A sacred zone such as this was created so that sacrifices could be performed within it. This ritual was performed at an altar that stood in the open air and used the facade of the temple as a backdrop. The interior of the temple usually housed a statue of the god but was rarely entered, since the rituals were conducted outside.

When the temple of Athena Pronoia (Athena of Forethought) was begun at Delphi in the eighth century B.C.E., the

foundation deposit included not only the bones of sacrificed animals but also a cache of Mycenaean religious statuettes (dating to about 1600–1000 B.C.E.) that had been hoarded and preserved for centuries, ever since the collapse of Mycenaean civilization. In this way the sacredness of the past was used to create a new sacred institution, which was different from what had gone before yet could not be separated from tradition. This is emblematic of what happened all over Greece in the Archaic Age as Greek civilization renewed itself.

A Greek god was always the god of a particular place. Athena, for example, was not simply one goddess but had a different aspect in each cult place. In Athens alone there were temples of Athena Parthenos (Virgin Athena), Athena Nike (Victorious Athena), and Athena Polias (Civic Athena)—to name only the most important—each with its own form of worship, sacred calendar of festivals and sacrifices, and myths.

The Greeks recognized themselves as a people bound together by common culture and language, and especially by common religion, above the level of the city. When the city-states were established in the Archaic Period, national religious institutions also came into existence, what modern scholars call "Panhellenic" shrines. These sacred sites were available to all Greeks (*pan* meaning "all" and *Hellenes* being what the Greeks called themselves) and helped form a Greek identity.

The most important such shrine was Delphi, where a priestess known as the Pythia gave oracles from the god Apollo. In legend Delphi had originally housed a temple of the earth goddess Gaia, but Apollo had slain the dragon (*python*) that guarded it and took the temple for himself. A stone stood near the temple of Apollo, as raised stones did in many Greek sanctuaries. This one was called the *omphalos* ("navel") of the earth because Zeus had released two eagles from the edges of the world at the same time, and this was the spot where they met: the exact center not only of the earth but of the universe. Each Greek city maintained its own treasury at Delphi, which housed the lavish gifts of artworks or precious materials that the city or its citizens might dedicate in thanks to Pythian Apollo.

Greeks had used athletic contests as a form of worshipping the gods since Minoan times. The most famous games were held at another Panhellenic shrine, the temple of Zeus at Olympia (the same Olympic Games that were revived in 1896 C.E. and continue today). These games (beginning in 776 B.C.E., according to tradition) were held once every four years in alternation with others held at Delphi, Nemea, and Corinth. The contests included artistic as well as athletic competitions. Although no cash or prizes other than honor were given, the contestants were not amateurs. Winners usually received valuable rewards from their home cities, and many other contests existed that did award cash prizes, so there was a large corps of professional athletes and performers, some wealthy from this kind of work. The temple at Olympia used a very ancient kind of altar, a simple pile of the ashes of the sacrificed animals that was allowed to build up into a vast mound year after year through the centuries.

View of Mount Olympus, in Attica (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

Other Panhellenic sites dealt with purely personal concerns that were beyond the scope of civic religion, such as healing and salvation. Epidauros in the Peloponnese was the home of the main temple of Asklepios. As a son of Apollo by a mortal woman, Asklepios was technically only a semidivine “hero,” but Greeks soon began to worship him as a god. His priests provided the healing of illness, a subject obviously removed from the collective religion of the city. Patients came to the shrine and slept in the courtyard of the temple overnight. The next morning the priests interpreted any dream a patient might have had and devised a treatment for him or her accordingly. Like many temples, this one had a sacred tree nearby from which offerings were hung—in this case figurines of the patients’ body parts that the god had healed. The temple of the grain goddess Demeter at Eleusis (outside Athens) offered initiation into mysteries that would secure for the participants a kind of personal salvation that would let them partake of the same kind of blessed existence as heroes after death, rather than the near nonexistence Greek believed to be the common end of humankind.

ROME

BY KATIE PARLA

Defining sacred space in ancient Rome was the responsibility of high authorities—first of kings and then later of priests. Both used ritual interpretations of occurrences in the natural

world when creating sacred sites. The myth of the founding of Rome itself by the twins Romulus and Remus describes such an event. Romulus, by interpreting the flight of birds more masterfully than his brother, was able to define the ritual boundary that divided the sacred space of the city from the world beyond. Supposedly he passed this skill and this privilege on to the kings who followed him. Over time, however, the right of establishing sacred areas became the province of priests called augurs (*augures*).

The augurs were one of the main priestly colleges in the augurs Roman state religion. Originally these authorities divined the will of the gods just as Romulus had done, by interpreting the flight of birds. Later in Rome’s history they also interpreted a variety of other natural phenomena: thunder, lightning, and different kinds of animal behavior. By reading these signs—or “taking auspices,” as it was known—the augurs could determine the boundaries of sacred space. Occasionally the signs came unsolicited—for example, the sudden appearance of an eagle over the Capitoline Hill—but more often they were the result of deliberate ritualistic attempts to communicate with the divine world.

In Rome—and later in the territories Rome controlled—the augurs could define several types of sacred sites. One type was the *templum*, a consecrated space or site where the augurs would take auspices. For the Romans a *templum* could be a building, but it could also be plot of ground or even a fixed place in the heavens where signs from the gods might

be read. Hence the word *templum* does not correspond to the modern concept of a temple, though it does have a religious connotation.

The concept of the *templum* was very broad. It covered areas where magistrates could exercise power and therefore included a wide range of government buildings, such as the Curia (Senate house), as well as open spaces of official public assembly on the Roman Forum. The *templum* could also refer to the city as a whole. In this case it was defined by the *pomerium*, a ritual boundary that divided Roman cities from the world beyond. Since the area within the *pomerium* was consecrated space, cremations, burials, military exercises, and other activities deemed inappropriate for a sacred site had to take place beyond it. The authority of a magistrate was no longer valid once he left the sacred space within the *pomerium*, emphasizing the strong bond between Rome's state religion and its political authority.

Another type of sacred site was an *aedes*. This word was applied to any place where a god was believed to dwell, whether an enclosed space or an outdoor area such as a forest, spring, mountain, or lake. An *aedes* did not have to be large or the god a major one. Many Romans kept small altars in their homes to venerate household divinities, and these altars were considered *aedes*. Minor deities, such as the female nature divinities known as nymphs, were believed to inhabit

countless outdoor settings. For instance, the nymph Albunea was worshipped at a sulfurous spring near Tivoli. The legendary she-wolf that suckled Romulus and Remus as babies was worshipped at a cave on the Palatine Hill. During Rome's republican era (ca. 509–27 B.C.E.) and through much of the existence of the Western Roman Empire (27 B.C.E.–476 C.E.), temples and altars were erected to divinities throughout Roman territory, often replacing the outdoor settings of archaic traditions.

The layout of major religious and ritual sites evolved during the course of Rome's history. The earliest evidence for sacred sites on the Roman Forum and the Palatine and Capitoline Hills are terra-cotta votive offerings left at a sacred place. A dearth of archaeological evidence makes it difficult to determine the precise layout of these places. During the republican and imperial eras proper temples begin to populate cities, frequently replacing older sacred areas. Contacts with Greece, Etruria, and Carthage influenced Roman temple architecture.

The development of religious structures in Rome began in the sixth century B.C.E. with the Temple of Jupiter Optimus Maximus on the Capitoline Hill. According to legend the king Tarquinius Priscus (r. 616–578 B.C.E.) located it on a site deemed appropriate by the augurs. Its style and decoration were heavily influenced by Etruscan architecture, and it in turn influenced early republican temple design. During the mid- to late republic Rome increased its contact with Greece through alliances and conquest and began to assimilate Greek gods into the state religion. Consequently Roman temples emulated Greek architecture.

During the republic private individuals such as victorious generals or politicians commissioned temples. Accordingly, these structures were less majestic in scale than the imperial structures that followed them. During the empire the Roman state and the imperial family commissioned sacred sites in monumental dimensions. The *aedes* of the empire served not just as holy places but also as symbols of Rome's power and the relationship between the gods and the state.

With the growth of Christianity in Rome and its empire new ideas about sacred places and sites emerged. In the fourth century C.E. the importance of Rome's traditional sacred sites diminished as Christianity spread and ultimately replaced the older state religion. To Christians pagan temples were not sacred areas, and with the end of the old religion the *pomerium* was no longer respected, and *templum* and *aedes* were pillaged, turned to other uses, and neglected. For Christians sacred areas included sites of martyrdom and pilgrimage, the locations of holy relics such as saints' bones, and the burial sites of saints and martyrs. During the first to fourth centuries worship, catechism, and baptism took place in small community centers, often apartment buildings or converted villas, rather than in large churches. Even in such rudimentary sanctuaries as these, however, some delineation of sacred and nonsacred space existed. For example, since unbaptized individuals could not enter the places of worship, baptister-

Roman gold ring bought by a pilgrim and showing the Temple of Aphrodite at Palaepaphos (ca. 150–250 C.E.), made in Cyprus and found near Koskieni, Rhodes (© The Trustees of the British Museum)

ies had to be built beyond the consecrated space. During the reign of the emperor Constantine (r. 306–37 C.E.), Christians began erecting the first large sacred buildings of their own, including several on the sites of martyr cults and burials.

THE AMERICAS

BY ALESSIA FRASSANI

Sacred sites in the ancient Americas were connected with the natural world and deeply rooted in the surrounding landscape. Either man-made or natural, sacred sites reflected AmerIndian cosmology that considered natural forces a manifestation of the divine. The ecological and cultural diversity of the American continent created cultural and subsistence systems that were highly integrated and interdependent. Sacred sites reflected this feature of AmerIndian life and usually attracted visitors from vast areas over periods of hundreds or even thousands of years. Sacred sites, from the northern woodlands to the southern Peruvian desert, share similar characteristics, which include orientation to cardinal points of the compass or landscape, giant effigy constructions, nearness to water resources, and economic importance as trade centers of valued and symbolic items. Religion was a pervasive aspect of AmerIndian daily life and could not be separated from economic activities. Religion and ritual, including pilgrimage to distant places, was an important part of the increasing social complexity that was developing during the rise of intensive agriculture in the ancient period.

In North America the earliest sacred sites recovered are related to the cult of the dead. The so-called Mound Builders left impressive man-made constructions throughout the eastern and midwestern woodland region of the present-day United States. These mounds, large and low, sometimes conical in shape, are most commonly found along the meanders of the Ohio, Illinois, and Mississippi river drainages, from the Gulf Coast to the Great Lakes region. These places were used and visited for generations before being eventually abandoned. People made special travels to these places to bury their dead. (No evidence of residential settlements has been found close to these mounds.) Once there, the pilgrims engaged in elaborate funerary rituals that probably lasted for several days. The mounds' closeness to the transportation system of the rivers and their visibility from afar, in an otherwise featureless landscape, made them significant and helped spread the cult of the ancestors over wide areas.

The mounds take different shapes. The Hopewell of south-central Ohio (ca. 200 B.C.E.–400 C.E.) created earthworks in the shape of connected rectangular and circular enclosures. They served as plazas for large public gatherings that were probably ceremonial. The Hopewell followed a tradition and geography of sacred places that had been previously established in the region. Serpent Mound, in Ohio, was long thought to be an Adena culture (1000 B.C.E.–200 C.E.) site because of ancient burials found nearby. Recent excavations, however, proved that the mound was built at least by

the end of the Hopewell culture. The mound takes its name from the serpentine shape that mimics the flow of the nearby river. Burials and other signs of occupation were found close to the mound, but not on it, indicating that Serpent Mound was visited only occasionally. Among the vast quantities of exotic materials found in the burials, a testament to the wide-reaching wealth accumulated by the deceased, are effigy pipes carved in the shape of birds, fish, and mammals. They were used to smoke tobacco, a ceremonial activity that linked the mundane world to the spiritual one. The animals represented may be mythical founders of clans, and the pipes may have been used in rituals to the ancestors during family burial rituals.

In Mesoamerica the earliest sacred sites either mimic or decorate natural features of the landscape, such as mountaintops or caves, where water supply is generated. Concerns for the crops and general well-being were primary motivations for the visit and care of sacred places. The cave of Chalcatzingo in the modern state of Morelos in central Mexico, dates to the Middle Formative Period of Mesoamerica from between 700 and 500 B.C.E. Chalcatzingo carvings are in an Olmec style, the major civilization of early ancient America settled in the Gulf Coast. Whether or not the site was actually built by foreigners, Olmec-related style and symbols at Chalcatzingo reveals cultural interaction between the different areas of Mesoamerica in a period of economic and religious change. The site is located on and around a mountain peak of the same name. The most famous carving depicts in low relief an enthroned character wearing elaborate attire. His headdress is tall, and he is holding a horizontal bar, symbol of authority, in his arms. He is shown in profile inside a cave, from which large volutes, or scroll-shaped forms, are emanating. The cave itself is an animal creature, as the oval eye on top indicates, while the scrolls can be interpreted as signs of water or of speaking. The enthroned character is perhaps an oracle or ruler in charge of bringing water to the region.

Teotihuacán, the most important urban center in Mesoamerica between 50 and 650 C.E., is dominated by the impressive Pyramid of the Sun. Located along the main axis of the city, the pyramid was both a symbolic and material manifestation of the power of the city throughout Middle America. The pyramid duplicates a mountain looming in back of it, called Cerro Gordo. In this way the gigantic monument is connected to its natural surrounding. In 1971 a man-made tunnel leading to a multichambered cave was discovered under the pyramid. Although it is natural, this cave has been remodeled by humans and was visited centuries before the pyramid was built. Water-related rituals took place inside this cave and contributed to making the place sacred enough that eventually the monumental pyramid was built there.

In South America sacred sites played a major role in the cultural, political, and religious unification of the Andean, coastal, and tropical regions. The earliest sacred place of interregional importance is Chavín de Huántar in the northern Andes, Peru. Set between two mountain ranges where

two rivers come together, Chavín is strategically located at the gathering point of natural forces and was visited and celebrated in an effort to maintain a prosperous balance of these forces. It was at the center of a pilgrimage network that extended for over 200 miles in every direction. The most sacred and secret place at Chavín is an inner chamber where hides the so-called Lanzón, a vertical stone in the shape of a knife depicting a mythical fanged creature. Archaeologists have found that openings inside the temple were carefully designed to create sound and light effects produced by water and wind.

In the southern desert coast of Peru hundreds of earth drawings, or geoglyphs, have been found, created between 200 B.C.E. and 600 C.E. by the Nazca people. These geoglyphs were created by removing the upper layer of pebbles and revealing the underlying darker stones. Their designs range from straight lines and geometric shapes to animal representations. The giant drawings can be seen only from the air and are located away from residential dwellings. Contemporary inheritors of the Nazca region still walk in processions along straight lines in the desert. Their pilgrimage is meant to symbolically connect water resources from the sea and mountains in this harsh environment, one of the driest places in the world. Drawings of monkeys, fish, and other exotic animals from the ocean and the Amazon forest lead scholars to believe that the Nazca Lines were sacred enclosures celebrating the economic and natural interdependence of the Andean area.

► scandals and corruption

INTRODUCTION

Bribery, corruption, and scandal were as much the part of the ancient world as they are of the 21st century—and of the centuries between. One problem historians have in reconstructing the nature and effects of corruption and scandal is that written records from the ancient world are often incomplete or nonexistent. Without a free press serving as watchdog over the activities of kings and queens, nobles, civil servants, and institutions such as churches, no one chronicled these events objectively. The written record in many cases is limited to royal decrees, letters, legal judgments, and similar documents—all written from the viewpoint of those in power or from the viewpoint of their political opponents. Court historians and similar figures in the employ of rulers were paid to enhance the reputation of their masters, not to expose scandal and corruption. Accounts provided by outsiders and later historians may have been colored by prejudices, oral legend, and incomplete information.

Bribery was undoubtedly commonplace in the ancient world. People struggled to survive and accumulate some measure of wealth that would secure their old age and give them something to leave to their heirs. In empires throughout the world, legions of inspectors, civil servants, tax collectors, surveyors, and other public officials were in positions to accept bribes to allow an illegal activity to go unnoticed, to modify records in someone's favor, to alleviate a tax burden, to extend the boundaries of a person's property, and so on.

Corruption in the ancient world often centered on the ruling classes. A common feature of government in the ancient world was the dynasty, where rulers inherited the position of king, queen, or emperor. Conflict arose, however, when the line of succession was unclear (for example, when a king died without a male heir), when the inheritor of a throne was mentally unbalanced or a minor, or simply when an individual or group wanted to seize the throne and the power that went with it. Sometimes the corruption resulted from power struggles among groups. The ancient Chinese Han Dynasty (202 B.C.E.–220 C.E.), for instance, fell because of corruption and infighting among powerful groups, including the clan to which the Han empress belonged and Confucian scholar-officials at court.

Finally, some ancient rulers themselves were simply corrupt and ruled entirely with a view to enhancing their own power and wealth rather than the welfare of their people. The ancient Roman emperor Nero (37–68 C.E.) is a good example—though much of what is known about Nero's life was written by his political rivals, who characterized him as a tyrant and even as insane. Nonetheless, many historians believe that in the year 64 Nero deliberately set the great fire of Rome that burned on the nights of July 18 and 19, destroying much of the city, because he wanted to rebuild Rome as a monument to his personal greatness. At a time when rulers held absolute power over their subjects, the potential for corruption and tyranny was enormous.

AFRICA

BY KIRK H. BEETZ

Most of ancient Africa was preliterate, and such matters as scandals and corruption are usually transmitted from the past via written records, leaving much of Africa a blank for the subject. Further, most of the writings of the major civilizations of Kush and Axum are in languages that have yet to be translated, leaving just the Kushite texts that were written in ancient Egyptian and the writings of outsiders, mostly Greeks, for records that modern readers consult.

A scandal that is still renowned involved Queen Makeda (r. ca. 1005–ca. 955 B.C.E.) of Axum, a kingdom of Africans and Sabaeans, a people who populated the southern Arabian Peninsula. The name Sheba is derived from Sabeans, and Makeda was probably the queen of Sheba mentioned in the Old Testament. The details of her meeting with King Solomon have been distorted over the centuries by writers seeking to modify the tale to support their particular social, political, or religious prejudices. In essence, the story says that a merchant named Tamrin from Axum ventured to King Solomon's court in search of trading opportunities and was very impressed by the king's display of wealth. He reported what he saw to Makeda, who chose to see for herself the wonders of Solomon's court. Solomon was enamored of her beauty and tried to seduce her. She refused his advances. Solomon made a bargain with her: They would sleep in separate beds in the

same room, and if Makeda took nothing without his permission, he would leave her alone, but if she did take something, she would have sex with him. He served her very spicy foods that evening, and she awoke very thirsty that night. Finding a glass of water on a table in the middle of the room, she drank from it; in an instant, Solomon was up, pointing out that she had no permission to drink. Her protests that water was common and surely not part of their bargain were to no avail. Makeda returned home and gave birth to Solomon's son.

The scandal endured during the life of Makeda and Solomon's son. When he was grown, the son visited Solomon, bringing a ring that Solomon had given Makeda. Solomon celebrated the arrival of his son and gave the young man the name Menelik. Solomon asked Menelik to stay with him and, as his eldest son, to become the next king. Menelik refused, insisting that he return to his mother to become the next monarch of Axum. Solomon declared that the eldest sons of his ministers were to go with Menelik and serve as his chief advisers. These eldest sons resented this order very much. For revenge, they sneaked into the temple room where the Ark of the Covenant was stored and replaced it with a copy, taking the original with them. It was not until Menelik and his companions reached Egypt that the theft was discovered. Solomon sent an army in pursuit of Menelik, but by the time the army reached Egypt, Menelik and the Ark had left Egypt. The army returned home, saddened by its failure, and Menelik was delighted when he learned of the theft. According to Axumite tradition, the ark has resided in or near Axum ever since.

How much of this entire story is true is open to debate. For instance, Axum's territory included the Sabeans region of the southwestern Arabian Peninsula as well as much of eastern Africa, and Solomon's army could have reached the Sabeans region without much trouble and could have waged war on the Axumites there, but it did not. Nevertheless, even if only the barest part of the story is true, it would likely have been a big scandal in Axum, where the queen was expected to remain a virgin until marriage. Further, it gave Axumite Christians a national tradition to cling to during the years in which they were cut off from other Christian nations by the pagans and Muslims of the medieval era.

The ancient African civilization of Kush had its own scandal of corruption that reshaped its national traditions: Egypt had long taken children of Kushite nobility and raised them according to Egyptian customs, especially Egyptian religious beliefs, hoping to make the kingdom of Kush a friendly ally. The children were treated like nobility, and they did indeed return home as practitioners of Egyptian religion when they were adults. As a result, when Egypt fell apart in the ninth century B.C.E., the kings and queens of Kush regarded themselves as the saviors of the Egyptian way of life and eventually invaded Egypt, founding the Twenty-fifth Dynasty of Egypt (770–657 B.C.E.).

At that time Napata was the capital of Kush. Jebel Barkal was a sacred hill or bluff on the other side of the Nile from

Napata, where a great religious complex had been built. The chief temple was dedicated to Egypt's chief god, Amun, who was also at that time Kush's chief god. The queens of Kush would go into the depths of the temple of Amun to give birth, implying that Amun was the father of their children, linking themselves with a tradition of Egyptian religion that Amun recognized his children in their wombs. An oracle also resided in the temple. A statue of Amun spoke to people, telling them the god's will. Priests conveyed Amun's words to the outside world. Thus, the priests had great power. Their temples and dwellings at Jebel Barkal were covered in gold, silver, and gems. Hallways were dazzling with their glittering walls and many statues of Egyptian gods. The statue of Amun even foretold when kings were to die. In fact, the priests actually ordered a king to commit suicide, on Amun's orders, and he obeyed.

Then came King Aspelta (r. 593–568 B.C.E.). The outset of his reign must have been very challenging because a revitalized Egypt had sent an army into Kush, and it had sacked Napata in about 593 B.C.E. Then the priests of Amun declared that the god had said Aspelta was to die. Perhaps not as gullible as his predecessors, or perhaps not as faithful, Aspelta not only refused to commit suicide but also conspired with one of his generals to have the buildings and caves of Jebel Barkal seized and the priests killed. Apparently, nearly every priest was killed, helping to end the importance of Jebel Barkal. Perhaps the invasion by Egypt had soured public sentiment against all things Egyptian enough for Aspelta to get away with such sacrilege. He moved his court to Meroë, farther south along the Nile, formerly an Egyptian military outpost but by then a thriving trading center. He and his successors promoted a lion god as their new chief god.

EGYPT

BY AMR KAMEL

Ancient Egypt, like any other place ancient or modern, was not an ideal society. People who engaged in bribery and all manner of crime and corruption existed alongside people who were humble, law-abiding, and religious. The Egyptians attempted to hold their society together using a group of fundamental principles called *maat*, which eventually came to represent the cosmic order as well, since Egyptians believed their land to be the center of the world. Maintaining *maat* was the major duty of Egyptian kings, and it was the subject of many ancient Egyptian teachings. Any abuse of power by an official could be controlled only if there was ethical awareness and a sense of loyalty in the community. When these faltered, officials increasingly took advantage of their positions, especially when the purchase of offices and the abuse of oracles were concerned. These abuses become apparent notably from the Nineteenth Dynasty (ca. 1307–ca. 1196 B.C.E.) forward.

Desiring reform, Horemheb, the last king of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.), conscientiously enforced *maat*, issuing a royal decree against bribery and cor-

ruption that can still be read on the 10th pylon at Karnak. In the decree Horemheb states that corrupt behavior on the part of the authorities represents an offense and warns that these offenses “from today onward” will be punished by such penalties as flogging and cutting off of noses and, in some cases, will require the redress of any damage inflicted on an individual. He advises his newly appointed officers: “Do not compromise yourselves with people! Do not accept rewards from others!”

Nonetheless, such instructions did not guarantee a peaceful life. Ancient Egyptian literature refers from time to time to scandals, corrupt people, and other illegal behavior. The earliest example was mentioned in the biography of Weni, an important Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) officer. There appears to have been an unsuccessful conspiracy against Pepi I plotted by one of his numerous wives. Weni seems to have been singled out to hear about that confidential matter when he was in the royal women's quarters. From the same Sixth Dynasty period, a scene in the Saqqara mustaba of the vizier Khentika depicts the judgment and corporal punishment of five district governors brought before the vizier and charged with corruption in collecting taxes. All were punished swiftly and harshly.

Egyptian texts do not mention other cases of immoral behavior until late in the New Kingdom, when abundant evidence of corruption appears, possibly because of a deficiency in the administration. The inscription of Mes, engraved in his tomb at Saqqara from the Nineteenth Dynasty, describes a lawsuit about the ownership of some fields inherited by various members of the family to which Mes belonged. The text refers to a certain Khay, who originally was not a family member but who claimed his right based on forged documents that he submitted to the highest law court in Egypt, presided over by the vizier who pronounced his judgment in favor of Khay.

A literary document dating from the late Nineteenth Dynasty describes the career of a corrupt man named Paneb—the foreman of a group of workers at Deir el-Medina—who, with his son Aapehti, committed several crimes. Paneb is accused of having obtained his position by bribing the vizier. Paneb stole some statues from the temple of King Seti I, with the intention of decorating his own tomb. He then went on to murder his adoptive father, Neferhotep. He was arrested and sent for trial before the vizier Amenope. Nonetheless, by the exercise of some influence or chicanery, he was able to secure his acquittal and not only obtained the murdered Neferhotep's position but also eventually had himself buried in a handsome tomb. He and his son made love with five of his colleagues' wives and their daughters. He was also accused failing to pay for clothes that had been made for him and of drunkenness.

In the reign of Ramses III legal documents describe a trial of persons who planned the murder of the king. The principal defendant was the secondary queen Tiy, who apparently wanted the throne for her son Pentewere. The jury was composed of 14 officials, four of whom were convicted of having sexual intercourse with the wives of some of the defendants and were accordingly deprived of their titles and punished

with mutilation. In year 17 of the reign of Ramses III a gang was being shortchanged by a greedy official who used undersized measures to distribute rations and then presumably kept the difference for himself. The matter was brought to the attention of Akh-pet, another scribe of the vizier, who checked the grain measure and found that it held 38 *hin* instead of the standard 40 (ca. one-half bushel). Thus the workmen had been receiving 5 percent less than their due.

The famous Tomb Robbery Papyri also describe the looting of graves and temples during the reigns of Ramses IX and XI, sometimes with the complicity of officials who took bribes to keep silent and release those who were under arrest. Another mid-Twentieth Dynasty (1196–1070 B.C.E.) papyrus records charges of large-scale embezzlement and misconduct against personnel of the temple of Khnum at Elephantine, including an unnamed priest. Another papyrus describes the crimes of a certain Djehutihotep, the chief guard of the Karnak temple. Since this was arguably the most sacred public place in Egypt, his crimes provide evidence of the extent of negligence and corruption at the highest levels of the Theban administration.

In the prayers of ordinary Egyptians, preserved in letters and documents from the village housing the workers at Deir el-Medina, there are pleas to the gods for justice after all other doors were closed to them, pleas to hear their petitions, and pleas to ease their suffering from the rapidly increasing corruption in their society. In one prayer, Amun is “the vizier of the poor; he does not accept bribes from the guilty, he does not speak to the one who witnesses, he does not look to (favor) the one who makes promises.” In another source, a lady invokes Amun to protect her from gossip and rumors. Although these documents portray the dark side of ancient Egyptian society, there were nonetheless ordinary good people who attempted to bring up their offspring with ethics and good principles.

THE MIDDLE EAST

BY HEATHER D. BAKER

In Mesopotamia political power was concentrated in the hands of the ruler. The surviving sources for the exercise of royal power therefore have to be treated with caution because they almost always originate with the king and his court; independent testimony is rare indeed. The written documentation available about political scandal at the highest level tends to concern episodes when the transition from one ruler to the next was contested or when a king saw fit to condemn the actions of his predecessor or both. In such cases as these the king whose account survives may have been motivated by a desire to enhance his own reputation at the expense of a previous ruler by seeking to question the legitimacy of his reign or his actions while in office.

The circumstances surrounding the death of the Assyrian king Sennacherib (704–681 B.C.E.) reflect one such instance of a troubled succession from one ruler to the next. Many de-

tails of what happened are still unclear, because the cuneiform sources are fragmentary and difficult to interpret. Still, it is clear that there was a plot to murder Sennacherib, who had taken the unusual step of naming his younger son, Esarhaddon, as his successor. Esarhaddon's case may well have been promoted by his mother, Naqia, a powerful woman well versed in palace intrigue. Following the death of his father, while Esarhaddon was in hiding for safety, his older brothers fought among themselves for the throne, but on his return Esarhaddon defeated them in battle. He took the throne and ruled for 11 years (680–669 B.C.E.).

Another political scandal, of a rather curious nature, involves the Babylonian king Nabonidus (r. 556–539 B.C.E.), who left his country to live in apparently self-imposed exile in Taymā' (in Saudi Arabia) for 10 years. Although he went to Arabia in the role of military conqueror, this does not explain why he remained there for so many years, leaving his son Belshazzar to rule in Babylonia in his stead. A conventional view holds that the Babylonian priesthood opposed his unorthodox religious beliefs, especially his attempts to promote the moon god Sin at the expense of the head of the Babylonian pantheon, Marduk. Nabonidus's own inscriptions hint at such a background to these events. His successor, Cyrus the Great, the Persian conqueror of Babylonia, certainly portrayed Nabonidus as an oppressive ruler who did not worship Marduk. Cyrus claimed to have been chosen by Marduk and to have restored Babylonian religious life to the peaceful state it had enjoyed before Nabonidus disrupted it.

A more informal insight into the affairs of state can be found in the correspondence kept in the royal archives. Of course, it has to be borne in mind that letters written to the king were intended to promote the cause of the sender by casting him in a favorable light, sometimes at the expense of his rivals. Sometimes the letters contain reports of alleged injustice; one scholar, for instance, writes to the king complaining that a local governor had taken away a field of his. It seems to be expected that the king will intervene personally in cases such as this where officials abused their power.

The sources for information about economic scandal and corruption are of a rather different nature. Some of the Laws of Hammurabi are concerned with the misappropriation of property, both private and institutional, and with fraud. They include, for example, the case of a (female) innkeeper who gives out short measures of beer. They also set out regulations governing the conduct of trading ventures so as to protect the merchants from fraud.

The great palace and temple institutions of the ancient Near East were extremely bureaucratic, and much effort was expended on controlling and recording the movement of goods between different establishments and their responsible officials. Precious items could be stored in sealed containers or rooms. Sealing was the ancient equivalent of a locking mechanism. The official in charge would impress his seal upon a lump of clay applied to the door bolt. When the room needed to be opened, the sealing would be broken

Stone panel from the palace of Sennacherib, Nineveh, northern Iraq, Neo-Assyrian, about 700–695 B.C.E.; this panel shows soldiers of the royal guard; the king's death was thought to have been the result of a plot within the palace to murder him. (© The Trustees of the British Museum)

in front of witnesses. In this way it would be immediately clear if someone had gained unauthorized access. Livestock could be branded in such a way that marked them as temple property, and even the temple dependents who formed part of its workforce could be marked to make it difficult for them to escape.

Thus the institutional administration contained inbuilt deterrents against fraud and theft, but they could not be entirely eliminated. Normally it is difficult to extract information on these subjects from the cuneiform tablets that made up the institutional archives. To shed light on them, documents that tell a story rather than simply recording the transfer of commodities are needed. In records of accounts there are many cases where the figures do not add up, but it is impossible to prove that these represent a deliberate attempt to defraud rather than simply errors on the part of the scribe.

Suitable sources include records of lawsuits and letters containing anecdotal evidence of corruption. Fortunately, some of the surviving archives contain material of this kind. The Eanna temple archive from Neo-Babylonian Uruk is

one; it contains many documents recording cases brought before the temple authorities. Most involve relatively minor episodes of theft and embezzlement. There was one particularly persistent offender, a man named Gimillu. His career is documented over a period of around 20 years; at first he was in charge of the livestock owed to the temple, and later he was responsible for the income from the temple's agricultural land. Gimillu misappropriated temple property on a large scale; even after being convicted and fined heavily and then trying to abscond, he continued to work for the temple in a responsible position. There does seem to have been a high degree of tolerance toward convicted thieves and fraudsters. From the private sphere in the Neo-Babylonian Period (625–539 B.C.E.) there is a court record concerning attempted extortion by a man who tried to pass off a forged cuneiform tablet. When challenged by the intended victim, he snatched the clay tablet from his victim's hands and tried to destroy it by chewing it. Other records reveal that even though he was found guilty, the villain continued to conduct business. The scribe who wrote the fake tablet was also liable to be punished when caught.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Although Confucius (551–479 B.C.E.) believed that China had an ancient past that featured good and just governments, it seems that no ancient Chinese government at any time was free of corruption. Written records for the Shang (1500–1045 B.C.E.) and early Zhou (1045–256 B.C.E.) dynasties are scant, but those that exist suggest that corruption among military leaders and government officials was constant throughout the history of ancient China. One corrupt practice involved the trading of women by powerful men. During the Six Dynasties (220–589 C.E.) women were used as bribes, and if the bribes persuaded generals to switch sides during a war, the fates of millions of people changed based on a man's lust for women. Many military leaders were not susceptible to being bribed with women but could be bribed with gifts of horses or money. Thus, the corruption of some Chinese leaders reduced women to the level of horses, and for the sake of their bribes they betrayed their province or country, their lord or king, and broke their oaths of loyalty. Sometimes tens of thousands of people died when the man who was supposed to protect them changed sides for a bribe and killed them.

Many historians consider the era of Confucius to have been notably corrupt. Most of the people of China were peasants who were forced to work every day in their fields. From the Zhou Dynasty through the end of the ancient era kings occasionally tried to redistribute land to peasants, but members of the nobility would confiscate land or loan peasants money at interest rates that were impossible to repay. They would then take the peasants' lands and force the former owners to work the lands for the profit of the nobles, making the peasants slaves in all but name.

A government that had intended to end corruption became one of the most corrupt of all. This was the government of the Qin Dynasty (221–207 B.C.E.), which imposed the legalist philosophy of government. Under legalism, every action was either sanctioned or forbidden by law. The idea was to regulate life so that everybody did what they were supposed to do and never did what they were not supposed to do. The laws were so strict and so numerous that people could not help but break a few every day, and punishments were harsh. Even slight offenses could result in a sentence of mutilation and several years of hard labor on the government's construction projects. Emperor Qin Shi Huangdi used the laws to force hundreds of thousands of people to work on the Great Wall and elsewhere, where many died from the harsh conditions.

When the emperor died, his advisers Li Si (ca. 280–208 B.C.E.) and Han Fei Zi (d. 233 B.C.E.) pretended that he was still alive and sent his eldest son a phony message ordering him to commit suicide. Prince Fusu ignored the pleadings of his father's chief general to make sure the order was real before he killed himself, but he committed suicide anyway. Prince Huhai became emperor, controlled by Li Si and Han Fei Zi. The corruption of this period was so severe that the Qin Dynasty was already crumbling when rebels toppled it.

During the Han Dynasty (202 B.C.E.–220 C.E.), Confucian scholars were allowed to try to impose a more benevolent form of government. It proved impossible to stamp out bribery, especially in remote provinces. The court system was corrupted by wealthy criminals who paid poor people to serve their sentences for them. In cities young people sometimes formed gangs and beat, killed, and robbed people. The government tried to eliminate the gangs with diligent police work and informants, but the police were too often bribed. Tax collectors frequently took more than the law allowed and kept it for themselves. The punishment for this practice was death, but it was common enough to help inspire a peasant revolt in 14 C.E.

Throughout the recorded history of India corruption was a problem. Indian literature, folktales, and historical writings from about the first century C.E. onward feature many tales of corrupt practices, and historians have found accounts in records from as early as the 300s C.E. In the court system witnesses often slanted their testimony in court to favor whichever side was paying them. This meant that innocent people were often convicted and punished for crimes. To make matters worse, the convicted criminal's spouse and children were imprisoned as well. They all were bound by the ankles amid filth and beaten and tortured two or three times a day.

Gambling and prostitution were common. Gambling was forbidden by Hindu religious rules of conduct, but it was usually sanctioned and regulated by the government. Gamblers often lost their family's fortune, forcing them to become slaves or to spend their lives trying to pay their debts. Sometimes a gambler made a fortune, which was known as "black" money, as opposed to money earned honestly through government service or a trade.

Prostitutes almost always associated with such criminals as con artists, burglars, and extortionists, so the government often used them as spies on criminals. A prostitute could earn a good name this way because she worked for the secret police, making her work in the public interest. Prostitutes varied from sickly streetwalkers just trying to earn enough for food to women who were well trained from childhood to seduce rich men. The latter group were well educated, had excellent taste, knew what to say on every occasion, and were gifted in all the various sexual acts that would ensnare men. The education of prostitutes was regulated by the national government, and their teachers were often paid by the government because the work of prostitutes was considered a contributing factor in the health of the nation. When beginning their careers in brothels, they were taught to be without pity; their object was to seduce men, discard them, and move on to the next rich man. Occasionally a prostitute became a man's wife, and typically she worked extra hard to be a good wife.

Sex scandals sometimes shaped India's history. For example, there is the legendary account of Amrapali, a famous courtesan in the Licchavi Republic in northern India around 400 B.C.E. She was so successful that she had become the land's leading lady. King Bimbisāra of Magadha, an enemy of the Licchavis, sneaked into their capital of Vaisali and spent a week undetected enjoying the company of Amrapali. Their pride injured, the knights of Licchavi attacked Magadha with great vigor and sparked a war that Magadha won, which helped to propel Magadha toward building an empire that eventually ruled most of India.

Perhaps equally scandalous was the death of Bimbisāra, who was starved by his son Ajatashatru (fl. 300s B.C.E.). This seems to have been common among the monarchs of ancient India. The king was alleged to have chosen to starve himself to death, but usually a scheming son was responsible. When Ajatashatru's old enemy Prasenajit, king of Koshala, was overthrown in his turn by his son, Prasenajit fled to Ajatashatru and then died of exhaustion. This gave Ajatashatru an excuse to avenge Prasenajit, and he attacked Koshala, ending its existence.

Very little is known of scandals and corruption in ancient Japan, but there are hints from Chinese observers. One such was an ambassador, Zhang Zheng, to Queen Himiko's court in the 200s B.C.E. Himiko lived to a great age but apparently died without a successor. Her kingdom was called Yamatai and was composed of about 50 states, each with its own chief. After her death the chiefs selected a man to replace her. According to Zhang Zheng, the king's rule was marred by constant murders and inept government administration. Zhang Zheng claims that after two years he helped engineer the ouster of the king and his replacement by a 12-year-old girl whose name may have been Inoye.

The rest of Asia and the Pacific's cultures probably had their own forms of corruption and scandal, but archaeologists and historians are making slow progress in uncovering evidence for such practices in central Asia, Southeast Asia,

Korea, Australia, and the Pacific Islands, with most records appearing as inscriptions on public monuments such as megaliths and temples—places where the people who erected them were unlikely to confess their misdeeds.

EUROPE

BY BRADLEY SKEEN

The peoples of Europe living outside the Greek and Roman worlds in a region that scholars often call temperate Europe did not leave behind any significant written records. What is known about their public affairs, including what they considered scandalous, comes only from Roman historians. Of these historians, Tacitus (56–117 C.E.) is the most important. Although he wrote during the Pax Romana, the height of the Roman Empire's power and prosperity, he was deeply dissatisfied with the political and social life of the empire. Much of his criticism is indirect, made in connection with Roman policies in temperate Europe. He denounces the decadent and politically and morally ineffectual life of Roman aristocrats by implicitly contrasting that life with his exaggerated account of the virtues of the Germans in his *Germania* (Germany), a work devoted to the national character of the Germanic peoples. In his *Annales* Tacitus openly criticizes the cruelty deemed necessary for maintaining imperial power in his famous aphorism, "They make a deserted land and call it peace!" referring to the Romans' tactic of slaughtering civilians and warriors alike in their campaigns in Europe.

Along with his praise of the Germans, Tacitus regularly describes German kings and chiefs as betraying the cause of German nationalism, which he considers they should have taken up in order to resist the decadent influence of Rome. He presents the local leaders as bribed and bullied by Roman officials and at the same time greedy for Roman luxuries. He sees these weaknesses on the part of German leaders as scandalous. Tacitus develops the scandalous weakness of German leaders as a literary theme to be used in the criticism of his own culture. What he writes cannot be accepted at face value as objective fact or even as a representation of how things might have seemed to the Germans themselves. He never considers alternative interpretations: for example, that the people outside the Roman Empire might have wanted the peace and prosperity that existed inside the empire in order to make their lives better lives. This very desire was certainly present in temperate Europe, as is seen from the works of a later Roman historian, Ammianus Marcellinus (ca. 325–391 C.E.). Ammianus makes it clear that when the German tribes invaded the Roman Empire beginning in the fourth century C.E. (eventually leading to the collapse of the Western Roman Empire), their initial goal was simply to be allowed to live inside the empire to gain protection from Huns and other tribes pressuring them from the East.

Julius Caesar (100–44 B.C.E.), in his account of his conquest of Gaul, establishes the stereotype of the tribal peoples of temperate Europe when he writes that they possess some

kind of innate virtue—characterized as manliness—because they live simple lives devoted to subsistence agriculture and warfare. This way of life could be corrupted through luxury by contact with Roman civilization into a morally inferior condition characterized as effeminacy. Tacitus takes up this theme. He treats as a social scandal the fact that the virtuous barbarian Germans should become corrupted like the effeminate civilized Romans, treating both Germans and Romans as stereotypes. For example, while the simple German people in the interior knew nothing of gold and silver, those living along the borders of the Roman Empire had been corrupted by the greed and luxury associated with these metals in the so-called civilized world, and this he considers scandalous.

Similarly Tacitus admires the Germans' idea of the sanctity of marriage, making a contrast with the adultery that he finds distasteful in his own society. On the other hand, Tacitus considers the Germans' love of gambling scandalous. He says that it is not uncommon for a German to become a slave by gambling away his own freedom after he has lost all his possessions. There is no way to verify this, but given the criticism of the Roman love of gambling by contemporary Roman authors, this was probably meant to make the Roman reader think of his own culture. Tacitus seems to move into fantasy at the end of the *Germania*, where he claims that the Germans farthest removed from the Roman world are even worse than Romans and are actually ruled by women, a condition that he says is worse than slavery. This must be a reference to the vast influence and great freedom of aristocratic Roman women in Tacitus's own society and not necessarily a true statement about ancient Europe.

Tacitus lived during an era in which the imperial government had curtailed the political power and even the property and freedom of his own senatorial class. Therefore he considered the greatest good for humanity to be freedom, the very thing that he and those like him had lost. Accordingly, he considered the greatest scandal among the Germans to be their trading of freedom to the Roman government for what

Base-silver radiate of Carausius, with the emperors Diocletian and Maximian, Roman Britain, late third century C.E.; in the years 287–296 C.E. Britain had its own emperor, Carausius, who had been accused of corruption and assumed power to save himself from punishment. (© The Trustees of the British Museum)

he thought to be luxury, which he considered trivial, since he and his class had it in abundance.

The last great chance for German freedom came with Armin (18? B.C.E.–19 C.E.). He was a chief of the German tribe of the Cherusci and served in the Roman army as an auxiliary. He became an important Roman ally and was given the wealth and status of a Roman knight, the second-highest position in Roman society. But he rejected all of this to turn on his Roman overlords and used his position to destroy the Roman army occupying Germany by ambushing them in the Teutoburg Forest (near modern Bremen). He fought other successful campaigns against the Romans also, until they abandoned all hope of conquering Germany as a province. According to Tacitus, Arminius boasted of fighting for the freedom of the German nation rather than for his own fame and power.

Tacitus contrasts Armin with Armin's father-in-law, Segestes, another German prince, who remained loyal to the Romans, claiming that this loyalty was in the Germans' interest since it brought peace and prosperity, if not freedom. Tacitus defames Segestes by pointing out that, acting as a coward, he handed over Armin's wife and son—his own daughter and grandson—to the Romans as hostages. Tacitus also relates how Armin fought against other German chieftains who were attempting to establish a united monarchy over all of Germany for the purpose of becoming a satellite of the Roman Empire and how still others offered to assassinate Armin out of servility to the Romans. Finally, Tacitus gives an account of Armin's death in a battle with other Germans who opposed his plans to become king of a free Germany.

While much of Tacitus's information may be factually correct, his interpretation of those facts served his purpose of criticizing his own culture. His writing tells more about what he considered scandalous in Rome than how the Germans themselves thought about the excesses of their political leaders.

GREECE

BY PAUL MCKECHNIE

The national myth of Greece began with scandal—namely, the corruption behind the Trojan War. Three goddesses, quarreling over an apple labeled “for the prettiest” that Eris, goddess of discord, had rolled into a party where she was not invited, decided to parade for a beauty contest. Zeus wisely refused to judge, and Hera, Athena, and Aphrodite were forced to select a mortal judge. They chose Troy's king Priam's son Paris, a foolish young man who was alone in the hills keeping his father's flocks.

When they appeared before him, each goddess proposed a bribe. Hera offered to make Paris a great king, Athena promised to make him a celebrated hero, and Aphrodite, goddess of love, pledged to reward him with the most beautiful woman in the world as his wife. Paris accepted the last offer and judged in Aphrodite's favor. The most beautiful

woman in the world, Helen, however, was already married to Menelaus, king of Sparta. When Paris visited Sparta on his father's business, Menelaus was out of town; Paris, captivated by Helen, whispered, “Run away with me,” in her ear, and she did not hesitate.

Homer's *Iliad*, written in (probably) the eighth century B.C.E., is the tale of the 10-year war fought by Menelaus, his brother Agamemnon, and their Greek army against Troy to get Helen back. There, the personal is the political with no dividing line between politics and war. But Hesiod, another Greek poet, perhaps after 700 B.C.E., refers to a more recognizably “political” scandal in *Works and Days*, his long poem about how to succeed as a farmer. He and his brother, Perses, were supposed to divide the land that their father left them, but (Hesiod claims) Perses took it all—and Hesiod's court case against him went nowhere because of the “bribe-devouring *basileis*” judging it. They expect presents from both sides, he says, but giving a present is no guarantee of a favorable result—though failing to give a present guarantees that you will lose. Reading *Works and Days*, we can hear only Hesiod's side of the story. If Perses could give us his version, we might look at the matter differently.

In his *Histories* the Greek historian Herodotus of the fifth century B.C.E. wrote about many stories of bribery and corruption, both successful and unsuccessful. He insists that the Alcmaeonidae, a noble Athenian family exiled from their home, caused the Spartans to march to Athens in 510 B.C.E. and expel Peisistratus, an Athenian tyrant. The Alcmaeonidae accomplished this by bribing the priestess of Delphi to give oracular answers to the Spartans in which the supposed voice of the god advised them to liberate Athens. The Delphic oracle was so deeply respected that any advice it gave had a good chance of being accepted: It was a matter (the Alcmaeonidae found) of ensuring that the right advice was dispensed.

Less successfully, in 499 B.C.E. Aristagoras of Miletus went to the Spartan king Cleomenes (r. ca. 521–490 B.C.E.) and tried to talk him into supporting the Ionians in their revolt against Darius I (r. 522–486 B.C.E.), king of Persia and their overlord. He showed Cleomenes a map and explained the campaign to him, but foolishly admitted that he was asking the Spartans to travel three months' march away from the sea. Cleomenes told him that this was an unrealistic request; but Aristagoras came back and tried to change his mind with cash, eventually offering 50 talents, which would have been a large sum of money. According to Herodotus, when Cleomenes hesitated, his eight-year-old daughter, Gorgo, said, “Get up and go, father, or the stranger will certainly corrupt you.” He took her advice, and the Ionians had to fight without Spartan help.

In other scandalous stories, Herodotus links the political with the personal. Periander, tyrant of Corinth from 627 to 586 B.C.E., once lost something he had borrowed. Hoping to find it, he sent to the oracle of the dead in Thesprotia to ask the ghost of his wife, Melissa, where it was. The ghost

told Periander's messengers that she refused to answer because she was cold—clothes had been buried with her at her funeral but not burned. (The idea seems to be that unless they were burned, the clothes could not go to the world of the dead.) The ghost added that Periander would know that she was really Melissa because he had put his loaves in a cold oven. When he heard this, Periander remembered that he had had sex with Melissa's corpse after she was dead. He announced to all the women of Corinth that they should come to the temple of the goddess Hera. They dressed as if it were a festival and turned out, but then Periander's guards stripped them naked, and all their clothes were heaped in a pit and burned. Afterward, Melissa's ghost revealed the information Periander wanted. In Book 5 of Herodotus's *History*, Socles, a Corinthian, tells this story and concludes by saying, "This, then, is the nature of tyranny, and such are its deeds." Corrupt governments treat people the way Periander treated the women of Corinth.

At Athens under the democratic government of the fifth and fourth centuries B.C.E. officials had to report to the boule, or legislative council, at the end of their year in office and have their accounts examined. In general, transparency was expected, but the Greek biographer Plutarch (ca. 46–after 119 C.E.), in his *Life of Pericles*, records how in the early 440s B.C.E. the Athenian statesman Pericles bribed King Pleistoanax (r. 459–409 B.C.E.) of Sparta and his assistant Cleandridas to lead their Spartan army home instead of fighting. When Pericles presented his accounts for the campaign, he listed 10 talents mysteriously as "necessary expenses," and the council passed the accounts without inquiring closely.

In the fourth century B.C.E. the growing power of Macedonia placed a strain on Athenian standards of conduct. Demosthenes (384–322 B.C.E.), the leading anti-Macedonian politician at Athens, prosecuted Aeschines in 343 B.C.E. over events in 347 B.C.E., when Aeschines had been part of an embassy sent to King Philip II (r. 359–336 B.C.E.) to administer oaths confirming a peace treaty. Philip cunningly made important gains between when the peace was agreed and when oaths were taken. Demosthenes alleged in his speech "On the False Embassy," in effect, that Aeschines (and other ambassadors) had been bribed to be complicit. Aeschines delivered a counter oration, and the jury acquitted him by a narrow majority. But in 324 B.C.E., when Alexander the Great's treasurer, Harpalus, had run away with 5,000 talents of Alexander's money and come to Athens for protection, Demosthenes was accused by the Athenian orator Hypereides (ca. 390–322 B.C.E.) in his speech "Against Demosthenes" of accepting a 20-talent bribe from Harpalus: Demosthenes was found guilty.

ROME

BY KIRK H. BEETZ

When looking at the great depravity of some Romans, it is worth remembering that Rome did not survive as a culture for over a thousand years because of fools such as Nero (r.

54–68 C.E.); it survived because for hundreds of years it had midlevel civil servants who were dedicated to the welfare of their nation. A multitude of hardworking government employees kept the empire running in spite of the greed, lust, and cruelty of some of its leaders.

The Roman Republic began with a scandal, the rape of Lucretia by Sextus, the son of King Tarquinius Superbus (r. 535–510 B.C.E.). At the time, the Roman army was laying siege to the city of Ardea, and as a game some Roman officers decided they would discover whose wives were the more faithful by paying them a surprise visit in Rome. Of all the wives only Lucretia was doing exactly what she told her husband she had been doing in her letters to him. The officers returned to the siege, but Sextus remained behind and forced himself on Lucretia, who wrote to her husband to tell him. Her husband, Lucius Tarquinius Collatinus, and some of his friends rushed back to Rome where Lucretia explained what had happened, then killed herself. This triggered the rebellion that threw King Tarquinius Superbus out of Rome and began the Roman Republic.

During the centuries after the founding of the Republic, the upper class of Rome, the patricians, who controlled the Senate and were expected to take leadership roles in government, worked hard to maintain their elite status. In the process, some of them engaged in extreme corruption. Magistrates of Italian cities and governors of provinces looted the public treasury. They stole taxes and property and sold free families into slavery for profit. This rapacious corruption reached its peak during the dictatorship of Lucius Cornelius Sulla (r. 81–79 B.C.E.). He was a Roman general who committed a grave breach of public trust by invading the city of Rome with his army.

Sulla had his political opponents murdered and then went on to murder anyone he disliked. He tried to undo reforms that had given power to common people. Among his laws was one that allowed only juries of senators to hear cases of senators accused of crimes. Senators found they could get away with murder, literally, because their fellow senators on the juries were easy to bribe. Among those who profited illegally was the governor of Sicily, Gaius Verres. He and his henchmen stole almost everything that could be moved. It took almost 10 years to bring the Roman legal system back to a condition where a rich criminal such as Verres could be brought to justice. The lawyer and orator Cicero prosecuted him and used the forum of the court to describe the corruption that had infected the Roman government.

The First Triumvirate (r. 60–53 B.C.E.)—Marcus Licinius Crassus, Gnaeus Pompeius Magnus (Pompey), and Gaius Julius Caesar—was formed in part as a way of ending corruption and conflict in government. Crassus died in an eastern military campaign, and Pompey was closely associated with Sulla and some of the corrupt officials who had profited from Sulla's laws. This left Julius Caesar the only leader common people looked to for help. Caesar became dictator in 49 B.C.E. Although he was a tough and sometimes brutal military

THE VILE VERRES

Gaius Verres (ca. 120–43 B.C.E.) belonged to Rome's social elite. He was a political opportunist who supported whatever person had power, first the reformer Gaius Marius and then Marius's enemy Lucius Cornelius Sulla when Sulla invaded the city of Rome. Already Verres was accused of embezzlement, but Sulla protected him. Verres became an assistant to the corrupt governor of Cilicia, Gnaeus Cornelius Dolabella, in 80 B.C.E. In 78 B.C.E. Dolabella was tried and convicted of numerous crimes, but Verres won a pardon for himself, despite having been Dolabella's partner in the crimes, by testifying against Dolabella. He became a government official in the city of Rome, where he used his office to promote the interests of Sulla, who appointed him governor of Sicily in about 73 B.C.E.

During Verres's time in Sicily he made himself not only one of the most corrupt but also one of the most loathed people in Roman history. He organized his administration like a gang of criminals, and there was no limit to his greed and cruelty. He and his henchmen stripped Sicily's temples of their art, especially their statues. Using government authority his gangs broke into private homes and looted them of everything that was valuable. The loss to Sicily was greater than the loss it had experienced in war. Its once-thriving tourist industry collapsed. When people protested, Verres accused them of being traitors and prevented their cases from being sent on to the city of Rome, which was their right under Roman law. He had them tortured and then crucified.

When Verres returned to the city of Rome in 70 B.C.E., Sicilians asked Cicero to prosecute him for his crimes. Cicero chose to use Verres as an example of corruption throughout government, detailing how Verres used his status as a high government official to brutalize and murder hundreds, perhaps thousands, of people. The lawyers for Verres tried to delay the trial, but Cicero pressed forward. In court he delivered a devastating case, and Verres fled into exile even before he was found guilty. In the south of Gaul he led a comfortable life, having kept much of the wealth he had stolen, until Marcus Antonius had him killed in 43 B.C.E.

leader, he tried to rule with compassion, pardoning many of his enemies. Some of these pardoned enemies murdered him in 44 B.C.E. Among the murderers was Cassius Longinus, who became a symbol of cruel selfishness. During his war against Marcus Antonius and Octavian, he sold four Judaeen towns

and many Judaeen officials into slavery to finance his army, and he looted Rome's ally Rhodes of almost all its wealth.

Octavian, renamed the emperor Augustus, ruled Rome from 27 B.C.E. to 14 C.E. Augustus's successor, Tiberius (r. 14–37 C.E.), was an outstanding general with a sober temperament. Yet his sober temperament became very dark. He neglected his civic duties and eventually retreated to the island of Capri in 26 C.E., where he indulged in a taste for sex with children. His absence from Rome allowed the leader of the Praetorian Guard, Lucius Aelius Sejanus, to take over much of the Roman government. Sejanus was greedy and ruthless, using the charge of treason as an excuse for murdering anyone who seemed to be between him and something he wanted. Tiberius was told by his sister-in-law Antonia about Sejanus's corruption, and Sejanus and his supporters were executed.

For sheer depravity historians tend to single out two Roman emperors, Caligula (r. 37–41 C.E.) and Nero (r. 54–68 C.E.). Both started out with a great deal of public goodwill. Nero, in particular, had experienced and talented advisers to help him. But Caligula seems to have been criminally insane. His behavior was bizarre, violent, and cruel. He had sex with all three of his sisters, raped a bride on her wedding day, and tortured people. His public acts were weird; he even nominated a horse, Incitatus, for a consulship. He was murdered and quickly replaced by Claudius (r. 41–54 C.E.). The greatest scandal of Claudius's reign was the marriage of his wife, Messalina, to consul-designate Silius while Claudius was away. She and Silius were executed. Claudius himself may have been poisoned by his last wife, Agrippina the Younger, apparently in the hope that she would rule through her son Nero, who instead had her murdered.

Nero castrated a boy and then married him. He fancied himself a singer and stage actor and forced people to watch him for hours as he performed. Pregnant women gave birth in the audience because they were not permitted to leave. After most of Rome went up in flames, Nero began the construction of a large and very expensive palace in Rome, and rumors circulated that he had started the fire and sang and danced while it burned. This story seems to have been untrue; Nero actually seems to have tried to put out the fire. To direct blame away from himself, he blamed the Christians. He took delight in torturing them and had many tied to stakes and ignited to serve as torches during celebrations at his palace or in the amphitheater. Eventually, when Nero was away from Rome, the Senate sentenced him to death, and he committed suicide.

During the 200s and 300s C.E. corruption was most often found in the collection of taxes. Wealthy men would buy a high public office in a province and then divert government funds into their own pockets. Courts were subject to bribery, and serving on juries and taking bribes proved to be very profitable. Emperors tried to put a stop to the corruption of the courts, and Diocletian (r. 284–305 C.E.), in particular, seems to have struck fear into the hearts of many a corrupt court official as well as provincial leaders who were enrich-

ing themselves at the public's expense. Even so, even after the general public had lost faith in government leaders, there were still the midlevel public servants, organizing tax collecting, maintaining roads, and seeing to it that the poor received food. After the Western Roman Empire collapsed, these public servants continued to work, serving the Germanic tribes that established kingdoms in Europe and North Africa.

THE AMERICAS

BY KIRK H. BEETZ

When people gather to live in groups, there tends to be scandal, and where they have governments, they tend to have corruption. Still, the nature of scandal and corruption in the ancient Americas north of Mexico is a mystery because there are no written records. In general, written records are the best and often the only way to learn the specifics of scandals and corruption. It is likely that well before 5000 B.C.E. North Americans had diversified enough that what constituted scandal in one tribe did not necessarily constitute scandal in another. For example, in some societies a man could have as many wives as he wished. Scandal would attach to him only if he had more wives than he could support. In another society, however, having more than one wife would in itself be scandalous. The ancient civilizations of South America also left virtually no records related to particular scandals or corruption.

When one looks at Mesoamerican cultures (those ancient societies of Central America and Mexico) that did have written records, another problem appears. Modern people may have very different views of what constitutes scandal or corruption than what might have been held by people living in ancient Mesoamerica. For instance, the torture and slaughter of people in religious rituals would horrify many modern people, but to most Maya torture and execution ennobled victims, turning them into honored offerings to the gods that satisfied the gods' needs for human blood for nourishment and thus staved off disasters the gods could cause if they were hungry. A chink in this confidence might be found in the sacrifice of powerless children. Children without families to protect them were commonly made slaves and sacrificed, mostly because they had no one to protest their murders.

A prominent Mesoamerican center was Teotihuacán, a city in Mexico that was not Mayan but through its military power forced many Maya cities to pay tribute to it. Rumors of scandals probably traveled quickly through the city, because most people lived in apartments that each housed three families and the apartments were tightly packed together in a grid pattern. Any scandal would have passed by word of mouth rapidly in such a place where people had little privacy and could be easily overheard. Of scandals and corruption in Teotihuacán there are few details, though an ever-increasing gap between the prosperity of the ruling elite and the common people probably was viewed as a sign of corruption by some commoners.

In Mayan culture every person was supposed to know his or her place and duty in society. Those who did not have places became slaves. The social contract of the Maya meant that even the *k'uhul ajaw*, or "divine king," had duties that he had to perform or risk losing his mandate to rule. He was expected to speak to the gods on behalf of his people. Members of his family were expected to join him in tormenting themselves with thorns. His wife would pull a rope with thorns through a hole in her tongue. She and others would pierce their ears and tongues to spill their blood, and the king and his first son would pierce their penises and draw their blood, all because the Maya believed that royal blood was the most nourishing blood for the gods. Giddy from blood loss and delirious from taking drugs, the king and his family might cross the divide between physical life and the spirit world and seem to speak directly with supernatural beings. If such communicating with the gods failed to alleviate a natural disaster, for instance, a drought that lasted for a few years, people might believe the king no longer had divine authority.

Knowing this can help one understand how scandalized the ancient Maya probably were by events in the late 300s C.E. In cities such as Tikal and Uaxactún, an increase in trade was generating wealth, but the wealth was going primarily to the nobility; this was creating social instability because commoners no longer perceived their leaders as sharing the risks of Mayan life in the way they were supposed to do. To hang on to their authority, the *ahauob*, or "nobility," tried to enhance their prestige by raiding their neighbors and bringing home goods that could be used for the city as a whole. Most important, they brought home captives for sacrifice, with captured nobles being particularly important because their blood was especially desired by hungry gods. Raiding for people to sacrifice had been a part of Mayan life for centuries, but Chak Toh Ich'ak I, known as King Great Jaguar Paw (fl. 376 C.E.), of Tikal changed the rules of warfare. Instead of trying to capture just enemies, he chose all-out killing; he chose conquest.

His brother Siyah K'ak', known as Smoking Frog, led an army to attack Uaxactún. This was no ordinary raiding party: It was a force drawn from Tikal's many communities; it may have been the largest Mayan army up to that time. One problem the Maya may have had with this event was that the king himself apparently stayed home. For the Maya, there could have been few excuses for this. Thus, his position at home would have been weakened. Meanwhile, Smoking Frog led his forces to victory, capturing the city of Uaxactún and seizing the king of the city. The sacrifice of a king was a special event because a king's blood was sacred and therefore most desired by gods. Kings were occasionally captured in battle, but they ruled their cities as divine monarchs; someone from their line was expected to replace them, perhaps paying tribute to the victors. In the case of Tikal and Uaxactún, Smoking Frog's forces exterminated the nobility and the royal line of Uaxactún, leaving the people of Uaxactún with no one to speak to the gods for them. This would have been

reprehensible; it would have been the murder of the spirits of an entire people.

The scandal thereafter became even more intense. Smoking Frog made himself king of Uaxactún, without the divine right to do so. When Great Jaguar Paw died, Smoking Frog put someone of his own choosing on Tikal's throne. This was Nun Yax Ayin, known as Curl Snout, who may have been the son of an as yet unidentified brother of Smoking Frog and Great Jaguar Paw. Although Tikal was supposed to be the preeminent city, it was controlled by Smoking Frog from Uaxactún. These events would have created anxiety among the people of Tikal and the lands Tikal controlled because the world order, which was a divine order, had been twisted and overturned by ambi-

tious leaders. It brought forth a new age of Mayan warfare in which total destruction of a rival society was the object.

Greece

~ Aeschines, excerpt from "On the Embassy" (343 B.C.E.) ~

[2.1] I beg you, fellow citizens, to hear me with willing and friendly mind, remembering how great is my peril, and how many the charges against which I have to defend myself; remembering also the arts and devices of my accuser, and the cruelty of the man who, speaking to men who are under oath to give equal hearing to both parties, had the effrontery to urge you not to listen to the voice of the defendant and it was not anger that made him say it; for no man who is lying is angry with the victim of his calumny, nor do men who are speaking the truth try to prevent the defendant from obtaining a hearing; for the prosecution does not find justification in the minds of the hearers until the defendant has had opportunity to plead for himself and has proved unable to refute the charges that have been preferred.

[2.3] But Demosthenes, I think, is not fond of fair argument, nor is that the sort of preparation he has made. No, it is your anger that he is determined to call forth. And he has accused me of receiving bribes—he who would be the last man to make such suspicion credible! For the man who seeks to arouse the anger of his hearers over bribery must himself refrain from such conduct.

[2.4] But, fellow citizens, as I have listened to Demosthenes' accusation, the effect upon my own mind has been this: never have I been so apprehensive as on this day, nor ever more angry than now, nor so exceedingly rejoiced. I was frightened, and am still disturbed, lest some of you form a mistaken judgment of me, beguiled by those antitheses of his, conceived in deliberate malice. And I was indignant—fairly

beside myself at the charge, when he accused me of insolence and drunken violence towards a free woman of Olynthus. But I was rejoiced when, as he was dwelling on this charge, you refused to listen to him. This I consider to be the reward that you bestow upon me for a chaste and temperate life.

[2.5] To you I do, indeed, give praise and high esteem for putting your faith in the life of those who are on trial, rather than in the accusations of their enemies; however, I would not myself shrink from defending myself against this charge. For if there is any man among those who are standing outside the bar—and almost the whole city is in the court—or if there is any man of you, the jurors, who is convinced that I have ever perpetrated such an act, not to say towards a free person, but towards any creature, I hold my life as no longer worth the living. And if as my defense proceeds I fail to prove that the accusation is false, and that the man who dared to utter it is an impious slanderer, then, even though it be clear that I am innocent of all the other charges, I declare myself worthy of death. . . .

[2.181] And all the rest of you, toward whom I have conducted myself without offence, in fortune a plain citizen, a decent man like any one of you, and the only man who in the strife of politics has refused to join in conspiracy against you, upon you I call to save me. With all loyalty I have served the city as her ambassador, alone subjected to the clamor of the slanderers, which before now many a man conspicuously brave in war has not had the courage to face; for it is not death that men dread, but a dishonored end. . . .

(continued)

(continues)

[2.183] A word more and I have done. One thing was in my power, fellow citizens: to do you no wrong. But to be free from accusation, that was a thing which depended upon fortune, and fortune cast my lot with a slanderer, a barbarian, who cared not for sacrifices nor libations nor the breaking of bread together; nay, to frighten all who in time to come might oppose him, he has fabricated a false charge against us and come in here. If, therefore, you are willing to save those who have labored together with you for peace and for your security, the common good will find champions in abundance, ready to face danger in your behalf.

[2.184] To endorse my plea I now call Eubulus as a representative of the statesmen and all honorable citizens, and Phocion as a representative of the generals, preeminent also among us all as a man of upright character. From among my friends and associates I call Nausicles, and all the others with whom I have associated and whose pursuits I have shared. My speech is finished. This my body I, and the law, now commit to your hands.

Speeches of Aeschines (Cambridge, Mass.:
Harvard University Press, 1919).

Rome

≈ Appian, “*The Civil Wars—On the Gracchi*”
(from *Roman History, before 162 C.E.*) ≈

Gaius Gracchus, who had made himself popular as a triumvir, stood for the tribuneship. He was the younger brother of Tiberius Gracchus, the originator of the law. He had kept silent concerning the killing of his brother for some time, but as some of the senate treated him disdainfully, he offered himself as a candidate for the tribuneship, and as soon as he was elected to this high office began to intrigue against the senate. He proposed that a monthly distribution of grain should be made to each citizen at the expense of the state. This had not been the custom prior to this. Thus he put himself at the head of the populace at a bound by one stroke of politics, in which he had the assistance of Fulvius Flaccus. Right after this he was elected tribune for the next year also, for in cases where there were not enough candidates the law permitted the people to fill out the list from those in office.

In this way Gaius Gracchus became tribune a second time. After, so to say, buying the plebs, he began to court the *equites*, who hold the rank midway between the senate and the plebs, by another similar stroke of politics. He handed over the courts of justice, which had become distrusted on account of bribery, from the senators to the equites, upbraiding the senators particularly for the recent instances of Aurelius Cotta, Salinator, and, thirdly, Manius Aquilius (the one that conquered Asia), all shameless bribe-takers, who had been set free by the judges, even though envoys sent to

denounce them were still present, going about making disgraceful charges against them. The senate was very much ashamed of such things and agreed to the law and the people passed it. Thus the courts of justice were handed over from the senate to the knights. It is reported that soon after the enactment of this law Gracchus made the remark that he had destroyed the supremacy of the senate once for all, and this remark of his has been corroborated by experience throughout the course of history. The privilege of judging all Romans and Italians, even the senators themselves, in all affairs of property, civil rights and exile, raised the *equites* like governors over them, and placed the senators on the same plane as subjects. As the *equites* also voted to support the power of the tribunes in the *comitia* and received whatever they asked from them in return, they became more and more dangerous opponents to the senators. Thus it soon resulted that the supremacy in the state was reversed, the real mastery going into the hands of the *equites* and only the honor to the senate. The *equites* went so far in using their power over the senators as to openly mock them beyond all reason. They, too, imbibed the habit of bribe-taking and, after once tasting such immense acquisitions, they drained the draft even more shamefully and recklessly than the senators had done. They hired informers against the rich and put an end to prosecutions for bribe-taking entirely, partly by united action and partly by actual violence, so that the pursuit of such investigations was

done away with entirely. Thus the judiciary law started another factional contest that lasted for a long time and was fully as harmful as the previous ones.

Gracchus constructed long highways over Italy and thus made an army of contractors and workmen dependent on his favor and rendered them subject to his every wish. He proposed the establishment of a number of colonies. He prompted the Latin allies to clamor for all the privileges of Roman citizenship, for the senate could not becomingly deny them to the kinsmen of the Romans. He attempted to give the right to vote to those allies that were not permitted to take part in Roman elections, so as to have their assistance in the passing of measures that he had in mind. The senate was greatly perturbed at this and commanded the consuls to set forth the following proclamation, “No one that does not have the right

to vote shall remain in the city or come within forty stadia of it during the time that the voting is taking place upon these laws.” The senate also got Livius Drusus—another tribune—to intercede his veto against the measures brought forward by Gracchus without telling the plebs his reasons for so doing; for a tribune did not have to give his reasons for a veto. In order to curry favor with the plebs they gave Drusus permission to found twelve colonies, and the people were so much taken with this that they began to jeer at the measures that Gracchus proposed.

► science

INTRODUCTION

In the modern world scientists adhere to the scientific method in pursuing their work. They make hypotheses about problems, test those hypotheses by gathering data under controlled conditions, and then arrive at generalizations that might in time gain the status of scientific laws, such as the law of gravity. Ancient scientists did not approach science in this systematic way and in fact might not have regarded themselves as “scientists” at all. Among ancient peoples, science was associated with magic and religion, two areas of thought that often overlapped. People saw themselves as subject to the will of the gods and to mysterious natural forces. Their only hope for survival was discovering ways of controlling those forces. Knowledge consisted primarily of knowing the will of the gods and possibly making predictions about future events.

Ancient science, then, often overlapped with what the modern world sees as superstition. In many ancient cultures the scientists were often the seers, the diviners, the shamans and priests, who acquired insight into the properties of nature, the movements of heavenly bodies, the functioning of the human system, and the like. Ancient astronomers and healers provide good examples. Both of these classes of scientists were believed to have divine, supernatural knowledge, which they could use for the benefit of people in their communities.

Another distinction between ancient and modern science is that ancient science was almost never theoretical. Ancient people did not have time to pursue purely theoretical knowledge, or scientific knowledge for its own sake. They were too busy with the practical concerns of day-to-day survival. Thus, science tended to be more in the nature of technology, of finding solutions to practical problems. In attacking those problems, they looked around and saw four fundamental elements that affected their lives: earth, fire, air, and water. Science represented an effort to control these four elements. Thus, perhaps the best way to categorize and summarize ancient science is to focus on how they learned to tame these four elements.

The earth was the most stable, tangible reality, so ancient peoples made efforts to achieve some understanding of it and of ways to use it. Stone Age peoples, for example, learned to make weapons, cutting tools, and the like out of the stones on the ground that surrounded them. Their Bronze Age and Iron Age descendants learned to make these weapons and tools out of metal. To do that, they needed to develop ways to find metal ore, mine it, smelt it, purify it, and cast it into the objects they needed. As ancient chemists, they learned ways to

harden metals. Copper workers discovered that by combining copper with tin, they could create bronze, a much harder and more useful metal that defined a historical period, the Bronze Age. Later scientists discovered that they could convert iron, an abundant but somewhat soft metal, into hard and durable steel by the addition of carbon.

The earth also provided abundant building materials. The earliest structures were built with logs, reeds, and mud bricks, but in time people learned to quarry stone such as marble, limestone, and sandstone to make buildings. Along the way they discovered principles for engineering these buildings and in some cases developed sophisticated mathematics to help them.

Early farmers became chemists and botanists by learning how to domesticate crops, cultivate them, store them, and convert them into food. Chemistry, for example, enabled them to convert milk from livestock into cheese. Perhaps one of the most successful plant-breeding programs in history was carried out by the ancient Mesoamericans, who domesticated maize (corn) from a wild plant. Other farmers became chemists when they learned that the dung from their domesticated animals or from animals such as bats promoted crop growth or that burning the stubble from last year's crop provided the soil with nutrients that encouraged this year's crop.

This leads to fire, the second element. Ancient civilizations learned to use fire not only for warmth and light but for other purposes as well. Ancient miners, for example, learned to crack stone during the quarrying process by building a fire next to the rock to heat it and then dousing the rock with cold water. The rapid temperature changes cracked the rock, making it easier to mine. They also learned to create blast furnaces that achieved the high temperatures they needed to refine and melt metal ores. Meanwhile, ancient pottery makers were making detailed scientific observations about materials that would work best for clay pots, substances that could be used as dyes for coloring the pots, and ways to fire and glaze the pots to make them more durable. They also learned to make such materials as glass, using silica (sand) and fire, and to use minerals mined from the earth to make decorative objects.

With regard to air, ancient civilizations observed the power in a gust of wind and decided that they could put the air to work. This led to at least two primary developments. One was to attach sails to boats, giving these boats far greater range for purposes of exploring, trading, and conquest. The other was the development of the windmill, allowing ancient farmers to pump water, irrigate land, and thresh grain in far greater amounts and with much greater efficiency. Meanwhile, ancient astronomers were looking into the heavens and observing regularities in the movements of the sun, moon, and stars.

Water posed a particular problem for ancient civilizations, particularly those that settled near rivers. The ancient Egyptians, for example, found their livelihoods tied to the Nile River and the thin strip of fertile soil along its banks. The problem they faced was that the river flooded each year.

When the floodwaters receded, they left behind a great deal of fertile silt. In ensuing dry months, however, the ground dried out, threatening the survival of the crops. Out of necessity, the ancient Egyptians developed skills as hydrologists and engineers. They learned to build systems of dikes, canals, dams, and storage grounds for water, which could then be released when necessary to irrigate crops. In order to become engineers and build these facilities, they had to acquire knowledge in materials science, construction techniques, and the like, all of which required some ability in mathematics and measurement.

The modern world takes for granted an extensive base of information about the physical world and how it works. Ancient civilizations had to discover this information out of nothing. Without their scientific achievements it is unlikely that they would have survived in any appreciable numbers. Had that happened, the world might still be a frightening place of pure mystery and magic.

AFRICA

BY TOM STREISSGUTH

Ancient Africans viewed the natural world and all that occurred within it as expressions of the unseen realm of spirits. Events on earth were predetermined, the result of malevolent or benign forces that acted at whim. Humans could never hope to control the fertility of the soil, the coming of the rains, the occurrence of drought or illness, or the seasonal flood of rivers and lakes. They could only propitiate the spirits of the natural world, look for guidance in signs appearing on the earth and in the heavens, and seek out the environments that were best suited to their own survival. They did not pursue science for its own sake or by the modern method of testing theories in controlled experiments. Ancient chemistry, botany, metallurgy, physics, medicine, astronomy, and so on came in the form of practical knowledge applied to everyday needs: growing food, fighting wars, curing the sick, or relieving the pain of giving birth. Further, there was no sharp line between religious and scientific practices, since a spiritual outlook governed virtually all aspects of life. Generally speaking, any activities that ancient Africans carried out for the purpose of enhancing their livelihood and manipulating their environment should be considered science.

TOOLMAKING: THE FIRST APPLIED SCIENCE

Early human beings needed to master the environment in order to find food, protect themselves from hostile strangers, and hide from dangerous animals. A vital ingredient in these endeavors was the use of tools. The shaping of stone implements, according to archaeologists, first occurred in Africa. At Olduvai Gorge (in present-day Tanzania) primate species probably ancestral to modern humans were using sharp rocks as tools some 2.6 million years ago. They may have created these rudimentary tools simply by cracking brittle stones to

produce a sharp edge. Later ancestral species and modern humans found ways to work harder stone into tools through abrasion or flaking. Drilling and incision allowed a still greater variety of tools as well as a means of fashioning decorative necklaces, pendants, bracelets, and rings. Stone axes and spear points were useful for killing game, stone adzes for hollowing out tree trunks to make canoes, and simple stone hoes for turning the soil and clearing brush.

The control of fire brought a revolution in useful technologies, allowing ancient Africans to harden earth for pottery and, later, to fashion metal tools and weapons. Pottery making developed along with settled agricultural societies, which needed storage for food, water, and seed. The first clay pots were made from river mud heated in a fire and decorated with simple geometric forms. Potters experimented with different soils, with controlled heating for firing and curing their vessels, and with various paints and dyes. Without understanding basic chemical principles or the complex effects of heat and light, they found better methods and ingredients through centuries of trial and error.

AGRICULTURE

Ancient Africa grew imported as well as native crops. Archaeologists believe that wheat and barley arrived in Africa from the Near East and were first cultivated in the Ethiopian highlands as well as farther north. These crops required intensive labor and close attention to weather, soil, irrigation, and general growing conditions. Seeking to enhance the soil, African farmers mixed it with the ashes of trees cleared and burned to make room for cultivating plants. They turned the soil with hoes to make it easier for roots and stalks to penetrate and found that cattle dung improved its fertility. In hilly regions they terraced land to control drainage and provide a greater area of cultivation. They rotated crops or allowed land to lie fallow in order to renew exhausted soil. All of these innovations came from centuries of observation and experiment.

In the northern half of Africa native crops such as millet, sorghum, and yams were cultivated and propagated. Instead of simply gathering edible plants, African farmers began working in a systematic manner, controlling the environment as best they could and reading the sky for signs of coming weather and for favorable or unfavorable omens. They shared their knowledge and passed it down to younger generations.

Animal husbandry developed as societies living in the Sahara region captured and raised wild cattle, a development that began around the fifth millennium B.C.E. Sheep and goats also flourished in what is now the Sahara, at the time a well-watered region with a moderate climate. Cattle herding spread southward across the Sahara. Cattle were useful as beasts of burden, for their meat and milk, for fertilization of the soil, and as a store of wealth. Herders bred their animals selectively to increase and improve them. They learned to avoid environments where disease-carrying insects such as the tsetse fly threatened deadly epidemics.

METALLURGY

The techniques of working and shaping stone were most useful for hunters in perpetual search of game. As land came under cultivation, African artisans began exploring the more complex science of metallurgy. Iron production in Africa dates to at least the second millennium B.C.E. For example, in what is now Nigeria the Nok civilization began making iron tools and other objects sometime around 500 B.C.E. The new iron implements allowed people to hunt more effectively, cultivate larger areas for crops, protect themselves from animals, and make war on their neighbors.

The craft of metallurgy gave rise to a new class of skilled artisans. Making and working iron were complex, difficult processes that could be mastered only through years of practice. The first step was to smelt the iron—that is, to separate the metal from the rocky ore in which it occurs in nature. This was done by heating the ore in a furnace, where the temperature could be controlled by the introduction of air through vents. Shaft furnaces were developed, which drew air through holes in the base. These furnaces were easier to use than bellows furnaces, in which air is blown over the fire, but they burned more wood fuel (a demand at first easily met in most regions of Africa, but one that often caused serious problems as local iron industries expanded). Metalsmiths learned to separate usable metal from impurities in order to produce a stronger material. The molten iron was consolidated in heavy crucibles and then poured into molds to cool. Once the iron solidified, the smith could craft tools and weapons by forging it—that is, by shaping it with heavy hammers while it was still hot enough to be relatively soft or after reheating it. The secrets of this craft were held closely by the few who could practice it, and who passed on its mysteries to their heirs and apprentices.

Metalworking encouraged long-distance trade, as iron tools and weapons were in high demand throughout the continent. The industry also supported permanent settlement, as groups with knowledge of the process located themselves near useful ore deposits. In many places the hunter-gatherer existence faded into memory, and life became more settled, with larger communities divided into distinct classes defined by their skills and employment. The need to adjust to the environment led to the development of more sophisticated tools. The iron implements used in the tropical parts of Africa, for example, tended to be stronger than the ones developed by people who lived in the desert.

From about 500 B.C.E. iron and copper metallurgy spread throughout sub-Saharan Africa. Copper deposits were discovered and worked in Mauritania and Niger, in the western Sahara region, and in central and southern Africa. Ancient ironworking sites have been found from about 500 B.C.E. in Nigeria as well as in the eastern Lake District, in what are now Rwanda and Tanzania, in Doulo (in modern-day Cameroon), and in the Termit Mountains region of Niger. In African societies the practice of metallurgy required cooperative effort and

expertise that was the privileged knowledge of certain clans, who knew the techniques of locating ore, building smelters, producing charcoal, and maintaining a constant high temperature in a closed furnace. Metal craftsmen trained in the art of iron making eventually mastered other media, such as jewelry making. Some historians believe that in ancient Africa, iron, copper, and bronze were most important in the production of ornaments, and not in the making of tools or weapons.

Historians have noted that Africa did not experience the usual transition from copper and bronze to iron. Copper making usually preceded the iron making in ancient cultures because copper has a lower melting point, making it easier to produce. Iron smelters had to mix burning charcoal and crushed ore in a closed furnace or crucible, steadily raise the temperature of the mixture, separate the metal from the ore, and then hammer their products into shape. As it was harder than copper, bronze, or tin, iron took greater strength and skill to forge into anything useful. Apparently, however, African smiths started working with these two very different materials more or less at the same time.

Further, there is no evidence in Africa for the usual first step in developing metalsmithing techniques—by experimentation in pottery kilns. Finally, no African metalworking sites date from earlier than similar sites in the Near East and Asia Minor, where ironworking technology originated. Together these facts suggest that metal technology probably arrived in Africa over a short period of time from outside the continent. African iron smelters may have learned metalworking from contact with the Near East, which spread new implements and the methods for making them into Africa via Egypt.

The first African iron kingdom was Kush, lying on the southern frontier of Egypt in what is now northern Sudan. This civilization was based on ironworking technology that was spreading from the Nile Valley and the Sahara to West Africa, the Sahel region south of the Sahara, and then to the Bantu populations of southern and southeastern Africa. The effect of the new technology in Kush and elsewhere was profound. Iron tools were better at clearing forests and cultivating the soil. Iron axes, machetes, and hoes increased the food supply, allowing communities to stay in one place longer and grow in population. Iron also made larger areas of the continent habitable, as people moving into a new region could cultivate more land and more effectively hunt. Iron weapons were important catalysts of urbanization; they also strengthened armies in wartime. Iron, copper, and gold produced in surplus were traded over long distances, allowing societies that mastered metallurgy to enrich themselves and, as a result, develop a merchant class and a wealthy aristocracy.

The iron industry of the capital city of Meroë allowed the Kushite civilization to flourish—and it may also have led to its downfall. To fire the charcoal furnaces, iron makers had to cut a tremendous amount of wood. The resulting loss of forests led to severe soil erosion and loss of soil fertility in the lands around Meroë, reducing the supply of locally grown food and requiring more and more food to be imported. The

cost impoverished the city and affected other forms of trade. In about 350 B.C.E. Meroë collapsed, its industries shutting down and its people scattering.

MEDICINE AND SPIRITUAL HEALING

In ancient Africa there was no sharp separation of religion, custom, and science. This can be clearly seen in the field of medicine. Although there is very little written evidence of ancient medical practices in sub-Saharan Africa, historians can surmise some general aspects of ancient doctoring through time-honored traditions that have survived into modern times.

Ancient Africans believed (and many people in present-day Africa still believe) in three different worlds: the worlds of the living, the dead, and the generation unborn. Ancestors, gods, goddesses, and other invisible entities resided in the world of the dead. Also in the world of the dead were spirits that brought bad omens, disease, and misfortune. In order to avoid such problems, the ancestors or gods who brought them had to be consulted to discover the underlying cause, which could be man-made or supernatural.

Man-made medical problems, for example, are those arising from such causes as poor hygiene or a lackadaisical attitude toward one's physical well-being. Some medical conditions, however, such as madness, infertility, or protracted sickness, demand more serious metaphysical understanding. They may result, it is thought, from malevolent humans who are capable of transforming themselves into a different spiritual realm for the purpose of doing mischief. Witches, for example, are human beings with the power of entering the spiritual realm. To counter this kind of problem, the doctor consults a deity that is associated with beneficial and restorative outcomes. In all instances remedies for spiritual anomalies and medical problems involve communication with the spirits by the doctor, who may also be a diviner (a person who has supernatural powers to discover hidden knowledge). Sacrifices are usually needed to appease the entities, return the sick to normal health, and beg for forgiveness.

A spiritual or medical problem can often result from disrespect to the deity. One of the numerous methods of enforcing laws in Africa is through oracular intervention. For example, a person who kills game in a sacred forest might develop a swollen belly until he or she confesses the offense. Remedies are procured through appeasements to the gods or through banishment from the community. In ancient times offenders might even be sacrificed to the affronted deity.

In sum, scientific understanding in traditional Africa is closely tied to spiritual insight and is the concern of doctors, shamans, and priests who are trained in an esoteric body of knowledge. The African priest was, and still is, responsible for conducting the spiritual affairs of the community in accordance with long-established customs. Most important, the priest ensures that the gods do not get angry with the people of the community. The best means of avoiding the wrath of the gods is by making sure that all the rules

and regulations of the community are adhered to. Whenever there are problems that might lead to a serious crisis, the gods communicate with the priest, who in turn works with the rulers and the entire community to ensure that the danger—a poor harvest, famine, or a short rainy season—is averted. Spiritual cleaning is needed to appease the gods and put things on the desired track.

ASTRONOMY AND DIVINATION

Astronomy was the most esoteric science known in ancient Africa. The appearance and movements of the stars, planets, and moon posed a difficult question to ancient observers. In attempting to explain their observations, African astronomers relied on religious traditions and their knowledge of the spirit world. They also devised pragmatic systems in order to make something useful of the mysterious celestial events. In some ancient societies the time and position of sunrise and sunset were gauged to plan journeys and decide the activities required for each day. The appearance of certain stars, particularly Sirius, the brightest star in the night sky, delineated the annual calendar of river flood and proper dates for planting and harvesting. The moon, the Milky Way, the constellation Orion, and the bright planet Venus also played important roles in astronomical science.

Archaeologists have excavated several sites in Africa that may have served as observatories or celestial calendars. Stones placed artificially in a row or circular arrangement may have marked the position of heavenly bodies at certain times of year. Such arrangements have been discovered in Zimbabwe, the Central African Republic, Sudan, Kenya, and the western African nations of Togo and Benin. For example, in what is now Kenya a stone circle known to archaeologists as Namoratunga II was laid out by ancestors of the Borana people. This site is an early calendar that fixed the dates of the year by measuring the positions of seven different stars and the moon.

One of the most famous ancient objects possibly relating to astronomy is the Ishango bone, found in what is today Zaire and dated to about 20,000 B.C.E. The bone (a baboon's femur) has markings that may indicate the 28-day cycle of the moon. Some experts have seen in the pattern of marks a counting system or some kind of mathematical table. Without a written record, however, the specific uses and purposes of this object and of such astronomical sites as Namoratunga II remain unknown.

Ancient societies commonly took celestial phenomena into consideration for important undertakings, such as wedding ceremonies, going into battle, migration to a new region, and building their homes. In Togo and Benin the people known as Tamalimba built their houses so that they were aligned with the sun at the time of the equinoxes. The pyramids of Meroë, the capital of the Kushite kingdom, are aligned to face Sirius as it rises on the eastern horizon. Contemporary Africans still hold to many of these traditions. Sirius, Orion, and the star cluster known as the Pleiades guide

coastal navigators in eastern and western Africa. The Dogon of Mali consider Sirius and a small companion star, known to them as Po Tolo, as celestial anchors, keeping all other heavenly bodies in their proper courses and guiding events and important decisions on earth.

The appearance of heavenly bodies was interpreted both as a guide to present events and as a portent of the future. Like medicine, divination was a skill reserved to those with specialized knowledge, whose secrets were carefully kept. The purpose of this craft was to access information not available through empirical means. Divination allowed people to understand problems or prepare for imminent danger. Diviners were, and are, consulted before naming a baby, before undertaking a journey, in preparation for war, and to judge the worth of a potential spouse.

The origin of African divination systems is shrouded in mystery. In modern times they fall into two broad categories: the tool system and the medium system. In the latter a human being serves as a medium who interprets coded information accessed through an earthly entity—typically, messages from dead ancestors who communicate through selected individuals. This type of divination is popular among the Shona of modern Zimbabwe. In the tool system a diviner makes use of tools such as palm-nut shells, stones, or animals. The Banen and Mambila of modern Cameroon use spiders and land crabs as tools of divination.

The Ifa system, as one example, is a well-studied system that survives among the Yoruba of Nigeria. The priest of Ifa divination is called *babalawo* (father of secrets). To become a *babalawo*, an apprentice required several years of training and the study of an enormous body of literature, the *odu*, which consists of 256 parts further subdivided into verses called *ese*. There are about 800 *ese* in each *odu*. A person becomes a *babalawo* after going through all the initiation ceremonies and mastering enough verses needed for communication with Orunmila, the deity associated with divination.

Among the Yoruba and other African cultures evidence of ancient divination science exists only in the form of modern practices that echo those of the past. In a continent where archaeological evidence is often scanty, this is the best resource historians have for reconstructing the knowledge systems of societies that have long been extinct.

EGYPT

BY LEO DEPUYDT AND TOM STREISSGUTH

Among the ancient societies of the Mediterranean region, Egypt was home to esoteric and practical knowledge that placed it in a realm apart from all others. Egypt was the center of advanced medicine, mathematics, and astronomy. Moreover, Egyptian engineering technology—embodied by towering monuments, pyramids, palaces, and public works—had no rival in the ancient world. The ancient knowledge of Egypt, however, was hidden in hieroglyphics, a system of picture writing that fell into disuse in the time of

the Roman Empire. Until the 19th century the tablets, papyri, and inscriptions of ancient Egypt were undeciphered, and Egypt's medicine, astronomy, and technology were lost to the world.

By the time of the pharaohs the Egyptians were making various household utensils, building clay vessels on a wheel, forging bronze weapons, weaving cotton, and controlling the flood of the Nile to the fields that bordered the river. Most importantly for scientific knowledge, the predynastic Egyptians developed a system of writing and record keeping.

Absent, however, was a tradition of experimentation, theory, and proof by empirical observation. Egyptian science was hidden knowledge, revealed to a select few among the priestly caste, who placed their skill and research at the service of the pharaohs. Their patron god was Thoth, the deity of knowledge and wisdom, represented by the figure of a human bearing the head of an ibis. The knowledge of Thoth was set down by scribes on papyrus rolls that were privileged reading for the few. In a broad sense, nearly every ancient Egyptian text exhibits some aspect, however minimal, of scientific thought. There were mathematical texts and medical texts, as well as astronomical texts and texts related to the reckoning of time and the calendar. Other genres include classifications of reality (as in *onomastika*, or name books) and explanations of dreams as well as texts on geography, botany, chemistry, metrology, mineralogy, pharmacology, philosophy, physics, and technology.

MEDICINE

Works of medicine and mathematics show that these were the most advanced scientific endeavors in ancient Egypt. Only one cluster of sources rivals mathematical texts in size, the medical texts. These include the Edwin Smith Papyrus, the Ebers Papyrus, and the Kahun Papyrus. Within these documents are spells and incantations, diagnoses of various diseases, and anatomy. The Kahun Papyrus focuses on the re-

productive system, the mechanisms of conception and pregnancy, and the complications of birth.

The various papyri reveal that medical science in ancient Egypt was bound closely to religious belief and ritual. All in all, Egyptian medicine is perhaps better known as systematic observation of disease and anatomy rather than medicine. For the Egyptians, disease was the manifestation of evil and malevolent spirits, and curing disease was the work of priests skilled in the use of incantation, ritual, talismans, and spells. Along with this magical approach came practical knowledge closer to the modern conception of medical science.

Without the benefits of sanitation and the knowledge of bacteria, viruses, and the nature of contagious illness, the Egyptian physician had a limited arsenal with which to treat a host of mysterious ailments. Egypt was home to endemic malaria, tuberculosis, measles, smallpox, cholera, and bubonic plague; waterborne illnesses included schistosomiasis (an infection of the blood caused by a parasite). Eye diseases, including trachoma, were common, as were malnutrition; neural diseases like epilepsy; hazards of the natural world such as snakebite, insect stings, and poisonous fish and vegetation; and digestive ailments caused by poor food preservation.

Ancient Egyptians classified afflictions and had an intimate knowledge of organs and their function. The practice of mummification contributed greatly to that knowledge. The first mummies were created naturally, by preservation of the human body by the dry heat of the Egyptian desert. The preservation of natural mummies led the ancient Egyptians to the conclusion that artificial mummification could render a body impervious to the forces of time and decay. The process of mummifying a body took as long as 70 days, with each step a ritual presided over by priests trained and expert in the art. The brain, lungs, pancreas, liver, spleen, heart, and intestines were removed with various instruments, and the body was placed on a bed of natron, a mineral salt that dried the skin and tissue. Once the body was dried, the priests

Unwrapped mummy of a woman, perhaps from Thebes, Egypt, Late Period, after 600 B.C.E.; the process of mummification contributed to the Egyptians' knowledge of anatomy and disease. (© The Trustees of the British Museum)

anointed it with oil and spices and then wrapped it in linen bandages. Amulets, talismans, precious stones, and other objects were placed within the bandages as they were wound about the body.

Mummification was not the sole privilege of Egyptian royalty. Members of the wealthy aristocracy also were afforded this practice, as were favored pets and sacred animals, such as cats. Some historians consider mummification as forming the ancient origins of medical science, because the elaborate process allowed Egyptian priests to make a careful study of the symptoms of disease and the causes of physical death.

Egyptian physicians developed skills in surgery, setting broken bones, treating burns and wounds, dentistry, and preparing medications from vegetable plants, herbs, and minerals. Treatments included honey to dress wounds and soothe pain; aloe vera for burns and headache; and frankincense, dill, camphor, mustard seed, onions, garlic, sandalwood, sesame, thyme, and poppy seeds for various ailments and symptoms. An ancient Egyptian prescription could comprise several of these ingredients as well as much more repulsive substances meant to drive away evil spirits: the blood or fat of lizards and snakes, ground pig's teeth, rotten meat or other food, and boiled beetles or rhinoceros horn.

Medical science in ancient Egypt was also preventive in nature. Ritual bathing and purification played a key role in the prevention of disease, and dream interpretation was used to diagnose the causes of illness. The ancient Greeks considered Egypt the home of the medical arts. It was common for Greek scholars and physicians to make pilgrimages to the Nile Valley to study and learn from Egyptian priests and shamans.

METALLURGY AND CHEMISTRY

The Greeks and the people of the Near East took much of their knowledge of metallurgy and chemistry from the Egyptians, who were already systematically mining copper in the Predynastic Period, which ended in the late fourth millennium B.C.E. In the Eastern Desert between the Nile Valley and the Red Sea, copper ores were dug from the earth, refined into base metal, and formed into tools and weapons—a business carried on exclusively under the control of the state. Later the Egyptians learned to combine copper and tin to make bronze and developed uses for lead, cobalt, and galena.

Around 800 B.C.E. Egyptian smiths learned methods of smelting iron, which may have first been mined from meteorites. The “metal of heaven,” as it was known, was rare and valuable, and its handling was restricted to the priestly caste and privileged artisans working for the state. By the middle of the seventh century B.C.E. these smiths had learned new ways of hardening iron to make tools more durable and to lend weapons a sharper edge.

Gold mining was another monopoly of the state. Gold (*nub*) gave its name to an entire region, Nubia, which was renowned for its valuable deposits. The precious metal was extracted from gold-bearing ore as well as river sands. The

Egyptians developed an efficient method of washing this “gold of the river” by placing the ore in bags of fleece and running water through it, thereby removing the soil and dross and leaving behind small gold fragments and nuggets.

The Egyptians also developed an early glassmaking technology in which glass threads were wound around a core of hardened clay. When the clay was burned away, glass jars and bottles were left behind. Glassmaking employed soda, lime, and lead in various combinations and was the subject of constant experimentation and refinement, with the goal to create larger and more transparent pieces. The Egyptians developed an extensive industry around the use of various paints and dyes to create imitation pearls and precious gems from glass. Egypt's glassmaking technology was exported to the Near East and later to ancient Greece and Rome.

MATHEMATICS

Of the two kinds of ancient scientific texts, mathematical texts are more compatible with modern standards of science. (Accomplishments in medicine possible before the discovery of bacteria were, after all, very limited.) The earliest evidence of hieroglyphic mathematics dates to the first half of the second millennium B.C.E. A similar but more sophisticated development in mathematics occurred around the same time in cuneiform sources from Mesopotamia. Near Eastern mathematics then stagnated until the Greek miracle of the later first millennium B.C.E. Two factors put Egypt at the forefront of this resumed growth. First, Alexander's conquest in the fourth century B.C.E. made Greek into an Egyptian language, Egypt's preferred vehicle of intellectual discourse. Second, royal philanthropy transformed Alexandria into the world center for the study of mathematics for several centuries.

Much knowledge of Egyptian mathematics is contained in the Rhind Mathematical Papyrus, a document dating from around 1600 B.C.E. and which contains tables of fractions; formulas for addition, subtraction, multiplication, and division; a table of prime numbers; and a method for solving linear equations. In ancient Egypt mathematics was a practical and not a “pure” theoretical science. Egyptian numbers and calculation developed with the need for precise measurement in construction; surveying land boundaries; building canals and roads; and performing government functions such as calculating taxes and measuring inventories of grain, gold, and other public goods. The numbering systems allowed merchants to trade and exchange goods of various weights and volumes and enabled the state to calculate the size of granaries used for storing corn. The Egyptians developed an advanced system of geometry, a key element in positioning and constructing pyramids and royal tombs and in building various public structures: monuments, sphinxes, obelisks, lighthouses, and gardens.

Egyptian mathematics attained great precision and sophistication. Its number system was decimal, without a zero or a place value system, such as the one in which the first 5 in 55 means 50 and the second 5 means just 5. The Eyp-

tians were the first to develop a base-10 numbering system, which allowed the use of unit fractions and binary fractions. Square roots were in use by about 2000 B.C.E., at which time the Egyptians were also calculating and using the value of pi, the ratio of the diameter of a circle to its circumference. Egyptian mathematicians created tables of addition and subtraction, solved algebraic problems, and developed a precise system of weights and measures.

The Egyptians also studied the aerodynamics of sails and the phenomenon of draft employed by a curving sail. Some historians speculate that the Egyptians used kites and sails to raise obelisks and other monuments.

ASTRONOMY

The gods of ancient Egypt were present in all creation and in visible form. They were present in the stars and the prominent constellations, a fact that bound astronomical knowledge with the practices and rituals of religion. Osiris was visible in the constellation Orion, for example, and the goddess Nut could be seen in the Milky Way. To the Egyptians, the sky was a great roof, supported by immense pillars at the four corners of the world, which corresponded to the four cardinal points of the compass. The sun made a daily course around the earth in a celestial boat, doing constant battle with Set, the god of darkness and night. This striving forced the sun to move from north to south in the course of the year; at the time of the summer solstice, the sun reached its furthest point north. The earth itself was a flat rectangle, extending north to south and having its center in the valley of the Nile, which arose in a great river that lay at the southern boundary of the world.

Egyptian astronomers were priests as well as scholars, for whom a close knowledge of the heavens was most useful in its application to agriculture. The annual rising of Sirius before the sun at the summer solstice, for example, presaged the flooding of the Nile, the event that renewed the fertility of the Nile Valley. The prediction of this event every year lent the priestly caste its aura of mysterious power and esoteric knowledge. It also provided a natural starting point for the annual calendar of days, weeks, and months.

The Egyptian methods of mapping and measuring the heavens gave the world one important basis for its advanced time measurement systems. Egyptian astronomers divided the heavens into 36 decans, with each group of stars covering 10 degrees of the sky. Each of these groups rose at dawn for a period of 10 days, which formed a basis for the Egyptian calendar of 12 months of 30 days, each composed of three 10-day weeks. Egyptian astronomers further divided the year into three seasons—the season of the flood, the season of planting, and the season of harvest—with each season four months in length. The system of months left an extra five days each year that were set aside for feasting and a rest from labor. These intercalary days (inserted between others) were associated with a legend of the god Thoth, who allowed the goddess Nut an extra five days to give birth to her children.

The actual solar year, being slightly longer than 365 days, caused the months and seasons to gradually go out of phase. The result was a long period known as the sothic cycle, in which the seasons returned to their original positions in the calendar every 1,460 years. Later astronomers of Alexandria created a new calendar in which an extra day was added every fourth year, a system adopted by the Romans and which gave rise to the modern leap year. The system of decans and constellations also led to the division of night and day into 12 equal parts, which in turn led to the 24-hour day now used throughout the world. The Egyptians also considered the position of the stars and constellations in raising the pyramids. The faces of these monuments are very carefully aligned. Most face the rising sun at the summer solstice; others are aligned with important stars or the points of the compass. The north face of the Great Pyramid at Giza, for example, lies almost precisely at a right angle to true north. Some have seen in the arrangement of the three pyramids at Giza an imitation of the stars in the belt of the constellation of Orion. The alignment of foundations and walls with the cardinal points of the compass was done with the help of an instrument known as a *merkhet*, a sighting tool made from the central rib of a palm leaf, a string, and a weight, which gives a precise vertical line and allows the user to make a determination of true north and set the north-south axis.

TECHNOLOGY

The Egyptians invented several devices to aid construction of their palaces, monuments, and pyramids. The ramp, an inclined plane that allows large blocks to be raised using less force, and the lever, which uses a fulcrum point to multiply lifting force, were both applied to moving and positioning heavy objects, such as the immense blocks of stone laid for the pyramids. The Egyptians invented papyrus as a writing medium, developed long-distance ships, and adopted the wheel and chariot—originally inventions of the Mesopotamians. Egyptian farmers developed sophisticated irrigation systems, including canals, dikes, and reservoirs to bring water to their fields in times of drought or low rainfall.

Weaving and dyeing technology also made important advances in ancient Egypt. The Egyptians developed new methods of weaving and dyeing cotton and invented the royal purple dye adopted by ancient Greece and Rome. They learned to manufacture pigments and dyes from minerals like cobalt (for blue), iron oxide (for red), azurite or copper carbonate (light blue), malachite (green), and charcoal or charred bone (black).

The perception is widespread that Egyptian science was less sophisticated than its Babylonian and Greek equivalents. Hieroglyphic mathematics and astronomy never reached the level of sophistication of Babylonian or Greek astronomy. But this fact needs to be put in a proper historical perspective. It would be false to conclude that Egypt somehow disappointed or did not perform to expectation. Historically, thinking progressed more or less along parallel lines in Egypt and other

advanced early civilizations. A significant increase in sophistication occurred sometime after 500 B.C.E. By then, however, the great epochs of hieroglyphic Egyptian civilization had ended.

Around 525 B.C.E. Persia conquered Egypt. The Persian Empire's intellectual capital, Babylon, lay outside Egypt. In 332 B.C.E. Alexander of Macedonia followed the Persians into Egypt and put a permanent end to the pharaonic dynasties. A Greek presence had been in Egypt since the seventh century B.C.E., but with the coming of Alexander began the Greek Ptolemaic Dynasty, which ruled Egypt until the Romans arrived in the first century B.C.E. Alexander's general Ptolemy made his capital at Alexandria, a city founded by Alexander, who kept a company of philosophers and scientists with him for the purpose of spreading Greek learning and civilization to the barbarous parts of the world he conquered. Ptolemy built the greatest library of the ancient world at Alexandria, which flourished as a center of learning. The Museum, or Temple of the Muses, which housed the library, was a precursor to the modern university, with lecture halls, laboratories, experimental gardens for the study of botany, a zoological collection, and departments of medicine, astronomy, literature, and mathematics. For several centuries Alexandria and its Museum attracted the most brilliant astronomers and mathematicians of the ancient world. The work of the Alexandrian scientists remained dominant even after the fall of the Roman Empire in the fifth century and until new systems of thought were developed in the 17th century by Galileo, Copernicus, and Isaac Newton.

The activity at Alexandria is Egyptian, even if research was conducted in Greek. Claudius Ptolemy, antiquity's greatest astronomer (second century C.E.), was an Egyptian who wrote in Greek and had a Latin-Macedonian name. Egyptian developments in science and medicine, therefore, were not minor but were made obscure by the medium of hieroglyphic writing. For much of the period in which the hieroglyphic script was dominant, Egyptian learning did not significantly lag behind that of any other nation.

THE MIDDLE EAST

BY MICHAEL J. O'NEAL

The Sumerians, Akkadians, Assyrians, and Babylonians did not think in terms of scientific laws, and nothing like the modern scientific method of inquiry existed, with its emphasis on formulating hypotheses and testing them to arrive at general principles about the physical world. They did, however, develop mathematical reasoning to a high level of sophistication, enabling them to calculate everything from the area of a field to the amount of seed required to be sown in order to achieve a predicted yield. Mathematics in turn fed into architectural design, astronomical reckoning, time keeping, and all manner of economic control over seed, yields, rations, and productivity. There was no self-conscious discussion of science per se, but it is clear that the ancient Mesopotamians

were fully capable of thinking and calculating in a rigorous, predictable, and, above all, accurate manner.

MATHEMATICS

The ancient Mesopotamians developed a sophisticated system of mathematics. Early on they learned that they needed a precise system of measurement. Arable land had to be measured accurately so that the requisite amount of seed and irrigation water could be calculated to make the land deliver a high yield. Irregularly shaped plots of land were divided into triangles and rectangles, and area was calculated by summing the areas of the parts. Volumetric calculations were also necessary. In constructing a wall or digging a pit, the need to calculate volumes of earth, the numbers of bricks required, and the amount of labor to be hired and for how long were all important to the planning of a project. The amount of food rations (barley, beer, salt, oil, fish, and so forth) had to be calculated as well. The best surviving records come from what historians call the Old Babylonian Period, dating roughly from about 2000 to 1600 B.C.E.

The mathematical system of the Babylonians (and the Sumerians before them) was a sexagesimal system, meaning that it was based on the number 60 rather than on the number 10. Any metrological system contains within it units of measure with fixed conversion factors. Thus, for example, a foot consists of 12 inches, a mile of 5,280 feet, and so on. The sexagesimal system of the Sumerians and Babylonians evolved out of their conversion factors. In the late third millennium B.C.E. a final step took place, that of place holding. In the modern numerical system, the value of the digit 3 varies depending on its place. By itself it stands for 3, but in the numeral 30 it represents three 10s, in 300 it represents three 100, and so on. The Babylonians developed a similar system. Now they needed only two symbols, one for the digit and one for its place. A vertical wedge was the "base unit." A corner wedge, derived from the small circle, had a value of 10 vertical wedges. A further vertical wedge was worth six corner wedges, and so on. These symbols could be repeated as often as necessary to arrive at such figures as 1, 60, 360, 3,600, and the like. From there it is easy to see the roots of many peculiarities of modern measurement systems. There are 360 degrees in a circle, 12 inches in a foot (for 12 is a factor of 60), three feet in a yard (for three is also a factor of 60), and the like.

Several hundred clay tablets exist in two forms: table tablets and problem texts. The table tablets could be considered an extension of the interest in listing discussed earlier. The tablets have a simple structure and show the two-symbol system of counting, along with the place-holding system. There are no subtraction or addition tables, but there are numerous tables for multiplication. These tables list multiples of one number, called the principal number (p). Thus, there were calculations for $1p$, $2p$, and so on. The tables calculate up to $20p$ and then skip to $30p$, $40p$, and $50p$. For a number such as 53, for example, the results for $50p$ and $3p$ were

added. Some of these tables also provide the square of the principal number.

The Babylonians had no division tables, but they did make extensive use of reciprocal tables. (A reciprocal is simply 1 divided by the number in question, so that the reciprocal of 60 is $1/60$.) Thus, instead of dividing, they multiplied by a reciprocal. To aid them in this task, they created extensive reciprocal tables. There are hundreds of these tables, along with tables for squares, square roots, and cubes, many of them compiled by students. Finally, there are coefficient lists, which list conversion factors used in geometry (for example, the ratio of a diagonal to a square's side) and weights and measures problems.

In addition to these tables are so-called problem texts, that is, exercises used in schools. Some of the tablets that record these texts contain a number of problems on a single topic; others contain problems related to different topics. They have given historians insight into the kinds of problems examined in schools. Nearly all of the problems ask students to come up with a number, never with any kind of proof. Thus, they are “algebraic” problems, in contrast to the “geometric” problems that ancient Greek students studied. (In algebra the goal is to arrive at a correct answer, expressed as a number; in geometry the goal is often to prove, for example, that the angles of a triangle add up to 360 degrees). Interestingly, modern mathematicians have taken a more extensive interest in Babylonian mathematics because of its emphasis on algorithms, or following a process to arrive at an answer.

Most such problems were what modern students know as “story problems,” that is, problems couched in everyday terms by calling for calculations of things in the real world: the length of a canal or broken reeds, the weight of a quantity of stones, or the number of bricks used in a building. Many of the problems are complex, requiring students to use not just single equations but more complex linear and quadratic equations. Some of the texts record the procedures students would follow to solve the problem, but none state general principles. Instead, the emphasis seems to have been on working problems as examples often enough so that the student could then work a new problem with different values. In many cases, all the problems in a group have the same answer, suggesting that the group of exercises was designed to teach a process of computation rather than to arrive at a correct answer.

Although the Babylonians did not have an organized system of geometry—they did not compute angles, for instance—many of the problems have geometric implications, and many contain drawings of squares, rectangles, circles, and triangles. Some problems required the student to compute such quantities as lengths of diagonals or sides or to calculate volume or area. Bricks and calculating a quantity of bricks seem to have been a preoccupation with Babylonian math teachers.

For reasons that historians do not fully understand, the mathematical record of the Old Babylonians comes to an abrupt halt after about 1600 B.C.E. What follows is a thou-

sand-year gap in the record. After this millennium the record resumes, and historians have records of continued interest in mathematics in the Mesopotamian region.

ASTRONOMY

During the first millennium B.C.E. the Babylonians compiled columnar lists of stars, with the columns listing the stars and their positions in relation to the positions of other stars. So great became the interest in observation of the stars that temples became astronomical observatories. It should be noted that at the same time, the Assyrians of the Near East also gave great importance to astronomy, and Assyria's capital, Kalhu (modern Nimrud), was a center of astronomical observation and study. In both Babylon and Assyria, lists of such events as eclipses were meticulously kept after about 800 B.C.E.—so accurately that future eclipses could be and were predicted.

Again, the Babylonians lacked a system, an underlying theory to explain and systematize the phenomena they observed in the heavens. Only after about the sixth century B.C.E. did they begin to organize their knowledge into a system. They did so only because they began working alongside Greek astronomers, who seemed, in common with the ancient Greeks, generally to have been better equipped to think systematically. Many of the famous Babylonian astronomers from this period even took Greek names. Naburimanni, who lived around 500 B.C.E., became called Naburianos, and the later astronomers Kidinnu and Belussur became, respectively, Cidenas and Berossus.

Babylonian astronomical observation was not, however, a “scientific” endeavor in the sense of an activity intended to develop an understanding of the atmosphere or the planets and the stars. Rather, the purpose of astronomical observation was completely different than it is today. It was employed in divination, akin to modern and medieval astrology. Celestial divination was used to foretell the fate not of individuals but of kings and the state. The decision to launch a military campaign, like almost all major decisions, was almost always preceded by celestial or some other form of divination.

MEDICINE

Much of the interest in the natural sciences among the ancient Mesopotamians focused on medicine and healing, an early effort to exert some human control over inexplicable forces. In the ancient Akkadian language, the word for *doctor* is literally translated as “fluids expert.” Over millennia doctors in the region accumulated a vast store of information having to do with drugs, salves, and other medicines either taken orally or applied to the body. Most of these drugs consisted either of minerals or plant extracts, including spices.

The practice of medicine was closely interwoven with magic and the science of omens. The application of drugs was typically accompanied by prayers and incantations. The goal was to strengthen the patient's will to recover. Interestingly, modern medicine has come to recognize that a patient's frame of mind can play an important role in recovery; mod-

ern scientists have begun investigating the power of prayer and religious faith in the healing process, believing that they can boost the patient's morale and promote healing. The ancient Mesopotamians, too, were interested in the psychosomatic properties of the healing arts—that is, the relationship between psychology and medicine.

From a modern standpoint, the fundamental flaw in Mesopotamian medicine was that practitioners were unable to formulate laws based on some overall theory of how the human body worked, in contrast to, for example, the ancient Greeks. Most of the medical literature that survives consists of what modern researchers would call case studies. That is, the texts record the particular cases of individual doctors, without any attempt made to impose some systematic organization on them. Other medical texts consist of letters, those written by both doctors and patients, along with questions that patients put to the doctors. From these texts, historians have even learned the names of some ancient doctors, such as Urad-Nanâ, the court physician at the city of Nineveh sometime around 680 B.C.E.

Most of these early texts contain only minimal efforts at diagnosis, with only cursory descriptions of patients' symptoms. Much of the emphasis is on diagnostic omens, along with indications of whether a particular illness can be healed or whether it is likely to result in death. If a disease was diagnosed as fatal, the texts often note that "the hand of" a particular demon was on the patient. Because some demons were more powerful than others, the demon specified represented a kind of prognosis for how long the patient might hope to survive. Similarly, when the prognosis was good, "the hand of" a particular god was on the patient. These kinds of statements, then, indicate the nature of the rituals that were to be carried out in connection with a patient's treatment. Somewhat later texts contain more exhaustive lists of symptoms and possible treatments, including lengthy courses of medicinal treatments with plants or minerals. Some of these later medical texts also include efforts by practitioners to summarize findings contained in earlier texts, allowing them to follow treatment plans from previous generations.

Again, this process of preserving records represents a form of scientific thinking. Scientists are members of a community of other scientists. They publish and share their findings, and other scientists can replicate their work and either confirm or deny the conclusions. That the Babylonians preserved medical records suggests an effort to forge a community of physicians who could draw on one another's work.

PERSIAN SCIENCE

Science in ancient Persia owed a great deal to Mesopotamia, and during the first millennium B.C.E., following the Persian conquest of Mesopotamia, much Babylonian mathematical, astronomical, astrological, and calendric lore certainly passed into Persian awareness and diffused, via the Persian Empire, as far east as India. Much scientific activity took place during the Sasanian Period beginning

in 224 C.E. In 271 the Sasanian king Shâpûr I (r. 241–272 C.E.) founded a learned academy at Gundeshapur, in what is today Khūzestân, the southwestern province of Iran. Gundeshapur became the empire's intellectual center. The academy was home to the world's first teaching hospital and included a library and a university. Two important contributions of Persian science include the discovery of alcohol and the development of a more sophisticated windmill than the Babylonians had developed.

One intriguing aspect of Persian science was the discovery of the principles of electromagnetism and possibly the world's first electric battery. Housed in a museum in Iraq is a 5-inch-tall clay jar that was discovered outside Baghdad, Iraq's capital city, in 1938. The jar contains a copper cylinder encased in an iron rod. Further, the jar itself shows evidence of corrosion, possibly by an acidic agent such as vinegar or wine. Since then, about a dozen similar jars have been found. While it is unlikely that the Persians understood the principles of electromagnetism, it is a common occurrence in science for something to be invented before scientists understand the underlying principles. What is known is that modern attempts to reproduce these ancient batteries have been successful in creating a current of 0.8 to 2 volts; batteries like these arranged in a series could have produced more voltage.

The basic principle that the Persians seem to have stumbled on is that an electric current is produced from two metals with different electric potentials, with some sort of an agent—an electrolyte—that carries electrons from one to the other, producing current. Wine and even grape juice can function as an electrolyte. It is quite possible that the discovery was made as a result of experiments by ancient alchemists, in both Mesopotamia and Persia. These alchemists, the forerunners of modern chemists, often worked with base metals such as lead, trying to turn them into gold. Alchemists, in their efforts to discover the chemical principles of the natural world, can be thought of as the world's first experimental scientists.

Historians have offered a number of explanations about the purpose of these batteries. One purpose may have been medicinal. Low-voltage electric currents can sometimes ease pain, a principle the Chinese use in the ancient art of acupuncture for healing. Another purpose might have been electroplating. To cover a base metal, such as lead, with a precious metal, such as gold or silver, ancient craftsmen typically had to pound the precious metal into a thin layer and then mix it with mercury to paste it onto the base metal. Electroplating is a much more efficient method for depositing a thin and even layer of one metal onto another.

Other historians have suggested that the batteries may have been used for religious purposes. The battery could have been held inside a metal idol so that a person who touched the idol received a slight electric shock and could see a blue spark. It has been speculated that ancient priests could have asked followers questions; if the follower gave the "wrong" answer,

he or she would receive a slight shock from the idol, convincing the person of the idol's power.

ASIA AND THE PACIFIC

BY TOM STREISSGUTH

The earliest scientists in Asia, as elsewhere, were farmers, miners, and smiths. The need to supply large communities with food gave rise to settled agriculture as well as the science of botany. Early Asian farmers cultivated rice, wheat, and barley, experimenting with those strains that could be easily grown, managed, and harvested. They domesticated fruit trees and collected wild plants they knew to have useful medicinal properties. Botanical knowledge came about through long periods of questioning, observing, and experimenting. In ancient China farmers developed new techniques of agriculture using the same methods. They learned to plant in rows, irrigate their fields, and build crop terraces on hillsides. Observation of the skies and measurement of the year and the seasons—the earliest scientific astronomy—gave them a method of timing their planting and harvesting.

The Chinese also undertook the world's first geological research. They collected and classified various kinds of rocks and came up with theories as to how the rocks were made. They investigated the properties of soil and climate that allowed crops to flourish in certain regions. They speculated that the earth and the mountains were in constant motion and that the weathering of rock and soil erosion lay at the origins of natural features such as valleys and mountains.

Throughout Asia the growth of farming allowed settlements to gather and store surplus food. This gave rise to a class of artisans who made weapons, tools, utensils, jewelry, and furniture. Mining and smelting metal ores that came from underneath the ground began the science of metallurgy. By observing the properties of ores and heating them in combination, metalsmiths created bronze, an alloy of copper and tin, as well as iron and steel. Bronze making arose independently in China and Southeast Asia, where hunter-gatherers in what is now Thailand were smelting copper and tin and making bronze goods as early as 2000 B.C.E.

ASIAN COSMOLOGIES

Pure science, or theoretical science, arose from observation of the natural world. Scientific understanding varied with the language, religion, and culture of the observers. During the Vedic Period (1500–600 B.C.E.) of India, for example, powerful deities were understood to reign over the earth, the heavens, and all manifestations of life. Brahma was the creator god who dreamed the world into being. Agni was the god of fire and Varuna the god of the sky. Surya was the sun and Mitra the moon. The ancient religious text known as the Rig-Veda, which dates to at least 1000 B.C.E., laid the groundwork for Indian science and mathematics through their ideas about the origin and nature of the universe and of all matter.

In China the philosophy of Dao (“the Way”) came to dominant the thinking of sages and scientists. Dao was the basic working principle of the universe, expressed through the concept of yin and yang, the balance of opposites. Yang was the expression of action, dominance, creativity, light, and the sun; yin was the moon and night, the completion of action, and the female characteristics of reticence and submission. Imbalance of yin and yang brought about sickness, poverty, and war; when the two forces were in harmony, peace and health reigned, with yin and yang in an uneasy and always temporary agreement.

In the Chinese view, the yin-yang balance was but one aspect of energy and matter (*qi*), which also manifested in *wuxing*, or the five elements of metal, wood, water, earth, and fire. The *wuxing* acted on one another in many ways: water overcame fire, for example, while wood restrained earth and generated fire. Fire symbolized upward movement, while water always ran downhill. Together these properties and their interactions gave the Chinese a comprehensive explanation of the infinitely varied phenomena of the natural world.

SCIENCE IN ANCIENT CHINA

During China's Han Dynasty, which began in 202 B.C.E., these various ideas and the schools of thought they had engendered, were melded into a single philosophical doctrine, known to historians as the Han synthesis. Chinese scientists of this period attempted to explain all natural phenomena—observations of astronomy, the human body, geology, botany, chemistry and alchemy, physics, biological processes, the weather, mathematics—in terms of the balance of opposing and complementary elements.

The Chinese had already been actively observing the natural world for millennia. Prehistoric Chinese accurately recorded the length of the year, at 365.25 days, as is recorded on inscribed bones. They also estimated the length of the lunar month to 29.53 days; this calculation gave rise to an accurate lunar calendar beginning at the winter solstice. (By order of the emperor's astronomers, a month was inserted at the appropriate time to keep this calendar aligned with the seasons.) A lunar calendar is still in use in determining festival days in China and throughout Asia.

Under the Chinese emperors, astronomers and all other scientists were part of the imperial household. They worked at the behest of the emperor to lend the ruler greater knowledge and glory and to strengthen his claim as the link between the earth and the unseen world. Astronomical observatories, first built during the Neolithic Age, were common structures in China by 1000 B.C.E. They were used to record the motion of the moon, planets, and comets against the apparently fixed stars and constellations. Chinese astronomers also observed sunspots, which are sometimes large enough to be visible to the naked eye, and began recording them in detail in the “imperial histories.” They recorded the appearance of comets (including the appearance of Halley's comet in 240 B.C.E.). In the fourth century B.C.E. the astronomer Gan De created a

comprehensive star catalogue, plotting the position of more than 1,000 stars. A tradition also records that Gan De made the first observation of Ganymede, a moon of Jupiter, without a telescope or artificial optics of any kind.

EARTH SCIENCE

Geology and metallurgy made important advances in the early Chinese dynasties. Geologists carefully recorded their discoveries while keeping the practical application of their knowledge foremost. For example, they constantly compared rocks and soils above the ground with those found beneath it. The Chinese discovered, for example, that the presence of hematite, or metallic stones, above ground indicates the existence of underground veins of iron ore and that the reddish mineral cinnabar is a good indicator of gold or mercury deposits. These observations led to classification systems for minerals, one of which is found in the *Shan hai jing* (The Book of Mountains), a work of the fifth century B.C.E. This book classified rocks according to their hardness, color, and shape, and guided metalsmiths in collecting mineral ores and smelting them into useful finished metals.

Ancient Chinese iron miners discovered magnetite, a rock with magnetic properties. This discovery led to the navigational compass, one of the most important technological breakthroughs in history. The Chinese built south-pointing compasses to guide themselves over land and sea. The pointers on these devices were commonly spoons or representations of animals such as frogs. Later the spoons were replaced by needles, which allowed the compass or pointer much greater accuracy.

The Chinese were also expert in the science of meteorology. They were setting down weather records by the second millennium B.C.E. and making daily calculations of temperature, rainfall amounts, and wind speed and direction. This diligent record keeping brought them knowledge of the earth's hydrologic cycle of precipitation and evaporation, which manifests in wind, clouds, and storms to keep the earth watered and fertile.

APPLIED SCIENCE

In all scientific endeavors of ancient China, theory and observation had practical uses. While observing the sun, an unknown Chinese inventor realized that the sun's position can be measured by the length of its shadow. He then created the gnomon, a simple vertical pole placed upright to cast the sun's shadow. The shadow shrinks to its smallest length at the summer solstice and to its greatest length at the winter solstice. Thus, using the gnomon, the Chinese measured the length of the year and marked the beginning of the seasons. The taller the gnomon, the more accurate the measurement; to raise large gnomons, the Chinese constructed massive brick structures, many of which still stand. The scientist Zu Gengzhi took the gnomon a step further by adding a horizontal measuring scale and making the device small and light enough to be carried.

Other Chinese breakthroughs include the making of cast iron and the forging of harder, more durable steel by blowing oxygen onto the cast iron and causing its carbon content to drop. This process relies on another ancient Chinese invention, the double-action piston bellows, which forces air continuously into a forge or oven. Chinese inventors also came up with gimbals—small iron rings that support an object and allow that object to remain upright no matter how the rings around it are turned. The gimbal became an important component of marine compasses, which must function accurately aboard ships in constant motion, and the gyroscope, which was invented by the second century B.C.E. The Chinese also invented, in the ancient period, umbrellas, stirrups, porcelain, hot-air balloons, iron plows, kites, and paper. Chain pumps, which allow users to raise water from a canal or ditch into a field of crops, are still in use in rural China. The south-pointing carriage was used for navigation on land. The device supported the figure of a man, pointing toward the horizon; no matter which way the carriage was turned, the figure always pointed south. A complex series of gears governed the transfer of motion from the wheels to the figure.

One of the marvels of early Chinese science and engineering was the curious object known as the spouting bowl. This large, precisely cast bronze bowl was filled with water. When the bowl was carefully rubbed at the handles, the water within the bowl began to spout and the entire bowl began to hum. The steady rubbing created a certain wavelength and frequency in the water's motion that caused a standing wave—one that moves up and down, not sideways.

One of the most important scientific quests of ancient China was the search for an elixir of life. Chinese alchemists sought to create gold and silver from baser elements and experimented with the properties of semiprecious stones such as jade. One could be made immortal, it was believed, if one ingested an eternal substance, such as gold, which does not rust or burn.

Chinese alchemists undertook long and complex experiments, always basing their work on the five elements and the concept of yin and yang. They heated and mixed chemicals derived from rocks, soil, and earth, as well as bones, teeth, and hair. They dissolved them in water, vinegar, mercury, and saltpeter. They studied the changes in the color and appearance of the elements, noting that different metals have different melting points and give off different colors when put in the fire. Alchemists also studied the effect of these substances on the body when applied to the skin or when taken in through drinking or eating them. Early chemical experimentation was held to be a great secret in ancient China and forbidden to common workers and peasants. Chemists, astronomers, geologists, and other scientists worked diligently for the emperor and were kept within the palace quarters and the imperial capital, where they were closely watched.

One of the most important scientists of ancient China was Zhang Heng, a scholar of the Han dynasty, who was born in 78 C.E. He served the dynasty as imperial historian

and studied astronomy, geography, and the physics of earthquakes. A brilliant mapmaker, he created detailed renderings of the empire while relying on the magnetic compass, which had allowed greater accuracy in maps and navigational charts. As tools for military campaigns, these maps were of vital importance to the emperor, who kept them a closely guarded state secret.

By recording the locations and dates of earthquakes, Zhang also took a scientific approach to understanding this dangerous natural phenomenon. His ingenious seismograph, known as the earth motion instrument, was a large bronze bowl that held thin copper rods placed horizontally across its mouth. The rods were attached to dragon's heads, positioned at the edge of the bowl at the eight major points of the compass. The dragon's heads held small copper balls and lay directly above small bronze frogs, cast with their mouths open and directed upward. A tremor or earthquake caused the ball to fall from the mouth of the dragon closest to the tremor into the frog's mouth, causing a small warning bell to ring. The device was activated by the wave motion of earth tremors, which move at great speed through the earth's crust. In 138 C.E. the instrument successfully recorded an earthquake 310 miles west of the Han capital.

As an astronomer, Zhang correctly surmised that eclipses were caused by the shadow of the moon passing over the earth. The ability to predict eclipses was sought after by the emperors, who thus gave themselves the aura of seers and prophets who lived closer to the gods. Zhang also constructed a model of the universe, showing the changing positions of the stars. In the field of mathematics he calculated the value of pi (the ratio of the circumference of a circle to its diameter) to 3.162, the most precise calculation of this number up to that time.

MATHEMATICS IN ANCIENT CHINA

Many historians also claim China as birthplace of the decimal system, in which place values are used to express single digits, 10s, 100s, and so on. The earliest Chinese counting systems used a system of rods placed in small boxes; the rods represented certain values depending on their position. No rods meant a value of zero, a concept that was vital to mathematical calculations and which originated in China (though its representation by a symbol came later and may have actually been invented in Southeast Asia.) Later this physical system of representing numbers developed into the abacus—a small, portable counting device that is still in use throughout China and the rest of Asia.

The Chinese also invented the concept of negative numbers, which in their counting system were represented by black rods (as opposed to red, used for positive numbers). The Chinese were the first to use decimal fractions and algebraic calculations for geometrical relationships. By the fifth century C.E. Chinese mathematicians had calculated the value of pi to 10 decimal places, putting them far ahead of Greek mathematicians working out the same value at that time.

The philosopher Mo Zi, who lived in the fifth century, applied himself to important questions in mathematics as well as physics, including the nature of light and matter. His followers, known as Mohists, lived in small communities and devoted themselves to scientific experiment and theorizing. They studied the force of gravity, the laws of motion, the nature of space and time, the use of fulcrums, and the equilibrium of objects floating in water. One of their inventions was a room-sized camera that projected an image through a small hole bored into a wall facing the sun. Mohists also carefully studied shadows cast by animals and natural objects, and the reflections in convex and concave mirrors. They were the first in the world to use experiments to draw conclusions about the nature of light waves. Their ideas were compiled in a book known as the *Mo jing* (The Mohist Canon), a work that has been closely studied by Chinese scientists since the 18th century.

SCIENCE IN INDIA

The civilization of the Indus River valley, in what is now northwestern India and Pakistan, developed while the first large cities were also growing in Mesopotamia (along the Tigris and Euphrates rivers in what is now Iraq) and the Yellow River valley of China. The early cities of India developed a precise system of measurement and made several breakthroughs in technology and engineering. Indus Valley cities, including Harappa and Mohenjo Daro, had drainage and sewer systems, indoor toilets, and paved roads. Chemists applied their knowledge to the craft of smelting molten metal ores to create steel and other useful products. Indus Valley steel was in wide use throughout Asia, the Middle East, and Europe by the first millennium B.C.E.

In later Vedic (or classical) times, Indian philosophers divided the natural world into five elements: earth, fire, air, water, and ether (or space). According to this philosophy, the first four elements are made of invisible small particles, the smallest of which was called *parmanu*. Each element has a corresponding sense in the human being: touch, sight, sound, taste, and smell. Everything on earth was created by chance combinations of the five elements, while the earth itself is a large round object under the control of the sun. The sun, in fact, controls all the planets that wander through the sky against the background of the fixed stars. The earth is divided into seven large islands, all surrounded by oceans of water.

The ancient texts known as the Upanishads delve into the essential nature, or *svabhāva*, of the elements and all objects in nature. These objects are subject to the workings of chance, or random occurrence, known as *yadracha*. The philosopher Kaṭāda, writing in the sixth century B.C.E., is given credit by some historians as the first creator of the atomic theory—the idea that all matter is composed of invisible, and indivisible, atoms—in his work known as the *Vaiśeṣika Sūtra of Kaṭāda* (which precedes a similar theory of the Greek philosopher Democritus). Kaṭāda claimed that matter can never be created or destroyed; atoms combine to form particles, which in turn make up all objects in the universe.

The school known as the Jainists came up with some startling ideas about the nature of matter. They theorized that atoms might have a positive and negative charge, a phenomenon that has been proved by modern particle physics. The Jainists also believed that atomic particles had a property of “spin,” or intrinsic motion. This is a central idea in quantum mechanics that was further developed by Western scientists in the 20th century.

INDIAN ASTRONOMY AND MATHEMATICS

The ancient Indians were skilled observers of the skies. Texts known as the *Siddhāntas* covered mathematics and astronomy. The authors tackled the problems of planetary motion, the force of gravity, and the position of the sun relative to the earth and planets. Indian mathematics was the most advanced of the ancient world. India developed the set of numerals that now prevail in calculations all over the world, including the Western world. These numbers date back to the earliest civilizations of the Indus River valley. They were employed in a system of weights and measures used by farmers and builders. The Vedic literature of ancient India contains calculations of the proper placement of sacred fires and the sizes and dimensions of sacrificial altars. The writers of these texts worked out the nature of square roots and the concept that became known as the Pythagorean theorem on the area of a right triangle, long before the Greek mathematician Pythagoras existed.

The ancient Indians used and understood addition, subtraction, multiplication, division, algebra, trigonometry, and logarithms. They worked out a basic form of calculus—the science of measuring and representing variable quantities in the natural world. The leading astronomer and mathematician of ancient India, Āryabhaṭa, collected all this knowledge in the *Āryabhaṭa*, a text explaining how to calculate square and cube roots as well as volume and area. Attempting to come up with unified mathematical models of planetary motion, Āryabhaṭa concluded that the apparent motion of the stars and planets is caused by the rotation of the earth and its movement around the sun. Āryabhaṭa understood that the other planets orbit the sun, they orbit in elliptical rather than circular paths, and lunar eclipses are caused by the shadow of the moon. He came closest of all ancient astronomers to understanding the true nature of the earth, sun, moon, and solar system.

Another important field of research in ancient India was the science of linguistics—the study of languages, vocabulary, and grammar. The religious texts of the Vedic Period advanced the idea of tenses, verbs, and noun cases and the concept of the two basic meanings of words: that expressed by the speaker and that perceived by the listener. The linguist Pāṇini, who lived in the early fifth century B.C.E., analyzed the elements of Sanskrit, the language used in religious texts of the Indian subcontinent, and detailed its working in 3,959 rules, which are still studied in modern times. His theories were further developed by Bhartrihari, a linguist of the fifth

century C.E. These two experts laid an important foundation for modern linguistics, which originated with studies in Sanskrit in the 18th century.

EUROPE

BY MICHAEL J. O'NEAL

The concept of *science* as a field of formal scholarly inquiry and organized thought has arisen only in recent centuries, so to speak of science in ancient Europe is not entirely accurate. Modern scientists pursue their research using the scientific method. They assume cause-and-effect relationships between natural occurrences. They make hypotheses about problems, test them by gathering data under controlled conditions, and then make generalizations about cause and effect that might in time gain the status of scientific laws. When the topic of science in the ancient world is discussed, what is generally meant is evidence for a system of observation of the physical world and the evidence for some forms of calculations. The challenge in ancient Europe is that there are no texts, so scholars have relatively few primary sources they can study to learn about ancient European science. In large part they have had to rely on the writings of Greek and Roman historians, who recorded what they observed about scientific practices in their northern colonies and client regions. Their observations, though, were made in late antiquity, so little is known about European scientific practice in earlier ages, such as the Bronze Age.

Ancient Europeans lived in a world in which they were subject to mysterious natural forces: the weather, disease, earthquakes, floods, and the like. Thus, one motivation for making observations about the physical world was to discover ways of controlling those forces, control that could be accomplished by trying to know the gods' will and make predictions about the future. Diviners, seers, shamans, and priests studied the attributes of nature—the movement of heavenly bodies, or the magical properties of plants—to learn how to exert some control over the natural world. These people were believed to have divine, supernatural knowledge, which they could use for the benefit of their communities.

Another way of considering ancient European science is to see it as the sort of science employed in engineering and medicine, where observations about the physical world are used to develop skills in various technologies, including, for example, agriculture, metalworking, and medicine. In the 21st century this is called *applied science*. Agriculture arrived in Europe about 9,000 years ago from the Near East, and over the next 4,000 years agricultural communities were established throughout the Continent. Early European farming communities planted wheat and barley as their main crops and raised cattle, sheep, goats, and pigs.

Clearly, these agriculturalists needed to make observations about the physical world and to develop innovative ways of raising crops that had been brought from the Near East into the European environment. They made observations about

the weather and soil conditions. They experimented with fertilizers and various types of crops, primarily grains such as barley and wheat. Early European farmers understood the differing properties of flint and other types of stone and used the ones that best suited their needs. They developed methods for storing their crops. Techniques for making pottery were continually refined using higher and higher firing temperatures. They learned that allowing fields to remain fallow for a period of time increased future yields. Herders learned to breed varieties of cattle that originated in the Near East but had to adapt to the colder climate of Europe. Animals like cattle that had previously been used primarily for their meat were harnessed for power to pull wagons and plows. Early Europeans learned that enzymes mixed with milk produce cheese and that reducing the moisture content of meat, fish, fruits, and vegetables by drying them is a way to preserve them. They also learned to make underground grain silos that kept grain from rotting and succumbing to pests by denying oxygen to the grain. All these activities presume some basic scientific knowledge about how the world works, about the properties of matter, about measurement and engineering, and the like. All of them presume, too, a process of trial and error over time, as agriculturalists tried crops and farming methods, passing along what they learned to their descendants.

Aiding the development of agriculture was the development of metalworking. Like most of the world's cultures, ancient European culture evolved from the Stone Age, when tools were crafted of stone, to the discovery of metals. The first metal widely used in tool making was copper. The Bronze Age began at different times in different regions when it was discovered that mixing tin with copper resulted in bronze, a much more durable metal than copper. At some point during the fifth millennium B.C.E. it was observed that certain ores contained copper, which could be smelted and collected and then pounded into simple forms. Over time, the technology for working copper improved to the point where it could be cast into more complicated shapes. Around 3000 B.C.E. in southeastern Europe, ancient chemists discovered that adding about 10 percent tin to a mixture of copper would produce an entirely new metal, bronze, which revolutionized metallurgy. Again these discoveries and innovations were the product of systematic observations that bordered on what might be considered science.

By about 1100 B.C.E. ancient Europeans entered the Iron Age, having discovered both that the ground in much of Europe was rich in iron ore and how to use that ore. Among the ancient Celts two primary cultures emerged around ironworking. The first was the Hallstatt culture, named after a town near Salzburg, Austria, where extensive mining operations were conducted beginning in about 1000 B.C.E. About 500 years later, the La Tène culture developed in modern-day Switzerland. These cultures produced an enormous amount of iron, and archaeologists have discovered numerous Iron Age artifacts from this region. These developments indicate that there were scientific advances in mining, separating

metal from ore, controlling temperatures in furnaces, and turning iron into useful products. Eventually ironworkers became chemists of sorts when they discovered that mixing carbon with iron produced much harder steel.

The development of iron led not only to better weapons—the Europeans carried the art of sword making to new heights—but also to better farming tools such as plows and harrows. Similarly, the Europeans were adept at building carriages and wagons and learned to cover wooden wheels with a metal band, or tire, that made the wheels more durable.

Medicine and healing were other forms of applied science. These activities were often associated with magic and with the ability of some people to understand the will of the gods. The Druids, the priestly class of the ancient Celts, gained wisdom about the healing power of plants. This wisdom was accumulated over long stretches of time by trial and error, as well as by making detailed observations about the effects of substances on the human body. Examples include willow tree bark, which contains a substance that is chemically similar to the active ingredient in aspirin. Celery and parsley were also thought to have healing powers. These substances were probably gathered according to a strict schedule based on the phases of the moon, in the belief that all the powers of nature worked hand in hand. In many senses ancient healers worked like experimental scientists, observing symptoms, trying herbal treatments, and seeing what seemed to help.

The ancient Europeans showed some skill in surgery. Near Munich, Germany, for instance, archaeologists discovered the tomb of a so-called warrior-surgeon that dates to about the third or second century B.C.E. and contained a number of medical and surgical implements: probes, retractors, and a trepanation saw, used for cutting holes in the skull. Trepanation was widely used to treat head injuries and psychological disorders, and healers used both saws and drills to make their holes. A large number of skulls have been found with neat holes drilled or cut into them. While many people died during this type of surgery, many others did not, for the holes in some skulls show evidence of healing. Earlier skeletal remains of two people found in Moravia, a region in the modern-day Czech Republic, show that surgeons operated successfully on them. In one case they removed a portion of bone, and in the other case they amputated a limb. In both cases the surgery took place sometime around 5500 B.C.E. The skeletal remains show that the patients healed and survived for several years following the surgery.

Little is known about the mathematical inquiries of the ancient Europeans. What is known has been discovered from practical applications. For instance, the circular stone megalithic monuments of the British Isles, including not only Stonehenge but also the megaliths at Avebury and other sites, suggest that their builders may have had some understanding of pi, the Greek letter that represents the relationship between the radius of a circle and its circumference. The geometric layout of these sites also suggests that their builders may have grasped the principle of the Pythagorean theorem

before Pythagoras, the Greek mathematician usually credited with discovering the relationship between the squares of a triangle's sides and that of its hypotenuse. Clearly, the ancient megalith builders understood principles of measurement and engineering. Measurement was also vital to European farmers, who had to devise ways to measure agricultural output and fields.

Extending back to the Neolithic Period the ancient Europeans were keen observers of the skies. A bronze disk with gold inlays found at Nebra in central Germany and dated to about 1600 B.C.E. is a controversial find owing to the circumstances of its discovery, but it is interpreted as bearing a depiction of the star cluster known as the Pleiades. By the time of the Roman Empire, Roman historians were praising the Celts for their astronomical skill. The writer Martial (ca. 40–103 C.E.), for example, noted that the Celts believed that the world was round, not flat. The Celts devised an astronomical calendar as far back as 1100 B.C.E., and for many years the ancient Greeks debated the question of whether the Celts borrowed their astronomical skills from the Greeks or the Greeks borrowed them from the Celts. In either case the Celts kept meticulous records of astronomical events and were even able to predict many regularly recurring events. A good example is provided by the tides and their relationship with the phases of the moon. A primary motivation was not simple human curiosity but the desire to understand the will of the gods, including the later Christian God, and to exert some measure of control over natural forces.

GREECE

BY PHILIPPA LANG

In ancient Greece before the sixth century B.C.E. people could roughly predict the movements of the stars and constellations throughout the year, relate the movements to seasonal change, and use the stars to navigate their boats and ships. They had the technology to make metals and other materials, such as pottery, both for practical use and pure decoration. They used plants and foodstuffs for medicine, and they had stories that explained the world around them and its origins, usually in terms of gods. The sea god Poseidon was the cause of earthquakes, and thunder came from Zeus. None of this is what is now called science. No word for science existed in ancient Greece, and the category of science, its methods, aims, and content, is a modern construction that does not transfer back to the distant past.

From the sixth century B.C.E. onward, however, some Greeks developed ways of thinking about the world and efforts at controlling it that were similar enough to the modern concept of science that the term can be used. Ancient science can be defined as attempts to explain, understand, predict, and sometimes control the natural world. But it is important to realize that the ancient Greeks did not think of themselves as doing science, and they had no agreed-upon scientific method.

In the sixth century B.C.E. a small group of people now known as the pre-Socratics developed several theories about the origins of the universe and its fundamental components. These theories survive only as fragmentary summaries and quotations in later writers, so not very much is known about them. They did not agree with one another, but what they had in common was the belief that the universe had a consistent and ordered nature that could be understood and explained by human reason. The Greek word for nature is *physis*, which is where the modern word *physics* comes from. The theories explain natural phenomena without involving traditional gods or other supernatural forces, though they may describe natural forces in terms of the gods or they may view the whole of ordered nature as itself divine. This new approach is now often called *naturalistic* or *natural philosophy*. Thales, the earliest pre-Socratic, suggested that the world floated on water and that earthquakes were caused by waves, not by Poseidon. Xenophanes looked at fossils of fish and argued that they showed parts of the earth had long ago been under water.

Most pre-Socratics also argued that the world and everything in it was made out of the combination of a very few elements, or sometimes that it was only one element in many different forms. Such basic elements were usually earth, air, fire, and water, but there were also other views. Democritus theorized that the basic units of matter were tiny unbreakable shapes called *atoms* that fell through a void. When they collided and stuck together, they made larger objects of many different kinds.

Another common pre-Socratic theme was a concern with what counts as truth and what kinds of evidence are reliable. This concern is called *epistemology*, the study of theories about knowledge, truth, and reliability, and it is closely related to science. But pre-Socratics were not scientists. Later Greek thought called them *philosophers*, which means “those who love knowledge.” Pre-Socratic inquiries made little to no use of experiment and appealed selectively to everyday observations. They agreed neither on most theories nor on how to evaluate them and decide which is better, or more nearly true. They were often as interested in ethics and politics as in scientific topics. Most pre-Socratics were charismatic individualists with radical and highly speculative views, rather than scientists in any modern sense. For example, Empedocles was a wonder-worker who claimed to be able to control the weather and cure the sick.

ARISTOTLE

The philosopher Aristotle (fourth century B.C.E.) was the first person to do something very similar to science as it is understood now. He argued that the causes of things were within the natural world and could be explained by a careful investigation of nature. He systematically collected information on living creatures and classified them by types and characteristics, trying to grasp how things worked and why. He dissected many animals; made first-hand observations of insects, fish, mammals, and birds; and asked experts and specialists such

as fishermen and beekeepers for information. His books *History of Animals* and *Parts of Animals* describe more than 500 species of living creatures, and his account of the dogfish was not equaled until the 19th century.

Aristotle's aim was not just to record details for their own sake but also to gather and use reliable data to arrive at theories about how and why things worked. An important guiding principle for him was the concept of teleology, which assumes that everything in nature is the way it is for a reason, except for unavoidable side effects. Aristotle said that "nature did nothing in vain." So when Aristotle looked, for example, at a heart, he assumed that the heart did something useful for the organism and did it well, and he tried to work out what that purpose might be and how the heart accomplished it. This can be a useful principle of discovery in biology, but it also meant that Aristotle and his followers rarely accepted that anything could happen just by chance, without a final purpose.

Aristotelian physics, though incorrect, was extremely influential. While Aristotle did a lot of sustained and organized investigation into nature, like most other Greek thinkers he rarely carried out experiments. Experiment was rare in the ancient world and did not usually have much authority, and the notion of test by falsification of a predicted hypothesis (the modern scientific method) was never suggested. After the ancient period a later thinker John Philoponus (sixth century C.E.) is said to have done experiments disproving Aristotle's claim that heavier objects fall faster than lighter ones, but no one took much notice until Galileo finally disproved Aristotle some 2,000 years later, in the 16th century.

Despite the lack of experiment, the concept of proof was very important in ancient science and philosophy. Aristotle developed the first explicit system of logic, in which, if the starting points are true, the proof is so constructed and worked out that the conclusion must also be correct. It is an important idea and works well in mathematics, but it is much more difficult, as Aristotle recognized, to apply to biology and other real-world situations that have many complicated variables.

THE LYCEUM

Aristotle set up a like-minded group of thinkers and learners, a school (the Lyceum or the Peripatetic), and many of his followers did similar research. Theophrastus (371–287 B.C.E.), the head of the Lyceum after Aristotle's death, investigated and collected data on plants and stones and wrote books about fire and weather. Strato (d. 269 B.C.E.), who was the leader of the Lyceum after Theophrastus, was interested in basic matter and problems such as how people could hear through solid walls. Little of Strato's work survives, but he seems to have argued that there were tiny pockets of void (empty space) within matter that explained how sound traveled through solids. Strato's theories had practical applications in the work of the mechanists.

The kind of science done by the ancient philosophers and other thinkers was an intellectual project largely restricted to the social and literate elite. Philosophers often justified what they did as the highest form of human endeavor, the acquisition of knowledge for its own sake and not for gain or use, practiced by people who did not need to work. But there were tensions. A comedy of the fifth century B.C.E., *The Clouds*, by Aristophanes, satirizes this kind of thought as ivory tower navel-gazing.

SPECIALIST THINKERS

For Aristotle, scientific understanding of the natural world, natural philosophy, or natural history was part of a broader project to understand and thus to be able to manage human life and ethics in its entirety, from poetry to theology and from politics (Aristotle defined humans as political animals) to the nature of friendship, and he was as interested in rhetoric as in logic. Thus philosophy is not the same as science, even for Aristotle, the most scientific philosopher of the ancient world.

But there were contemporaries of Aristotle who specialized in certain areas of intellectual and scientific enquiry. Mathematics was a developing field. Greek mathematics is primarily geometrical rather than arithmetical (algebra had not been invented). Although many theorems were known to other older civilizations, such as the Babylonian and Egyptian, a distinctive Greek addition, perhaps influenced by philosophy's concern with standards for truth and certainty, was a concern to prove a general theorem would be true for all possible values.

Well-known mathematicians of this era include Theodorus and Theaetetus, both of whom have roles in one of Plato's fictional philosophical dialogues on the nature of knowledge. The Pythagorean philosopher and mathematician Archytas, in the early fifth century B.C.E., viewed mathematics as essential to understanding reality. Archytas developed many solutions and proofs, including the solution to the problem of doubling the cube, and provided a mathematical account of musical scales. There was increasing agreement on methodology, terminology, and what counted as a proof. By around 300 B.C.E., the mathematician Euclid could write a book called *Elements* (of Mathematics) that laid out all known mathematics as a set of demonstrated proofs from which, beginning at the most basic hypotheses and definitions, increasingly complex theorems could be reliably derived. Mathematics had become an ideal of intellectual inquiry, the successful pursuit and discovery of knowledge for the sake of knowledge. It was also vital in several other kinds of investigation, especially astronomy and mechanics.

ASTRONOMY

Naturalistic theories about the universe and its origins, called *cosmology* and *cosmogony*, respectively, had been a major theme of pre-Socratic thought. Anaximander, for example, said that the world was a cylinder, with humans living on one

of the flat ends, surrounded by a thick mist that obscured the spheres of fire that enclosed the mist. People could glimpse the enclosing fire through pinpoint holes in the mist, holes that were perceived as the sun, moon, and stars.

Astronomical observations of the movement of the stars and their relationship to seasons were much older, because they were crucial to a largely agricultural society. Official calendars followed the phases of the moon, but over many years such calendars became out of phase with the solar year, until an event originally placed in the spring took place when the leaves were falling.

In the fifth century B.C.E. Meton, probably working partly from Babylonian written observations of the movements of the heavens (going back much further than those of the Greeks), worked out a 19-year lunisolar calendar that would have kept the moon and the sun in step over a 19-year period to a precise degree of accuracy. The Athenian state did not adopt this as the official calendar. The results of specialist intellectual inquiry were not always viewed as socially useful or as an improvement on tradition.

In astronomy itself, however, observations were becoming fuller and more detailed, including Callippus's work (fourth century B.C.E.) on the exact dates of the summer and winter solstices and the realization that the year's four seasons are not of equal length. These observations were incorporated into attempts to produce models of the cosmos that would account for such phenomena as the movements of the sun, the lunar cycle, and the movements of the so-called wandering stars—the planets. (*Planet* is Greek for "wanderer.")

The traditional story is that Plato challenged astronomers and mathematicians to come up with such a model and that in response Eudoxus developed his theory of concentric spheres. In this theory the sun, moon, and five planets are fixed to 27 spheres around the common center of the stationary earth, and these spheres revolve on different axes of rotation and at different speeds. The theory was elaborated by Callippus, mechanized by Aristotle (by which time it had 76 spheres), and eventually abandoned in the second century B.C.E. when the mathematician-astronomer Apollonius of Perga and Hipparchus invented models of epicyclic and eccentric rotation. Their model was further refined into the Ptolemaic universe worked out by the astronomer Claudius Ptolemaeus (Ptolemy) in the second century C.E., a system that survived until Copernicus.

The aim of all such models seems at least partly to have been "to save the phenomena"—that is, to discover a working mathematical model of the heavens that allowed observations to be accepted and not explained away as optical illusions or untrue in some other way. Some of these models may have been largely exercises in mathematical ingenuity, but many astronomers were certainly interested in trying to discover how the universe actually worked. In the third century B.C.E. Aristarchus of Samos proposed a heliocentric cosmos, but only one person supported the idea, and later astronomers such as Claudius Ptolemaeus attacked it on the grounds that

it was not supported by observation or by current (Aristotelian) theories of physics.

Astronomy was an enterprise that required considerable mathematical knowledge, beyond that even of most philosophers, although most people probably had a very basic form of astronomical knowledge. Specialized and difficult though mathematics was, it did have practical applications in the everyday world in meteorology, geography, and especially astrology.

METEOROLOGY

The Greeks traditionally associated changes in the weather with changes in the sky. Storms, for example, were more frequent around the time of the equinoxes. The sun, moon, stars, and planets were thought to be much closer to the earth than they actually are, and so their movements were thought to affect the air around the earth and thus the weather. As astronomy's observations and models became increasingly detailed and precise, predictions of the weather also grew much more elaborate. In the third century B.C.E. the poet Aratus of Soli recast a famous astronomical book by Eudoxus about the movements of the stars and related weather patterns into poetry. It was extremely popular among the literate population of the ancient Greek and Roman world.

GEOGRAPHY

The early Greeks believed that the lands around the Mediterranean Sea were surrounded by a huge ocean. Going far enough east, west, north, or south would take a person to the edge of the world. Slowly, traders and other travelers brought back information about foreign lands, and the world the Greeks knew about got bigger.

By the fourth century B.C.E. many intellectuals had realized the world must be a sphere. Aristotle pointed out that someone watching a ship sailing away sees the front end of it disappear first. In the third century B.C.E. Eratosthenes calculated the circumference of the earth, possibly to within about 311 miles. (The exact length of the unit of measurement he used is not known.) Although only a few experts and, to a smaller extent, educated laymen, traders, and the military needed to know much about astronomical geography, those who did were slowly building up a three-dimensional picture of the Northern Hemisphere.

ASTROLOGY

Before the Greeks, Babylonian priests watched the sky for omens, and their long-term observations provided vital astronomical data for the Greeks. The data enabled astronomers to predict the future movements of the stars based on past patterns. Although the details are unclear, sometime between the third and first centuries B.C.E. this ability to predict movements developed among the Greek population of Egypt into an astrological system, a synthesis of Greek thought with Babylonian omen-based astronomy and some small Egyptian influence. An important part of this astrological system was

the notion of a horoscope, in which the positions of the heavenly bodies at the moment of a person's birth determined that person's future; thus astronomy was crucial. There are surviving Greek horoscopes from the first century B.C.E. Astrology quickly became extremely popular, though not everyone was convinced and those who were held many different views as to how it worked. Astrology relied on the astronomical and mathematical knowledge of a very small group of experts, and thus made mathematics relevant to the lives of many people in society other than the literate, intellectual elite.

MECHANICS

Mathematics, with an understanding of certain physical principles, was also crucial to the emerging discipline of mechanics. From very early times in Greek society there had been craftsmen and engineers who could build a ship, a fountain, or a defensive wall. This kind of specialist expertise, which could be written down but was usually passed on in oral and practical lessons from teacher to apprentice, is called a *techne*, usually translated as "art" or "craft." The word *technology* is derived from it.

Some arts, such as architecture, required mathematical knowledge. The physics of motion, materials, and machines was also a topic of interest to some philosophers and other intellectuals. Aristotle's school, the Lyceum, produced a treatise called *Mechanical Problems* that discussed the workings of common machines such as pulleys and windlasses, not to mention the physics of the knee joint.

Theories were developed about the behavior of air and liquids under pressure, or pneumatics and hydraulics. Pneumatics, hydraulics, and other applications of physics resulted in the production of machines made by a specialized group of intellectual inventors, the mechanists. Many of the mechanists' devices involved steam power. Ctesibius of Alexandria, working in the third century B.C.E. invented, among other things, a water organ and statues and doors that moved automatically. These kinds of toys and spectacular set pieces did not usually have any practical purpose. The ancient world had very little industry in the modern sense. They were perhaps made to display cleverness and to surprise and entertain a client base, an audience of the social elite, or anyone else who saw the mechanists' products.

But there were important practical roles for mechanists as developers of improved military technology, defensive structures, and civic buildings. The mechanist Philon of Byzantium, in the second century B.C.E., described how the Greek kings of Egypt, the Ptolemies, funded engineer-mechanists to conduct a series of experiments that would result in building the most effective kind of catapult. The lighthouse of Alexandria was also an example of the mechanists' practical technology.

Mechanics was heavily utilized by governments and had considerable social importance. Many relatively well-off individuals used architects and engineers to construct private buildings and machines for them. But the fact that mechan-

ics and engineering were largely practical and that practitioners were professionals who got funding and payment—and probably also because manual labor was involved—meant that many of the elite regarded the discipline of mechanics as inferior to mathematics and natural philosophy. The ancient Greek intellectual ideal was to study the nature of the universe for the sake of knowledge alone.

Many mechanists argued against this downgrading of their expertise, and some experts managed to become famous both for their mathematical ability and their useful machines. Archimedes (287–212/211 B.C.E.), known for having allegedly shouted "Eureka" (I've found it!) in the bath on discovering the law of buoyancy, was well known both as a highly theoretical mathematician and the inventor of many practical machines. The Archimedean screw, named after and probably invented by him, made it much easier to lift water from the ground and was widely used for centuries in agriculture. During the siege of his city, Syracuse, by the Romans, Archimedes is said to have constructed many innovative war machines, such as a claw that pulled ships out of the water. It is unclear how reliable these reports are in their details, but certainly Archimedes was believed to have been important to the defense of Syracuse.

MEDICINE

Traditional healing in Greece consisted of a combination of the use of plants and foodstuffs as drugs, surgical procedures that were traumatic in themselves, and the use of incantations. This combined approach to medicine became a *techne*, an art, though people might also take care of themselves by self-medicating, appealing to the gods and participating in healing cults, or going to experts such as drug collectors (root cutters), purifiers, and magicians.

In the fifth and fourth centuries B.C.E. many practitioners of medicine adopted a more exclusively naturalistic approach, which both influenced and was influenced by contemporary developments in philosophy. In this naturalistic concept of medicine, physicians developed theories about the nature of the human body as a biological animal and treated illness on the basis of this understanding. The texts of the so-called Hippocratic Corpus were written by an unknown number of anonymous authors during this period. They were later collected together under the name of the famous physician Hippocrates of Cos (fifth century B.C.E.), though it is not known whether Hippocrates actually wrote any of them.

Some of these Hippocratic texts explicitly assert a naturalistic approach and describe theories of physiology and pathology; others are more practically oriented but assume a naturalistic view. The theories described in these works differ, but they often involve one or more substances in the body called *humors*, such as phlegm, bile, and blood, which need to be in balance for health. Physicians demonstrated their authority and expertise by being able to predict the course of a disease and, if it did not seem likely to be fatal, by intervening

with advice on diet and activity and sometimes with more drastic remedies such as purgative drugs or bloodletting, all with the aim of rebalancing the humors. They also practiced traumatic surgery and cauterization of wounds. Diet and exercise (together known as *regimen*) were also widely prescribed as preventive measures.

Anatomy in the Hippocratic corpus is very speculative and often inaccurate. Aristotle carried out animal dissections in the fourth century B.C.E. In Alexandria during the third century the physicians Herophilus and Erasistratus performed human dissection and even, according to a later but almost certainly reliable report, human vivisection, or operation on living beings. This greatly improved anatomical knowledge, including discovery of the heart valves, the ovaries and Fallopian tubes, the structure of the eye, the difference between motor and sensory nerves, and many other findings. But physicians still disagreed widely on how to interpret their findings. Herophilus seems to have held a largely traditional theory of humoral imbalance. Erasistratus developed a radical new theory, influenced by contemporary developments in mechanics, of the heart as a pump and the mechanical movement of fluids around the body according to pressure and vacuum. He argued that the arteries contained only air, while veins contained only blood.

Possibly because even systematic investigation of human anatomy had produced neither agreement on theory nor improvements in clinical treatment, some doctors rejected theory altogether as useless. They called themselves *empiricists* and said that doctors should merely remember that certain remedies had in the past been associated with recovery from certain symptoms, without speculating about causes and effects.

Medicine consisted of a specialized and practical expertise carried out by professionals, usually for a fee. As such, some philosophers criticized it as being limited in scope and as having less intellectual status than philosophy. In response, some physicians claimed that medicine was an exemplary form of knowledge and very difficult to master. Other doctors argued that medicine should not be too theoretical but should be based on practical experience and paying attention to the individual case.

Some contemporary dramas and epitaphs for the dead attacked doctors as incompetent. Certainly their rate of success was not high, though probably not noticeably worse than other kinds of healers. The Hippocratic text *Epidemics* seems to imply that physicians treated all social classes, including the very poor, but it is difficult to assess whether doctors were called in for routine illness or only when the situation became obviously serious.

Medicine, in the sense of a naturalistic or scientific medicine exclusive of other forms of healing such as religion or magic, had several roles in society. First, as a practical system of knowledge like that of a craft, it was widely used but perhaps little trusted. Second, as an intellectual enterprise, it tried to investigate and understand the human being as a biological animal, using methods of observation, dissection,

and occasionally experiment and reasoning from the data thus produced. This role was strongly associated with literacy, high social status, and natural philosophy, and there was some conflict between philosophy and medicine over their relative intellectual merits.

ROME

BY PHILIPPA LANG

The word *science* is derived from the Latin verb *scio*, which means “to know” and in particular “to know by finding out,” though it is not simply equivalent to what we mean by science today. We can roughly define science in ancient Roman as any investigation or understanding of the material and natural world that proceeds by carefully reasoned argument on the basis of empirical data and assumes that the world will be consistent and ordered. If a stone always rises for a little way and then falls back to earth, the presumption of natural philosophy, or science, is that the stone will always behave in the same way and for the same reasons and that we can work out why it does so.

Science in Roman society and culture was derived to a large extent from science and philosophy in Greek culture. Many of the Roman aristocratic elite during the late Republic (second to first centuries B.C.E.) and then in the Roman Empire of the following centuries translated and discussed Greek philosophy and science, while many Greeks in the Roman Empire also continued to investigate and argue about the way in which things worked. In fact, many leading figures in the fields of science during the Roman Empire were of Greek descent and culture, but they resided in places under Roman control and worked for Roman emperors.

These kinds of investigations were strongly associated with the upper classes, who had the education, time, and inclination to pursue scientific and philosophical knowledge either for its own sake or as part of a general understanding of the world. At this time the major Greek philosophies of the Hellenistic Period (323–31 B.C.E.) each offered a comprehensive understanding of the world and humankind’s place in it, though none of them agreed with each other. Many Roman aristocrats and intellectuals aligned themselves with one of these philosophies and contributed to them, and their ethics and theology were interdependent with their natural philosophy—their theories of biology, physiology, psychology, and what we would call physics and chemistry.

At the same time, areas of science with important technological and practical applications were used by both Roman individuals and the Roman government. These included civil, personal, and military engineering and surveying, from architecture to ballistics. Medicine was also very important. Roman and Italian culture incorporated a large amount of traditional medicine in which foods and plants were administered for illness, often accompanied by incantations, magical rituals, and appeals to the gods and other supernatural powers. Contacts with Greek culture, however, introduced the professional phy-

Bust of Pseudo-Seneca, before 1626, by Peter Paul Rubens; this drawing is of a Roman portrait bust thought to be the Roman Stoic philosopher Seneca, who wrote several scientific treatises. (Copyright the Metropolitan Museum of Art)

sician and methods of surgery, cauterization, and sometimes strong drugs. The first Greek doctor in Rome was nicknamed “the butcher” because of his use of such methods, and some Romans, like Pliny the Elder (23–79 C.E.), criticized medicine as un-Roman. Nonetheless, Greek medicine became popular, and doctors in Rome and throughout the empire were usually Greek.

In general, Roman reactions to Greek ideas, including much of Greek science, were complicated. Many traditional Romans thought that the influence of Greek culture might weaken Roman society through its focus on inessential speculation and ways of life, unlike the conventional Roman emphasis on farming, the army, and the duties of political office. Many elite Romans, however, could speak Greek and were interested in such ideas, and they adapted or developed them, writing epic poetry, history, and drama of their own—all forms of literature that the Greeks had invented. Similarly, Greek works on science and philosophy found an elite Ro-

man audience and some Roman practitioners. The Roman politician and philosopher Seneca (4? B.C.E.–65 C.E.), tutor to the future emperor Nero (r. 54–68 C.E.), wrote many works related to his Stoic philosophy, including *Natural Questions*, which explains and discusses such scientific problems as the causes of rainbows and comets.

SOCIAL AND INTELLECTUAL STATUS

There was to some extent, as in Greek society, a social divide between those working on science and philosophy as a matter of intellectual interest and personal development and those who practiced scientific specialties as a profession, for which they received payment. This was closely related to a common attitude, at least among the first kind of intellectuals, that scientific inquiries were greater if they did not involve actual physical materials or things. “Pure” mathematics, for example, was thought to be superior to applied math. This idea was held partly because the notion of the general proof—one that applies to a class of objects and can be logically proved in the abstract rather than having been tested only for specific, concrete examples—was central to the development of Greek geometry and became an ideal for all intellectual enterprises. Thus, Pythagoras’s theorem is expressed thus: “The square of the hypotenuse is equal to the sum of the squares on the other two sides.” It is not stated as the numerical formula $5^2 = 3^2 + 4^2$, and so on for every actual set of triangle lengths actually tested.

There was also a common assumption that abstract reasoning was more reliable than sense perception and observable data, even though the former obviously must rely to some extent on the latter. The result is that “practical” or productive forms of knowledge, including some applied science, were seen as less true and certain than more abstract inquiries, as well as being usually practiced by people of less wealth and social status.

However, many people actually working in such fields as engineering and medicine strongly resisted that their subjects were evaluated at this lower status. The Roman Empire Greek mechanist Hero of Alexandria claimed—possibly as a joke—that mechanics was actually better at producing the philosophical ideal of a tranquil life lived without fear or worry than philosophy was because a city with good mechanists and ballistics engineers would never be attacked. The Greek physician Galen (129–ca. 99 C.E.), who was the personal physician of the Roman emperor Marcus Aurelius (r. 161–80 C.E.), tried to work out a set of logical and mathematical rules for medicine, such as a theorem for the length of time it took for a wound to heal based on its size and shape.

Many such practitioners, certainly those at the top of their fields, were literate and well-educated men who argued that their discipline was just as reliable and worthwhile as philosophy or pure mathematics. The dividing line was far from absolute. Many elite lay Romans read works on medicine and mechanics, even if they did not regard them as suitable subjects for a gentleman to practice.

PHILOSOPHY SCHOOLS

Scientific theories formed an extensive and integral part of several philosophical schools of the Roman age. In this context, a school was a group of like-minded people who learned from each other, sometimes at a shared physical location. No qualifications or formal educational process was implied by the term. These groups had formed in Greece in the third century B.C.E., though their arguments continued to develop. Two important schools were the Stoics and the Epicureans. They had systematic—though completely different—theories about such things as the basic materials of the universe, the physiology of sense perception, and the workings of body and mind. They offered a naturalistic understanding of every kind of phenomenon, from lightning to the way mirrors work to the development of human society. These theories were compatible with, and used to supply evidence for, the Stoics' and Epicureans' theories on ethics, epistemology (the study of nature and the grounds of knowledge), and theology. The Stoics, for instance, considered God to be a material substance present throughout the actual world. Everything that happened was according to God's plan via a mechanistic, completely determined, causal chain. The Epicureans, on the other hand, maintained that the gods were perfect beings made like everything else of constituent particles and void, and they were completely irrelevant to human affairs. For both groups, science was not separable from other areas of human understanding.

A third group, the Skeptics, was not committed to any theory at all because their epistemological position was that there was no definite, clear instance of incontrovertible knowledge about anything and there was no definite proof that any theory was more true than any other. These radical Skeptics in philosophy, and their medical equivalent, the empiricist physicians, criticized the theories and beliefs of everyone else. This meant that people who believed that some theories were true had to improve their arguments against the Skeptics' attacks. It can be argued that skepticism was overall not helpful to philosophy and science because it focused attention away from the actual content of scientific theories and instead highlighted underlying epistemological positions. All theories, whether they were well supported by the evidence or not, were equally vulnerable to skeptical attack because 100 percent certainty was the only standard for truth they would allow.

The scientific theories of the philosophical schools were not often updated. This is primarily because their main aim was to offer the best understanding of the world as a means of achieving what they called *ataraxia*, or a life without disturbance, fear, and worry. They competed with each other as to which of them offered the most convincing way of achieving this state of being, so the philosophical schools had no incentive to revise their basic principles or their scientific theories and tended to be conservative.

MEDICAL SECTS

Professional physicians in ancient Roman society—most of them Greeks—were divided into three broad methodological

categories: the Empiricists; the so-called Rationalists or Dogmatists; and, from about the first century C.E., the Methodists. These groups were called the medical schools or sects.

The Empiricists emerged in the third century B.C.E. as a group of doctors who shared a common epistemology and methodology. They seem to have been popular among patients, including high-status ones such as kings. Their position was in many ways similar to that of the skeptical philosophers. The Empiricists said that there was no point in investigating the body with the aim of deducing theories about physiology or illness because no such theory could be proved true beyond any doubt and so might be false. They also said that this kind of theoretical knowledge was unnecessary for good medical practice. Empiricist doctors relied on their own experience of treating diseases (*autopsia*) and the recorded or reported experience of other people (*historia*). They associated certain symptoms with particular successful treatments and when they saw the symptoms again, they were reminded to use the same treatments. But they did not draw any conclusions from this about the nature of the disease or why the treatment seemed to work. Empiricists rejected dissection as useless and maintained that observation of internal organs exposed by accident when someone was wounded was enough to learn basic anatomy for the purposes of surgery.

Methodism may go back to the physiological theory and treatments of Asclepiades, a famous Greek doctor who lived in the Roman province of Bithynia in the first century B.C.E. and taught himself medicine as a second career after having been an orator. Asclepiades developed a theory in which he determined that pores in the body are sometimes blocked by some kind of corpuscle (thought of as a minute particle) and that this is what makes people ill. But Methodists themselves did not think that this information was relevant to being a good doctor. According to the Methodists, all diseases shared one of three common features: the patient was too constricted, too lax, or a mixture of the two. They believed that treatment should be based on that alone and that patients should be treated "by opposites"; thus, patients who were too constricted should be treated with relaxants. This was the method (*methodos*). Other knowledge acquired through experience, deduction, or dissection may have been possible but was unnecessary for medical practice. Medicine was, therefore, easy to learn—the Methodist founder Thessalus is reported to have said it took only six months. Methodists did not think that dissection was useful, though they may have thought it was interesting. One famous Methodist, Soranus, a Greek physician of second century C.E. who practiced in Rome, is remembered for his work on gynecology, which has survived largely intact.

All physicians who were neither Empiricists nor Methodists contended that reliable knowledge about physiology and illness could be rationally deduced to at least some extent. For this reason they became collectively known as "Rationalists" or "Dogmatists." This very general agreement, however, was their only common factor. There were many subgroups and even individuals within the rationalists who disagreed with

each other about theories, methods, and treatments. Most of them would have agreed that dissection was useful, but few physicians seemed to have done any themselves in the Roman period, even on animals. A notable example of a rationalist who performed dissections is Galen, who carried out dissections and vivisections (operations performed on the living) on many animals, including dogs, goats, Barbary apes, and once an elephant. Galen's dissections were often carried out in public settings, where anyone could watch as a kind of popular theater that Galen used to lend dramatic visual support for his claims about physiology.

MEDICAL TRAINING AND TREATMENTS

The usual way to learn medicine was by apprenticeship to a practicing physician. Sons of physicians probably often became doctors themselves as part of a family business. Many elite doctors studied in several places famous as centers of intellectual medicine, such as Pergamum and Alexandria. They may also have been educated in philosophy more generally, as Galen was. It was possible to teach oneself by reading works on medicine, as Asclepiades is said to have done. There were no examinations or legal qualifications to take, so anyone who wanted to set up as a doctor could do so. However, whether people came to a particular doctor depended on his reputation and what they knew about him, and in the early stages of a practice it would have helped to have learned from a locally known doctor or a famous physician elsewhere. Doctors were usually men, though it is possible that female midwives, some of whom were literate and trained in medical methods, treated female patients for a broader range of problems than those associated with childbirth.

In ancient Rome a very common medical treatment was the prescription of a combination of diet and lifestyle recommendations, such as exercise and baths, known as a *regimen*. For illness, drugs could be prescribed. In the Roman period these became increasingly complicated. Drugs that contained only one or two ingredients were called simples, but many drugs were made of numerous ingredients, sometimes more than 100, and such a medicine was called a *polypharmacy*. Women might use contraceptives, abortifacients (a drug that causes abortion), and drugs to bring on menstruation. There were many kinds of surgical operations, both for trauma and internal conditions, including an operation to remove cataracts from the eye. Since there were no anesthetics, several assistants were needed to hold conscious patients still for operations.

The combination of mathematics and astrology produced *iatromathematics* (medical astrology). The movements of the stars were thought to affect the course of a disease and the times and ways in which a physician could most effectively intervene. Medical astrology was popular and accepted by many physicians, but not all.

MATHEMATICS

The administration of the Roman Empire required a great deal of organization, much of which depended upon some de-

gree of mathematical knowledge. Arithmetical expertise was needed by the government and army officials and secretaries who dealt with taxes on land, trade, and goods; public expenditure and accounting; army provisions and the payment of soldiers; the regular census of the population; and many other aspects of a large empire. Many traders and other businessmen also needed to be able to manage numbers quickly and reliably or to employ people who could. Bronze abaci were widely used in this period.

Geometry was also vital for the taxation and management of land. Architects and engineers used geometrical theorems in major civic projects like Rome's sophisticated water supply of aqueducts, fountains, sewers, public baths, and private houses; in private enterprise such as the building of luxury villas; and in the military. The Roman architect Vitruvius of the first century B.C.E. describes how to build a water system for a city, as well as many other machines.

The Roman army employed surveyors for mapping military terrain as well as for constructing and attacking siege defenses and fortifications. One example of such a fortification is Hadrian's Wall in Great Britain, a stone-and-turf wall that ran for 73 miles across the width of the country at a height of almost 20 feet and with regular forts. Roman roads tended to be very straight, and roads within the empire might be tunneled straight through a mountain. Surveyors used mathematical techniques and simple instruments like the *dioptra*, or sighting rod, to keep the construction on track.

ASTRONOMY AND CALENDARS

By the Roman period the movements of the stars were well understood. The traditional Roman calendar had 12 months and a year consisted of 355 days. To keep the calendar year in approximate agreement with the solar year, which is longer than 355 days, the state priests in charge of the calendar had to add a month every other year. In the first century B.C.E. the calendar was not properly managed, so in 45 B.C.E. Julius Caesar replaced the old system with a solar calendar on the advice of a Greek astronomer, Sosigenes of Alexandria. This system was slightly altered again by Pope Gregory XIII in 1582, and the Gregorian calendar is the one we still use today.

The Julian calendar reform shows that technical expertise in astronomy belonged largely to the Greek tradition of mathematical astronomy. Although many elite Romans took a lay interest in the stars, they were not concerned with exactitude. The main source for astronomical theory was the Hellenistic Period poem of Aratus of Soli (ca. 315–ca. 240 B.C.E.) on stars and weather titled *Phaenomena* (Appearances). This work had been adapted into verse from a much older astronomical text, which by the time of the Roman Empire was, in fact, rather out of date.

Caesar consulted foreign experts and then used the results to organize the way in which the Roman Empire counted time. (Local cities and regions would have simultaneously often used older methods as well.) Mathematical astronomy thus had an enormous impact on the Roman world because

Roman government perceived it as reliable and useful. It remained, however, the specialty of a few experts, usually those of Greek descent and culture, often from the Greek populations and settlements of Asia Minor, Syria, and Egypt.

The ancient Romans also used armillary spheres, an astronomical device that had moving parts and modeled the movements of the heavenly bodies. Some scholars have suggested that Nero's Golden House contained one. An armillary sphere is depicted in a wall painting of a luxury villa from the Stabiae (modern-day Castellammare di Stabia) region of Italy. The Roman elite liked to own gadgets and to demonstrate an awareness of contemporary intellectual endeavor, but they did not build their own.

GEOGRAPHY AND ASTRONOMY

Ptolemy, a Greek astronomer of the second century C.E. who worked in Alexandria, is known for his theory on the motions of the stars and planets, which built upon earlier Greek astronomy and became the accepted model of how the cosmos worked until the discoveries of Nicolaus Copernicus and Johannes Kepler in the 16th and 17th centuries, respectively. Ptolemy's *Geography* gives the latitudes and longitudes of over 8,000 places on the earth, just as astronomers located the stars in the heavens through their celestial coordinates, though not all of his information was accurate. He also developed a mathematical way to project the three-dimensional world onto a two-dimensional surface such as a map.

Maps existed in ancient Rome but were probably not often used by ordinary individuals for the purpose of finding their way about. More common were "itineraries," which listed the times it would take to travel between two places. Geographical knowledge of the Northern Hemisphere in the Roman period was quite detailed and extensive, especially of the lands of the empire and, to a lesser extent, of the trade routes to India and China. There was a strong link between geographical knowledge and imperial power, both ideological and practical. To know a terrain well was to have some control over it, especially from a military point of view. To be able to display maps, such as the map of the empire that the Roman general Agrippa (63?–12 B.C.E.) had carved in marble, showed the general population the size and importance of the empire and demonstrated the competence of the empire's leaders. Individuals may have known much less about the world beyond the places that concerned them directly.

ASTRONOMY AND ASTROLOGY

Astrology was almost indistinguishable from astronomy in the ancient world since its development in Ptolemaic Egypt over the third to first centuries B.C.E. Many astronomers believed that the stars and planets influenced human lives. The astronomer Ptolemy wrote *Tetrabiblos* (Four Books) as a scientific account of astrology. He thought that the heavenly bodies shaped earthly environments and so affected the character of people according to what time of the year they were born. Although not every event in a person's life was

entirely determined in this way, a good astrologer could estimate the probability of certain events. For instance, a very confident, adventurous person was more likely to die at sea. Other astrologers and intellectuals had different accounts of how astrology worked or how rigidly deterministic it was. Some viewed it as a matter of theology, contending that the movements of the stars were messages from the gods.

There were also skeptics, especially among intellectuals such as the philosopher Favorinus (fl. second century C.E.), who attacked inconsistencies in astrological theories, asking why twins did not always have the same fate and pointing out that many astrological predictions did not come true. The Roman philosopher and statesman Cicero (106–43 B.C.E.) gave similar arguments in his dialogue *De divinatione* (On Divination), which discusses methods of predicting the future through the observation of signs. It was, however, always possible to explain a false prediction by saying that the astrologer was incompetent or that astrology, like medicine, is difficult and that using it cannot always be done with perfect success. Some astrological predictions could be self-fulfilling, or identified in retrospect. The horoscope of the emperor Augustus (r. 27 B.C.E.–14 C.E.), drawn up after he had become ruler of Rome, unsurprisingly predicted a remarkable career. Augustus put his sign of Capricorn on some of his coinage.

Astrology could also be politically dangerous. Predictions that the emperor would die could easily be connected to assassination attempts. In 11 C.E. Augustus made it illegal to make a prediction about anyone's death. Astrology was also seen as in origin a foreign expertise, connected to Greece, Egypt, and Babylonia. Astrologers were usually called Chaldeans, which was the name of the Babylonian order of priests who watched the sky for omens. Both astrology and magic were at times banned in Rome.

Nonetheless, astrology rapidly became extremely popular in Roman society. In his poems the Roman satirist Juvenal (ca. 55–ca. 127 C.E.) mocks many of its adherents, especially women and the lower classes. Most astrologers were not, in fact, astronomers. By the early second century C.E., however, there was sufficient data to compose planetary tables in which the relevant information could simply be read off for any year and time.

Astronomy and astrology had a close relationship. Astronomy remained a demanding and specialized form of mathematics. Astrology, on the other hand, was widespread and practiced both by professionals and by individuals who wanted to predict their own future. Astrology was, however, ultimately dependent on astronomy and using astronomy's reputation for precise mathematical certainty for its own advantage. Astronomy, meanwhile, could explain its relevance to human life through the predictions of astrology.

SCIENCE IN THE LATE EMPIRE

The late empire included many notable mathematicians, such as Pappus of Alexandria, Theon of Alexandria, and Eutocius, as well as medical writers, such as Oribasius and Paul of Ae-

gina. However, intellectual activity in such subjects increasingly centered on the explication of earlier works, and little new research was done. Philosophy flourished for a while in the form of the Neoplatonism and also as Christian theology, but neither of these doctrines emphasized the investigation of the natural world. Non-Christian philosophy was increasingly linked to magic and to evil, and Christian understanding of the world located authority in sacred texts rather than in inquiry and experiment and the pagan works of the past. Saint Augustine, considered a brilliant theologian of the fourth and fifth centuries C.E., did not believe that the world was round, a fact well known to Greek and Roman intellectuals since the fourth century B.C.E. Many pagan works of science and philosophy were translated into Arabic and survived in the Islamic tradition. The Western world became reacquainted with them after the Middle Ages.

THE AMERICAS

BY MICHAEL J. O'NEAL

Although the chronology and routes by which the Americas were populated are still debated, one version envisions people spilling over the Bering land bridge into Alaska beginning some 30,000 years ago. Migrating steadily southward to form communities throughout North, Central, and South America, they had to become astute observers of nature. For thousands of years they had to adapt to new and sometimes changing climates, new flora and fauna, new food supplies, and new landscapes and terrains. Some settled in the wet regions of the Pacific Northwest, some in the dry regions of Central America, some in the flat plains of the American Midwest, some in the mountainous regions of South America. Some coped with tropical heat and others with arctic cold. In time they adapted so successfully that they were able to build some of the greatest civilizations of the ancient world.

COSMOLOGY AND SCIENCE

The way the aboriginal peoples of the Americas looked at their universe can be difficult for the modern world to understand. In modern life a sharp distinction is made between the natural and supernatural worlds. Some people do not believe in a world of the supernatural, but among those who do, the two realms tend to be thought of as separate; the very word *supernatural* suggests that the world of the gods and the spirit exists above (“super”) or outside the physical world. This separation, however, would have been unthinkable to ancient Americans. Every aspect of their lives had religious significance. They saw the universe as composed of spiritual and divine forces that affected them every moment of their lives.

At the center of this view of the world was a cosmos that ancient Americans saw as a hierarchy of spheres or planes. Some of them were superior to the world of the earth; others were inferior. One example is provided by the Nahua people of central Mexico, precursors to the Aztec, also a Nahua people. The Nahua believed that above the earthly level were

numerous other spheres, variously nine, 11, 12, or 13, with 13 being the most common. This belief influenced the calendar, which was composed of 13 periods, somewhat inaccurately called “months,” each in honor of the divinity that ruled each sphere. The highest divinity was referred to as Ometeotl, which translates roughly as the “god of duality.” Ometeotl was responsible for what the Nahua saw as the duality of the universe: positive and negative, male and female, the spirit and the physical worlds. Artworks depicting Ometeotl are few. Modern researchers working in sophisticated laboratories with the most advanced equipment might regard this duality as myth, not science. To the Nahua, however, it was science. Their belief was based on observations of the world they lived in and explained the origins and development of their universe and humankind.

Because they were keen observers and experimenters, like many other ancient civilizations, the ancient Americans can be regarded as scientists in fields like agriculture, architecture, engineering, construction, metallurgy, and mathematics. Ancient American peoples, for example, made early observations in the fields of astronomy, biology, chemistry, geology, and physics. As astronomers they learned about the movements of heavenly objects and used those observations to create calendars and to predict changes in the seasons. They observed the “hole” in the Big Dipper long before European astronomers did. In fact, so keen was the interest of the ancient Americans in astronomy that priests and astronomers were often one and the same. Because science throughout much of the ancient world was associated with magic and with understanding the power and will of the gods, the earliest scientists were shamans, priests, and others who claimed knowledge of the divine and could read it in the heavens.

As geologists, early Americans knew long before the Europeans did that the world was round. This knowledge was reflected in their myths about the origins and creation of the world. (In this context, a myth is not something that is untrue; rather, it is a narrative that conveys a fundamental truth about the nature of the universe and humans’ place in it.) For example, the ancient Lakota nation of North America saw the world’s four original beings—Inyan (rock), Maka (the earth), Taku Skan Skan (the sky), and Wi (the sun)—as round, because in the cosmology of the Lakota roundness was the most sacred shape.

As chemists, early Americans often turned their attention to their food supply. They learned, for example, how to deal with stored corn that had become lignified, or hardened. They learned that if they applied alkaline substances (that is, substances that are bases rather than acids) to the corn, they could break down the hardened outer layer and soften the kernel inside. In this way they could return dried corn to an edible state, and the alkaline substance, usually lime water, added valuable calcium to their diet. Sometimes they left the corn in its hardened state to make popcorn.

Even in physics the early Americans made astute observations. During lightning storms, for example, they learned

to throw pieces of cedarwood onto a bonfire to ward off the lightning. Even though they could not have fully understood the physical laws that explained why this was successful, successful it was. When cedar burns, it emits a negative electrical charge that repels the negative electrical charge in the atmosphere that produces lightning.

As biologists, the ancient Americans also recognized the principle modern scientists refer to as biodiversity—the notion that there is value in maintaining diverse genetic strains of plants and animals. Doing so allows species to adapt more successfully to changes in conditions. Thus, for example, they developed a bean that sprouted in underground storage chambers; their purpose was to develop a plant they could use in winter religious ceremonies. The bean, it turned out, was resistant to a common pest that attacked bean crops. Thus the new bean became a reliable source of food when pest outbreaks occurred. In cultivating various crops, the ancient Americans appear to have valued diversity in strains of the crop and did not try to breed that diversity out.

MAIZE

The ancient Mesoamericans (that is, the people who inhabited modern-day Mexico and parts of Central America; from the prefix *meso-*, meaning “middle”) carried out one of the most successful plant-breeding programs in the history of the world with the development of maize, known to most North Americans as corn. Maize became an important staple crop among early Americans, contributing to immense population growth and cultural development in regions throughout North and South America

Maize, however, does not reproduce wildly and could not grow without human cultivation. Early Americans bred maize out of a wild plant called teosinte over a period of many years, though whether their success was an event or a process cannot really be known. Teosinte can be found in small patches at higher elevations west of the Sierra Madre in western Mexico. Historians estimate that it was domesticated into maize sometime between 4000 and 3000 B.C.E. Using sophisticated tools they can even locate where it was domesticated: in the drainage areas of the Balsas River in Michoacan, in western Mexico. Its origins lay with small hunter-gatherer bands that had migrated throughout the region, following the changes in the seasons to find deer, antelope, rabbits, and plant foods like nuts and berries. Archaeological evidence, found primarily in excavated caves in Puebla, shows that these early Mesoamericans were experimenting with meals and grains.

Maize was not the first cereal grain the early Mesoamericans domesticated. The first was a grain related to modern-day millet. But by about 2700 B.C.E., historians believe, people in the region were subsisting in part on a type of maize with very small ears and just six to nine kernels per ear. The process of domesticating maize continued over the next 2,000 years, and by about 1400 B.C.E. maize cultivation had spread throughout Mexico, along with methods for grinding and cooking the dough in the form of round, flat cakes. By that

time maize had become the staple crop of the Mesoamericans, and the development of Mesoamerican culture, including the invention of irrigation and the emergence of pottery and weaving, corresponded with the spread of maize as a reliable food source.

The development of maize is intimately bound up with Mesoamerican cosmology and creation myths. (Cosmology is the branch of philosophy that deals with the origins, structure, and purpose of the universe.) In these myths the world originated at a time when maize was trapped inside mountains and boulders, where it was inaccessible to humans. Small animals such as foxes could get to the maize, but humans were able to get to it only as a result of divine intervention. Both the Maya and the Aztec envisioned the process of creation as one of the gods progressively providing humans with better and better food. In the earliest stages of humankind, humans ate only fruits and acorns. In the next stage pine nuts were a primary food, followed by a third stage dominated by millet. In the fourth stage of human development, people ate the grains of the teosinte. The Mayan version of the story relates that they were attracted to the teosinte plant because they had observed grains in the dung of wildcats that had eaten the plant. Finally, in the fifth stage the gods gave Mesoamericans maize, the perfect food. Even early Mesoamerican mythology incorporated a kind of anthropology and recognized that over time the conditions of their lives improved.

Maize, put differently, was divinity itself. It meant life, so it was closely associated with fertility and regeneration. The rain that nourished it, which came from the heavens, enabled people to share in the fundamental life spark of the divine. So important to the ancient Americans was maize and maize cultivation that the plant was central to their everyday thought and activity.

MAYAN MATHEMATICS

The ancient Maya occupied the Yucatán Peninsula in modern-day Mexico, Belize, Guatemala, and sections of Honduras and El Salvador. The Maya began to inhabit the region in roughly 2000 B.C.E., reached the peak of their influence in the early centuries of the Common Era, and began to decline in the ninth century C.E. In studying Mayan history and culture, historians refer to the classic period, extending from about 250 to 900 C.E., as the period of the Maya's greatest achievements. While much of what historians know about them dates to that period, they also know that classic Mayan culture was built on the achievements of their ancestors dating back many hundreds of years before then.

In the 16th century Spanish explorers landed on the Yucatán Peninsula and eventually overran the regions inhabited by the Maya and the Aztec. Unfortunately, the early Spanish explorers and missionaries regarded all manifestations of Mayan religious beliefs as the work of the devil and had them destroyed. These included not only religious artifacts but also written texts on many subjects. Only a handful

of these texts survived and are housed in museums in Paris, France; Dresden, Germany; and Madrid, Spain. While these texts, called codexes (or codices), date to the centuries just preceding European contact, they were based on texts originally written in earlier periods, which in turn were based on knowledge that had been acquired for hundreds of years before that.

Historians of science are especially intrigued by the ancient Mayan system of mathematics, which they applied to fields like astronomy and architecture. Much of this system has been preserved in the codices. Mayan mathematics was a vigesimal system, meaning that it was based on the number 20. Such a system probably evolved because ancient people probably first counted with their fingers and toes, and when they reached the number 20 they had to start over with a new set of 20 in much the same way that modern systems of mathematics are based on the number 10 and its multiples.

Thus in Mayan texts the numeral 1 was represented by a thick dot, 2 by two dots, and so on. The numeral 5 was represented by a straight horizontal line, 6 by one dot above a line, 7 by two dots above a line, and so on. The numeral 10 was then represented by two horizontal lines, 11 by a dot above two lines, and so on up to 15, represented by three lines, and so on up to 20, represented by a single dot above a shell representing zero.

The Mayan system, though, had some irregularities that historians of mathematics believe related to the Mayan calendar—or rather, the two Mayan calendars. One was a ritual calendar that consisted of 13 periods, each with 20 days. Historians are unsure why this calendar was structured in this way, but they speculate that each of the 13 periods represented a god and the 20 days represented humans (because of their base 20 system of math). The other calendar was a solar calendar consisting of 360 days, with 18 periods each consisting of 20 days (and the extra five days regarded as unlucky). The two calendars coincided with each other after 18,980 days, equivalent to 52 years or 73 ritual years. The Maya also observed that the planet Venus returned to its original spot after two 52-year cycles, and in fact they held a great celebration after 104 years—that is, after two 52-year solar cycles or one 104-year cycle of Venus.

But how does this explain the irregularity in the counting system? To answer that, it is necessary to recognize that the Maya also counted time as a linear sequence of days. They calculated, for example, that the world was created on a date that coincides with August 12, 3113 B.C.E., and they dated many of their historical monuments in terms of the number of days that had passed since this creation. In the city of Tikal, for example, is a historical marker dating construction of the structure as occurring 1,253,912 days after the world was created. Put differently, rather than counting determining the structure of the calendar, the structure of the calendar determined counting, enabling the Maya to incorporate into their mathematical system their conception of the gods, creation, the movement of heavenly bodies, and the like.

GEOMETRY, ARCHITECTURE, AND ASTRONOMY

Ancient Americans had a sophisticated grasp of geometry, and geometric patterns can be found in a wide range of Native American structures, from major temples to small ceremonial structures. Geometry and architecture intertwined with astronomy as well, with many of these structures mirroring the movement of heavenly bodies, particularly the sun as it changes position in the sky throughout the year. The geometric regularity of these buildings reflects geometric and astronomical understandings that date back at least 2,000 years.

Ancient American geometry in many respects reflected the geometry of the natural world. It included not only simple squares and circles but also arcs, hexagons (six-sided figures), octagons (eight-sided figures), and dodecagons (12-sided figures, as in a clock). Thus, geometric understanding among the ancient Americans was a process of discovering and unfolding the geometry found in nature, rather than an artificially constructed system of thought. Ancient Americans began with the simple notion that two points could define a line that extended infinitely in either direction. Additionally, either or both of those two points could become the center of a circle, and the line connecting the two points could serve as the radius of a circle. If circles were drawn using each of the two points as the center, the two circles would intersect at two points. In turn, each of those points could serve as the center of yet another circle. If the process is continued, the result is a six-petaled “flower,” known among some ancient American cultures as the Flower of Life.

More important, this system of intersecting points can be used to make many other geometric shapes, including perfect triangles, pentagons (five-sided figures), hexagons, octagons, decagons (10-sided figures), dodecagons, and even polygons with 24 and 48 sides. (The word *polygon* refers to any of these enclosed, flat shapes with angles; *poly-*, means “many.”) Once these shapes and how to derive them were understood, architects could apply them to the construction of buildings, including temples, homes, and ceremonial structures, with simple tools like string. Each of the points in an octagon, for example, would become the position for a vertical post, which then evolved into more complex architectural designs.

What role, though, did astronomy play in all this? Historians and archaeologists have long noted that many of the structures of ancient America were oriented along north-south and east-west axes. In recent decades, however, many scholars have turned their attention to a subfield called archaeoastronomy—the study of the relationships between building practices and astronomical knowledge. In connection with ancient American structures they have found that many are built with an understanding of the concept of azimuths, particularly the azimuth of the sun at the points of the winter and summer solstice.

An azimuth is an angle measured from a reference point. Perhaps the best way to understand azimuths is to think about satellites in the sky that beam down television signals. When

the customer's dish is mounted, it has to be pointed at the satellite; otherwise, it fails to pick up the signal. But satellite dish installers do not have a single, fixed angle at which they mount the dish. This is because while the satellite is in a fixed place relative to the horizon, usually over the equator, homes are located at various points north or south of the equator. For a home near the equator, the satellite dish would have to point upward at a severe angle; for homes in Alaska, the dish would point at a much lower, flatter angle. This angle is the azimuth. Like the azimuths used to point to satellites, the azimuths of the sun at the summer and winter solstices—that is, the dates when the sun is highest in the sky in summer and lowest in the sky in winter—differ depending on latitude.

Evidence shows that many ancient American structures were positioned with their angles lined up with the point in the sky that marked the azimuths of the summer and winter solstices. The purpose in doing so was probably part religious, part practical. From a religious perspective, it reflected the ancient Americans' view that all of creation is unified. From a practical perspective, it enabled ancient Americans to take maximum advantage of light and warmth from the sun.

SOUTH AMERICA: THE SEARCH FOR RESOURCES

The ancient South Americans, particularly the people of Peruvian Andes, made remarkable technical advances in metalwork, agriculture, and energy production, all based on early understanding of science. In the field of metallurgy, archaeologists have discovered that the Peruvians began to exploit deposits of copper beginning sometime around 1400–1100 B.C.E. They created an alloy called tumbaga, which was a mixture of gold and copper, though the ratio of these elements varied widely, from 97 percent copper to 97 percent gold. A chief technical innovation was adding the element mercury, which hardened the metal and made it more durable.

Additionally, the Peruvians found gold and silver resources and developed complex technologies for mining, purifying, smelting, and crafting them into useful and decorative objects. Along the way they found uses for other minerals they mined, including hematite (an iron oxide), limonite (a mineral with various combinations of other minerals, including hematite), and manganese oxide. The many varieties of hematite, including rainbow hematite, kidney ore, martite, bloodstone, iron rose, and paint ore, suggest that depending on the mineral's composition, it had different appearances, making it a versatile mineral for objects with differing aesthetic properties.

With regard to energy, the ancient Americans, like people throughout the world, burned wood, along with dried dung and charcoal. In time, however, they also discovered and mined coal, particularly as some of the forests became depleted. Archaeologists disagree about whether the Peruvians used coal in the metal-smelting process. Some argue that little evidence suggests that they did, but others claim to have found coal ash in ancient Peruvian smelting sites. The Peruvians also found uses for bitumen, a substance that is similar

to asphalt or tar and can occur naturally or as a byproduct of a refining process. The Peruvians used this sticky material as a sealant in coffins and as caulking for ships. The effectiveness of that sealant, along with the Peruvians' skill in mummifying bodies, has given modern scientists unique insight into the physical condition of the ancient Peruvians.

The Peruvians learned to make use of guano, or bat dung, on nearby islands as fertilizer. Guano is still used as a fertilizer because it is high in nitrogen, phosphate, and potassium, all substances essential to healthy plant growth and abundant crops. It is believed that the Peruvians used small reed boats to travel to the islands and transport the guano back to the mainland for use on fields. In some places the guano is believed to have been as much as 65 feet thick.

MEDICINE

An important part of the scientific achievements of any civilization is its ability to find treatments for illness and disease. Again, much of what might have been known about medical lore in ancient Mesoamerica has been lost because the invading Spaniards destroyed the manuscripts that recorded their various branches of knowledge. Some of this ancient knowledge was later reconstructed, and modern paleopathologists—those who study disease and illness by examining preserved tissues from ancient times—have been able to add to that knowledge. Generally, medical practitioners in the ancient Americas were shamans. Like the astronomer-shamans discussed earlier, shamans who practiced medicine were believed to have had access to supernatural power and wisdom.

In common with ancient civilizations the world over, the ancient Americans made wide use of herbs and other medicinal plants. One early colonial manuscript catalogues 204 medicinal plants from a wide variety of climate zones. While this manuscript was copied much later, it doubtless reflects insights into medicinal cures that were hundreds, if not thousands, of years old. Modern people who think of themselves as addicted to chocolate might take heart in knowing that ancient healers of Mesoamerica recognized the therapeutic benefits of chocolate and cacao. They used it not only to deliver other medicines but as a medicine in its own right. It was thought to help people gain weight, stimulate the nervous system, and improve digestion and elimination. Ancient Americans also used cacao to treat anemia, poor appetite, gout, kidney stones, fevers, and, in paste form, burns. Interestingly, modern medical researchers have confirmed what the ancient Americans knew. Chocolate has been shown to be an effective cough medicine. More important, consumed in moderation, it is a good source of polyphenols—chemicals that protect the heart.

Egypt

~ *Herodotus, "Mummification," from
The Histories (ca. 440 B.C.E.)* ~

The mode of embalming, according to the most perfect process, is the following: They take first a crooked piece of iron, and with it draw out the brain through the nostrils, thus getting rid of a portion, while the skull is cleared of the rest by rinsing with drugs; next they make a cut along the flank with a sharp Ethiopian stone, and take out the whole contents of the abdomen, which they then cleanse, washing it thoroughly with palm wine, and again frequently with an infusion of pounded aromatics. After this they fill the cavity with the purest bruised myrrh, with cassia, and every other sort of spicery except frankincense, and sew up the opening. Then the body is placed in natrum for seventy days, and covered entirely over. After the expiration of that space of time, which must not be exceeded, the body is washed, and wrapped round, from head to foot, with bandages of fine linen cloth, smeared over with gum, which is used generally by the Egyptians in the place of glue, and in this state it is given back to the relations, who enclose it in a wooden case which they have had made for the purpose, shaped into the figure of a man. Then fastening the case, they place it in a sepulchral chamber, upright against the wall. Such is the most costly way of embalming the dead.

If persons wish to avoid expense, and choose the second process, the following is the method pursued: Syringes are filled with oil made from the cedar-tree, which is then, without any incision or disemboweling, injected into the abdomen. The passage by which it might be likely to return is stopped, and the body laid in natrum the prescribed number of days. At the end of the time the cedar-oil is allowed to make its escape; and such is its power that it brings with it the whole stomach and intestines in a liquid state. The natrum meanwhile has dissolved the flesh, and so nothing is left of the dead body but the skin and the bones. It is returned in this condition to the relatives, without any further trouble being bestowed upon it.

The third method of embalming, which is practiced in the case of the poorer classes, is to clear out the intestines with a clyster, and let the body lie in natrum the seventy days, after which it is at once given to those who come to fetch it away.

Greece

~ *Archimedes, Letter to Dositheus (ca. 220 B.C.E.)* ~

Archimedes to Dositheus, greeting: Formerly I sent to you the studies which I had finished up to that time together with the demonstrations, which were to show that a segment bounded by a straight line and a conic section is four-thirds of the triangle on the same base as the segment and of the same height. Since that time certain propositions as yet undemonstrated have come to my mind, and I have undertaken to work them out. These are: 1. The surface of any sphere is four times

the surface of its greatest circle; 2. The surface of any segment of a sphere is equal to the surface of that circle the radius of which equals the straight line drawn from the vertex of the segment to the circumference of the circle which serves as the base of the segment; 3. That a cylinder with a base equal to the great circle of a given sphere, and a height equal to the diameter of the sphere contains half the volume of that sphere and its surface is equal to half the surface of that sphere.

These propositions, of course, were always true of these figures, but they were hidden to the men who studied geometry before my time. Therefore, since I have discovered that these things hold true of these figures I do not fear to place them alongside my own previous results and the most thoroughly established theorems of Eudoxus, such as: any pyramid is equal to one-third of the prism of the same base and height, and any cone is equal to one-third of the cylinder of the same base and height.

First Postulate. Supposed that a fluid is of such a character that when its component parts are undisturbed and in immediate contact the part which is subject to the less pressure is moved by the part which is subject to the greater pressure; and that each part is forced in a perpendicular direction by the part above, if the fluid is compressed.

Proposition 1. If a surface is always cut by a plane passing through a given point, and if the section thus formed is always a circle whose center is the given point, the surface is that of a sphere.

Proposition 2. The surface of any still fluid is always the surface of a sphere whose center is the center of the earth.

Proposition 3. Those solids which are of the same weight as a fluid in proportion to their size, when sunk in that fluid will be submerged in such a way that they neither extend above that fluid nor sink below it.

Proposition 4. A solid which is lighter than a given fluid will not sink below the surface when placed in that fluid, but part of it will extend above the surface.

Proposition 5. A solid lighter than a given fluid will, when placed in that fluid, be so far submerged that the weight of the solid will be equal to the weight of the fluid displaced.

Proposition 6. If a solid lighter than a given fluid be forced into that fluid the solid will be driven upwards again by a force which is equal to the difference between the weight of the fluid and the weight of the amount of fluid displaced.

Second Postulate: If a solid lighter than a given fluid rest in that fluid the weight of the solid to the weight of an equal volume of the fluid will be as the part of the solid which is submerged is to the whole solid.

► seafaring and navigation

INTRODUCTION

Seafaring has always been a dangerous business, and it was no less so in the ancient world. The fact that ancient civilizations took to the sea despite the dangers of storm, shipwreck, and piracy is testimony to their courage and unquenchable desire to explore the world that surrounded them. Ancient seafarers faced a number of obstacles. One was a lack of navigational tools. More modern seafarers had sextants, compasses, chronometers, and other implements that enabled them to fix their position at sea and determine their direction and speed. Ancient civilizations did not have these tools, though one tool, which was found off the coast of a Greek island and dated from about the first century B.C.E., may have been used for navigational purposes. Otherwise, seafarers learned to navigate using the sun and star constellations, water currents, and the movements of birds and marine animals, and they passed their knowledge along orally.

Few ancient seafarers, however, took to the open sea, although ancient whalers and fishermen sometimes traveled far from land in search of their prey. For the most part, ancient seafarers tended to follow coastlines. They could use mountains visible from sea to maintain their course, and by staying close to the land they could find refuge during storms as well as put in for fresh water and provisions. The ancient Greeks and Romans navigated the coastlines of the Mediterranean Sea; seafarers from the Near East and Middle East navigated the Red Sea, the Persian Gulf, and other bodies of water in the region; and the ancient Chinese, with their large fleet of massive ships, explored the coastline of China and the areas around Japan and Korea. Ancient Americans and Asians of the South Pacific, much like the ancient Greeks, took to the sea to hop from island to island.

Another constant danger was storms and shipwrecks. In general, ancient seafarers kept to the land during the spring and autumn, when storms were more prevalent. Nonetheless, many ancient ships were caught in storms at sea and went down, often carrying valuable cargo with them. Because most of these shipwrecks occurred in deep water, and because water is not kind to the wood from which ships were made, relatively few ancient shipwrecks have been located. The lack of harbors was also a problem, but ancient seafarers learned to make use of natural harbors to escape storms when possible.

Ancient ships lacked artificial sources of power, so seafarers relied on river currents, the power of the wind, or the backs and arms of rowers. Sails were typically square, making them useful when the wind was at the ship's back but of little use when a ship was sailing into the wind. Most ancient ships made use of rowers. The so-called triremes, used by the ancient Romans, were ships that were powered by three rows of rowers. Some ships had up to 10 such rows. Rowers were able to power ships when the wind was not favorable or when the ship needed a burst of speed and maneuverability, as during naval battles.

AFRICA

BY MARK ANTHONY PHELPS

People from the western Mediterranean and Atlantic regions were engaged in trade with the Phoenicians, based in modern Syria and Lebanon, since at least the ninth century, despite the claim of classical authors who placed colonization of the Atlantic coast in the 12th century. On or near the Atlantic coast from Morocco to Senegal lie 13 Phoenician or Carthaginian sites. It is generally not possible to attribute colonies to either, as the distinction between the two centers of Semitic seafaring civilization was blurred by ancient authors. Likewise, technology bearing the label "Phoenician" by ancient authors could have denoted Carthaginian developments as well. One will recall that the wars with Carthage are known to the Romans as the Punic Wars, as *Punic* is derived from the Greek word for the Phoenicians. (The English term is likewise derived from the Greek root.)

Colonies served a variety of economic purposes. Primarily they served to protect Phoenician and Carthaginian (the latter are also known as Punic) vessels. This was accomplished by using their own navies as defense against pirates and other potential enemies and providing safe haven for endangered ships. This ensured that Phoenician and Carthaginian ships would have access to the resources of the western Mediterranean and Atlantic to themselves. These ports also were outlets for their own economic production, both from the cities and the hinterlands. The ports provided repairs for ships and resupplied provisions for ships continuing on their circuits.

Navigation in the Mediterranean was a skill acquired by experience. An intimate knowledge of nature was a requisite for sailing in antiquity. Navigation at night, which tended to be rare, was done by fixing points in relation to stars. Ursa Major was known as the "Phoenician star" because it served as their prime orientation point. The sun, by contrast, is a relative guide, moving as the seasons progress.

Understanding winds was important to navigation. The Phoenicians or Carthaginians invented the wind rose, a device to discern the direction of winds. Winds possessed discernable features to the trained observer. By the first century C.E. Greek sailors were aware of eight distinct winds. Winds were valuable for determining direction and predicting coming danger in the form of storms. Storms and unpredictable winds limited most commercial sailing in the Mediterranean to the months between March and October. Warships patrolled all year long.

Birds were of value in determining distance and direction of land. Land-based birds released from a ship would elevate to locate land and head directly toward it. Likewise, an awareness of the flight patterns of flocks of birds could help one discern direction or nearby landfall.

Naturally, the easiest way to navigate distance was to be in sight of land. This was probably the method employed by the Phoenicians and Carthaginians along the Atlantic coast of Africa and nearby islands. For Greek and Roman sailors,

handbooks known as *periploi* described landmarks to guide one along a coast. The *periploi* also gave information about the lands, peoples, and resources the sailors might encounter.

The Phoenicians are credited with circumnavigating Africa on an expedition funded by the Egyptian pharaoh Necho II (r. 610–595 B.C.E.), a feat that took three years. Having no ports, the crews had to plant and harvest wheat twice to provide provisions. The report describes the sun changing sides of the ship, confirming that the crew had entered the southern hemisphere. Based on the account of the Carthaginian navigator Hanno (fifth century B.C.E.), some scholars hold that the Carthaginians may have explored the Atlantic coast of Africa as far south as Mount Cameroon, though a majority assume they never ventured south of Senegal.

During the period of Greek colonization from the eighth to the sixth centuries B.C.E. the region known as Libya to the Greeks (northern Africa outside of Egypt) was an ideal place for establishing new centers. The hinterland of the coast in this region possessed a plain useful for agriculture. In addition, the southern Mediterranean shipping route passed close by as ships looking for the African coast after passing Crete would typically sight landfall in this region. Likewise, east-bound ships would head north from this landmark.

Trade on the Indian Ocean is dictated by the monsoons. The northeastern monsoons occur during winter in the northern hemisphere. These winds abate in March and reverse (become southwesterly) in April. The period from mid-May to mid-August is typically too rough for sailing. The equatorial current flows southward after striking the Somali coast, facilitating vessels heading west from the Arabian Peninsula. With the coming of the southwest monsoon, the current strikes farther south, near Cape Delgado in Mozambique. This produces a strong northern current, facilitating the return from the east.

The kingdom of Axum was located in northern Ethiopia and Eritrea. Its port at Adulis, founded in the mid-second century B.C.E. by the Egyptian king Ptolemy III (r. 246–221 B.C.E.), became a major center for exchange of goods between the Roman, Red Sea, South Asian, and sub-Saharan African worlds. Few of its coins are found in the homeland, while most appear in Yemen and in India.

The kings of the Ptolemaic Dynasty sought to circumvent the Seleucid stranglehold on overland trade by exploiting water routes to India. By the end of the era, Ptolemaic weakness and political anarchy had reduced the trips to some 20 a year. Under the Roman emperor Augustus (r. 27 B.C.E.–14 C.E.) that number was elevated to 120 a year. After destroying Carthage in 146 B.C.E. the Romans had assumed control of shipping throughout the entirety of the Mediterranean, including all African ports.

EGYPT

BY AMR KAMEL

Although ancient Egypt was considered a riverine civilization, where everything was associated with the Nile, it was

thought also to be a nation of sailors, navigators, and explorers, who were able to navigate and sail up and down the Mediterranean and the Red Sea as early as the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) and perhaps even before. Although no seagoing ship has survived, numerous pieces of textual and pictorial evidence have fortunately been preserved from most of Egyptian history and particularly from the New Kingdom (ca. 1550–ca. 1070 B.C.E.) onward, referring to the activation of an Egyptian maritime network on both seas.

The earliest evidence for Mediterranean seafaring is a short text from the reign of Snefru (r. ca. 2613–2589 B.C.E.), which mentions 40 ships that sailed to the land now known as Lebanon to obtain cedar and other woods. An Egyptian crew on such a voyage almost 50 years later left its name on an inscribed ax head at Byblos (modern Jubayl). However, the earliest detailed portraits of seagoing ships come from decorated blocks in the mortuary temple of the Fifth Dynasty ruler Sahure (r. ca. 2487–2475 B.C.E.) at Abusir, which illustrates 12 ships, with careful attention to construction, rigging, and passengers, including a mixture of Egyptian and Syrian crewmen. In a relief from the time of Unas (r. ?–2345 B.C.E.), two slightly later ships are shown returning from Syria. Such scenes could help modern archaeologists to estimate the actual sizes of these ships; for instance, a cedar ship built in the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.) was 100 cubits, or 50 yards, long.

As early as the reign of Sahure ships sailed on the Red Sea for Punt, famed for its incense, precious woods, gold, and other raw materials. Punt is most likely located on the Somali coast of East Africa. In the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) a helmsman named Khnumhotep left an inscription describing his 11 round-trips to that land. Although no textual or representational evidence exists for seagoing ships in the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.), recent excavations have revealed a Red Sea harbor used by Middle Kingdom ships that sailed to Punt and to the turquoise mines of the Sinai Peninsula, at Marsa Gawasis, about 15 miles south of modern-day Safage and 31 miles north of Quseir. At this site archaeologists have unearthed 12 large stone anchors, fragments of cedar wood imported from Lebanon, and a man-made cave in which ancient Egyptian sailors stored their gear.

In the New Kingdom seafaring seems to have been more common, with refinements in rigging and steering gear traceable through images and models of ships. No physical remains of New Kingdom hulls have been found as yet. The most remarkable report is preserved in both text and images on the walls of the mortuary temple of Hatshepsut (r. 1503–1482 B.C.E.) at Deir el-Bahri. These scenes show five ships with upright bows and curved papyriform sterns, hogging trusses (thick ropes to keep the bow and stern from sagging), and single masts with broad sails, entering and leaving the anchorage at Punt. Only one includes an illustration of beam ends; otherwise, artistic attention was lavished on the rigging. Fifteen oarsmen shown as well on the side facing the

viewer would have required about a yard of room each, suggesting that the ships were at least 24 yards long and perhaps three times longer than broad. Apparently, Hatshepsut reactivated Egypt's Red Sea route to Punt, and this extraordinary series of illustrations suggests that she invested heavily in this expedition.

Records from the reign of Hatshepsut's successor, Thutmose III (r. 1504–1450 B.C.E.), document the movements of ships in an expedition to Syria-Palestine, and further records describe cedar acquired and goods stored at harbors for Egyptian use. An Amarna tablet refers to a royal ship moored at Tyre (modern-day Sūr), in southern Lebanon. According to cuneiform texts, Egyptian products, notably grain, were transported to Palestine and Anatolia in vessels, but whether Egyptian or local ships were used is still obscure. In the first two years of Ramses II's reign (1304–1237 B.C.E.), Ramses had to conduct a military campaign against sea pirates, known as Shirdana. Several Egyptian seagoing ships participated in the war of Ramses III (r. 1198–1166 B.C.E.) against the Sea Peoples, as is illustrated on the walls of his temple at Medinet Habu.

In the Late Period (ca. 712–332 B.C.E.) as well as in Greco-Roman times, the Egyptians apparently continued investment in seafaring, and they sometimes built special cargo ships. For instance, they transported obelisks from Alexandria to Rome, and textual evidence refers to a seagoing ship built for Caligula (r. 37–41 C.E.). Unfortunately, ancient Egyptian sources do not say much about the life of the sailors, the length of the sailing season, the durability of ships, and their costs. Nonetheless, these sources refer to numerous titles associated with seafaring occupations and activities, held by ancient Egyptians and sometimes by foreigners, especially Syrians, notably in the construction and operation of maritime ships. Among these titles were navigator, sailor, man at the prow, man at the poop, manager of the crew, captain, and commander of the ship. These titles suggest that their holders had a sufficient knowledge of navigational techniques required to make a voyage possible.

These techniques, theoretically at least, developed over years in the form of oral tradition, with no trace in any written records. A few glimpses can be obtained from Egyptian tomb paintings reflecting these skills. To ancient Egyptians, navigation apparently was an art rather than a science, and it was based mainly on determining position and location. They had several methods for determining direction, among them the winds. The ancient Egyptian language reflects the Egyptians' knowledge of the four winds, from north, east, south, and west, and includes terms for favorable winds and headwinds as well. A scene from an early Old Kingdom tomb shows a ship commander teaching the crew how to steer the ship with the wind. The Egyptians sometimes called upon various gods associated with creation of these different winds to aid in the journey, notably Amun, who was believed to drive back the adverse wind. In daytime a gnomon (the pointer of a sundial) also could be used as a tool to indicate northerly direction

in navigation, as shown on a ship model in an Egyptian museum, where it was mounted on the ship's axis.

A scene from a tomb at Thebes suggests that the Egyptians were familiar with using birds in navigation. It shows a Syrian fleet moored at an Egyptian quay (a wharf built parallel to the shoreline) and a bird flying toward the city. In the ancient Near East, land birds that were unable to land on water, such as ravens, crows, doves, and swallows, were carried on board and released when the crew needed to know how to reach the shore. This scene and a few others show that river and seagoing ships had crow's nests with lookouts, who played a role in determining the direction of land lying beyond the horizon.

THE MIDDLE EAST

BY EDWARD M. W. A. ROWLANDS

In ancient times the sailors from the Near East were famous for their seafaring skills. Written evidence suggests that sailors from Mesopotamia were able to navigate great distances, but there is a lack of archaeological evidence available to support their navigation capabilities. Sailors established successful sea routes by following the coastline. They learned the best times for sailing and discovered ways to counter harsh weather conditions. Navigation was improved by the observation of the sun and stars; seafaring was further enhanced with the addition of several rows of oars to increase speed.

There was a great abundance of cedar trees in what is now Lebanon. These trees supplied the local inhabitants with a valuable supply of wood, which was used in the construction of ships. The port of Byblos, close to modern-day Beirut, is thought to have traded considerable amounts of wood to Egypt (under the reign of the pharaoh Sahure) as early as around 2487–2475 B.C.E. The availability of wood to the inhabitants of Byblos, Sidon, and Tyre meant that they had the resources to attempt seafaring very early in their histories. It is from those locations that the Phoenician civilization, well known for its highly developed seamanship, began.

It is difficult to go into great detail about Mesopotamian seafaring owing to a lack of shipwrecks available for study and the poor quality of the surviving representations of ancient ships in the area. Depictions of ships have been found on seals and reliefs, but this evidence is inadequate to paint a complete picture of seafaring. Sumerian texts, however, do refer to Mesopotamian trade with Magan (Oman or Egypt) and Meluhha (a civilization in the Indus River valley or Africa) in the Akkadian Period, the Third Dynasty of Ur, and the Isin-Larsa Period. This activity spans a period from around 2350 B.C.E. to around 1800 B.C.E. It thus appears that from a very early time in Mesopotamian history, seamen from this area were able to navigate their way down the Persian Gulf to locations as distant as Africa and India, implying a considerable degree of navigational skill.

In ancient sea travel following the coast was essential. Staying near the coast made shelter, fresh food, and water

supplies available on a daily basis. Following the coastline and keeping in sight of land also helped with navigation. For example, ships trying to find the right direction in the Mediterranean were helped by the many high mountains that are visible from the sea. The Uluburun (late 14th century B.C.E.) and Cape Gelidonya (late 12th century B.C.E.) shipwrecks are both thought to be ships that were following the eastern Mediterranean trade circuits, through which ships would travel from the Levant to Cyprus and on to Rhodes and Crete. These ships would have stayed close to land as much as possible and traveled from port to port.

Before Artabanus's attack on Greece in the early fifth century B.C.E., the Greek historian Herodotus (ca. 484–between 430 and 420 B.C.E.) quotes Artabanus (younger brother of King Darius I) as saying to the king of the Persians that harbors would be needed all along the coast to receive his fleet “and give it protection in the event of storms.” The weather plays an important role in seafaring, and ancient sailors tried to avoid sailing in the autumn and winter. By sailing in the spring and summer, sailors hoped to avoid the worst storms. Protection could be achieved by taking cover behind islands or high points of land. In the eastern Mediterranean many such harbors could be found and were exploited, giving ships the best access to land as well as the best shelter from weather conditions.

It was crucial for any ancient vessel to have experienced sailors who could observe changes in the wind, tides, and current. They would have had the expertise to navigate by monitoring changes in the sky. Navigational instruments, such as the compass, would not have been available to them. By day, Near Eastern sailors would have used the direction of the sun to distinguish between east (Asu) and west (Ereb). By night they would have navigated by following star constellations, such as Ursa Major and Ursa Minor. The Phoenicians developed a reputation as excellent celestial navigators, with the North Star, for example, being known to the Greeks as the “Phoenician Star.” Such navigational skills allowed the Phoenicians and their successors, the Carthaginians, to travel considerable distances. Herodotus wrote that the pharaoh Necho II (r. 610–595 B.C.E.) manned ships with Phoenicians, and the ships were then able to circumnavigate the whole African continent.

The use of oars gave ships speed and flexibility. Ships could adjust their position using steering oars. Ancient ships used a square sail that was very effective in helping the ship through heavy seas. When there was a lack of wind to move the sails, the oars were used to move a vessel. From the seventh century B.C.E. there was a gradual increase in the number of oars and the manpower used to propel a ship. Warships developed several rows of oars in the aim of outmaneuvering the enemy, which required extensive manpower and coordination. The Hellenistic Period (323–31 B.C.E.) saw an explosion in the number of the rows of oars. This development was seen in the Wars of the Diadochi (322–281 B.C.E.). For example, in the Battle of Salamis in 306 B.C.E., next to the

island of Cyprus, ships were in battle with as many as seven rows of oars.

The ancient Near East and Mesopotamia was to be dominated by such peoples as the Assyrians, the Babylonians, the Hittites, the Persians, the Greeks, and the Romans. Nevertheless, the necessity to maneuver a ship with precision and accuracy remained the same. Sailors needed to focus their attention, to maintain the safe navigation of the ship, and to watch out for any possible dangers. Examining changes in the weather and the sea, keeping a close eye for land, and observing the stars and the sun required an understanding and an awareness that were essential throughout the whole of this period.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Among the great seafaring feats of ancient times was the migration of people from southeastern Asia to Australia during the last great ice age in about 30,000 B.C.E. At that time the ocean was lower than it is now, and much more land around Australia was exposed. Australia, Tasmania, and New Guinea were all connected by land. The areas where seafarers would have landed are now underwater; consequently, archaeologists have little evidence for how ancient sailors crossed the open sea. Even though there would have been less sea to cross, those sailors still had to cross hundreds of miles of ocean. Archaeologists disagree about whether the sailors used rafts or dugout canoes, with some saying canoes had not yet been invented.

It is possible that people had learned to fish in the ocean and had gained knowledge of the currents for their particular fishing areas, so when winds blew them away, they were able to return home by finding the currents they knew. Some of these fishermen may even have landed on Australia and then returned home and brought their families with them to live in the new land they had discovered. At that time Australia would have been much wetter than it is now, with forests filled with inviting life. These people would have rowed, used currents, and possibly used sails to cross not only to Australia but also to islands between Australia and the Asian mainland.

The most accomplished seafarers of ancient Asia and the Pacific that are presently known about were the Polynesians. Archaeologists disagree considerably over the dates for Polynesian exploration, but by the end of the ancient era they had probably reached Easter Island but had not yet reached many islands such as those of Hawaii in the Pacific. There were about 20,000 unpopulated islands scattered across an enormous expanse of ocean when the Polynesians began their push to explore and settle them beginning in about the third century C.E.

Their process of exploration seems to have been very risky, but it had a high rate of success. They would have outfitted outrigger canoes—boats with floats extended by wooden

spars, or poles, from the sides of the craft to prevent the craft from capsizing. Carrying men, women, and probably children, as well as pigs, seeds for planting, and other foods, they would have set sail into open ocean beyond the last island they knew. This practice probably caused many people to be lost at sea, but the Polynesians had great navigational skills to aid them.

Even today, some Polynesians still can read wave patterns to navigate across large expanses of water with no land in sight. Where most people would just see a chaos of waves, Polynesian navigators would recognize patterns in the directions of the waves, their heights, and their speed. They would be able to tell where a boat was by how waves of different types bumped into each other. This knowledge made navigating between known islands mostly science, not luck. Polynesians also used the sun, moon, and stars to help them find their way. The sun and moon told them whether they were going west or east. For these ancient seafarers, this method alone was valuable for exploring because they knew they wanted to go eastward. The stars gave them an idea of how far they had gone in their journeys. To determine their latitudes—how far north or south they were—they chose what they called “on top stars.” By keeping under a particular star, they could sail east or west and know how far north or south they were. For example, the star Sirius was over the latitude for Tahiti, and if one were west of Tahiti, then sailing east under Sirius would enable one to find Tahiti. For exploration, knowing the latitudes of the stars enabled sailors to avoid retracing unsuccessful routes and to find home if they had to do so.

For the mainland cultures of ancient Asia, navigators tended to stick close the coastlines. The Chinese tended to emphasize sailing on China’s great rivers, and China’s navy was intended primarily for warfare inland on rivers. Piracy was a problem along China’s eastern coast, which provided many coves and inlets in which pirates could hide, and the navy was expected to patrol the coastline. It is possible that one reason the Chinese sought out the Japanese as allies in the third century C.E. is that they hoped the Japanese would aid them in curbing the activities of pirates in the ocean near Korea and northeastern China. In about the fourth century C.E. Chinese merchants began to venture farther from the coastline, following routes used by Indian traders. Although the Chinese long knew of the tendency of lodestones (magnetite) and magnetized iron to point north and south, they did not employ them in navigation until the medieval era, perhaps the 12th century C.E.

The feats of Indian seafarers were justifiably legendary because these sailors overcame many great hazards as well as their own fears of giant fish, dragons, and other monsters of the deep that could swallow them up. Under Hindu religious law, people were not supposed to sail across the sea. A Brahman who did so could lose his status, becoming an outcast without home or sanctuary. Others could suffer the loss of funeral rites. This practice left Buddhists, outcasts, and those

willing to risk the loss of their status in their communities to be sailors.

The most important person on a ship was the pilot, and no ship left port without one. The pilot knew how to read currents, winds, stars, and birds for directing the course of a ship over open water. A pilot actually trained birds to fly in the direction of land but to return to the ship if they did not see land midway in their flight, and several of the birds would be kept in cages on deck for this purpose. Pilots had their own guilds, through which captains could find pilots for their ships and which regulated the work of pilots. Ordinary sailors were expected to show their inferior status at all times, to pilot, captain, and passengers. Living quarters on ships were always cramped and uncomfortable, with the rocking of the ship causing misery for passengers, but apparently those ships that sailed west toward the Near East, Africa, and the Mediterranean were filled with people willing to take the risks of a sea voyage to visit foreign lands. If they made some good trades, they could return home as rich people.

It seems that most Indian ships reached their destinations despite the dangers. When a ship was in trouble, its crew and passengers would pray to the goddess Manimekhala, who drowned sinners but would save others. When a ship sank, those on board had little hope of survival. If they did not drown, sharks and other predators would eat them, sometimes turning the sea red with blood. If a ship were becalmed for days, those on board would draw lots to see who would be put out of the ship on a raft to be abandoned as a sacrifice to bring wind.

EUROPE

BY MICHAEL J. O’NEAL

The oldest-known European boat, hollowed out from a single log, was discovered at Pesse in the Netherlands and dates to about 7000 B.C.E. Many other such prehistoric boats have been found at submerged and waterlogged sites across northern Europe in which wood was preserved. For example, the Hasholme boat, in Yorkshire, England, dates from about 300 B.C.E. It was crafted from the trunk of a single oak tree that was probably more than 800 years old when it was felled. In inland areas such boats were used along streams and across lakes, but in coastal areas people rowed them a short distance out to sea to catch fish and also used them for transportation along the coast and to nearby islands. Scholars have traditionally believed that during this period navigation relied primarily on the observation of landmarks along coasts and that people usually did not venture far out of sight of land. Supporting this assumption is the large number of ancient boats that have been discovered in shallow coastal waters.

In recent years some archaeologists have been rethinking this long-held belief. In 2005, for example, archaeologists discovered flints and other objects on the Mediterranean island of Cyprus that date from about 10,000 B.C.E. Cyprus, however, was not inhabited until about 9000 B.C.E., so the ob-

jects had to have been left there by seafarers from the mainland who had ventured out of sight of the Turkish or Syrian coast at least 30 miles away. This find provides evidence of the earliest seafaring in the Mediterranean Sea. Evidence for adventurous seafaring has also been found in northern waters. The first Stone Age settlers to reach Ireland would have required watercraft to cross the Irish Sea, for example; except for the very narrow northern part where Ireland is visible from Scotland under ideal conditions, they would have been out of sight of land for some part of this trip.

In any case, the sea may not have been the obstacle that historians long thought it was. They note that the archaeological record shows remarkable similarity among cultures up and down the Atlantic seaboard and around through the Strait of Gibraltar into the Mediterranean Sea during the Mesolithic Period, or the Middle Stone Age, ranging roughly from 12,000 or 10,000 B.C.E. to at least 7000 B.C.E. and perhaps as late as 3200 B.C.E. (Dates for these broadly defined periods can differ for different geographical regions.) Some believe that these similarities could have come about only if people along the Atlantic coast traveled by sea, carrying artifacts and practices of their culture with them. The cultural connections seen around the coasts of the North Sea and the Baltic Sea could have been possible only thanks to the ability to navigate across open seas.

An increasing number of finds have offered considerable insight into prehistoric European seafaring. By the Bronze Age people in northern Europe were building boats out of planks that were propelled by more than a dozen rowers. The earliest-known plank-built ships date from about 1900 B.C.E., and others have been found dating from perhaps 800 B.C.E. An important recent example is the Dover Boat, found in 1992, which appears to have been used for crossing the English Channel. In addition, a large collection of bronze axes found at the bottom of Langdon Bay, also near Dover, appears to be a cargo load that did not make it all the way across. The chief advantage of these plank boats was that the freeboard, the distance between the waterline and the top of the hull, was higher than those of other boats, making them more stable in ocean swells. Meanwhile, the Iberians (in modern-day Spain and Portugal) and the Irish were building lightly framed boats covered with hides. These types of vessels were probably used for trade, particularly to carry tin to Gaul and Rome.

The ancient Celts, in particular, were seafaring peoples and developed sophisticated boat-building and navigational skills. The Celts were an ethnic group that spread across large portions of Europe and into the British Isles. One Celtic group was the Veneti, who, along with several other nations, inhabited the region of Gaul the Romans called *Aremonica*. This region included Brittany, a peninsula that juts westward and is surrounded by the English Channel and the Bay of Biscay. Largely surrounded by water, the Veneti developed sophisticated seafaring technology.

The Roman emperor Julius Caesar (r. 49–44 B.C.E.) fought his greatest naval battle against the Veneti in 55 B.C.E. In his

account of the battle in his work *Commentarii de bello Gallico*, he described the Celtic fleet as consisting of 220 ships. The ships were tall and graceful—Caesar called them “swan ships”—and each was able to carry 200 men. The ships were powered by leather sails rather than rowed with oars; because the hulls did not need openings for oars, the hulls were far stronger than those of the Romans’ ships. These ships were able to navigate the open seas during storms, but because of their broad beams and shallow draft, they were also able to sail in shallow waters and estuaries. Their timbers were made of oak and fastened with iron nails rather than the wooden pegs the Romans used in constructing ships. Adding to the Veneti’s advantage was the rocky and tempestuous coastline, which they could navigate better than the Romans could in their oar-powered galleys. Caesar eventually was able to defeat the Veneti by having his sailors use long grappling hooks to shred the ships’ sails, leaving the ships dead in the water.

GREECE

BY EDWARD M. W. A. ROWLANDS

Ancient Greek sailors were first able to sail to the islands around them and then later used those islands as stepping-stones to other locations in the Mediterranean and into the Black Sea. They learned how to use the sun and the stars as a means of direction and determined the best times of the year to sail. Seafaring could be tough, but the experience that sailors would acquire, along with the technological improvements to ships, meant that speed and flexibility would increase over time.

In the Late Bronze Age (ca. 1600–1100 B.C.E.) people from Greece were able to travel from island to island in the Aegean. The Minoan and Mycenaean civilizations spread throughout the Aegean from Crete and Greece, respectively. Depictions of ships, for example, have been found on fresco fragments from the island of Thera (now Thira) that date from around 1600 B.C.E. Islands were used as landing stages and could be accessed in a day’s journey. Shelter, fresh water, and food supplies could then be found on land. Navigation was accomplished by keeping in sight of land and following the coast.

Greek ships were constructed so that they could be moved onto dry land upon arrival. This design was to prevent the destruction of the boat by any sea storm. Homer describes boats as being fast and hollow, suggesting that these boats would have been light and easy to move ashore. This practice continued for many centuries. Ships were also moved overland so that sailors could gain access to other branches of the sea. The port of Corinth became very famous for its Diolkos. The Diolkos was a paved road that was used for the transportation of boats on a platform from the Saronic Gulf to the Corinthian bay, which are on either side of the Peloponnese in Greece. This route proved very successful and was used from the seventh century B.C.E. up to the ninth century C.E.

Ancient Greek navigation was based on observation, and it was important for every ship to have experienced sailors.

Early Greek sailors were able to travel throughout the Aegean Sea and from there eventually to other locations in the Mediterranean and the Black seas.

Having an understanding of wind, currents, and tide was vital to maintain the correct course. For long-distance voyages, the Greeks made use of the sun and the stars. Since no compass, chronometers, sextants, or octants existed, and as it could be difficult to observe landmarks, using the North Star (known to the Greeks as the Phoenician Star) and following the sun were vital in gaining direction. By 600 B.C.E. a philosopher named Thales (ca. 625–ca. 547 B.C.E.) was able to teach sailors how to get to Miletus (on the Aegean coast of modern-day Turkey) by following the Ursa Minor constellation of stars. However, a mechanism found on a wreck off the Greek island of Antikýthēra, dating to the end of the first century B.C.E., may have been used to calculate astronomical positions and could have been used in seafaring.

The weather and the season of the year in which the voyage was to take place were very important factors. Large cargoes were carried by Greek ships all across the Mediterranean, and it would have been wise to avoid the autumn and winter rains and storms. Goods could be lost and crews of men killed, and ship owners would have been well aware of the financial risks. In the spring and summer, as the Greek writer Hesiod (ca. 800 B.C.E.) says, “You are not likely to smash your ship, nor the sea to destroy your crew. . . . At that time the breezes are well defined and the sea harmless.”

Seafaring could be a harsh experience for sailors. For hundreds of years little accommodation was given to living space or preparation of food on ancient Greek ships. There was a threat from being attacked by pirates, and iron spear-

heads found rooted into the hull may suggest that a ship had been attacked. The use of oars provided speed and flexibility. Single steering oars are seen depicted on the frescoes from Thera as early as the 16th century B.C.E. and double steering oars from the sixth century B.C.E. The oars were important to ships in helping them maneuver around islands, keeping close to the coast. Oars were used to propel a ship when there was not enough wind. For vessels such as warships, oars could also provide a valuable means of gaining speed during battle with an enemy. Several rows of oars could be used to give the ship additional pace. According to the Greek historian Thucydides (d. ca. 401 B.C.E.), triremes (ships with three rows of oars) were the invention of boat builders from Corinth around 700 B.C.E. Later the kingdoms of the Hellenistic Period (323–31 B.C.E.) would have tens of rows of oarsmen. These ships required extensive manpower and coordination.

The ancient Greeks would have used a square sail when traveling by sea. A single square sail could be effective in heavy seas. However, it was not very adaptable when the wind was blowing against the course of a ship. The settlement of Troy was situated on the Dardanelles. As it was a protected harbor, it became prosperous, since ships would often stay there while they waited for the direction of the wind to change so that they could move through the Dardanelles and into the Black Sea. Numerous images of square sails on ships have been found. For example, Attic black-figure pottery dating to the mid-sixth century B.C.E. depicts ships with square sails.

Only small amounts of evidence for nautical guides have survived; it may be that sailors passed on their expertise orally. Even as the Roman Empire came to dominate Greece and the Mediterranean, ships still needed to be maneuvered with precision and accuracy. Watching out for changes in the weather and the sea, keeping a close eye for land, and observing the stars and the sun required an understanding and familiarity that were essential throughout the whole of this period. Sailors needed to maintain total concentration to navigate their ships safely and to watch out for any possible dangers.

ROME

BY JAMES A. CORRICK

The fastest method of transporting freight and passengers during the Roman Republic and the Roman Empire was by sea. With the exception of some swift naval vessels, Roman ships averaged 6 knots, a knot being 6,076 feet per hour, and thus they moved along at about 7 miles per hour. A ship, for example, took one to two days to travel from the Roman port of Ostia, at the mouth of the Tiber River, to Massalia (present-day Marseilles in southern France). By land the same journey took weeks. Business travelers, government officials, tourists, and others journeying long distances consequently sought passage via ship.

Despite a healthy passenger trade, no passenger ships existed in the Roman world. Instead, voyagers had to travel on merchant vessels. Nothing except drinking water was

provided to passengers, who had to bring their own food, cooking utensils, beds, and servants. Travelers slept on deck with the crew. The crew was generally foreign born, its members most commonly being Greeks or Egyptians because few Romans became sailors. Even on military ships, except for officers, the crew was not Roman. Additionally, it was not unusual for merchant ships to be crewed entirely by slaves, one of whom was the captain.

Without any method of weather prediction, a ship could easily be caught in a sudden storm, and if it could not quickly reach a safe harbor, it might well be sunk or run aground. Because of numerous storms, few ships sailed in the winter months, the summer being considered the best sailing time. Another danger that Roman ships faced was attack by pirates. After seizing a vessel, the attackers either killed the crew and

Altar to the sea god Neptune, an offering from the Roman admiral of the British fleet, second century C.E., from Lympne, Kent, England
(© The Trustees of the British Museum)

passengers or, as was more common, sold them into slavery. Indeed, until the middle of the first century B.C.E., pirates were one of the chief sources of slaves for the Roman world. Important captives, particularly high-ranking Roman citizens, were held for ransom. Even Julius Caesar was a captive of pirates. The pirate menace was ended in 67 B.C.E., when the Roman general Pompey swept the Mediterranean free of them. Pirates would not again be a threat until the empire began to lose control of the seaways in the third century C.E.

Navigating a Roman ship was more art than science, since the Romans had no navigational instruments. As a consequence, whenever possible, a ship of the period kept the shore in sight, its crew watching for landmarks to tell them their position. An important aid to navigation was the lighthouse. Most major Mediterranean ports had such structures, the Pharos at Alexandria being the most famous. Lighthouses ranged in height from four to 12 stories and used a mirror of polished bronze to reflect light from a fire. The beacon would warn night-traveling ships of hidden rocks and shallow water or act as a guide into port.

In addition to landmarks and lighthouses, Roman crews often depended on changing water depths to tell them where they were, since specific locations along a coast had known depths. To measure the depth of water, mariners used a lead line. This line was a rope that had a series of knots at spaced intervals and that had a lead or stone weight tied to it. The weighted end of the line was tossed overboard, and when it hit bottom, the number of knots were counted to determine the depth.

Another piece of knowledge useful in Roman navigation was the composition of the sea bottom across which a ship was sailing. That composition could often provide a clue as to a ship's location because certain types of material—gravel, sand, or mud, for instance—were known to be present off certain coastlines. Roman mariners sampled the sea bottom with the lead line, whose weight had a depression filled with tallow, or animal fat, to which sea floor material stuck then to be drawn up to the surface.

The Romans probably had charts and certainly had *periplooi*, books containing the distances between various seaports, along with the locations of rivers and freshwater sources. A ship's navigator could calculate his ship's position along its route using the distances given by a *periplus* if he knew how far his vessel had traveled during a day. He made this calculation using dead reckoning. He first had to determine how fast his ship was traveling. The navigator estimated this speed by observing seaweed or driftwood passing by the ship. This observation gave him an approximation of how much distance the ship covered in an hour. Then, at the end of a day's sail, based on his observed speed, the navigator calculated how far the vessel had traveled. He now had a rough idea of where along its route the ship was. The method was imprecise, and often the calculation was far off the mark.

Determining position by dead reckoning also required that the navigator know in which direction his vessel was

headed; otherwise, the craft might be sailing away from its destination. During the day the navigators determined direction by observing the sun. Sailing into it was going west; sailing away from it was going east. Additionally, the navigator knew the ship was going north or south depending on the sun's height above the horizon at noon. The sun would be higher or lower in the sky depending on whether a ship was headed north or south. The height of the sun also depends on the time of year, the sun rising higher in the summer than in the winter, but an experienced navigator took this fact into account. To measure the sun's height, the navigator would hold out a hand and determine how many fingers were needed to span the gap between the sun and the horizon.

At night the navigator established direction using the stars. One star—the polestar, or Polaris—was particularly useful since it marks the position of the North Pole and remains fixed throughout the night. (Other stars appear to revolve around the sky due to the rotation of the earth.) A ship traveling east would have the polestar on its right, and a ship traveling west would have the polestar on its left. A navigator could also obtain a rough idea of a ship's north-south position using the polestar by counting how many fingers were needed to span the gap between Polaris and the northern horizon. The fewer the fingers, the farther south the ship was since in moving south, Polaris drops toward the northern horizon.

THE AMERICAS

BY LAWRENCE WALDRON

Native American hunters have long been credited with possessing the most acute tracking skills. Their ability to observe signs on the earth, in the air, and in the movements of animals and birds has astounded many observers. There is no reason to assume that Native American seafarers were any different. Just as earthbound hunters would observe the movement of celestial bodies to predict changes in weather, animal behavior, and crop growth, so too would Native Americans living on coasts, along rivers, and on arctic ice navigate by observing and predicting their environment.

Native Americans in ancient times were intimately familiar with the courses of key celestial bodies; the different kinds of cloud cover; the varieties of terrestrial, riverine, and marine species; and the flight patterns of birds. They also would have possessed some knowledge of geology, though they would have employed taxonomic classifications and nomenclature very much unlike our own. All these skills would have constituted the Native American navigation kit, necessary knowledge not only for achieving intended destinations and predictable travels but also for preserving self, family, and culture along the course of those travels.

Both on foot and by boat, Native Americans displayed great maneuverability and speed, due largely to their success as navigators, trackers, and aquatic farers. The American continents from Alaska to Argentina appear to have been settled within a thousand years of the first arrival of

Asiatic migrants, testimony to the Native Americans' ability to navigate and negotiate even unknown territories. Once in America, Native Americans greatly diversified their means of water travel and their techniques of navigation as well. From predominantly coastal seafaring, they developed great prowess in the negotiation of rivers, rapids, lakes, and various inland waters unlike anything that would have existed in their Paleolithic Siberian homeland.

Ancient Native Americans took to the water for many reasons, including trade, whaling, and fishing. Ancient whaling could be quite dangerous. Boatmen harpooned the massive animals and attached animal-skin flotation devices to the prey to fatigue it, mark its location, and float its carcass. North American whaling traditions, among Alaskan peoples especially, included journeys in open water far beyond the sight of land. Thus, northern whalers, among the most proficient seamen of all Native Americans, illustrate that Native Americans did not always follow coastlines in their maritime expeditions.

Circum-Caribbean groups such as the Maya and the Arawaks of the Caribbean also made long journeys across open water, culminating in discoveries of the island territories of today's Caribbean. Arawak explorers in the Caribbean some 3,000 to 4,000 years ago encountered Paleo-Indian hunter-gatherers who had arrived thousands of years even before they arrived, bearing out the theory that even the most ancient Native Americans were expert seafarers. In the case of the Maya mariners, the impetus for their travels was largely trade, and Maya objects have been found from the North American Southwest to the Mississippi to the Caribbean islands.

The ancient Americans are known to have exhibited a highly developed directional sense in the building of their monuments and architecture. Palaces, pyramids, and other tombs often opened facing one of the cardinal directions or were aligned to the solstices. Likewise, the celebrated Nazca Lines in Peru demonstrate that ancient Andeans possessed advanced surveying techniques, which they would have also used in their fishing and military expeditions up and down the Peruvian, Ecuadorian, and Bolivian coasts. Both the Nazca and Moche civilizations maintained their empires through the movement of troops, goods, and ultimately their cultural influence by sea.

Their orientation to cardinal points and navigation through the unpredictable marine conditions induced by mist, glacial cycles, and the occasional El Niño effect show a great familiarity with the movement of heavenly bodies and marine currents. There was knowledge of true north and perhaps even magnetic north. The discovery of what is believed to be a 3,000-year-old Olmec compass may confirm that ancient Americans also possessed some tools that helped them approximate the location of cardinal points when celestial bodies could not be seen.

The ancient Americans are not known to have ventured far upon the high seas. They never devised the large ocean-go-

ing sailing vessels of their contemporaries in Europe, Africa, Arabia, or Asia. Rather, with their development of a variety of quick-moving and highly maneuverable vessels, from one-man kayaks to massive canoes, they were able to feed communities, stimulate economies, and even build empires.

► settlement patterns

INTRODUCTION

Before the advent of agriculture, people did not settle in one place for very long. They survived as hunter-gatherers, moving about in search of game animals and edible plants. The basic unit of settlement was the camp, which small numbers of people, usually related by clan ties, used as a base of operations for hunting and gathering. As the seasons changed and food supplies diminished, they moved on to a new camp. Ar-

chaeologists learn about prehistoric ways of life by studying stone tools, artifacts, and middens (trash piles) that survive from these ancient settlements.

After the advent of agriculture in roughly 8000 B.C.E. people began to form more permanent settlements. Generally, they favored areas that provided fertile soil, a moderate climate, and water for irrigating crops. Accordingly, settlements in the ancient world were most often formed on the banks of lakes and rivers and along ocean coastlines. Major civilizations such as those of the ancient Mesopotamians and Egyptians grew up along rivers, where fertile soil was left behind after annual flooding. By this time the basic unit of settlement was the village and hamlet, where clusters of houses were built by farmers who tended the land and their herds of livestock. In time, some of these villages grew into towns, which served as administrative centers and places where farmers could sell their crops. Some of these towns evolved into cities, becoming the seats of kings and emperors.

Patterns of settlement could change as a result of changing climatic conditions. As glacial ice receded at the end of the ice age in about 11,000 B.C.E., people moved northward into such regions as Europe, including Scandinavia. Sometimes, though, climatic conditions took a turn for the worse. Parts of ancient Egypt that were (and are) desert were once fertile and green, but climate changes forced people to abandon their settlements to cluster in the fertile Nile River Valley. A similar fate awaited some of the peoples of Mesoamerica, whose fertile land turned into desert, forcing many of them into cities.

Settlement could be influenced by changes in the face of the earth. A good example is provided by Japan, which consists of about 3,000 islands, about 600 of them inhabited. Throughout most of its history, Japan was cut off from Asia and thus remained home to a Stone Age culture long after the rest of Asia had progressed. But Japan was not always an island nation. Sometimes around 30,000 B.C.E. people moved from the Korean Peninsula across a land bridge that connected Japan to Asia; at the same time, many of Japan's islands were connected until rising ocean levels separated them. For thousands of years the Neolithic Jomon culture dominated Japan, but this domination came to an end in about the third century B.C.E. when northern China experienced an extended drought that turned the region into desert. The northern Chinese, in search of more hospitable ground, streamed into Korea, in turn forcing Koreans into Japan. These types of migration patterns, brought about by changing conditions, were commonplace in the ancient world.

AFRICA

BY MICHAEL J. O'NEAL

Settlement patterns in ancient Africa were largely a function of geography and climate. Because Africa is a large continent—about 4,600 miles from east to west and approximately 5,000 miles from north to south—and is bisected by the equa-

tor, it contains a wide range of terrains and climate zones. Much of the continent is covered either by savanna (broad, open plains covered with grasses) or desert. Additionally, the continent includes forested lowlands as well as high mountain peaks, such as Mount Kilimanjaro (in Tanzania) and Mount Kenya. The continent also features five major river systems, including the Nile, the Congo, the Zambezi (where Victoria Falls, the world's largest waterfall, is found), the Volta, and the Niger.

Human history began on the plains of east Africa. During the Stone Age people migrated from these plains to other regions of the continent. They were able to do so because the human species became more intelligent and thus able to develop tools that enabled them to survive in new environments. Central to this history was the search for resources. Among the earliest Africans, the chief resource was food sought by nomadic bands of hunters and gatherers. In time, Africans searched for fertile land where there was sufficient water and a temperate climate for growing crops. Others settled along lakes, rivers, and the coasts, where bodies of water provided fish and seafood. Additionally, this search for resources included materials for building shelters and making household goods and, in time, resources that could be traded for other, scarcer resources provided by people in the ancient Near East, around the Mediterranean Sea, and from other regions within Africa.

The climate zones of Africa had a profound impact on settlement patterns. These climate zones differed by temperature and rainfall. In the lowlands along the equator, rainfall was frequent in lush forests. The heavy forests made farming difficult, and herding was not practicable because of the prevalence of disease in livestock. For this reason, the people who settled in the equatorial regions of Africa relied on hunting and gathering, fishing, and trade and exchange for their livelihood.

Farther from the equator the forests thinned out, and the climate was somewhat dryer. To the north and south were the savannas with seasonal rains (rather than the nearly daily rains of the tropical forests), longer dry seasons, and warm days but cool nights. Although the quality of the soil was poorer than in the forest regions, the open land, combined with sufficient rainfall and moderate temperatures, made these regions attractive to farmers and herders. Historically, the savannas were home of Africa's breadbaskets, where people settled to grow fruits, palm oil, peas, yams, sorghum, millet, and other crops. Incidentally, much of the modern Sahara was savanna until about 3000 B.C.E. Climate change at this time forced people to adopt new settlement patterns.

It was in the savannas and the border regions between the savannas and the forests that the major civilizations of ancient Africa emerged—for the simple reason that these regions provided the most resources combined with the most hospitable climate. Historians have identified at least eight such civilizations in a band from east to west. To the east were the ancestral lands of the Bantu-speaking peoples. Next was

the region surrounding Lake Chad, the ancestral lands of the modern Kanuri. The lower Niger River region was home to the Nok, a metalworking culture. The middle Niger River region and Volta River valley were the ancestral homelands of the later Akan, Mossi, and Songhai peoples. The upper Niger River provided a home for one branch of the Mande, while the area surrounding Tichit (in modern Mauritania, the likely site of Africa's oldest city) was home to another branch of Mande. The Wolof and Serer (also spelled Sérère and Sereer) settled in the Senegal River valley and along the African coast. Finally, the ancestors of the later Fulani, Taureg, and Berber peoples occupied semiarid regions on the border of the desert. This band of civilizations formed a major east–west trading route.

Farther away from the equator are deserts, including the vast Sahara of northern Africa. Here, people settled primarily around rivers such as the Nile. The Nile River valley was home not only to the ancient Egyptians but also, farther south, to the Nubians and the Kushites. Water was provided entirely by the rivers, which flooded during rainy seasons at their source and then carried silt and water for irrigation to the desert regions. This fertile silt was the lifeblood of agriculture for these cultures. Nomadic herders lived in the deserts, where they could move their livestock about in search of scarce brush.

Finally, the northernmost and southernmost portions of the continent became temperate, with seasonal climates and rainfall similar to those of agricultural regions in the United States and Europe. Here people settled to grow such crops as grapes, olives, and wheat, and to raise livestock, such as cattle and goats. The emergence of agriculture produced major changes in settlement patterns. People had to gather and strike down more or less permanent roots to tend their fields and herds, and they lived their lives according to the rhythm of planting, tending, and harvesting crops. The result was the formation of villages and the allocation of the land that surrounded them. As people gathered in villages, more formal lines of authority had to be developed, typically those surrounding the rights and duties of the lineage or clan. In general, these communities did not form “states.” Rather, they remained autonomous (independent), forming alliances and networks as necessary.

Resources had to be managed so that people had equal access to them. Practices surrounding marriage and the raising of children became more formalized. Social and economic patterns changed as people developed new specialties, such as pottery making. Religious practices became more formalized as people worshipped ancestors and gods associated with land, crops, the weather, and so on. African society

became more “female” as the emphasis shifted from hunting, the preserve of males, to social and family relationships combined with sedentary gardening and crop raising. New roles developed as people took the lead as heads of clans, as storytellers and historians, as healers and diviners, and the like. Meanwhile, nomadic herders developed their own settlement patterns. While they did not stay in one place, they had to return regularly to places where they could provide shelter and pasturage for their herds. As people produced surpluses of food and other goods, commerce and exchange became more common, with people settling along trade routes and providing services to traders and their caravans. Finally, as communities formed and competed with other populations for resources, conflict and ways of managing it developed. The result of this conflict was often warfare.

EGYPT

BY WOLFRAM GRAJETZKI

In order to understand the location of Egyptian towns and villages, knowledge of the special landscape of Egypt is important. As was true in ancient times, Egypt is dominated by the Nile River and the desert. The Nile, flowing from south to north, was the only regular water source. Fertile land, only a narrow strip along the river, was less than 2 miles wide. There were some oases in the western desert, and in the north the Nile divided into several branches, forming the Nile delta, a broad and highly fertile region. In the west there was also Lake Moeris, connected to the Nile via a branch of the river. The Faiyûm Depression, a region area around this lake, was low and marshy and needed human intervention to convert it into arable land. It was only in the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) and in the Ptolemaic and Roman periods (304 B.C.E.–395 C.E.) that there were substantial towns and villages in this part of the country. In late summer the Nile rose and flooded most of the fertile land, making transport here only possible by boat. An important point, at least for bigger towns, was the connection to the Nile, either directly or via a canal. In ancient times transport over land was very expensive while water freight was easier to handle.

All settlement types in Egypt adapted to this special environment and the Nile flood. The settlements had to be placed close to the Nile to secure a regular drinking water supply and proper transport, and they had to be built on a place that remained dry throughout the year and was not flooded by the Nile. In general, these are natural “islands” of higher ground within the flood plain. (These hills in the Nile delta are often called after their general appearance “turtle-backs.”) The mounds are sometimes not very big, and thus the space for settlements was restricted. If a town grew larger, people might move to another island. In the Nile delta there arose several double cities where the population lived on two or even more of these hills, which were treated in inscriptions as separate towns but were indeed single-population centers.

Desert areas were settled more often in the Greek and Roman periods, when towns and villages were built into the desert around Lake Moeris. Other settlements built at the desert edge often had specific functions, such as workmen villages for quarries or building projects like the tombs in the Valley of the Kings in Thebes. When these building projects were finished, the settlements were abandoned. The biggest building projects in Egypt were the pyramids in the Old Kingdom (ca. 2575–ca. 2134 B.C.E.). For these projects special towns for the workmen and the administration of the building project were erected. While the workmen’s places were no longer used after the pyramids were finished, other parts of the settlements could develop into regular towns. Here the cult for the dead king buried in the pyramid was performed, and from this starting point these places became local centers. This is most clearly seen at El-Lahun, the pyramid town of Sesostri II (r. 1897–1878 B.C.E.). El-Lahun flourished as an administrative center for the whole region for the next two centuries. The mortuary temple of Ramses III (12th century B.C.E.), called today Medinet Habu, also became a center that functioned as an important town for 1,500 years. The temple had strong walls, and after the death of the king the local population moved there, perhaps for security reasons.

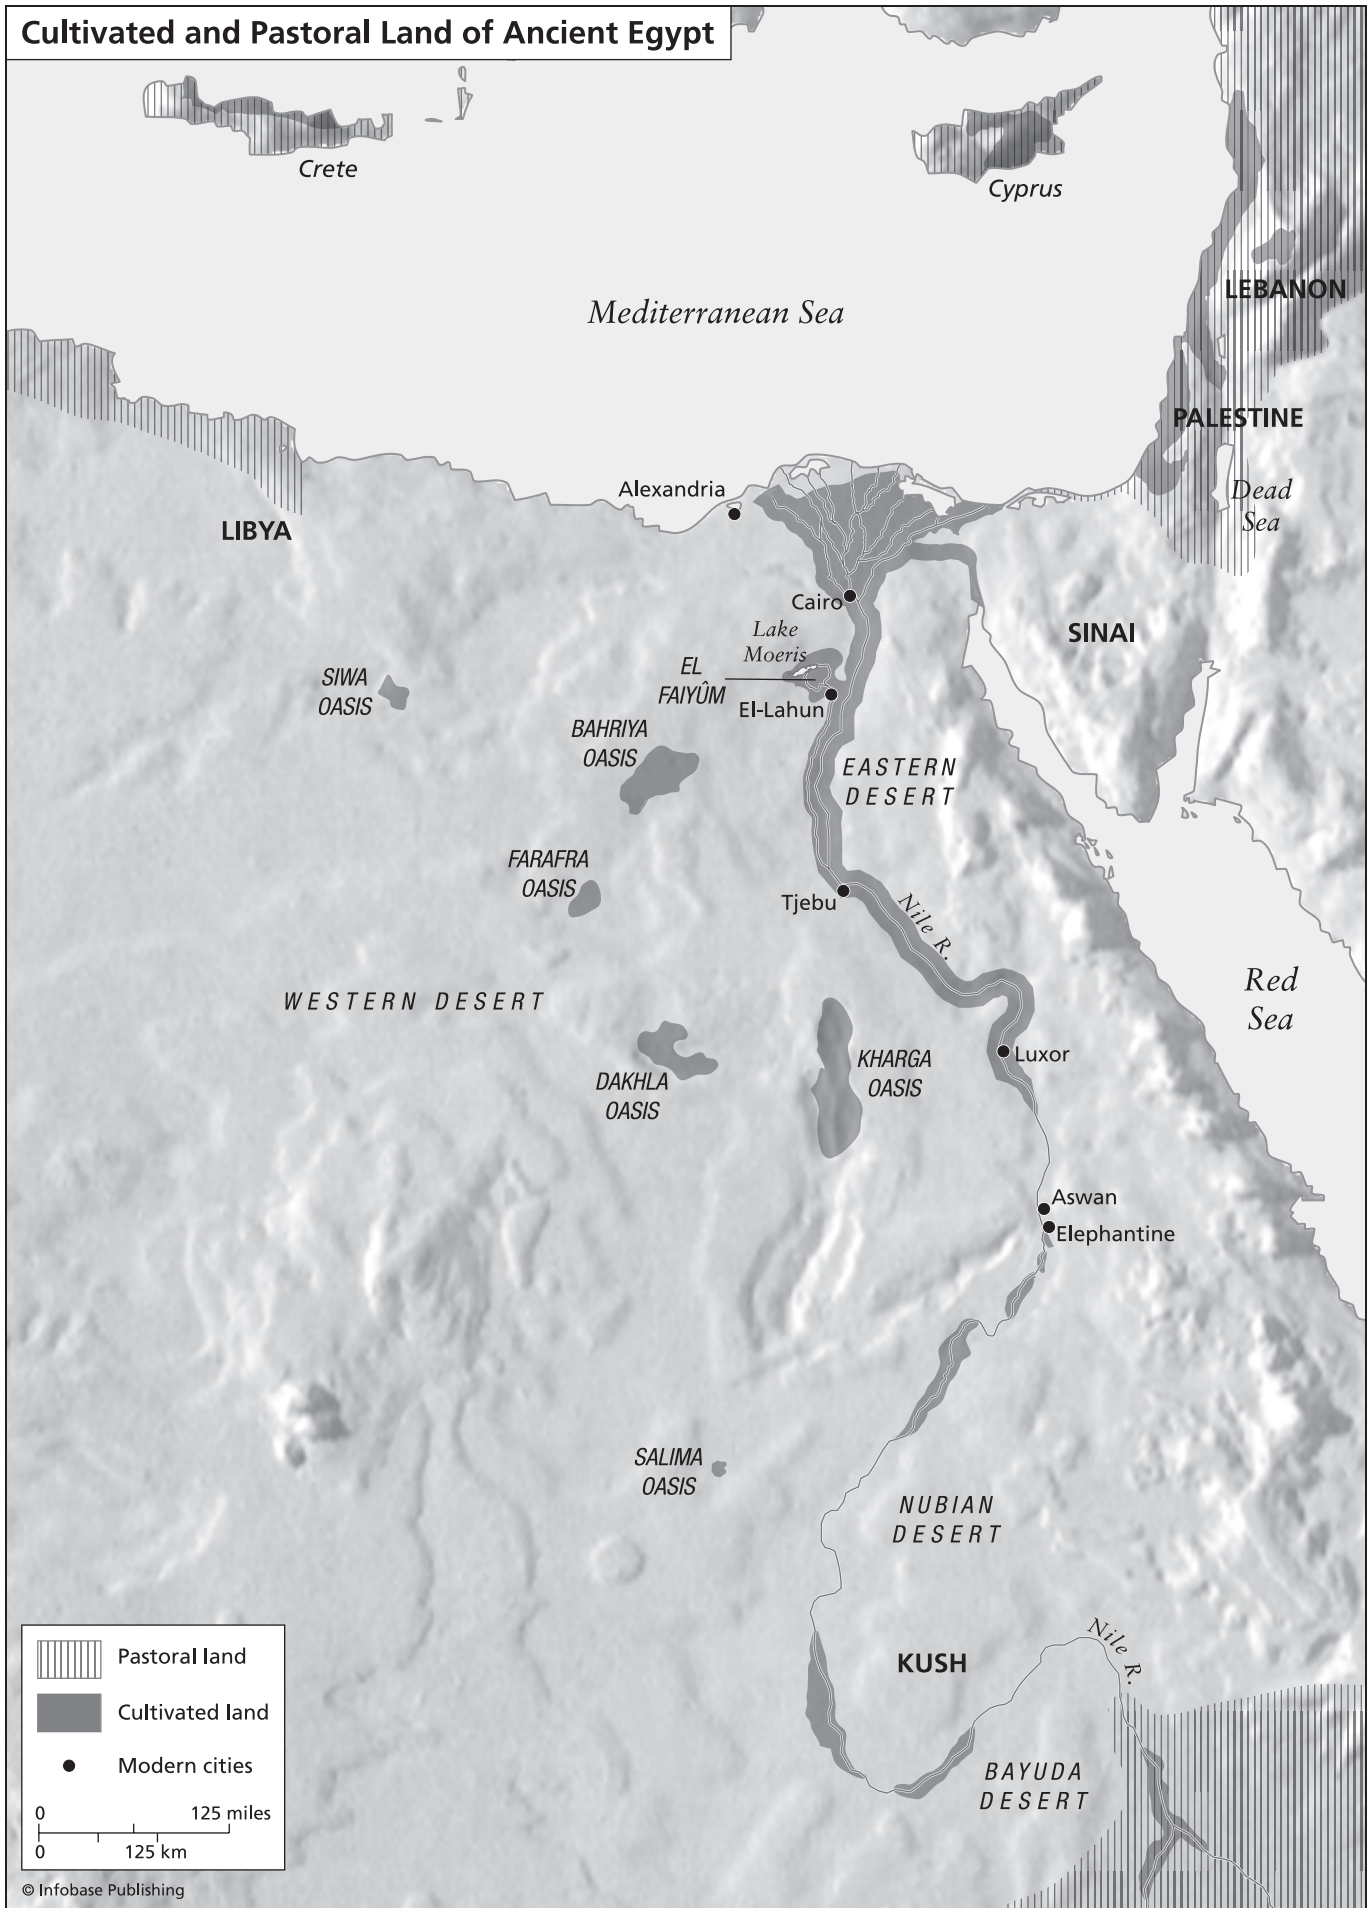

It is hard to identify the pattern of settlement types in the Nile Valley and the Nile delta, as only a few have been surveyed and a small percentage of the sites have been excavated. In addition, the excavated examples are often exceptional rather than the norm. One such place is the well-researched island of Elephantine. The southernmost settlement of Egypt, Elephantine had special significance as a trading post for Africa and also functioned as a frontier and fortress town.

In Middle Egypt near the modern villages of Qau and El Badâri, a chain of cemeteries was excavated. These cemeteries were placed close to the ancient settlements, and at least for this region it is possible to gain a picture of the distribution of settlements in pharaonic times. The center of this region was the town called in ancient times Tjebu (modern-day Qau el-Qebir). Here was found the biggest cemetery of the region, including the monumental tombs of the local rulers. Tjebu was the center of the local governor with the palace of the local government. It was also the location of an important temple. The temple was closely connected with the administration of local government. Here the taxes of the province were stored and given back to the people when needed.

From ancient texts we know that each province had a main town with a temple of the most important deity of the province. These temples in the local centers not only functioned as religious capitals of a region but were also the contact place between the royal capital of the country and local

(opposite page) Most settlements in ancient Egypt were placed close to the Nile. A high proportion of the population of towns probably lived from agricultural work, taking advantage of the yearly rise and fall of the Nile that left deposits of rich black silt along the riverbanks.

Cultivated and Pastoral Land of Ancient Egypt

government. Around these centers, which must have covered the whole Nile Valley, were villages of different sizes, visible from a chain of smaller cemeteries north of Tjebu. In ancient Egyptian times they were rather small; from what is known of the cemeteries we can expect that populations reached not much more than 100 people per village. However, in Greek and Roman times Nile Valley settlements were often quite big, and many of them had the size of small towns. The Egyptian language does not distinguish between town and village in precisely the way that English does. There are several words for settlements, but they may relate to their function and not necessarily to their size.

Not much is known about farmhouses and small agricultural units. In general, we can assume that even in towns and local centers a high proportion of the population lived from agricultural work. From written sources we know that houses or estates existed in the countryside and were involved in food production. Only farmhouses of the Ptolemaic Period (ca. 304–30 B.C.E.) have been excavated showing that they at least were sometimes big buildings.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

When the last ice age ended about 11,000 B.C.E., humans spread through the Middle East. The climate was good, and rainfall was relatively high for the region. As a result, grasslands and forests expanded and provided more food for humans, who quickly inhabited the entire Fertile Crescent, an area stretching from Israel and Lebanon to the Zagros Mountains. These hunter-gatherers sought out regions that included more than one ecological zone so that they could exploit a variety of food sources. They lived in small, highly mobile bands, sheltering in temporary camps that they could easily dismantle when conditions deteriorated.

Starting around 10,000 B.C.E. people began settling in locations for longer periods as they grew dependent on certain types of plant foods. For example, the Natufian people of modern-day Israel lived on acorns and pistachio nuts that grew in a belt in the central part of the region. They built permanent villages with underground storage pits and occupied these settlements for many generations. The people of Abu Hureyra on the Euphrates River in Syria also built a permanent village, hunting and fishing and gathering plant foods from the nearby forests. By about 9500 B.C.E. permanent settlements were common throughout the region.

The first farming settlements appeared around 8000 B.C.E. in the Levantine corridor, a narrow strip about 15 miles wide along the Jordan River from the Damascus Basin to Jericho. This corridor had ample water supplies with a naturally high water table, a rarity in the region. The readily available water meant that people could farm without irrigation. The area also had plentiful sources of wild food, including legumes, nuts, and game. These settlers built villages of mud-brick huts that housed perhaps 100 to 200 residents. As the products of

agriculture furnished more of peoples' diets, settlements became more nearly permanent with farmers tied to their fields and women tied to their grinding stones. People now lived in the same place for generation after generation. When populations grew, it became harder for people to deal with sudden catastrophes such as droughts.

Because rainfall was low and rivers were the only reliable source of water in the region, settlement patterns in Mesopotamia were dictated by the presence of rivers. All major Mesopotamian cities were built near the banks of either the Tigris or the Euphrates. Some of the earliest-known Mesopotamian cities were Ur, Uruk, and Eridu, built by the Sumerians near the mouth of the combined Tigris and Euphrates sometime between the sixth and the fourth millennia B.C.E. Some archaeologists believe that Eridu was the first city ever built; Sumerian tradition held that Eridu was the first city before the Great Flood to have a king. Southern Mesopotamia was wetter than it is now, and it was conveniently located on trade routes, which made it an attractive location for settlement.

The population of the Mesopotamian river settlements grew quickly. At first the cities were fairly small and surrounded by farming villages, but the climate changed this pattern. Around 3800 B.C.E. the climate grew drier, and the floods that the farmers relied on began arriving later, after harvest. People who had lived in the countryside were unable to farm anymore and abandoned their homes. Some became nomadic herders, wandering with their animals in search of pasture. Others left the outlying villages and moved into the cities in search of food. By 3200 B.C.E. Sumerian civilization had become highly urbanized. Historians estimate that by 2800 B.C.E. some 80 percent of the Sumerian population lived in cities clustered in southern Mesopotamia.

Ur, Eridu, and a group of several other cities within sight of one another were home to thousands of Sumerian farmers who used the rivers' annual floods to irrigate their fields. Small villages extended out from the cities along networks of canals that carried water away from the rivers. Different communities specialized in different products, such as pottery, fishing, or metalwork. Each city had a government that organized irrigation and food distribution and conducted the rituals considered necessary to propitiate the gods. Several land and sea trade routes converged on the area. The cities in the region constantly fought over scarce water and land resources.

People had begun colonizing the upper part of the river during the fifth millennium B.C.E. These cities grew larger during the third millennium B.C.E. and came under the leadership of warlords who competed with one another for water and land. When water was plentiful the settlement pattern resembled that of the early fourth millennium in southern Mesopotamia, with towns spread out from cities, but urbanization proved inevitable there as well. The Akkadian civilization (2350–2100 B.C.E.), for example, arose in the fertile Habur plain south of the Anatolian plateau when, as had hap-

pened around 3800 B.C.E., a drought drove people from the countryside into the cities.

While cities were a viable solution to minor drought, major droughts were too much for them. Around 2200 B.C.E. a major drought afflicted all of Mesopotamia. The cities could no longer feed their residents, and the people dispersed, leaving their former homes to sink into ruin. When the rains returned about 1900 B.C.E., the people returned as well, though to different sites; the rivers had changed course, and some of the former city sites were no longer habitable. Cities continued to be the dominant settlement form in the region.

Throughout the Middle East people followed similar patterns, gathering around rare water sources. In the Levant people settled near rivers, lakes, and other sources of water. The Jordan River and the Sea of Galilee were major population centers from early times. The coastline was also valuable to fishermen and sea traders. In Arabia there was so little water that very few people lived there. The ones who did manage to settle there permanently built towns on the coasts of the Persian Gulf and the Red Sea.

In Anatolia most people lived along the Black Sea and Aegean coastlines, which had fertile land and a healthy climate. People had settled the coast of the Black Sea (at that time called the Euxine Sea) by the seventh century B.C.E. When the weather grew warm and wet around 5800 B.C.E. the population on the shores of the sea increased as more farmers took advantage of the fertile soil. Also around 5800 B.C.E. the waters of the sea began rising, and the entire area flooded, forcing residents to abandon their homes and flee to higher ground. Many of them moved into eastern Europe. The central part of the Anatolian peninsula was mountainous and heavily forested, which made living conditions difficult, though some hardy souls lived in caves in the rocks. By the time of the Greek and Roman empires, the western and northern coasts of Anatolia were heavily populated with towns, large cities, and farmsteads.

In Persia the most fertile area was the coastline of the Caspian Sea, which received more rain than any other part of the

country. Human settlements were concentrated in this region. Settlements also clustered along the trade route that led between India to the east and Mesopotamia to the west. Persian rulers built cities throughout their realm; major cities were Susa, near Babylon, and the Seleucid capital of Persepolis.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Most paleontologists believe that early humans spread eastward from Africa along the southern coast of Asia. Many of their settlements would now be underwater. They would have chosen to settle where the fishing was good, spreading inland only where the hunting and gathering were easy and probably not establishing villages inland until population pressures forced them to move. Their villages would have been far apart and their overall population would have been thinly spread over the landscape.

Humans reached the southeastern edge of Asia long before the beginning of the last ice age. From Southeast Asia people moved slowly to outlying islands. In about 30,000 B.C.E. people began to settle Australia, probably inhabiting its northwestern coast, where they could establish fishing villages. They spread slowly through what was then a mostly wet continent, arriving at Tasmania in about 29,000 B.C.E. and reaching the far southern edge of Australia in about 22,000 B.C.E. By 10,000 B.C.E. they were a thinly spread population of about 300,000 people whose villages tended to be near sheltering rocks and forests, where they could escape direct sunlight in what was becoming a mostly dry, hot land.

The earliest-known Indian culture is the Harappan civilization (ca. 2600–ca. 1500 B.C.E.) of the Indus River valley in northwestern India and Pakistan. The first major cities discovered by archaeologists were Harappa and Mohenjo Daro. Both of these cities were near the Indus River, which for a long time had archaeologists believing that the Indus River was the focus of Harappan settlements. Yet the Vedas tell of a major river, the Sarasvati, that was the focus of important events. The Vedas are sacred works of Hindus that were the oral tradition of the Vedic peoples who invaded India in about 1500 B.C.E. and which were written down sometime between the 500s and 300s B.C.E.

It turns out that the Sarasvati had existed but dried up between 2000 and 1000 B.C.E. It was east of the Indus River, and it appears to have had far more Harappan settlements along it than did the Indus. The Harappans were farmers and traders. Most of their population lived near rivers, and they used irrigation canals to water their farmlands. In general, they used every bit of arable land for growing crops and built their homes on land that was more rocky than the land they farmed. Although most of their settlements were along the Indus and Sarasvati rivers, every river in the valley had at least one village along it. They also had many villages in wet lowlands near the Gulf of Kachchh and the Gulf of Khambhat on the coast of the Arabian Sea and at least a few villages well

to the east on the Narmada and Tāpi rivers. To further their trade with other cultures, the Harappans established towns far from their river valley: Shortughai in the Hindu Kush mountains to the north and Mundikak, Shahr-e Sokhte, and Bampūr far to the west. Shortughai was in a place to take advantage of trade in lapis lazuli, and the far western settlements may have been for trade with Mesopotamia. The oldest settlement appears to be Mehrgarh near the Bolan Pass west of the Indus River, which was first settled in about 6000 B.C.E.

By about 1500 B.C.E. the Harappan civilization had collapsed, probably because of a combination of natural disasters and invasion by nomadic Aryan groups from central Asia. These groups became the Vedic peoples, and over hundreds of years they migrated through the Indus River valley and southeastward through northern India. They did not immediately settle down into permanent homes but migrated with their cattle. In about 1000 B.C.E. they began to adopt agriculture, and during the 800s B.C.E. small Vedic kingdoms arose, mostly along the Ganges and Yamuna rivers that ran southeastward across northern India. Much of the Ganges flowed through plains that were good for both growing crops and herding cattle.

While the Vedic peoples were slowly expanding southward, they encountered other peoples, often called Dravidians by archaeologists. Many of these people belonged to Stone Age cultures, living in forests as hunter-gatherers. They resisted efforts to settle their territories and continued their ways of life all through the ancient era. Others became farmers. Like the Harappans, they tended to settle along rivers, but in central and southern India rains were so frequent that communities could settle in wet, open lands away from rivers and reasonably hope to receive enough rain to water their crops. When India formed kingdoms, governments tried to take advantage of rains by building dams to create reservoirs, particularly in mountainous highlands. Public works such as dams and irrigation canals allowed people to spread their villages into areas previously unsuited for farming.

Although the Harappans are still mysterious to modern archaeologists, societies in China during the same era are even more perplexing. In much of what is now China, people did not create settlements until modern times, and many in the north still remain nomads, pitching their tents in different places every day. In about 6500 B.C.E. people began farming. By about 5000 B.C.E. there was a fairly cohesive culture farming millet along the lower reaches of the Yellow River, also known as the Huang River. Around the Yellow River and its tributaries was a belt of loess soil, silt blown into layers over many years, and the Yangshao culture of about 5000 B.C.E. spread villages away from rivers into regions where the soil allowed for easy digging. Rice farming was introduced from the south, and the Longshan culture of about 3200 B.C.E. developed to organize people to take advantage of rice's superior yields and nutrition, because rain was less frequent in the Yellow River area and irrigation requiring community cooperation was needed to provide rice with the moisture it needed.

South of the Yellow River was the Yangtze River, where farmers settled along the riverside to grow mostly rice. From about 4500 B.C.E. on the region around the mouth of the Yangtze and a region upstream around the lake Dongting Hu became heavily populated by farmers. The Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) tried to absorb the people of the Yangtze, but it took until the Zhou Dynasty (ca. 1045–256 B.C.E.) for China to conquer the Yangtze settlements, and thereafter the Yangtze farmlands became vital to feeding the empire.

The Zhou, Qin (221–207 B.C.E.), and Han (202 B.C.E.–220 C.E.) dynasties each made the establishment of settlements part of government policy. They made special efforts to settle peasants from central China in the north near the Great Wall to act as deterrents to nomadic raiders, and during the Han Dynasty to help make the Silk Road secure. To absorb conquered lands into the empire, Chinese governments often moved large groups of peasants south or west, going as far south as North Vietnam.

For almost all of the ancient era the majority of people in Korea and Japan settled near ocean shores. Those people who moved inland tended to settle beside lakes or streams. In Japan the mountains were sparsely populated. In Korea invasions and wars influenced some people to move into highlands, where travel was difficult and water sometimes scarce but where the rough territory helped them defend themselves. During the Yayoi Period (300 B.C.E.–300 C.E.) of Japan people often settled near marshes or swamps because they would scatter rice seed in the marshes or swamps and later harvest the new rice. This unsophisticated approach to growing rice was sufficient for Japan's population of about two million people.

Extensive rain forests grew in southeastern Asia. That these lands were populated is known from the records of Chinese and Indian explorers, but little is known of their settlement patterns. The Mekong River attracted many settlements, probably at first because of good fishing and later because rice could be cultivated along it. By about 100 B.C.E. the Mekong Delta in modern southeastern Vietnam was heavily populated, mostly by farmers.

EUROPE

BY JUDITH A. RASSON

The Paleolithic cultural period dates to the geological Pleistocene (the ice ages). Although the climate all over Europe was affected, there were many large ice-free areas. People lived in small groups that moved around throughout the year to hunt and gather wild animals and plants, resulting in a settlement pattern made up of campsites used by different groups at different times. A good campsite needed not only a safe place to set up tents or other shelters but also access to water and food. Some campsites were near sources of stone for tools. People returned to favorable locations year after year, such as Dolní Věstonice in the modern-day Czech Republic, which was on a nonglaciated route between eastern and western Europe.

The shelters that people constructed were only temporary; they took their tents with them when they traveled or built new shelters from brush and tree branches. A conveniently located cave also made a good temporary home that might be revisited every year.

During the Paleolithic everyone lived in groups based on families, and their settlements were similar, though the groups varied in size depending on how much food they had available and what tasks they were carrying out. These tasks and activities mainly had to do with everyday living, such as preparing and cooking food and making tools and clothing. While no group stayed long in any particular place, perhaps once a year different groups gathered for a day or two to renew friendships, find marriage partners, and share information. A few special sites, like the Lascaux Cave complex in France, were not just for the activities of everyday life. At Lascaux and a handful of other places the cave walls were decorated with pictures of animals and other designs. They had social and religious significance.

At the end of the Pleistocene the climate changed, although people remained gatherers and hunters for hundreds more years, adapting to the supply of plants and animals brought by the new warmer climate. Eventually people found out how to domesticate plants and animals to supply their needs for food and other materials, and they developed ceramics, though they still relied on stone for sharp-edged cutting tools. This was the beginning of agriculture, called the Neolithic Period, which began in about 7000 B.C.E. in Greece but not until 2000 B.C.E. in England.

Houses built by Neolithic settlers were made of timber and mud plaster (or the equivalent), more substantial and usually larger than in the Paleolithic. They were occupied for long periods, probably because groups now maintained their own food supplies. Settlements functioned as hubs from which many activities were carried out, such as cultivating fields and herding animals. It is hard to generalize about the locations of Neolithic settlements because their locations were always compromises that made it possible to meet a number of needs, such as access to water, arable land for crops, and grazing land. More people lived in Europe than before, and because their lifeways left more remains than earlier, hundreds of Neolithic settlements are known throughout Europe, for example, Cuiry-lés-Chaudardes in France, Brześć Kujawski in Poland, and Selevac in Serbia. In general, each settlement fulfilled the same social and economic functions as every other settlement, but Neolithic people in many parts of western Europe built special-purpose monuments interpreted as expressions of their supernatural beliefs. Arrangements of large stones called *megaliths* can be seen at Carnac in Brittany (France). Passage graves were made with stones grouped in various ways with or without soil coverings; the most famous is New Grange in Ireland.

Although settlements were similar, the length of time each was occupied differed. Some settlements were used for long periods throughout the Neolithic, resulting in the accumula-

tion of cultural debris in a large mound (or tell), like Karanovo in Bulgaria. These are more common in eastern and southeastern Europe than in western Europe. Sometimes smaller settlements, occupied for less time, were located surrounding a tell, as at Polgár-Csőszhalom in Hungary. This suggests that the older (tell) settlement had some economic or social function beyond that of the smaller younger settlements.

During the Bronze Age, when metalworking became widespread, some earlier patterns persisted. The basic economic activities of cultivating fields and grazing livestock continued; thus settlement sites were still placed to provide access to the necessary resources. But settlements began to be distinguishable from one another by the number or variety of their differing functions. In western Germany and the Low Countries, for example, there were both single farmsteads and larger villages. As can be seen by their size and internal complexity, some settlements began to benefit from increased trade activity.

In the social system of the Bronze Age (starting as early as 2800 B.C.E., in southeastern Europe) some people earned elite status and political power. Trade intensified, even with far-distant areas, including trade in valuable bronze objects. It was during this period that many settlements throughout Europe began to show signs of defensive fortifications, such as being located on hilltops (sometimes called hill forts) or being surrounded by ditches and wooden palisades. A Bronze Age tell in Hungary has a double ditch and palisade system surrounding it; in Spain, a Bronze Age site with stone walls stands on a high promontory. In Sardinia, in addition to village settlements, Bronze Age people built stone towers called *nuraghi*.

Later still, iron objects began to be made and used in different parts of Europe—albeit at different times. By the Iron Age (starting around 1000 B.C.E.) iron objects and tools became widely available to most members of society for all aspects of daily life. New technology, such as iron-tipped plows, enabled people to occupy new areas. The Iron Age is associated with increasing social and economic complexity, which was reflected in a hierarchical settlement pattern. Territoriality was evident when some groups began to control important locales, such as river fords or mountain passes. Some villages or farmsteads remained strongly connected to farming and stock raising, whereas others added functions, such as being the residence of a socially elite group. In the Halland area of Sweden agricultural villages are located on well-drained soil, and smaller sites are located adjacent to wet areas, perhaps for special purposes such as hunting. The large site of Slöinge was probably the residence of elite people because the artifacts found there include such unusual items as garnets, amber, gold, silver, and imported glass.

Important settlements were usually protected in some way, often by a ditch, palisade, or rampart, sometimes even by a water barrier such as the crannogs, or artificial islands, constructed in Ireland. In Poland the site of Biskupin is fortified and located on a peninsula in a lake for protection. The Iron

Age settlement of Százhalombatta Földvár in Hungary was protected by both a ditch and an earthen rampart, construction of which was a huge earth-moving project that probably required direction by a respected person of higher social status than most people. Another manifestation of the existence of a social elite was the use of distinctive burial practices. In many areas the elite were buried in specially constructed mounds (sometimes called tumuli). The Iron Age is the first time in European prehistory that something is known about the group names people called themselves. The most famous are the Celts, who were spread from southeastern Europe to the British Isles. Their elite lived in hill forts (often called *oppida*). The settlement of Bibracte, now called Mont Beuvray, in France was surrounded by a wall of timber, stone, and earth, 3 miles long.

GREECE

BY MARK ANTHONY PHELPS

Two geographic factors are paramount in understanding Greece from either a social or an economic context. First, this is an extraordinarily hilly and mountainous land, as over 40 percent of the land is more than 1,600 feet in elevation. The Pindus Mountains extend the length of the region until they submerge into the Aegean Sea, creating most of the islands found there as well as a jagged coast that provides a vast number of protected harbors. Settled life focuses on valleys and a handful of plains scattered throughout the country. Second, no point of the peninsula is more than 38 miles from the sea.

The soil of the region is rocky and often of marginal fertility. Adding to the fragility of the soil is the climate, known as dry summer subtropical. Summer dryness, wind, and heat contribute to crop failure, while winter rains demand modifications of the farmland to enhance drainage and to stop soil erosion. Natural springs and man-made cisterns, necessities for rural life, influence where cities can grow. In ancient times the marginal land that could not lend itself to intensive agriculture was used for pastoralism. After the collapse of the Mycenaean civilization (ca. 1100 B.C.E.), the depopulation of cities may reflect a period of nomadic pastoralism. For the rest of the ancient history of Greece, transhumant pastoralism was the norm.

The hills and mountains of Greece contributed to the political fragmentation that characterizes Greek history. Isolation fosters ethnocentrism, which contributes to the history of independent city-states and continual rivalries. The majority of ancient Greeks were farmers. Wheat was the dominant crop in the plains and valley bottoms, while olives and grapes were typically grown on terraced hillsides.

The model traditionally espoused for ancient farmers is taken from the pattern of farming found in medieval and modern Greece. Historians theorized that farmers lived in villages, leaving in the morning to tend to scattered plots. The distribution of plots was the product of equal devolution of property among sons and the usage of land in dowries.

This dispersion was ultimately advantageous, as land in plots that have some ecological differentiation serves as insurance in the face of droughts, because one piece of land may fare better than others. Further, the village provided protection from raiders. Given the scarcity of water, it was assumed that farmhouses in the countryside would have been impossible to maintain.

However, this model has been successfully challenged by the recent attention to rural archaeology and a closer reading of certain classical texts. The rise of villages and the increase in trade at the beginning of the Iron Age points to a rise in agricultural production. The need for land for intensive farming was a contributing factor to the phenomenon of colonization as Greeks established colonies throughout the Aegean coasts, the Black Sea, Libya, and other scattered centers in Asia Minor and the rest of the eastern Mediterranean.

The image of Odysseus's father Laertes in Homer's *Odyssey* serves as antithetical evidence to the traditional model of ancient Greek farming. In contrast to the notion of living in a village, Laertes resides in a house on his farm with outbuildings constructed on it for storage and drying. He works his farm daily, which must be done if one is growing vines and maintaining orchards. He has a fence and dogs for protection. He labors alongside his slaves, sharing equally in toil. He rarely enters the town, where he owns a lavish house, and he has a profound disdain for urban dwellers. He has a reputation as a warrior.

Archaeological evidence indicates that small-scale irrigation emerged at the time of Homer and Hesiod in the late eighth century B.C.E., providing another argument for the need to have farmers on farms for continual maintenance. In his writings Aristotle (384–322 B.C.E.) asserts that in early days the population of the polis was small, as most were working farms. Surveys in Attica, Boeotia, the Argolis, the Peloponnese, Aegean Islands, Magna Graecia, and the Crimea all support these images where a number of rural structures from these areas have been located.

Ancient Greek farmers would have needed to both protect their land from raiders and hide from invaders. Given that most farms were small, neighbors were not terribly distant. Protection from farming neighbors seems to have been a greater concern than raiders given the attention that Plato assigns to legal codes regulating the relationship between farming neighbors in his work *Laws*. Clearly, settlement in rural areas was dense enough to cause troubles. The largest estates were by no means enormous. The politician and general Alcibiades (fifth century B.C.E.), nephew of Pericles, was fabulously wealthy with an estate of some 80 acres.

The choice for urban settlement was based primarily on access to water, generally springs or (less often) rivers. Sites needed to have an agricultural hinterland to support the urban population that did not farm. This hinterland would have needed a population base to trade its surplus for certain manufactured and imported goods. The two most powerful states during the bulk of the ancient Greek period were

the two city-states with the largest agricultural hinterlands, namely, Sparta and Athens. Access to the sea was beneficial for trade but by no means a requisite for cities in classical Greece. These factors account for the resettlement of former urban areas (usually with the same Mycenaean name) during the Iron Age, as Greece has always been a land of limited water and limited agricultural land.

The abundance of harbors and ease of access to the sea for most of the interior fostered a culture of seamanship. This orientation was further driven by the poor mobility between Greek regions and cities owing to the mountainous and hilly terrain. In turn, the period of colonization of distant shores from the eighth through sixth centuries B.C.E. was facilitated by the experience of the Greeks in managing the geographic circumstances of their homeland.

The hills contributed to the isolation and fragmentation of the city-states that emerged in the Iron Age. The rare plains lent themselves to the formation of leagues among the cities and villages ringing them. The members of these leagues would fight among themselves over access to resources, but they formed a united front against outside invaders.

The origin of the institutions of classical Greece can be traced and attributed to the values and experiences of farmers living on this land. The sense of individual worth, egalitarianism, and independence all followed from attitudes expressed by and attributed to farmers. Greek writers took pride in the difficulty of their climate and soil in regard to agricultural production. Such characteristics as courageousness, fierceness, physical strength, and intelligence all sprang from life on farms, according to classical authors.

ROME

BY DAVID B. HOLLANDER

In the Roman world agriculture was the foundation of the economy, and owning land was the basis of social status. Thus both the settlement and use of land were of considerable importance in the development of the empire. Political and military factors influenced where colonies were established, while economic, cultural, climatic, and geographic factors determined the location of farms, villages, and towns and whether they flourished or failed.

A number of different kinds of sources shed light on Roman settlement patterns, each with its drawbacks. Literary sources, such as agricultural manuals and the writings of elite Romans including Cicero and Pliny the Younger, provide some information about the size and location of farms and villas, but these authors rarely discuss the situations and concerns of any but the wealthiest Romans. Survey archaeology, in which a team of archaeologists examines land for surface traces of ancient activity by walking over it, can provide a much fuller picture of settlement patterns. In many parts of the empire one still finds traces of the boundaries established by centuriation, the process Roman surveyors used to mark out land allotments for new settlers. Surveys reveal the

remains of ancient farmhouses and villages as well as those of larger villas. They can also indicate how settlement patterns changed over time. Nevertheless, survey archaeology cannot determine who owned a given structure or how much land was associated with it. Furthermore, it is likely that the dwellings of the poorest farmers left few traces for archaeologists to find. The excavation of the remains of rural structures can suggest how the surrounding land was exploited and the nature of a villa or farm's interaction with the local environment and market. Inscriptions and papyrus manuscripts also sometimes provide information concerning the ownership and use of land.

Several Roman agricultural manuals have survived from antiquity. The earliest, written by Cato the Elder, dates to the second century B.C.E.; Varro wrote another about a century later, and a third was composed in the first century C.E. by Columella. Pliny the Elder, author of 37 volumes on natural history, provides additional information. These writers discuss not only estate management and the cultivation of crops but also the question of where to build a farm. Many factors had to be considered when buying agricultural land. According to Cato, ideally, the climate should be good, and the property should be at the base of a mountain facing south, having access to water and a supply of labor as well as roads, navigable waterways, or a nearby town. Good neighbors and land capable of growing a variety of crops also were considered desirable features. Varro discusses two other important factors related to the establishment of rural estates: health and safety. Proximity to swamps and marshes is undesirable, while, in certain regions, a farmer might have to contend with brigands. Varro stresses the advantages of having property near a town or village, where one could sell produce and purchase necessities.

Small estates on the outskirts of Rome could prove immensely profitable if their production was geared toward the city's insatiable demand for game, fish, and flowers. Wealthy Romans frequently built luxury villas where they might relax or entertain guests. Prior to the eruption of Vesuvius in 79 C.E., the land around the Bay of Naples was a particularly popular location.

Little can be said with certainty about the earliest phase of Roman settlement during the regal period. Tradition held that shepherds and outlaws formed the bulk of the followers of Romulus, Rome's legendary founder. It is likely that pastoral agriculture played a more important role in Rome's first centuries than it did later. Romans of the late Republic believed that their ancestors had worked small plots of land on the outskirts of the city. As the Roman Empire expanded, three important trends emerged: colonization, the designation of conquered land as *ager publicus* (public land), and growth in the size of upper-class estates. Colonies served several functions. The Romans founded some small colonies, such as Antium and Ostia, on the coast to protect against sea-borne attacks. Other colonies were essentially garrisons in newly conquered territory.

Colonists, who might be Roman citizens, veterans, or allies, received small plots of land to farm in their new communities. Vast tracts of land were confiscated from Rome's defeated enemies and designated *ager publicus*. Despite the efforts of some Roman lawmakers to limit individual holdings, wealthy Romans came to control much of this land. The rich landowners used slave labor to operate their large estates, which were called *latifundia*. In the 130s and 120s B.C.E. the plebeian tribunes Gaius and Tiberius Gracchus attempted to enforce the limits on holdings of *ager publicus* and distribute the recovered land to less fortunate Romans. They encountered stiff resistance from the Senate; even though both men were ultimately murdered in riots, they did manage to settle thousands of Romans on small plots of Italian land. Such conflicts over land possession and ownership continued into the first century B.C.E. The proscriptions instituted by Sulla in the 80s led to the confiscation of tremendous amounts of land. A number of the Roman general Sulla's associates gained wealth by purchasing confiscated estates. Many landowners continued to rely heavily on slaves to work their estates, as the great slave revolt led by Spartacus suggests. Civil war, debt crises, and the need to find land to reward Roman veterans made the Italian real estate market especially volatile in the final decades of the Republic.

Given the size and varied nature of the Roman Empire, it is difficult to make generalizations about settlement patterns in the Imperial period. Farms of varying sizes, villages, towns, and rural sanctuaries as well as seasonal shelters for farmers and shepherds could be found dotting the landscape. While some individuals amassed large landholdings and debt frequently forced peasants to sell their land, the practices of dividing inherited land among heirs and colonizing conquered regions tended to create new smallholders. Many provinces received groups of Roman colonists, especially in the early empire. Some provincial cities grew substantially under Roman rule due to their status as provincial capitals, their role in the transportation of foodstuffs to Rome, the presence of military units, or the patronage of the emperor. Alexandria, Carthage, and Antioch became particularly important. Other cities and regions suffered from natural disasters, revolts, or proximity to volatile border areas. The relative peace of the first two centuries of the Common Era saw an increase in population and rural settlement in many regions. But beginning in the late second century C.E. plague, civil wars, and Germanic invasions caused a decline in population and rural settlement in some places.

THE AMERICAS

BY J. J. GEORGE

Settlement patterns in the ancient Americas overlap with traditional migration theories on the origin of the first peoples. The traditional theory held that the first Americans crossed Berengia, the Bering Sea land bridge from Siberia to Alaska, around 11,500 years ago. The term *bridge* is somewhat mis-

leading because some models suggest that open land was in excess of 1,000 miles wide, affording ample territory for multiple bands of persons traveling on foot to make their way into the New World. Why did they come? In brief, they came because they were following megafauna, or large animals hunted for food, such as mammoths, mastodons, bison, and giant sloths—the latter as large as 20 feet tall. While Berengia is now under water, save for a scattering of islands, during the period of initial settlement much of the earth's water was locked up in ice sheets that covered much of Canada, dramatically lowering the earth's sea levels and exposing greater expanses of land.

The appearance of the first Americans coincided neatly with evidence indicating that an ice-free corridor had opened between two large Canadian ice sheets referred to as the Laurentide and Cordilleran, allowing these early migrants access to nonglaciated lands in mid-latitude America. These original inhabitants are now called Clovis people, named after the town in New Mexico where their fluted spear points used for hunting mammoth were first found in 1932. Clovis and Clovis-like points are recorded from the late Pleistocene in Alaska to Panama and in California and Nova Scotia. Following this model, the first settlements spread slowly southward, eventually reaching the edge of North America to the east and the southern tip of South America.

However, a well-studied site called Monte Verde in southern Chile, dated to around 12,500 years ago, calls into question the traditional model of a slow and orderly procession southward. The site contains the buried remnants of simple residential structures, stone tools including bifacial projectile points—a stone tool with two sides or faces worked to form an edge for scraping or cutting—and preserved edible and medicinal plants. The question, then, is how did these peoples reach so far south so fast? A competing settlement theory posits a much more rapid southern advance via open coastal routes along the Pacific Coast into Alaska and northwestern Canada and eventually south to Peru and Chile by approximately 12,500 years ago. Any remnant archaeological data that might pinpoint and date coastal settlements are unfortunately lost; as the last ice age receded, rising sea levels worldwide advanced inland, burying the previous coastline and along with it any markers of coastal inhabitation. To date, then, there is agreement only in that the first Americans were *Homo sapiens sapiens*, who were in North and South America by Clovis times, about 11,500 years ago.

Viewed archaeologically, settlement patterns are, like any prehistoric residue, the incomplete and fragmentary markings of something that was once vital and whole, essentially a reconstruction of the physical and material presence of long-disappeared persons. A settlement might be thought of as an archaeologically discernible site, a unit of space that was characterized during some culturally definable period of time by the presence of one or more dwellings or structures. The arrangement of structures on a site with respect to one another forms unit patterns. The arrangement of these pat-

terns, in turn, through a wider segment of space, might be termed a complex pattern. These complex patterns relate to the adjustments of human beings and culture to environment and to organization of society in a broad sense.

Over time a range of settlement types developed, some coalescing into complex settled social units based on agricultural production and others maintaining hunter-gatherer economies. Classifying the variety of settlements presents its own difficulties, with definitions differing by scholar and discipline. In general, however, much of the literature includes the following settlement types: camps, villages, towns, ceremonial centers, village clusters, and, eventually, cities. Generally speaking, these classifications represent advancing complexity based on differing social, economic, and political determinants, and it should be further noted that characteristics are often complementary and overlapping.

The simplest archaeological discernible site, or *camp*, would cover sites with areas between a few hundred square feet and perhaps an acre, where midden (refuse) deposits are thin and impermanent, lightly built shelters were erected without any definite community plan. Camps are most closely affiliated with hunter-gatherer and semisedentary units. Camps persisted in areas such as the eastern United States, Brazil, Central America, Mexico, and the Caribbean from the time of the first human being until at least the historic period, or the period when Europeans first arrived and began recording written history.

A *village* occupies an area of several acres. The number of dwellings might run as high as 30 to 40. The appearance of sturdier structures, which remained in place and were occupied for extended periods of time; deeper refuse deposits; and some level of village planning are in evidence. The spatial and temporal distribution of villages is similar to that of camps, which they began to replace or at least to supplement. It would be common for a village to be politically dominated by a chief with extended kin or clan affiliations. Examples of this type of settlement range from the Tehuacán Valley of Mexico, with pit houses and domesticated plant use in evidence by 3400 B.C.E.; to Hopewell Indian sites in the American Midwest by roughly 200 B.C.E.; to coastal villages in British Columbia and Southeastern Alaska, with evidence of plank houses by 200 B.C.E.; to the burial mounds and earthworks of the Adena people in Ohio, Kentucky, and West Virginia between 1000 B.C.E. and 200 C.E..

Village clusters and *ceremonial centers* are closely related and particularly common, representing a number of neighboring villages so closely related culturally that it is assumed constant contact was common and sociopolitical organization overlapped. It was not uncommon for these affiliated villages to share a ceremonial center. Unlike camps, which lacked complex patterns and seemed not to cluster, religious sites often became linked by larger social and ceremonial considerations and thus could be called a village cluster. Hopewell and Adena temple mound complexes between 1000 B.C.E. and 200 C.E.; Mayan centers in the Central America,

including Cuello in Belize (possibly as early as 2400 B.C.E. until 500 C.E.) and Tikal (250–850 C.E.) in Petén; Guatemala in the second through ninth centuries C.E.; Chavín between 900 and 200 B.C.E.; and Moche from perhaps 1 to 600 C.E. in Peru are all examples of villages or village clusters with a ceremonial center in common.

The key relation in settlement is between settled life, domestication, and population. Greater population density becomes possible with advanced domestication, where people tend to favor plants and produce food in surplus, which is necessary to support larger populations as well as nonagricultural members of society, such the elite, craftsmen, and soldiers. In one sense, towns and cities are simply greater agglomerations of persons gathered in a single area with refined abilities to domesticate and store foodstuffs, such that by the second through eighth centuries of the Common Era a city like Mexico's Teotihuacán, it became possible to support a population estimated at around 125,000.

► ships and shipbuilding

INTRODUCTION

The archaeological record concerning ships and shipbuilding is thin. Few watercraft from the ancient world have survived, because generally they were made of perishable materials. Some of the earliest were made with such materials as reeds, and ancient kayaks, canoes, and similar small craft were typically covered with animal skins. Later, lumber was used in boat construction, resulting in larger, more durable craft, but over the centuries the wreckages of these ships have largely deteriorated. Still, marine archaeologists have located portions of the wreckages of ships in such areas as the Mediterranean Sea, giving them insight into ancient shipbuilding techniques. The archaeological record also includes artwork that depicts boats and ships, watercraft that were entombed with ancient rulers, and in some cases written descriptions.

Ancient civilizations constructed ships and other types of watercraft to serve a variety of purposes. One, of course, was exploration. As ancient peoples migrated into new regions of the world, they used watercraft to navigate rivers and coastlines, often in search of new food supplies or new places to settle. These craft were powered by oars or, in the case of river barges and rafts, poles. In some parts of the world, this impulse to explore led to the development of larger, more ocean-worthy vessels, along with sails to harness the power of the wind. However, other ancient cultures, such as those of the Americas, were less interested in exploring the world than they were in exploring the region that surrounded them.

Fishing required the use of watercraft. People who lived in coastal communities or along rivers developed a range of watercraft that allowed them to harvest fish, seafood, and in time even whales. These types of watercraft had to be highly maneuverable and able to operate in shallow water. Rafts, canoes, barges, and small boats and ships were used for this purpose.

Trade in the ancient world was often conducted with the help of watercraft. Because large volumes of goods had to be transported and because land routes were both dangerous and difficult, transport by water was often the preferred method. The wreckage of one ship found off the coast of Turkey yielded 20 tons of cargo, an amount of cargo that would have been nearly impossible to transport by land. Similarly, watercraft often were used to transport materials for construction. Many of the stone monuments that survive from the ancient world were built with massive stones quarried in one location and then transported by barges closer to the construction site. In some case, barges were used to ferry goods between islands, such as the many islands of Greece.

Finally, watercraft were used for military conquest. As shipbuilding methods became more advanced and ships be-

came larger, they could be used to transport troops, weapons, and provisions. Additionally, some of the world's great naval battles took place during ancient times. The Chinese, with their immense coastline, led the world in shipbuilding technology during the Qin (221–207 B.C.E.) and Han (202 B.C.E.–220 C.E.) dynasties and built a large fleet of huge warships that came to symbolize China's power and prestige.

AFRICA

BY JUSTIN CORFIELD

Although many ships—Roman, Greek, Persian, and Phoenician—in the ancient world sailed to Africa, the only African state besides Egypt that maintained a large fleet of its own was Carthage. It had not only a massive navy, located in a secret inner harbor at Carthage, but also a sizable merchant navy.

The Carthaginians inherited their naval traditions from the Phoenicians, from whom they trace their civilization. At the height of their power during the First Punic Wars (264–241 B.C.E.), the Carthaginian navy was very large. The Greek historian Appian (second century C.E.) wrote that the naval harbor at Carthage had the capacity to take 200 ships, and archaeological work at the site confirms this possibility. Because the Carthaginians had bases throughout North Africa and also Sicily, they probably had many more ships. The Greek historian Polybius (ca. 200–ca. 118 B.C.E.) stated that in 256 B.C.E. Carthage was able to put to sea some 350 ships, which would involve a crew of about 150,000: 300 oarsmen and 120 marines on each vessel. Given the number of people used to make the ships, it is evident that Carthage placed a great deal of emphasis on its navy.

The major fighting ship used by the Carthaginians was a quinquereme. There are no archaeological remains of such vessels, but historians believe that they had a large central sail and three rows of oars, with two men pulling each of the top two oars. The Carthaginians also had quadremes and triremes. The trireme had three banks of oars, but the quadreme is thought to have had one row of oars with four men pulling each oar, two rows of oars with two men pulling each oar, or three rows of oars with two men pulling the top oars. All three types of designs might have been used. The ability of the Carthaginians to produce such large numbers of ships was confirmed in 1971 when the hull of a Carthaginian galley was found near the port of Marsala in Sicily. Some of the wood had the marks of shipwrights, proving that they were mass-produced, which would be the only way they could have had such a large fleet.

Many of the Carthaginian sea battles of the First Punic Wars took place around Sicily. The Romans initially copied the design of a Carthaginian ship for their vessels. It must have been an old design because later in the war they captured a faster vessel, which enabled them to build better ships. At the first encounter, at Milazzo in 259 B.C.E., a Carthaginian admiral called Hannibal (not to be confused with the general of the same name who invaded Italy during the Second Punic Wars) attacked the Romans but lost 50 ships.

The admiral narrowly escaped being captured himself and lost his flagship. After they were defeated by the Romans off the coast of Sardinia, the Carthaginians crucified Hannibal as a punishment.

In addition to their navy, Carthaginians also had a large merchant fleet. Their vessels sailed the Mediterranean before the First Punic War and through the wars until just before the outbreak of the Third Punic War in 149 B.C.E. These were the ships involved in trade with Spain and Cornwall, where the Carthaginians and the Phoenicians bought tin. The Roman poet Avienus (fourth century C.E.) makes a reference to a visit of the Carthaginian navigator Himilco (fl. ca. 450 B.C.E.) to Cornwall. Carthaginian ships also sailed down the western coast of Africa. They are believed to have traded with West

THE RA EXPEDITIONS OF THOR HEYERDAHL

The *Ra* expeditions of the Norwegian explorer Thor Heyerdahl, which took place in 1969 and 1970, followed the Norwegian adventurer's success with the *Kon-Tiki* crossing of the Pacific. Heyerdahl intended to demonstrate that it was also possible for people to cross the Atlantic Ocean. He had been interested in connections between the ancient civilizations, and he believed it might have been possible for seacraft to have made the long and hazardous voyages.

For that reason Heyerdahl hired boat builders from Lake Chad, and the boat was constructed out of reeds in Egypt based on designs shown in ancient Egyptian drawings, and then taken to Safi, Morocco. It was accepted that the Egyptians could have sailed along the coastline of North Africa and through the Strait of Gibraltar. Here they might have taken on extra crew or replenished supplies on the boat. Although Heyerdahl's intent was to show that ancient Egyptians could have reached the Americas, the fact that the boat departed from the Atlantic Coast of Morocco also showed that people before even the Carthaginians could have made the journey.

With a seven-man crew, *Ra* sailed on May 25, 1969, but foundered in July after traveling 2,700 miles. It was abandoned after being waterlogged and in danger of sinking. It was a great disappointment for Heyerdahl and the multinational crew, but, undeterred, the team started work on another boat. The second boat, *Ra II*, with almost the same crew, was built by Aymara Indians from Lake Titicaca on the border of Peru and Bolivia. It was then taken to Safi, from where it managed to cross the Atlantic and arrive at Bridgetown, Barbados, in the West Indies in 1970, having completed the crossing in 57 days.

Africa, although whether they did this directly or through middlemen is not known. According to one theory, the Carthaginian navigator Hanno (fifth century B.C.E.) sailed to modern-day Cameroon.

Apart from the Carthaginians, the Numidians had small trading vessels, but as a client state first of Carthage and then of Rome they had no need for their own fleet. Trading vessels were certainly being built on the western coast of Africa, but most traveled short distances and kept close to the coastline. However, the Norwegian explorer Thor Heyerdahl (1914–2002), in his *Ra* voyages in 1969 and 1970, managed to prove to his skeptics that it was possible to build a vessel that could cross the Atlantic Ocean. Archaeologists have not found the remains of any of the Carthaginian trading vessels, but from descriptions of the goods they carried it would seem that they were similar to the Phoenician merchant ships. These ships relied far more on the use of sails, as the costs of maintaining large numbers of oarsmen, even slaves, would have been too high to justify the gains in speed and the loss of large storage areas for merchandise.

Many small vessels undoubtedly traveled the eastern coast of Africa, including Egyptian ships sailing to Punt, the Egyptian name for a coastal region probably in modern-day Eritrea and Djibouti. Merchants from these and other ships were probably the transmitters of knowledge of metallurgy from Nubia to southern Africa. The dates of the iron objects found in Africa seem to show that the technical advances occurred in coastal areas before permeating inland, which may explain why the Buganda people of modern Uganda learned to utilize iron in comparatively recent times. It is also possible that this trade was carried out not by African ships but by ships from India or elsewhere whose owners plied their wares along the African coast. Items designed by the Chinese and Indians have been found in Madagascar, indicating that this trade did exist from ancient times. In addition, beginning in the second century B.C.E. the use of dhows—sailing vessels with triangular sails—for trade between Africa and southern Arabia started to become important as the exchange of goods between Axum and Arabia significantly increased.

Besides the ships used for navigating in seas and oceans, there was also a need for vessels for crossing rivers and trading along rivers. Rafts would have been used to cover the shorter distances, along with boats made from hollowed logs and small watercraft. Being made entirely of wood, none of these have survived, although some archaeologists have suggested hints of their existence in some of the rock carvings found in the Sahel.

EGYPT

BY ERIN FAIRBURN

Because ancient Egyptian civilization developed in the valley and the delta of the Nile River, it is only natural that watercraft appeared early in Egyptian history. Developed technology in the creation of river craft appeared in the Predynastic

Period (before ca. 3000 B.C.E.), and clear evidence of seacraft is known by the Old Kingdom (ca. 2575–ca. 2134 B.C.E.). Egyptian traditions in boat construction were unique in the ancient world until late in the Dynastic Period, and some techniques have persisted into modern times.

The earliest Egyptian watercraft were developed in response to the need for transport along the Nile and the marshes of the delta, especially during the inundation season, when settlements along the Nile Valley would effectively be turned into islands. These were simple rafts, constructed by tightly binding bundles of papyrus reeds. They were easy to construct, made of readily available material, and required little technology. Longitudinally binding the bundles as tightly as possible made the craft more watertight and reduced the rate at which the reeds would become waterlogged. The binding gave the resultant raft a crescent shape, the front and rear curving upward, with the ends of the bundles splaying outward in the shape of a lotus flower. The appearance of these river craft would be imitated in later Egyptian wooden vessels.

These rafts are probably the types of boats that are depicted on Naqada II (ca. 3500–ca. 3200 B.C.E.) pottery from the late Predynastic Period. Such images show cabin structures and standards on these vessels and seem to indicate that they could carry a fair contingent of rowers. One representation on a Naqada III (ca. 3200–ca. 3000 B.C.E.) jar seems to indicate that sails had been developed by this time and were used on such craft. These simple vessels were used throughout the history of ancient Egypt.

Construction of boats in wood is not known in Egypt prior to the Early Dynastic Period. Native Egyptian woods are of very poor quality and produce only short lengths of timber. However, longer lengths could be produced from timbers imported from the eastern Mediterranean, and it is of note that the apparent advent of wooden boat construction in Egypt coincides with the earliest evidence of imported woods in Egypt. It does seem that Egyptian craftsmen frequently used native and imported woods in combination within a single vessel.

Wooden craft from their inception until the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) are evidenced archaeologically only from royal funerary contexts, where special pits were excavated in order to inter the boats alongside a king's tomb. This practice began in the First Dynasty (ca. 2920–ca. 2770 B.C.E.), and more than 30 such pits from this time have been identified, at a handful of sites throughout Egypt. Most of the pits' contents were no longer recognizable, but 12 brick structures from the funerary enclosure of the king Khasekhemui (d. ca. 2686 B.C.E.) were discovered in 1991 with their planked boats intact.

Most other known boat pits from the Old and Middle Kingdoms were found at Giza and Dahshûr. From these pits came eight vessels: the famous reconstructed boat of Khufu housed today beside the Great Pyramid in Giza; a second, unexcavated boat from the same pyramid complex; and six boats from the pyramid of Sesostri III (r. 1878–1841? B.C.E.)

at Dahshûr. These vessels give vast insight into the construction of planked vessels in Dynastic Egypt.

Egyptian wooden vessels were created hull first, any framing being installed afterward. Egyptian vessels did not have a keel proper, but they were sometimes built up from a long plank (or a connected series of planks) that was somewhat thicker than the surrounding planks and that may have served as a rudimentary keel. More planks would be placed around this central piece, building up the bottom and sides. These planks were initially attached through a series of mortise-and-tenon joints and then fastened by lashings made through a number of V-shaped cuttings within the thicknesses of the planks. This "sewn" technique persisted through the Ptolemaic Period (304–30 B.C.E.).

Once the hull was complete, crossbeams and other framing elements would be installed, and decking would be laid. Cabin structures could be built on the deck planking. The stem and stern posts were often large and decorative affairs, curving upward to a vertical or bent post with a lotiform (like a lotus petal) finial; as noted earlier, such features mimicked the appearance of reed rafts. The boats would be fitted out with a number of oars and one or two rudder paddles at the stern.

When ships were fitted with sails, they were hung from a bipod (forked) or post mast that was set well forward of the middle of the ship. At first the sails, probably made of linen, appear to have been taller than they were broad, but by the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) they were consistently broader than they were tall. The use of a bipod mast was soon abandoned, and the mast itself moved closer to the middle of the ship through time.

Seagoing vessels had additional adaptations. One important addition was the hogging hawser, a rope extending from stem to stern that could be twisted to maintain tension. This line helped maintain hull tension and kept the bow and stern from sagging. Before the New Kingdom (ca. 1550–ca. 1070 B.C.E.) sailing vessels also seem to have had rope netting fitted around the hull above the waterline, which probably served to maintain hull integrity. New Kingdom vessels, however, do not seem to have included this feature. Some of these later vessels do seem to have had a different internal layout that allowed rowers to sit below the hull line.

These seagoing vessels were used by Egyptian kings to conduct trading and military expeditions in the Mediterranean and Red Seas. Egypt is known to have had contacts with the eastern Mediterranean by the First Dynasty and with the Aegean by the late Middle Kingdom and into the Second Intermediate Period (ca. 1640–ca. 1532 B.C.E.). Military campaigns were launched against kingdoms of the Levant as early as the Sixth Dynasty and sporadically throughout the rest of the Dynastic Period. Beginning in the Old Kingdom, trading expeditions were also sent to Punt, a kingdom located on the eastern coast of Africa in the Red Sea region. Hatshepsut (r. 1473–1458 B.C.E.) famously recorded an expedition during her reign on the walls of her mortuary temple at Deir el-Bahri, including wonderful depictions of her ships.

Painted wooden model of a boat, from Meir, Middle Egypt, Twelfth Dynasty, around 1900 B.C.E. (© The Trustees of the British Museum)

One other type of vessel had a vitally important purpose in ancient Egypt and was used throughout the Dynastic Period: the barge. These vessels were similar in construction to seagoing vessels but had no sails and were of potentially massive size. They were used from the earliest times to transport stone for monumental sculpture and construction from quarry sites between modern Cairo and Aswān. These boats had to be tugged upstream or downstream by up to 30 smaller vessels.

Once Egypt fell under foreign rule, first by the Persians and then by the Greeks, Egyptian methods of seagoing vessel construction shifted to those of the greater Mediterranean region. However, river craft design remained essentially the same, as recorded by the Greek historian Herodotus (ca. 484–between 430 and 420 B.C.E.) and the famous Palestrina mosaic of Roman date.

THE MIDDLE EAST

BY EDWARD M. W. A. ROWLANDS

In the ancient world people began to design ships specifically to carry goods on long journeys. They left the eastern

Mediterranean and Persian Gulf to travel great distances. Warship designs were constantly modified to keep up to date with any changes in naval warfare tactics. Various weapons, such as the ram, were developed to fight the enemy, and boats were continually enhanced to increase their speed and defensibility.

In the second millennium B.C.E. merchant ships were broad-beamed craft, which enabled them to have a large cargo space. Square sails were used, and oars were utilized in the absence of wind. Early evidence of these ships comes from the tomb of Kenamun, a mayor of Thebes, in Egypt (ca. 1400 B.C.E.). Ships that are thought to have come from modern-day Syria had dense beams at the front and back ends of the ship. At the front of the ship was a large clay amphora that was probably used to store potable water. On the back end of the boat were two stern oars that would have been used for steering. A wicker fence also stretched across the ship to protect the deck cargo.

By the first millennium B.C.E. merchant ships had adapted to react to any possible enemy attack by placing iron on the bow (front) of the ship. The bodies of these ships were low in height and less rounded than their predecessors. The

ships are depicted on pottery beginning in the eighth century B.C.E. For short distances, there is evidence of a small craft that was rowed by one or two men. This ship is represented in the reliefs of the Assyrian king Sargon II (r. 721–705 B.C.E.). The front of the ship, which carried a cargo of timber, is in the shape of a horse's head. The ship's oars would have been used to steer the ship.

There is little archaeological evidence of Mesopotamian ships, owing to the poor quality of surviving representations and a lack of shipwrecks. They certainly once existed, however, as Sumerian texts refer to ships sailing down the Persian Gulf to locations as far away as Africa and India. These texts date from around 2350 to 1800 B.C.E. and suggest that from an early period the Mesopotamians were able to construct ships that traveled great distances. The Persians did not have a standing fleet, since most of their military campaigns were on land in Asia Minor. They relied instead upon their conquered coastal territories to supply them with the ships they needed. They also used sailing ships from the Levant to import wine, oil, metals, and other products into their empire.

In the 11th century B.C.E. a group known as the Sea Peoples caused havoc along the eastern Mediterranean. Areas of the Hittite Empire, Cyprus, and important cities in the Near East such as Ugarit (in modern-day Syria) were laid waste. The Sea Peoples seem to have been defeated by the Egyptians under the reign of Ramses III (r. 1198–1166 B.C.E.). Representations from Medinet Habu in Egypt show the naval battle between the Egyptians and the Sea Peoples. They suggest that naval warfare at first involved mainly hand-to-hand combat, with troops boarding each other's vessels.

Beginning in the late eighth century B.C.E. naval warfare changed with the invention of the ram. Representations of the ram have been found dating from this period in the sculptures of Sennacherib (ca. 681 B.C.E.), who followed Sargon II as king of the Assyrian Empire. This new weapon could cause considerable damage to opposing vessels. The oldest ram that has been discovered was found off the coast of Israel at 'Atlit and dates from the second century B.C.E. The ram was found without any other ship wreckage around it.

Besides the right weaponry, speed was an important factor in naval warfare. The ability to outmaneuver a rival

was vital. Large steering oars on the back of the boat meant that the ship could change direction quickly. Ships were also built very long to counter the effects of a bow wave. This wave was created when ships attempted to sail at high speed. Vessels needed to use a great deal of energy to climb the wave created, which would slow down the ship. Longer, narrower ships could better cut through this wave and so travel more quickly.

On the reliefs of Sennacherib there is early evidence of vessels with a second row of oars, called biremes. This increase in the number of oarsmen helped to propel ships at ever-increasing speeds. To maintain the stability of the ship, the platforms where the oarsmen sat were lowered. As a defensive measure, warships often had a balustrade on the top deck that was covered with shields. By the late sixth century B.C.E. ships called triremes had developed a third row of oars. Such ships were used in large numbers at, for example, the battle of Salamis between the Persian and victorious Greek navy in 480 B.C.E.

Beginning in the fourth century B.C.E. changes in design were needed to adapt ships to new changes in battle tactics. Vessels became increasingly used as stages to fire artillery at the enemy. In naval warfare the frequency of troops boarding other ships increased. To counter this, larger and larger ships were constructed. During the period of wars between the rival successors to Alexander the Great (r. 336–323 B.C.E.), called the Diodochi (322–281 B.C.E.), *sexiremes*, vessels with six sets of oars, were used in the battle of Salamis in 306 B.C.E. After the political unification of the Mediterranean by the Romans the demand decreased for such large war vessels. Triremes were used again, for example, in the Battle of the Hellespont in 324 B.C.E. when Constantine's son Crispus (d. 326 C.E.) defeated the Roman emperor Licinius (r. 308–324 C.E.).

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

Nautical technology in China was highly developed in the ancient world. The Chinese had vessels for traveling along rivers and navigating the seas. Asians took a number of sea voyages around the Pacific, although details on many of them rely on legends or remain conjecture. With few images surviving of the ships used and no archaeological confirmation, much of the evidence for ships and shipbuilding techniques come from descriptions in chronicles.

It seems probable that vessels were used during the Shang (1500–1045 B.C.E.) and the Zhou (1045–256 B.C.E.) dynasties, but most of the historical records were destroyed during the famous burning of the books by the order of the emperor Zheng (r. 221–210 B.C.E.) in 213 B.C.E., so little information about them survives. The kingdoms of Wu and Yue were known to be important naval powers with significant coastlines, and they often used river-based fleets to attack the inland kingdom of Chu. Their boats would have been constructed entirely from wood, using sails and a rudder for nav-

Terra-cotta model of a merchant ship, Amathus, Cyprus, about 600–500 B.C.E. (© The Trustees of the British Museum)

igation and rowers for military vessels. Given their developed use of siege machinery, it is highly probable that they would have used rams on the front of their ships as was common in Europe during this period. One surviving fifth-century vessel shows the scenes of several battles, including one of a naval battle with oarsmen rowing barges that have mounted platforms with marines engaged in combat. These were made from wood lashed together with rope and, instead of sails, relied entirely on large numbers of oarsmen. While they were easy to maneuver in battle or as river ferries, this design was impractical for ships at sea.

There are many written records from the Han Dynasty; one of them, the *Han shu* (the history of the Han Dynasty), includes detailed accounts of sea voyages to “Tu-yüan” and “I-lu-mo.” It took five months to travel from China to the first and another four months to reach the second. It is believed that the first refers to a settlement on the northern coast of Sumatra and the second to Arramaniya, in southern Burma. There are also references to sailing to a place called “Huang-chih,” which some scholars surmise is Kanchipuram in south-eastern India. Although no images of the boats survive, they were clearly reliant on the use of sails and rudders. The boats were designed with a hull that was large enough to transport goods and supplies and to shelter the crew in bad weather or at night. Surviving descriptions of voyages at the time make it clear that pirates could be a problem. This would have necessitated building the boats with relatively high sides, not only to protect the merchandise from the sea but also to prevent surprise attacks by people using canoes. Although the story survives only in legend, the attack on the ship carrying Prince Kaudinya of India, the legendary founder of the empire of Funan, when he arrived in coastal Cambodia presents the possibility of surprise attacks.

Ships may indeed have gone farther, judging by the existence of Chinese and Indian goods—or at least Chinese and Indian styles—in Madagascar. Silk from the Han Dynasty was sold to the Romans, though it may have gone by land or through middlemen. There are records of a man who claimed to be a Roman envoy arriving at the Han court in 166 C.E., and two Roman coins have been found in Oc-Eo, a Funanese port in what is now southern Vietnam. That Roman merchants might have sailed to eastern Asia is also surmised from the name the Han used for Rome: “Country West of the Sea.” In addition to trade, it seems probable that the Han also used ships for war. Officials had government barges that were rowed along rivers and canals. It is recorded that the general Han Xin was able to cross the Yellow River with rafts that were made from wood and empty, closed pottery vessels used as floats.

Throughout Southeast Asia there would also have been many merchant ships and river vessels. The Funan Empire (first through sixth centuries C.E.) constructed large canals, and they probably used vessels to navigate them, though none have been found. They could have used rafts or simple barges. For their missions to China beginning in 243 C.E. they would

have needed vessels capable of navigating the South China Sea, but it is possible that the embassies used Chinese vessels. Mention should also be made of a delegation from the embassy of the Roman emperor Marcus Aurelius (r. 161–180 C.E.) in 166 C.E., which is said to have visited southern China.

In northern Vietnam there are images of ships on the side of several drums that date to 300 B.C.E.; similar drums from the early first century C.E., found in the Sunda Islands, show images of vessels with somebody clearly working a rudder. Carvings on the temple of Borobodur in Java (eighth century C.E.) show the type of vessel that existed at that time.

Canoes with outriggers were used in the Pacific to travel from one island to another, and larger vessels would have been used for making more significant journeys. The presence of people in most of the Pacific Islands, in Australia, and on islands off the coast of Australia during this period is clear evidence of substantial seafaring skills, and the Norwegian explorer Thor Heyerdahl (1914–2002) in the *Kon-Tiki* expedition of 1947 proved that it would have been possible for groups of people to navigate the Pacific. Although there are no historical records detailing these ancient voyages, the aboriginal people of Australia and those of many of the Pacific Islands have preserved legends of sea voyages.

EUROPE

BY MICHAEL J. O'NEAL

The oldest-known European boat, made from a single log, was discovered at Pesse in the Netherlands and dates to about 7000 B.C.E. Numerous other Mesolithic and Neolithic dugout canoes have been found in many parts of Europe, such as the ones at Noyen-sur-Seine in France and Tybrind Vig in Denmark. Dugout canoes were used for fishing in lakes and streams and for transportation on slow-moving rivers and in coastal waters. Paddles found at Tybrind Vig were carved with geometrical designs. Dugout canoes continued to be used in ancient Europe throughout the remainder of prehistoric times. Other early European boats were made of animal hides stretched over frames made of flexible saplings called withies. They were waterproofed with pitch and possibly even butter. Eventually this early form of boat-building technology was overtaken by more sophisticated methods, yet ancient seafarers continued to use skin-covered boats until well into the Common Era. Because these types of boats were made of organic materials, they survive in the archaeological record only when conditions permit their preservation.

During the Bronze Age the inhabitants of northern Europe developed greater skills in shipbuilding, including the construction of boats from planks. Among the first boats that show evidence of advanced shipbuilding technology are the three so-called Ferriby boats, which archaeologists found buried in clay in northeastern England. These boats, built of oak, date to about 1600 B.C.E. While still relatively crude, they show evidence of woodworking skill. The keel was built in two sections joined by a scarf joint, or a joint made by notch-

ing the wood so that the pieces overlap, where they can be joined together. Additionally, the keels were grooved to accept vertical planks, and crossbeams were used to strengthen the boat's bottom. The result was a broad, flat-bottomed boat, the largest of which is 5.33 feet wide and 43.5 feet long. This boat illustrates the convergence of two European shipbuilding traditions: One was the "skeleton" structure of hide-covered boats; the other was a tradition of heavy timbered boats. Similar to the Ferriby boats is the boat found at Dover in 1992, a large craft that is estimated to have been rowed by as many as 18 oarsmen during its crossings of the English Channel.

Archaeologists have discovered other wooden boats that date from the second and first millennia B.C.E. Many of these were constructed from a single tree trunk, in effect making them dugout canoes, though they also included transoms (cross pieces, or beams), decks, joinery, and fastenings made with iron and, in some cases, wooden dowels. One of these, called the Brigg raft, was found in Brigg, Lincolnshire, England, and dates to about 600 B.C.E. It is called a raft because only the flat bottom survives. Another, called the Hasholme boat, was discovered in Yorkshire, England, and dates to about 300 B.C.E. This boat and others like it show that their builders lived in a wood-rich environment where trees were cut down to build boats and a good deal of the wood was likely wasted.

The importance of boats in Scandinavia is reflected by their frequent appearance in the rock carvings that cover exposed outcrops in many parts of Sweden and Norway. Long boats constructed by planks carried goods and people across the Baltic Sea and North Sea and among the numerous small islands that line their coasts. The Hjortspring boat, built around 350 B.C.E., was found in a bog in Denmark in 1921. It had probably been used to carry a raiding party, which was then defeated. The victors then dragged the boat to the bog and sank it there as a war sacrifice, along with the weapons and shields of the raiding party. Like the Ferriby and Dover boats from the previous millennium, the Hjortspring boat was built from planks, but its framing system is very sophisticated.

The ancient Celts exhibited relatively advanced shipbuilding capabilities by the first century B.C.E. While the Celts were spread out over large regions of Europe, many groups lived in marine environments, particularly along the Atlantic coast. These ancient mariners faced problems that were much different from those faced by the Romans. While the Romans navigated primarily in the Mediterranean Sea, the northwestern Celts navigated in the more open waters of the eastern Atlantic and Baltic seas. Heavy swells and rocky coastlines required the development of heavy, stable craft that could survive this environment. And unlike the ships of the Romans, these ships could not be powered usefully by rowers.

One group that met the challenges was the Veneti, who lived in Brittany, a peninsula that juts westward into the Atlantic. The Veneti built a large fleet of massive, heavy-bottomed ships with tall masts, sails made of animal hides, and heavy metal cleats to hold the ships together. These ships were

highly maneuverable in the ocean. While broad and flat-bottomed, reflecting the tradition of log shipbuilding that was more than 1,000 years old in northwestern Europe, they were also tall and graceful, with high sides that enabled sailors to keep their feet relatively dry. These ships were far more advanced than anything the Romans could throw against them. When the Veneti refused to submit to Roman authority, Julius Caesar (r. 49–44 B.C.E.), before he became the Roman emperor, led a fleet of Roman ships against the Veneti, whose ships he referred to as "swan ships." Caesar initially met with frustration, for his ships were powered by rowers and could not match the nimbler Veneti ships or navigate in the rough waters of the Atlantic. He finally defeated the Veneti in 55 B.C.E. by outfitting his soldiers with long, sharpened grappling hooks, which they used to shred the masts on the Veneti ships. Once the ships were still in the water, Roman soldiers could board them and fight.

In the centuries following Rome's conquest of Europe, Celtic shipbuilding began to show evidence of Roman design. The New Guy's Hospital ship, dating from about the second century C.E., was built with a keel that was similar to Roman keels. The County Hall ship, dating to about the third century C.E., used the mortise-and-tenon joinery common on Roman ships. It had to have been built in the north, though, because it was made of northern oak. The Blackfriars ship, also from the second century, continued the tradition of Celtic shipbuilding but used Roman wood-joinery techniques.

Shipbuilding was not restricted to the seas. River and inland lake societies also built and used ships. Small ships have been discovered in Swiss lakes, and barges were built for transport on the Rhine River. The Romans actually copied certain Celtic shipbuilding methods to design ships with shallow drafts that could navigate the Rhine and other rivers.

GREECE

BY DEBORAH N. CARLSON

The evidence for early seafaring in Greece is indirect and consists of tools of obsidian (a black volcanic glass) and large fish bones excavated in the Franchthi Cave on the Greek mainland and dated to about 9000 B.C.E. Chemical analysis of the obsidian indicates that it can have come only from the Cycladic island of Melos, meaning that it had to have traveled by boat with the earliest seafarers, who were apparently also skilled fishermen, though we have no idea what their vessels looked like. Farther east on the island of Cyprus, stone tools appear suddenly about 8000 B.C.E. in association with the bones of pygmy hippos, pointing again to the presence of ancient mariners.

Travel by sea was a logical development of prehistoric life in the Aegean, which has at its heart a network of small islands known as the Cyclades. In the Early Bronze Age (3000–2000 B.C.E.), a dynamic and artistic culture of stone carvers inhabited several Cycladic islands, including Melos and Syros. The importance of seafaring to the Cycladic way

of life is immortalized in miniature model boats of lead and painted depictions of what seem to be long, open galleys. Evidence for the ships themselves has not survived in the archaeological record, but they may have resembled skin boats or dugout canoes.

A Late Bronze Age trading vessel wrecked off the southern coast of Turkey at Uluburun ranks among the most significant finds in the history of archaeology. When it sank around 1300 B.C.E. to a depth of between 140 and 200 feet, the Uluburun ship was carrying a mixed cargo of copper, tin, and glass ingots as well as finished materials, such as glass beads, faience (glazed earthenware) drinking cups, Cypriot pottery, gold and bronze jewelry, and ivory cosmetic boxes. These 20 tons of cargo were sufficiently heavy, and the seabed conditions sufficiently favorable, to preserve intact a small portion of the ship itself, which currently represents the only substantial section of a ship's hull from the Bronze Age Mediterranean.

Study of the hull remains from Uluburun has shown that the ship was constructed in the "shell-first" technique, which was to become the conventional method of Greco-Roman shipbuilding across the Mediterranean for the next two millennia. Unlike the modern approach to building a wooden boat, the ancient shipwright conceived of his vessel from the outside in, first building up a shell of planks connected to one another at their edges with mortises (cavities) and tenons (pieces of wood used to join planks), which were locked in place with wooden pegs. Once the shell was complete, the shipwright made it stronger and stiffer by nailing wooden frames to the planking at regular intervals along the bottom and sides of the hull. The excavation at Uluburun uncovered no indication of a framing system, perhaps suggesting that the Bronze Age shipwright did not feel the need to incorporate frames or that the surviving hull section is simply not large enough for evidence of these timbers to have been preserved.

Roughly a millennium after the Uluburun shipwreck, another small merchant vessel sank in the eastern Mediterranean, this time off the northern coast of Cyprus at Kyrenia. More than 60 percent of the Kyrenia ship's hull was preserved on the seabed, giving archaeologists an opportunity to excavate, raise, conserve, and reassemble over 6,000 pieces of this ancient Greek merchantman. An in-depth study of the Kyrenia ship has made it possible to recreate the construction process: First the keel and posts were erected, and then the hull planking was built up. The floor timbers were fastened to the hull by driving copper nails through wooden treenails, helping to make the vessel watertight. Finally, to protect the wood from the destructive effects of timber-boring worms, the ship's 47-foot-long hull was smeared with goeey, black pitch.

The Kyrenia ship carried a cargo of oil and wine stored in amphoras—two-handled clay jars used for shipping commodities like wine, oil, nuts, fruit, meat, and pine tar. Because many Greek city-states tried to manufacture unique amphora

shapes and because these shapes change over time, amphoras are among the most diagnostic and ubiquitous artifacts found on the seafloor. Two other important amphora wrecks from the Greek world illustrate the range in scale of ancient shipping: The modest merchantman excavated at Tektaş Burnu, Turkey, was laden with 213 amphoras, while the shipwreck explored at Alónnisos, Greece, is estimated to have been carrying as many as 4,000 jars.

Pegged mortise-and-tenon joinery was the benchmark of ancient Greek ship construction, but it was not the only method utilized. Excavations of several Archaic (600–480 B.C.E.) wrecks off the coasts of France, Italy, and Turkey reveal the existence of an alternate tradition of sewn or lashed construction. In this method, the planks are still edge-joined according to the shell-first philosophy, but in the place of mortises and tenons the shipwright stitches planks together with plant fibers pulled through angled holes drilled in the plank edges. In one ship from the late fifth century B.C.E., excavated at Ma'agan Mikhael, Israel, both construction techniques (pegged mortise-and-tenon joinery and lashing) were utilized in different parts of the same vessel.

Any study of Greek warships must rely heavily on iconographic and written sources, since the archaeological evidence is effectively nonexistent in that most galleys were likely towed away by the victors or, if badly damaged, floated away in pieces at the surface. The most significant development in Greek naval warfare was the invention of the ram, which probably occurred in the Iron Age (ca. 900 B.C.E.) as suggested by images painted on vases. The ram became the primary offensive weapon of the Greek fleet, and for the next five centuries galleys underwent a rather linear progression, increasing in size and speed with the addition of more and more rowers.

In 480 B.C.E. an allied Greek navy under Athenian leadership won a stunning victory over the Persian king Xerxes at Salamis. The ships taking part in the battle included some older-style pentecontors (50-oared ships), but the majority consisted of larger, faster triremes (warships with three banks of oars), the classic Greek ship of the line. Scholars have long debated how the oarsmen aboard a trireme were arranged—did they sit on three superimposed benches, or were there three men to a bench? The visual evidence, which consists mostly of vase paintings and sculptural reliefs, is plentiful and varied, while the textual evidence includes historical and theatrical works as well as naval inventories from the Athenian port at Piraeus.

Debate about the trireme question, as it is known, will likely continue in earnest until nautical archaeologists can provide more conclusive physical evidence (if it survives) for Greek warships. Until this happens, scholars and naval historians continue to test their hypotheses on full-scale working models, such as the trireme *Olympias*, launched in 1987. The replication of the ancient merchant ship lost at Kyrenia, too, has proved to be an effective tool for understanding the characteristics and capabilities of an ancient sailing ship.

ROME

BY DEBORAH N. CARLSON

During the last three centuries B.C.E. the monarchs of several Greek kingdoms embarked upon a kind of naval arms race dedicated to the construction of enormous oared warships, or galleys, descended from the famed Athenian trireme (a warship with three banks of oars). Various ancient authors describe the thousands of oarsmen required to row these enormous vessels, called polyremes. If the numbers are to be trusted, then these ships must have been outfitted with multiple-rower sweeps, or several rowers pulling each oar on one or two levels. The growth in vessel size brought with it an increase in the number of marines as well as a tactical shift away from ramming and toward the deployment of artillery, such as arrows, grapnel, and missiles, fired from catapults.

According to the historian Polybius (ca. 200– ca. 118 B.C.E.), Rome's entrance into the world of naval warfare occurred rather suddenly, with the emergency construction of a fleet against the Carthaginians in the First Punic War (264–241 B.C.E.). The warships built and employed by the Romans during the Punic Wars were quinqueremes, or "fives," powered by 300 oarsmen and equipped with 120 marines and 50 crewmen. The Romans' early success at sea was due in no small part to their efforts to turn a naval confrontation into a land battle at sea, as exemplified by the *corvus* (Latin for "raven"), a boarding plank outfitted with a large metal tooth, which, when deployed onto the deck of an enemy ship, held fast, locking the two vessels together and allowing Roman marines to board and fight at sea as they did on land.

The large polyremes that had dominated the fleets of Hellenistic Greece gradually became less and less common among Roman commanders, who favored instead a smaller, more maneuverable vessel called a *liburna*. The *liburna* was probably the creation of piratical groups living along the Dalmatian coast of Illyria (modern-day Croatia), for whom speed at sea was a professional necessity. Piracy remained a persistent threat to commercial shipping in the Mediterranean until the campaign of Pompey the Great in 67 B.C.E. The *liburna* played a key role in Octavian's (r. 27 B.C.E.–14 C.E.) historic defeat of the allied fleet of Marc Antony and Cleopatra at Actium, Greece, in September 31 B.C.E. Following his victory at Actium, Octavian erected a commemorative stone monument that had as its centerpiece about 30 bronze rams taken from the captured ships of Antony and Cleopatra.

Although none of the rams has survived, comparison of the sockets in this image with the bronze ram found in isolation off the coast of Israel at Atlit suggests that the latter belonged to a vessel about the size of a quinquereme. The Actium monument continued a tradition that dates back to at least the fourth century B.C.E., when the Romans, fighting the Italian Volsci at Antium, captured some enemy ships and displayed the prows along the facade of a low platform in the

center of the forum. This speaker's platform, called the *rostrum*, takes its name from the Latin word for "prow."

Nautical archaeologists have virtually no detailed information about the construction of Roman seagoing warships, since none has yet been found, but they are markedly better informed about the size and construction of Roman merchant vessels, owing to the thorough and meticulous excavation of dozens of ancient shipwrecks. The Roman shipwright followed the same general principles of "shell-first" construction as did his Greek predecessor, first creating a shell of wooden planks fastened together using pegged mortise-and-tenon joinery. Next he nailed large frames (often called floor timbers) inside the hull over the keel and shorter timbers (often called half-frames) along the sides of the hull's interior. Atop the frames the shipwright nailed thin ceiling planking to protect the frames from the weight of the cargo, and outside he coated the ship's planks with pitch or thin sheets of lead to protect the hull from the destructive effects of wood-boring worms. Depictions of sailing ships indicate that most were rigged with a single square sail and occasionally a second smaller sail at the bow and were maneuvered by a pair of steering oars slung on the stern quarters.

Other, less conventional but no less interesting construction techniques existed in various regions of the empire, including the Adriatic, where some shipwrights produced what may be the vessels that the Romans called *naves sutiles*, or "sewn ships." Farther north, archaeological excavations have shown a distinct tradition of assembly characterized by large iron nails, represented in part by the shipwrecks at Blackfriars (England), Zwammerdam (Netherlands), and Mainz (Germany).

The shipwright himself was called either a *faber navalis* or an *architectus navalis*, to judge from various surviving epitaphs and dedicatory inscriptions. In some Roman cities, like Portus at the mouth of the Tiber River, shipwrights organized themselves into *collegia*, or guilds, and excavations at nearby Ostia have uncovered the remains of that local guild's headquarters building. The excavation of Roman harbors on occasion also has yielded the remains of boats and ships abandoned and covered with riverine silt (as at Pisa) or deliberately incorporated into the various concrete structures that constitute the quays and breakwaters (as at Ostia). Careful study of the harbor at Caesarea, Israel, suggests that shipwrights were directly involved with the construction of several concrete-filled wooden caissons (large water-tight chambers) that formed part of a massive breakwater.

Archaeological evidence indicates that most Roman merchant ships transported a wide range of commodities, including wine, oil, garum (fish sauce), fish, nuts, and fruit, in two-handled clay storage jars called amphoras. To date, the largest amphora carriers are represented by the shipwrecks at Madrague de Giens, France, and Albenga, Italy, with thousands of jars amounting to some 400 to 600 tons. The Romans would have classed these vessels as *naves onerariae* (ships of burden), but there also existed a number of specialized ship

Wall painting of *Ulysses and the Sirens*, Roman, mid-first century C.E., from Pompeii, Italy; the ship, a war galley, is shown in considerable detail. (© The Trustees of the British Museum)

types, such as *naves lapidariae*, or the stone carriers, which transported hundreds of tons of marble and granite from virtually every quarry in the ancient world, to be sculpted into architectural elements (columns, friezes, and monuments), sarcophagi, statuary, and furniture. To gain a better sense of the wide range of vessels that existed in the Roman world, one need only examine the late Roman ship mosaic from Althiburus, Tunisia, or consult the lexicon of ship types assembled by the grammarian and lexicographer Nonius Marcellus in the early fourth century C.E.

By the early seventh century C.E. the shell-first ship construction technique of the Greeks and Romans had changed drastically, as evidenced by the shipwreck excavated at Yassi Ada, Turkey, in the early 1960s. The shallow, widely spaced mortises and loosely fitting, unpegged tenons of this Byzantine cargo vessel no longer contributed the primary source of hull strength; they probably served only to keep the planks aligned long enough for them to be nailed to the ship's frames.

THE AMERICAS

BY LAWRENCE WALDRON

The history of watercraft in the Americas harks back to the very first arrival of people in those continents. As scholars continue to debate whether people during the ice age first arrived from Asia on foot or by boat, it is evident that the original settlers already possessed some knowledge of seafaring. Watercraft and maritime navigation in and around the Ber-

ing Strait in the late ice age would have been used mostly for fishing in coastal waters. Any seafaring skills would have had to adjust to many new environments once people had arrived in the Americas.

Varied American coastal conditions as well as reefs, rivers, rapids, lakes, swamps, and estuaries all presented unique restrictions and opportunities to early American boatmen. Despite the numerous local innovations, ancient American watercraft can be grouped into four major types: skin boats (including kayaks, umiaks, and other bullboats), canoes, rafts, and reed boats. Such watercraft served either as transportation between one seasonal habitat and another or as fishing or whaling vessels. Watercraft were also used in trade expeditions between neighboring groups and between civilizations as far apart as Mexico and Peru.

Coastal and riverine voyages of exploration were made in search of new food sources and trading partners, but it appears that once in the Americas, ancient Indians were never again moved to cross to another continent and so never developed large oceangoing vessels. Many ancient natives turned their attention not to developing sailing ships that might carry seamen beyond the horizon but to pioneering a wide variety of small, highly maneuverable watercraft.

The ancient Indians along the northwestern coast of Canada and the United States developed an unusual kind of boat. In the absence of a steady supply of timber, the obvious choice of wooden boats was not available to far-northern and Arctic Indians. These groups were already adept at making a series of aquatic devices out of sealskin and whale skin, including inflatable flotation devices and wetsuits that remained relatively warm and buoyant in the icy northern waters. Before the Common Era, therefore, the idea of a skin boat had already occurred to them. Made of skin stretched across a frame of wood, these boats proved to be lightweight and easily manageable in water that could sometimes be an obstacle course of floating ice chunks. The Inuit, Aleuts, and other groups call these craft umiaks or kayaks depending on their design.

Seasonal movements enabled ancient northern Indians to maximize their food sources. When it was time to move, they gathered their possessions and piled into large, round skin boats called umiaks. These boats were probably paddled mostly by women, as they were in later times. The male hunters would have traveled alongside the umiaks in smaller boats also made of skin. These smaller, one-person craft were the kind later known as kayaks and were used in both fishing and the hunting of large marine mammals.

Made in a sleek, elongated shape that seemingly sliced through water, kayaks were made of skin stretched over even the top of the boat. Only a small opening was left topside into which the rider could slip his lower body and sit comfortably. In this way the kayak acted like an extension of the boater's body, with only his upper torso visible as he whisked through the water, arms moving the paddle in a circular motion. An ingenious aspect of the craft's design was that it could eas-

ily be righted if it was capsized by rough water or large prey. With a skillful turn of his body, the paddler could quickly roll his kayak back into an upright position without even getting his feet wet. The single opening in the top trapped air inside and would not permit water to enter.

While the kayak and umiak are the best known of American Indian skin boats, several other varieties of this technology were used by western Indians as far south as California. The Indian group later called the Gabrielino by European colonists may have used their skin bullboats (a circular vessel much like an umiak) since ancient times. Groups as far inland as Wyoming and the Great Plains also used skin boats, although these were made of the hides of buffalo and other land mammals. The Crow, Omaha, Assiniboin, and Arikara are all known to have used skin boats for inland travel on rivers and lakes.

In wooded areas many of the ancient Americans employed wooden rafts of various kinds for the short transportation of people and heavy goods, often within a single territory. They would have been common in river systems throughout North and South America. The high and often frigid Andes may not have seemed a likely place for residents to develop a strong tradition of rafting, much less boating, but the Andean peoples were daring seafarers and creative builders of rafts and boats.

Some 2,000 years ago early seafarers from the Nazca civilizations employed a kind of inflatable sealskin raft in a number of ways. These inflatable rafts were used not only as vehicles and flotation devices for the fishermen but also as water transports for heavy loads. Nazca and later Moche farmers are known to have acquired tons of guano (bird and bat droppings they used as crop fertilizer) from caves and rocks on the islands off the coast of Peru. Loads of this guano were put in containers and floated back to the mainland on the inflatable sealskin rafts.

Additionally, the Lake Titicaca region between Bolivia and Peru has been inhabited for millennia by groups of natives who employed the use of reed and grass rafts. The Aymara Indians devised a raft, more like a temporary boat in its shape, made entirely of the fibers of *titora* and other kinds of bulrush that grew in the region. The raft of tightly bound reeds was used until it became waterlogged, after which it was discarded. Many centuries later the Inca and various descendants of the Aymara were still making and using the same kind of raft.

The canoe, a boat with two pointed ends, is by far the most common and varied of ancient American watercraft. The majority of canoes, from the northwest coasts of Canada to the islands of the Caribbean, were made of local trees. These canoes varied in design from the plank canoes of California's Channel Islands to the dugout canoes of ancient British Columbia, Florida, Nicaragua, and Venezuela. All canoes, like their kayak counterparts, were propelled by paddles rather than oars so that the boatmen faced the direction they were headed rather than rowing backward as in some Old World boats.

Ancient Indians living in California, such as the Chumash or their ancestors, developed a canoe that at first glance might have resembled a European rowboat in its carvel-planked construction, in which long strips of wood are joined at their edges. Upon closer inspection, however, an ancient observer would notice that the planks were not nailed to the underlying boat frame but rather were cleverly strapped to that frame and to each other with vegetable fibers or strips of leather. To waterproof all the joinery and stitches in this unusual craft, the ancient Californians took advantage of a unique resource: pitch from the La Brea tar pits.

Except for those along the U.S. West Coast, almost all canoes were one variety of dugout or another. The dugout canoe was made by felling a tree of a suitably buoyant species, carving out its shape from the wooden matrix, then hollowing out the hull. The "digging out" from which the design derives its name was usually done with simple stone or bone axes and awls. The shaping of a canoe could take weeks and perhaps even two or three months, especially if any other work was required, such as decorative carving or special treatments of the wood. The types of wood varied with the local habitat, and these different woods might have exerted some influence on the shape of the canoe.

Some canoes, such as the small cedar, poplar, and cypress ones used by the ancient Seminoles, Caddo, and Creek, had a shallow design for skimming across the meniscus of vine-choked swamp or river water. The large, elaborately decorated canoes of early Haida, Kwakiutl, and other Northwest Coast Indians could hold as many as 50 people and were hewn from a variety of large trees, including red cedar, spruce, and birch. These canoes were designed to displace water with their heavy hulls and pointed bows and were used for both river transport and whale hunting. Delaware Indians were known to have used pine for their streamlined dugout canoes, which also glided across the water in the manner of their Seminole counterparts.

Amazonian and Caribbean Indians from the Mesoamerican Maya to the Antillean Taino, like their northern neighbors, fashioned large dugout canoes out of single lengths of trees. Slightly earlier Olmec dugouts were used for inland river travel and for journeys along the coastal waters and swamps of the Olmec heartland in eastern Mexico. Olmec boatmen may have caulked their damaged dugouts with the latex from their Veracruz rubber trees. The Maya of the first millennium B.C.E. diversified into greater coastal travel once they settled the Yucatán. They also built much larger canoes than the earlier Olmec to supply their extended trade expeditions throughout Central America.

Ancient Americans used various different kinds of heat-expansion techniques to alter the shape of their dugout canoes. Amazonian groups expanded the width of their canoes using heat expansion to twice the width of the original tree trunk. They achieved this pot-bellied shape by filling the dugout portion of the canoe with water and heated rocks. The heated water slowly softened the fibers along the grain

of the trunk, expanding the hollowed hull. Heat-expansion technology was also used by North American Indians along the Northwest Coast to alter the shape of their canoes. Many Central and North American groups were likewise aware of the use of steam to render wood pliant in the construction of boat frames and hulls. The rounded hull of the vessel not only increased the capacity of the vessel but also added to its stability in rough water.

► slaves and slavery

INTRODUCTION

Slavery was a nearly universal practice throughout the ancient world, and some of the world's great civilizations, such as that of ancient Rome, were built on the backs of slaves. Slaves served a variety of functions. Some were domestic slaves,

working in homes, while other worked in fields. Many did the most backbreaking work, including mining, stone quarrying, digging, and construction, though some who were relatively privileged did work that was more administrative.

Slavery took on differing complexions in different parts of the ancient world. In some cases, slaves were pure chattel. They had no rights and could own no property, and their masters had absolute power of life and death over them. A master could arbitrarily kill a slave with no legal consequences in some parts of the world. Sometimes slaves were ritually killed and sacrificed in religious observances, and in ancient Rome they were even trained as gladiators to provide amusement for the upper classes. In other cases, slavery was at least a little bit more bearable. Sometimes people lacked freedom because of the social class—the caste—into which they were born. They might enjoy some legal rights and protections and might even have been able to lift themselves out of servitude. Their masters could not legally abuse them and in fact were sometimes required by law to teach them a trade. Many such slaves, especially those who were literate and showed aptitude, were promoted to responsible positions on estates, in municipalities, and the like. In some cases, child slaves could not legally be required to do adult work.

Slavery was the only option for survival for some people. A person with no prospects in life or who was heavily in debt might have found servitude, with food and a place to live, preferable to imprisonment or a slow death from starvation. Indeed, some people became voluntary slaves as a way of working off debt. In parts of the ancient world slaves were able to own their own property, have their own money, and even themselves own slaves. They could participate in economic activities on their own account, enabling them in time to buy their freedom and attain the rights of full citizenship.

The sources of slaves varied, and slavery was rarely based on racial categories; slaves in ancient Rome, for example, came from all over the known world. Again, some slaves volunteered to become slaves as a way to pay off debt. Others became slaves because they had been convicted of a crime, and slavery was a common form of punishment at a time when there were few prisons. The most common source of slaves was warfare. Wars or raiding parties were launched with the purpose of acquiring slaves, and slaves were part of the normal booty of conquest, seized in the hope that someone would pay a ransom for their return. In many cases, women and children became slaves as a result of conquest. Because conquerors did not want to have to deal with captured soldiers, who might pose a danger to slave owners, they seized family members instead.

AFRICA

BY SAHEED ADERINTO

Slavery was prevalent in ancient Africa. Its history can be traced roughly to the time Africans began to develop villages and towns. The development of a sedentary lifestyle, which

paved the way for the emergence of large settlements, has been attributed to the agricultural revolution that took place on the continent some 200,000 years ago. Slavery in ancient Africa is akin to that in other parts of the world: It involved physical, emotional, and psychological containment. By and large, the master of a slave had the power of life and death over the slave. A slave, like chattel, could be sold and bought by someone who occupied a privileged position in the prevailing power configuration.

It is important to differentiate between slavery and other forms of servitude. In Africa pawnship was a form of subordination that differed from slavery. A person could be pawn as a collateral security for debt. People could surrender themselves to pawnship because of the need to raise money for marriage, a funeral, or another purpose that required a lot of money. A pawn was most likely a member of the community where he or she served, but a slave in most cases was brought from another community. While slaves were not likely to be free throughout their lifetime and their masters could enslave their children, a pawn was automatically free after rendering the services equivalent to the debt owned. A master could not exercise any form of control over the relatives of a pawn. A master did not have the power of life and death over a pawn but could kill a slave at will.

The condition of a slave was degrading; a slave could be asked to perform any type of labor, and the most unpalatable works were reserved for slaves. A Yoruba proverb from West Africa that highlights the difference between slavery and pawnship is *Ohun t'o ni oun o so ni d'eru, bio ba so, ni d' iwofa, ki a dupe*, meaning, "If what threatens to make us a slave makes us a pawn, we should be thankful." Only in rare instances did slaves manage to remove the yoke of domination and rise to important positions. Royal slaves in some communities, such as the western Sudanese region of West Africa, were said to have been able to gain freedom, inherit the property of their dead masters, and emerge as prominent members of the place where they had previously served as non-entities. Aside from this exceptional situation, former slaves could not remove the stigma of being formally enslaved.

There were many sources for slaves in ancient Africa. People accused of antisocial behavior, such as murder, thievery, and witchcraft, were sold into slavery. Wars, kidnapping, and raids also produced slaves as part of the booty. There is limited evidence, however, to suggest that wars were fought for the sole purpose of acquiring slaves. Although a trans-Saharan slave trade had already existed, the act of waging wars primarily for the purpose of enslavement came largely through the advent of the trans-Atlantic slave trade, which did not begin until the second decade of the 16th century.

Ancient Africa was predominantly agrarian, and the use of slaves for agricultural purposes was important. Slaves could also be part of tributes that a subordinate state paid to an overlord. Aristocratic families had slaves, and slaves in some palaces were eunuchs (castrated men) who watched over

the large harem of royal wives. Others performed domestic functions associated with royalty. A master had control over a slave's sexual relations and reproduction. This implies that a slave could not get married without the knowledge of his or her master. Unsanctioned copulation among slaves carried a serious degree of punishment. A male slave master could use his slaves as concubines, which partly explains why female slaves were more expensive or highly priced than their male counterparts. The offspring produced from such a union became free upon birth, and the status of the mother improved considerably compared with others who did not have children for their masters.

Slaves could serve religious functions. There is much evidence that slaves were killed and used as offerings during periodic sacrifices to the gods. In fact, in most parts of Africa slaves of different ethnic groups were traditionally used to appease the gods and goddess. There is an important connection between this aspect of the religious use of slaves and African belief in life after death. The oral history of people of Africa is replete with references to how slaves were killed and buried with kings and important rulers. According to one belief, dead kings entered another realm, where they lived and communed with the gods and ancestors. In this realm or world they would need the services of domestic servants.

EGYPT

BY MARIAM F. AYAD

In its most basic definition, slavery implies a loss of freedom, regardless of the degree or nature of this loss. There is little doubt that in ancient Egypt certain groups of people enjoyed less freedom than others. Egyptian slavery, however, was very different from forms of slavery experienced centuries later in Europe and North America. In Egyptian there are no words for *slave* or *slavery*. The word sometimes translated as "slave," *hem*, was also used to indicate "servant." Thus, the Egyptian word for "priest," *hem-netjer* can be translated as either a "god's servant" or a "god's slave." Inherently, the word *hem* did not necessarily indicate servitude. It was used, for example, to refer to the king of Egypt. *Hem-ef*, traditionally translated as "his majesty," may also be rendered as "his incarnation" or "his body."

Meret, a collective noun, is another term that may refer to a group of people without complete freedom, in particular, agricultural workers who could be owned by individuals or temple estates. Mostly found in legal and administrative documents, the term *meret* is closely linked with the transfer of property, especially land and cattle, from one owner to another. Like other kinds of property, people who were considered *meret* could be passed down from father to son as part of an individual's inheritance. *Meret* may have referred to serfs, a special kind of conscripted workforce.

There were several different sources of slaves in ancient Egypt. War and conquest was the principal and oldest way to acquire slaves. Some information about enslaved prisoners of

war comes from the tomb biography of Ahmose, son of Ibana, a military officer whose career spanned the reigns of three different kings of the early Eighteenth Dynasty: Ahmose I (r. ca. 1550–1525 B.C.E.), Amenhotep I (r. 1525–1504 B.C.E.), and Thutmose I (r. ca. 1504–ca. 1492 B.C.E.). The inscription indicates that not only were slaves captured at war, but they also were often granted to individuals who exhibited exceptional military prowess. Detailing the conquest of the Hyksos cities of Avaris and Sharuhén, Ahmose indicates that from the former he brought “one man, three women; total, four persons,” and “His majesty gave them to [Ahmose] as slaves.” Ahmose also was allowed to keep the two women he had captured at Also Sharuhén. Ahmose’s valor was recognized by the king and duly rewarded with gold.

While occasionally military officers retained their captives as slaves, such was not always the case. While fighting in Nubia, Ahmose, son of Ibana, captured “two living men” but was rewarded with “two female slaves.” On another occasion he brought “two young warriors as captives” but was given “five persons” as a reward. In all four accounts Ahmose’s receipt of slaves was part of a greater package that showed the king’s appreciation of his military prowess. In addition to slaves, Ahmose was rewarded with gold, parcels of land in his hometown, and a promotion. This and similar texts indicate that prisoners of war were not limited to soldiers from the rival army but also included the inhabitants of the captured towns. The process outlined in Ahmose’s biography indicates that Egyptian military personnel were obliged to present their captives to the king, who became the primary owner of these newly acquired slaves. It was the king’s prerogative to assign captured prisoners to his officers, the temples, or his own royal household. Occasionally Near Eastern slaves were imported into Egypt.

Certain legal documents dating to the sixth century B.C.E. indicate another source of slavery in ancient Egypt: self-enslavement. To satisfy a debt, not only would a debtor offer all the property he owned, but he also could offer himself, his family, and his children as slaves if the value of his property was insufficient to repay his loan. Legal documents suggest that debts and the inability to repay loans were the primary motives for this type of enslavement. Another source of slaves were the children born to a slave woman. Children inherited their mothers’ freedom status and could not become free men or women regardless of the status of the father.

Very little information survives regarding slave trading in ancient Egypt. According to a document dating to the eighth century B.C.E., a special tax was levied on the sale of 32 slaves. In another document 35 slaves were part of a sale involving of some fields. This transaction took place before the council of magistrates (the *qenbet*) and seems to imply that special registers recorded transactions involving the sale of slaves. Royalty and private individuals alike often handed over slaves to the religious establishment to serve at a temple. Bequest, reassignment, acquisition, and the sale of slaves had to be registered with the *qenbet*. The small community

of workmen at Deir el-Medina included several state-owned and a few privately owned slaves.

Egyptian slave owners had several obligations toward their charges, foremost among which was to legally record the acquisition or relinquishment of slaves at the *qenbet*. As soon as a slave was purchased, the owner gave the slave a name and taught him or her a trade. A literate slave could be promoted to the position of estate manager. The owners were also responsible for the slaves’ health, making sure they were adequately nourished and well cared for. A letter from the Eighteenth Dynasty indicates that enslaved children could not be given hard labor.

Egyptian slaves could enjoy a measure of freedom and dignity. They could negotiate transactions and own personal property. For example, the Wilbour Papyrus, a document dating to the New Kingdom (ca. 1550–ca. 1070 B.C.E.) on which is recorded the sale of some agricultural land, lists at least 11 slaves (*hem*) as holders of agricultural land. Slaves could also testify at court. Several appear as witnesses in the legal account of the great tomb robberies at the end of the Twentieth Dynasty (ca. 1196–ca. 1070 B.C.E.). In fact, it was the testimony of these slaves that later implicated their master as the main culprit in these tomb robberies. The slaves were not treated any worse than any of the other individuals named in the document: All were made to swear to the truth, and some were beaten to extract confessions.

Although no extant documents record marriage agreements among enslaved men and women, in the New Kingdom freed slaves could marry into high society. In one instance a king’s barber gave his niece in marriage to his former slave, indicating that freed slaves could marry members of their former masters’ immediate families.

THE MIDDLE EAST

BY FRANS VAN KOPPEN

Slavery in the sense of legal ownership of persons in the manner of chattel was universally accepted in cultures of the ancient Near East, with slaves being extracted from foreign soil but also legally drawn from among the slave owner’s fellow citizens. Notions of race or skin color were immaterial for enslavement, and slavery was in effect the most radical form of control over humans alongside other servile conditions that did not constitute full ownership. Slave labor was in demand at wealthy urban households but was economically less important in the ancient Near East than in the Mediterranean world of classical antiquity.

Ancient slavery and the livelihood of slaves have been studied on the basis of literary texts and law codes, including the legal parts of the Old Testament and numerous archival sources in cuneiform script. The terms for slaves in many of the region’s languages primarily connote social status and could be used for any socially inferior individual. This ambiguity means that it is sometimes difficult to distinguish slaves from other people who endured exploitation within

the framework of social and economic dependency relationships and whose conditions share characteristics with slavery. Some servile conditions could be temporary; for instance, debt bondsmen labored for their creditors as long as the debt was unsettled, or famine refugees voluntarily accepted a servile status in exchange for food and shelter. Other forms of servitude were permanent, such as those of oblates and serfs. Oblates and serfs are modern terms for categories of dependent people who were attached to the temples of the gods and the soil they tilled, respectively. Their status of property was immutable (oblates were actually branded with the god's symbol) and heritable, but their standing also gave them rights that were denied to chattel slaves, such as protection against separation from their families through sale. The distinctive characteristic of slaves is hence their legal status of chattel, which included the owner's right to sell, donate, or devolve them to his heirs but also to liberate them at will.

Slavery was typically a permanent condition; only few people experienced a transition into or out of slavery. The status of slave was heritable, and most slaves were born to unfree mothers whose offspring belonged to their master unless special provisions had been made. Sources for slaves other than biological reproduction were threefold. The first was the capture of foreigners and the purchase of foreign slaves. Second, fellow countrymen could be obtained as slaves as a result of economic failure, with people being sold into slavery by the head of their household or by themselves. Finally, people could be enslaved for their crimes, a punishment that could be imposed by the head of the household (for example, by fathers punishing disobedient adoptive sons) or by the public authorities.

Foreigners were an important component of the slave population since early times: the cuneiform signs for male and female slave, first recorded around 3000 B.C.E., are pictographs combining the sign "foreign land" with the signs "man" and "woman," respectively. Severed from their remote homelands, foreign slaves were considered loyal and more devoted to their masters than domestically created slaves. Many of them had been captured during foreign military campaigns and were brought into the country as the soldiers' share in the booty, where they could, if not redeemed by their families, be sold profitably on the slave market. Supply for these markets was also in the hands of traders, some of whom are known to have specialized in long-distance trade in people. Not every foreigner, however, was prey to slave agents, as subjects of allied sovereigns partook in the state's protection of its citizens against kidnap for the purpose of enslavement.

The state's care at safeguarding its subjects against involuntary enslavement did not mitigate the fall of insolvent people into slavery. Nonpayment of debts brought the human pledge or the defaulting debtor into a servile condition in the household of the creditor. Their condition was, at least in theory, temporal and would be remedied once the debt had been settled; in practice, however, this was often impossible. The transition of debt servitude into slavery can be repre-

sented in legal texts as a voluntary act of sale, with debtors selling their children or themselves to their creditor with the original debt functioning as their purchase price. This way into slavery was often considered a social abuse, and different solutions were proposed to repair this disorder; for example, there existed the biblical rule of releasing debt slaves in the seventh year and the Mesopotamian "clean-slate acts" that canceled consumptive debts and stipulated the repair of their negative consequences, including the release of debt slaves. These measures were largely ideologically motivated and their implementation usually failed to halt a trend of the rural underprivileged toward economic dependency on the rich and powerful.

Although slaves were owned by temples and the palace, most of them were found in urban residences, where many of them, females in particular, were occupied in household tasks. Some slaves had received training in specialist skills and practiced their trade within the master's household or as hired hands for others, but workshops that employed large numbers of slaves seem to have been uncommon, as was the use of slaves in agriculture. Slaves who were particularly trustworthy could be employed as their owners' agents, take up managerial tasks, and have documents drawn up in their own name on behalf of the family business.

Slaves were sometimes distinguished from free citizens by certain marks, such as a distinct hairstyle or a brand with their owner's name or symbol. The risk of slaves absconding was real; their freedom of movement was often controlled with chains and shackles, and they were mostly not allowed to leave the city unattended. Masters could punish their slaves physically, but they usually did not have the legal power to take a slave's life.

As lifelong members of a household, slaves often developed close ties with their owners, although they were never regarded as part of the family. Slaves could be married, even to freeborn persons, and female slaves could become concubines of the master of the house. This relationship could be legally recognized in a polygamous marriage, where the second wife was regarded as a slave of the main wife but a spouse of the man, and her children were considered the free, legitimate issue of their father. Slaves could also be adopted, most often in combination with their emancipation, with a duty to support their former owner in old age. Termination of slavery was an uncommon phenomenon; however, when freedom was granted, it was most frequently bestowed by the owner.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

When slavery began or whether the practice always existed in Asia is not known. Many anthropologists assume there were slaves of one sort or another throughout Asia and the Pacific, mostly in the form of people belonging to a particular person or to a particular family. So little is known, however, of the ancient cultures south of China and east of India, as well as

of Japan, the Philippines, and other island cultures, that it is possible that there were places where slaves were unknown.

In China the earliest details for slavery come late in its history, from the Han Dynasty (202 B.C.E.–220 C.E.). During the Han Dynasty slaves, tradespeople, and merchants were legally nonpersons, ranking lower in importance to peasants, government officials, professional warriors, nobility, and royalty. Writers during the Han Dynasty often noted, however, that slaves lived better than peasants. The generally cruel conditions for peasants during the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) and the Zhou Dynasty (ca. 1045–256 B.C.E.) have led some historians to refer to ancient China having a “slave economy” similar to that of ancient Rome, but the actual status of peasants probably put them outside the realm of slavery.

Peasants would sometimes borrow money they could not repay, and the lender could take over their land and require that they work it. Nobles and rich merchants could gather land to themselves this way, and the peasants would work for them with little hope of ever owning land again. Emperors occasionally tried redistribute land to the peasants, but the nobility would just start reacquiring the land. Nonetheless, in times of crisis peasants ranked higher in China’s priorities than anyone except the nobility and royalty. It seems that the Chinese government, from the era of the Shang on, recognized that peasants were essential to the nation’s survival, and governments usually tried to see to it that peasants were cared for.

Slaves primarily served in households. Rarely did slaves work on farms. The proportion of slaves to the general population was always small, perhaps less than 1 percent of the people. The proportion may have seemed higher to people living in cities because most slaves lived in cities or towns, where they served in the households of nobles and wealthy people.

Relatives of convicted criminals were often enslaved by the government. Government-owned slaves worked to haul barges up and down rivers. They cared for the emperor’s horses and dogs and worked as gamekeepers in government parks, especially those used by royalty. In the emperor’s court they kept track of water clocks and banged drums to mark the hours of the day, they waited on guests and the royal family, and they opened and closed doors for people walking through the palaces. These duties were fulfilled by both men and women.

During hard times peasants sometimes killed their children because they could not feed them, and they sometimes sold their children into slavery in exchange for money. Others sold themselves into slavery to have food to eat or a place to live. Some merchants traded in slaves even though the government disapproved of the practice. A few emperors tried to abolish the slave trade but failed.

Privately owned slaves were house cleaners, cooks, and kitchen staff. Some were used as bodyguards or to guard ancestral cemeteries. Others waited on their masters or mistresses, helping with hairdressing and other cosmetic tasks. Skilled slaves made ceramics and fabrics for sale. Some own-

ers used slaves to form gangs to batter or even kill their enemies, terrorizing a town or city. Both government-owned and privately owned slaves were sometimes given confidential tasks such as bookkeeping and carrying messages.

It was possible for slaves to earn their own money, but in general a slave was a slave for life, without being able to buy freedom. Slaves typically were regarded as lazy and greedy, and many free people resented that slaves were able to earn their own money, especially when ordinary people had to work to survive while slaves had food and housing even when they did no work.

A similar resentment prevailed in India, where slaves were often regarded as lazy and insolent. As sometimes happened in China, people without financial resources would sell themselves into slavery to have food or a place to live. They often received cash from their new owners, and they were allowed to live freely until the money ran out, at which time they had to work for their owners. They lived much like members of the Sudra caste, as laborers and servants. They were rarely Brahmins (members of the highest Hindu caste) because people were expected to give food and other goods to Brahmins without getting anything in return.

Hindu religious law forbade the mistreatment of slaves. An owner was expected to feed slaves well, to provide them with good clothing, and to give them good quarters in which to live. A slave could be beaten in certain cases, but only on the back. A pious owner would treat his or her slaves well. Under law, slaves were allowed to try to escape once; if they were successful, they were allowed to rejoin their caste. The reality of slave life was often very different from what was required by religious law. Slaves were beaten, maimed, and killed. Any slight to their owners could occasion their torture or death, and their lives were constantly beset by terror.

The royal governments often imported slaves. Both men and women imported from Greece served as palace guards. Women often protected the king’s harem of concubines, and sometimes the imported female slaves were themselves made concubines. People could become slaves when they were prisoners of war, but they served only one year of involuntary servitude and were then freed. People convicted of crimes could be sentenced to serve as slaves for a certain time, but they were freed when the time ended. Others who lost lawsuits or bets could become slaves, but they were freed if they paid the fine or bet. Still others became slaves to their creditors when they failed to pay their debts, and they were freed if they managed to pay what they owed. Those who sold themselves into slavery had to buy their freedom. In many cases people remained slaves for life, and children born to them were also slaves.

For many slaves life was one of hard labor. They were expected to haul water from a nearby stream or lake regardless of the weather, to carry loads of goods, and to maintain the homes of their owners. Owners often complained of their slaves’ laziness, noting that their slaves tended to watch for sundown, when their labors for the day were supposed to end, rather than attending to their chores. Others complained that

slaves in cities were not only lazy but arrogant, using much of their time to earn money of their own while having none of the expenses of feeding, housing, or clothing themselves. Even so, household slaves were often treated like part of their owner's family, and when they became too old to work, they were cared for by their owners.

EUROPE

BY AMY HACKNEY BLACKWELL

Slavery was a fact of life throughout the ancient world. Almost every society had some form of servitude in which people exploited the labor of others. Among ancient Europeans slavery existed but not nearly to the extent that it did in the Mediterranean region. European society was not heavily agricultural or urban, so there was not as much need for labor as there was in the Greek and Roman economies. Many thousands of Celts and Germans became the slaves of Greeks and Romans, who used them in a variety of ways.

The Celts, like many ancient peoples, often enslaved the people they conquered when they moved into a new territory. For example, this may have happened in ancient Ireland when the Celts arrived; some historians believe that the Celts enslaved the prehistoric people to build tombs such as Newgrange. The favored slaves were usually women and children, who were more docile than men and better suited for the domestic tasks the Celts needed performed. Celts would use slaves to gather wood, carry water, cook, weave, and perform sexual favors.

It appears that the Gauls, the Celts who lived in France, were using slaves during the eighth and seventh centuries B.C.E. Slaves came from conquered nations in the region. Well-to-do Gauls used women and children as domestic slaves to do basic household chores. Noble families would exchange gifts of slaves as a way of solidifying friendships. Historians believe that Gauls of this period engaged in trade of slaves with the Etruscans in Italy, and some further contend that the Gauls were still engaging in the slave trade with Italy during later Roman times. During the late second and first centuries B.C.E. Gauls are said to have sold their brethren as slaves in exchange for wine. Some 15,000 Gauls may have been enslaved in this way. It is not known whether these slaves were family members of the traders or if they were already slaves of the Gauls.

The Celtic peoples had clear laws about slavery. They divided themselves into several social classes, including nobles, free property owners, and freemen who did not own property. The bottom of the Celtic social ladder was occupied by people who were not free. Some nonfree people were not slaves at all; these individuals did not hold the full rights of the group, but they were still allowed to support themselves by farming on tribal lands. In Ireland, for example, there was a class of nonfree farmers called *fudirs*. These people were not exactly slaves in the modern sense, in that their master could not buy and sell them, but they had almost no legal rights.

They worked the land for their master and were forced to pay rent or tribute every year. This rent supposedly obligated the master to feed and house them. However, their master could throw them off the land at any time and for any reason. When a *fudir* died, the land he occupied did not pass to his children unless the master chose to allow them to stay.

Other individuals were genuine slaves, that is, owned by other people and forced to work without wages. Celtic law set values for slaves; male slaves were considered more valuable than female ones. Celtic slaves were usually Celtic peoples who had lost their liberty through a variety of causes, such as financial misfortune or losing in battle. Sometimes Celts imported slaves from other areas, but usually slaves were local. Occasionally parents sold their children into slavery if they felt they needed the money. Slave traders often raided farms at night to steal children and sell them for slaves. These raiders typically attacked houses on the coast of Roman Britain (modern-day Wales) and carried their slaves over to Ireland. The Irish Saint Patrick (fifth century C.E.) was himself stolen as a boy from his family's estate in Britain and spent several years working as a slave shepherd in Ireland before escaping and taking on a religious vocation. Some sources say that it was a law in Ireland that slaves were freed every seventh year and suggest that Patrick may have been freed under this law instead of escaping.

Both categories of slave were at a severe disadvantage under the Celtic legal system. A person's rank determined the value of his evidence and whether he would be allowed to testify at all. A freeman could testify against a *fudir*, but a

SLAVERY AND DIVINE VISIONS

A youth spent in slavery produced what many consider to be Ireland's greatest saint. Born in Roman Britain (modern-day Wales), Saint Patrick was a teenager when he was stolen from his home and sent to Ireland to work as the slave of a pig farmer. He ate the pigs' food and dressed in whatever rags he could scrounge up. He was always hungry and cold.

In his misery, Patrick prayed to God 100 times a day and 100 times a night. After a few years he began to see visions telling him that he should escape. These visions instructed him to walk to the sea, where he would find a ship waiting to take him away. The visions were persuasive and certainly more attractive than his current life as a slave, so Patrick walked away from his pigs and continued walking to the ocean. Sure enough, there was a ship waiting to take him to Europe. He sailed away and became a priest, but Ireland was deeply ingrained in his soul. He devoted the rest of his life to converting Ireland's people to Christianity.

fudir was not allowed to testify in response. Punishments for slaves who committed crimes were harsher than those meted out to freemen.

The Roman historian Tacitus (ca. 56–ca. 120 C.E.) observed that the Germans kept and used slaves. According to Tacitus, when Germans defeated enemies in battle the losers would go into voluntary slavery, allowing the victors to bind them and sell them. The victors always sold or traded away such slaves because they would have been ashamed to keep them around. German slaves lived in their own households, and their masters treated them as tenants; each slave was required to pay his master a yearly tribute of grain, cattle, or cloth, but otherwise the slaves were free to live as they liked. Slaves did not perform the master's household duties, as Roman slaves did. Tacitus remarked that Germans did not chain or beat their slaves or work them to death. Masters occasionally did kill their slaves in anger; this was apparently acceptable behavior and not considered worthy of punishment.

During the Roman Empire, German society adopted many Roman laws concerning slavery. German slave owners of this time treated their slaves much as Romans did, sometimes paying them and offering them opportunities for social advancement. Slaves were allowed to marry free people, though this meant that the free partner would become a slave. A woman slave owner was not allowed to marry her own slave, and sexual contact with slaves was discouraged. German men, however, had ample sexual contact with their female slaves.

Many ancient Europeans experienced slavery under the more powerful and better organized Greeks and Romans. Some 40,000 Gauls, for example, became slaves of the Romans after Julius Caesar's army won the battle of Alesia in 52 B.C.E. Historians estimate that Caesar may have enslaved half a million Gauls throughout his career. During the early Roman Empire huge numbers of European slaves passed into Roman territory. Romans and Greeks appreciated the exotic appearance of slaves from northern Europe and admired the strength of large German men, who made excellent soldiers and gladiators.

GREECE

BY JEFFREY S. CARNES

For the Greeks, as for most human societies until quite recent times, slavery was an accepted fact of life and, with rare exceptions, it was not subject to analysis or moral criticism. Greece, however, stands out for the degree to which slavery was central to the economy, and every Greek polis had a significant number of slaves, both agricultural and urban.

There existed in Greece both chattel slavery, in which the slave was the legal property of another person, and a number of intermediate forms of servitude, in which a person was forced to labor for another while still remaining technically free; in other words, an individual was not subject to sale. One such form was debt bondage, in which a free person who

was unable to pay off a debt came under the power of another until such time as the debt was paid. In practice, interest on a debt could turn this into a form of long-term or permanent servitude, and the creation of a "sharecropper" class in many Greek cities was a key factor in the rise of tyrants and other political reformers. For example, in Athens the lawmaker Solon (ca. 630–ca. 560 B.C.E.) canceled debts to eliminate debt bondage. In Sparta nonchattel slavery took a political form: A permanent noncitizen class—the Helots, literally "the captured ones"—was created as a result of Sparta's conquest of Messene in the 10th through seventh centuries B.C.E. Helots were forced to perform agricultural labor for their Spartan masters (who were themselves forbidden from engaging in such labor), and they were subject to terror at the hands of the Spartans. Helots were not, however, subject to sale or removal; on the contrary, they were bound to the land, and their status was akin to that of serfs.

Chattel slavery dates back to the earliest historical records. Indeed, the initial written records of most societies reveal slavery as an already existing institution. Documents from Mycenae, dating to before 1200 B.C.E., refer to slaves, and Homer's *Iliad*, the earliest work in the Greek literary tradition, begins with a dispute over a slave. The Homeric world shows the Greek attitude toward slavery both explicitly and through its silences: no one questions the morality of slavery, and the lot of slaves is pitied. One of the distinguishing factors of Greek slavery (as opposed to the more familiar model from the pre-Civil War United States) was that anyone could become a slave.

Wars were frequent, and those captured in war were typically ransomed (if their families could afford to pay), kept as slaves by their captors, or sold on the open market. Piracy and brigandage were also common throughout antiquity, and anyone whose fortune was sufficiently bad could wind up a slave. There was some sentiment (particularly from the fourth century B.C.E. onward) that Greeks should not enslave their fellow Greeks, but this was by no means a hard-and-fast rule. By the fourth century B.C.E. it seems that most slaves in Athens were non-Greek, coming instead from a variety of areas, particularly those to the north and east of mainland Greece, including Thrace, Scythia, and Asia Minor. Slaves were not normally permitted to have families, so most of the slave population was purchased rather than homebred, and the slave trade was a thriving one throughout antiquity.

Slaves worked in every sector of the economy, and only a few occupations (such as mining, which was harsh and dangerous work) were viewed as exclusively servile. In Athens state-owned slaves formed the police force and served as clerks in certain courts, but there was no large slave-dominated civil service bureaucracy as there was in Rome. Since Greece was an agricultural society, most slaves worked on farms, but in cities they formed part of the industrial labor force. The largest factory we know of produced shields and employed a labor force of 120 slaves, but many enterprises employed a mix of slave and free labor. Inscriptions for public

Apollo (left), a Scythian slave (middle), and the satyr Marsyas (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

works projects, which list the status of the laborers, provide ample evidence for this. Household slaves were generally better off than those who worked in the fields, and their duties could include child care and education. The loyal household servant became a common character on the dramatic stage.

Buying a living human being was not very expensive: inscriptional evidence from the late fifth century B.C.E. shows prices below 100 drachmas (perhaps three months' wages for a semiskilled worker), so slave owning was widespread. The slave population in Athens is estimated to have been at a third of the total inhabitants of the city, perhaps 100,000 in the late fifth century B.C.E.; even states with less developed industry must still have had a large percentage of slaves. The absence of large-scale slave revolts is perhaps a consequence of the ethnic diversity of the slave population. Revolts were more likely when large numbers of slaves shared a common language and culture, as the major slave revolts in the Roman world and the Helot rebellions in Sparta made clear. While organized resistance was rare, running away was not: some 20,000 Athenian slaves escaped during the chaos caused by the Spartan capture of Dhekélia. Many of those who escaped

were said to have been skilled craftsmen who would presumably have sought employment elsewhere as freemen. Professional slave catchers were as much a part of the slave economy as were slave traders.

It was possible for Greek slaves to obtain their freedom, though this was not nearly as common as in the Roman world. In some cases slaves were freed in their owners' wills, and in others they were able to purchase their freedom; typically they were denied citizenship and would have a status equivalent to that of other free noncitizens. The case of Pasion, an extremely wealthy freed slave and banker of the fourth century B.C.E. who was granted Athenian citizenship because of his generosity to the city, was exceptional, as was the granting of freedom to slaves who fought on behalf of Athens in the battle of Arginusae.

The intellectual revolution of the late fifth century B.C.E. brought the institution of slavery into question for the first time. Aristotle's defense of slavery can be seen as a response to these issues: He refers to slaves as "animate tools" and argues that some people are by nature suited to slavery, which runs counter to the usual Greek perception that anyone could

become a slave. In political theory and popular discourse the concept of slavery was an important one for the definition of citizenship, since the slave was everything the citizen was not: unfree, forced to labor for another, and lacking enforceable rights.

ROME

BY PAUL McKECHNIE

Most slaves in Rome were foreign in origin, captured in war or bought in slave markets. In the early days it was also possible for a Roman citizen to become a slave; the Twelve Tables (a code of laws of the early Roman Republic, established around 450 B.C.E.) allowed a creditor who was not paid to sell the debtor “beyond the Tiber” as a slave. Within Roman territory it was possible for loan agreements to involve a kind of voluntary mortgage on the debtor’s person (*nexum*). A borrower who failed to pay became a debt bondsman but was still a Roman citizen of a sort and not exactly the property of the creditor. The historian Livy (59 B.C.E.–17 C.E.) tells of the abolition of *nexum* in his *Annals of the Roman People*. Livy’s account describes public outrage at the sexual abuse of a debt bondsman, whereas the sexual abuse of a slave would not have provoked such outrage. An important disadvantage of the system was that it made Roman debt bondsmen ineligible to fight in the Roman army. The *lex Poetilia Papiria*, a law passed in 326 B.C.E., ended the system of *nexum*.

Slaves, as distinct from debt bondsmen, were the property of their masters and could be bought and sold. In principle, they had no rights at all and could be punished or abused exactly as their masters chose. The emperor Antoninus Pius (r. 138–161 C.E.) changed the law that had given masters the power of life and death over their slaves and introduced the principle that if a master killed his slave without good reason, he would be subject to the same penalty as if he had killed another person’s slave; in effect, he could be fined up to the value of the slave.

Slaves were a source of unpaid labor anywhere for the Romans: in homes, in agriculture, and in supporting the army. They were not expected or trusted to fight for Rome. Slaves who survived being captured in war were usually women and children because it was normal for men captured in war to be put to death if there was no one to pay a ransom for them; keeping them alive was a risk their captors would not usually take.

In the third and (especially) the second centuries B.C.E. the Romans’ successes in expanding their conquests across the Mediterranean resulted in a great influx of slaves to Italy. The Roman upper classes were able to buy larger estates and work them with slave gangs. The disadvantage was that one had to be a landowner to serve in the army, and as Roman and Italian peasants sold their property to the rich their absence from the military ranks threatened to weaken Rome. Gaius Marius (ca. 157–86 B.C.E.), who was consul seven times between 107 and 86, solved this problem by making it possible for unpropertied Romans to join the army.

Although they could not fight for the army, slaves could be made to fight for sport. Gladiators, who fought in the amphitheaters, were usually either slaves or condemned criminals. Along with his law discouraging killing slaves, Antoninus Pius legislated against sending a slave to the gladiator school without a good reason; making a slave into a gladiator was a punishment virtually equivalent to death.

Life for most slaves was difficult most of the time, but the Roman system of slavery had features that presented opportunities for some slaves. A slave could own no property, but Roman law recognized something called a *peculium*, which was in effect a slave’s own money. In a case where, for example, a master went into business with his slave, the fact that some of the capital behind the business was the slave’s *peculium* might prevent the master from being liable for all legal claims that might arise against the slave in the course of business. Even though the idea behind a *peculium* was perhaps to protect masters from liability for their slaves’ mistakes, in practice a successful slave might manage to use his *peculium* to buy his freedom from his master.

During the Imperial Period (after 31 B.C.E.) the Romans seem to have freed many of their slaves. The emperor Augustus (r. 27 B.C.E.–14 C.E.) was behind the *lex Fufia Caninia* of 2 C.E., a law that limited the number of slaves a master could manumit in his lifetime, and the *lex Aelia Sentia* of 4 C.E., which made 30 the minimum age at which a slave could be manumitted. When the slave of a Roman citizen was manumitted, he became a Roman citizen himself. Slaves had one name, while characteristically Roman citizens had three names: *praenomen* (first name), *nomen gentilicium* (family name), and *cognomen* (last name). A freedman (*libertus* or *libertinus*) had his original name as his *cognomen*, and he took his first two citizen names from his former master. Freedmen had most of the rights of freeborn Roman citizens—for example, the right to vote, to make wills, to marry Roman citizens, and to produce legitimate-citizen children—but they could not hold political office.

Slaves were important at the very heart of the Roman Empire. When the first emperor, Augustus, took over, he used his own slaves and the resources of his own household to administer the empire by, for example, making appointments, keeping accounts, directing the army, keeping records, and managing relations with the Senate and political officeholders.

He and later emperors based bureaus that were virtually government ministries in the palace under the direction of their own freedmen: The *ab epistulis* (minister of the provinces) managed correspondence with Roman governors across the empire; the *a rationibus* (minister of finance) kept the emperor’s accounts; and the *a libellis* (minister of justice) processed the petitions that came to the emperor from across the world. As the first and second centuries C.E. went forward, emperors brought in Roman knights instead of freedmen to hold many important posts in the palace, but they were cautious enough to keep the money in the hands of someone they could rely on—one of their own freedmen.

Image of Psyche on a lead coffin lid, Roman; made in Lebanon during the second to third centuries C.E., said to be from Sidon, Lebanon; the lead is thought to be an import from Spain or Sardinia, where there were extensive mines worked by Roman slaves. (© The Trustees of the British Museum)

THE AMERICAS

BY KIRK H. BEETZ

It is not known when slavery began in the Americas. It is possible that the first migrants to the New World already practiced slavery. How ancient Americans north of Mexico practiced slavery is something that anthropologists infer from archaeological information and the practices of Americans when first recorded by Europeans. The earliest peoples to populate the forests and grasslands of North America were nomadic. Their slaves probably would have been people taken captive from other groups during raids that may have been staged for the very purpose of taking slaves. Because there were no beasts of burden native to North America, the captives would have been responsible for carrying goods during migrations.

Some early nomadic people settled and built one village to inhabit during warm months and another for cold months. Others settled year round into permanent villages. Slaves in

such villages might have been responsible for mundane chores such as cleaning and cooking. The ancient villagers may have raided other villages or preyed on nomads, taking captives, possibly children. When a village had a shortage of women, girls and young women would sometimes be taken to provide men with mates and to bring in children to repopulate a village that had been decimated by natural disasters or warfare. It is possible that both nomadic peoples and settled peoples had rituals in which slaves could become free members of the nations that held them.

The region for which there is the most information about slavery is Mesoamerica, made up of parts of modern Mexico and Central America. Perhaps the greatest ancient Mesoamerican city was Teotihuacán, in Mexico. Its peak of power was from the first to the seventh century C.E. It was the greatest military power in Mesoamerica during that period, and it forced distant Mayan communities to pay tribute. It seems that the government of Teotihuacán preferred goods such as jade, obsidian, and brightly colored feathers, but sometimes a city did not have enough goods for tribute and sent instead human beings. These slaves were probably used as human sacrifices. The other aspects of slavery in Teotihuacán are unclear, but it is probable that through debt or conviction of a crime, a person could become a slave, and that such a slave might have had the opportunity to earn his or her freedom. In the case of people enslaved because of crimes, their slavery might have been limited to a specified period of service.

The Maya had a long-lived culture, and their practice of slavery almost certainly varied as customs changed over time and from one Mayan city-state to another, but Mayan writings and archaeological evidence allow for some generalizations about how the Maya practiced slavery. Slaves were at the bottom of the social structure. Commoners caught in battle and then enslaved were possibly regarded as almost nonhuman, ranking no higher than animals and perhaps lower than jaguars and other animals associated with Mayan mythology. They existed only to serve their owners, such as the individual warriors who had captured them. During festivals they were often sacrificed. To the Maya these sacrifices, which involved torture, elevated the victims from the status of commoners to temporary gods. If slaves survived long enough, they could earn freedom either through clemency or through good service to their owners.

Nobles captured in battle might also be enslaved. After being tortured, they were usually sacrificed, because their deaths brought prestige to those who captured them, to their cities, and to their kings. Much Mayan warfare was conducted for the purpose of capturing enemy nobility, and warriors who captured nobles often added the nobles' names to their own, enhancing their standing in their community. A captured noble or member of a royal family rarely served long as a slave because sacrificing him or her to a god was valuable in winning the god's favor.

The Maya had an elaborate social structure with a multitude of customs that governed behavior and specified the

duties of each member of society. Slavery involved many such customs as well as laws. Children without parents almost always became slaves. People convicted of crimes could become slaves of the people they had victimized. It is possible that people could voluntarily become slaves, perhaps because of burdensome debts or the loss of place in a community. For instance, tradespersons who lost the ability to practice their craft would no longer have a niche to fill in Mayan society.

There is disagreement among archaeologists about how slaves who were not prisoners of war were regarded and treated. These disagreements may stem from variations in Maya culture over hundreds of years. One view is that these slaves were cruelly abused and counted as nothing in Mayan society. They were worked to death, tormented, and sacrificed. They could be killed any time or for any reason by their owners. If someone other than the owner killed a slave, that killer took the place of the slave.

Another view holds that slaves were protected by laws that prohibited an owner from killing a slave anytime the owner wanted to do so. The slaves could hold important positions in households, even becoming the directors of the estates of wealthy people. They could earn their own money, save it, and spend it as they wished. Indeed, the law seems to have specified that a person was a slave only until he paid off a debt he owed someone. Slaves could be as well dressed and well fed as their owners. An owner who did not properly care for a slave could lose the slave, who might be freed, and in extreme cases might find himself the property of his former

slave. Thus, slaves were not beaten or otherwise abused. In some cases, if slaves died before their debts were paid, their families would be expected to provide a substitute. How long the substitutes served is unclear; the substitute either served until the debt was paid or was replaced periodically by another member of the family until the debt was paid.

Slavery was practiced in South America, but to what extent has yet to be established. For many South American groups the customs regarding slaves would be much like those of the nomads and villagers of North America. Girls especially were valued, becoming sexual partners of their captors or possibly serving as a sacrifice to the gods. The Moche culture of about 100 to 600 C.E. seems to have practiced slavery. They may have raided other cultures to obtain captives who would be ritually sacrificed. Otherwise, slaves probably became servants in prosperous households.

The Middle East

~ *The Code of the Nesilim, excerpt*
(Hittite, 1650–1500 B.C.E.) ~

1. If anyone slay a man or woman in a quarrel, he shall bring this one. He shall also give four persons, either men or women, he shall let them go to his home.
2. If anyone slay a male or female slave in a quarrel, he shall bring this one and give two persons, either men or women, he shall let them go to his home.
3. If anyone smite a free man or woman and this one die, he shall bring this one and give two persons, he shall let them go to his home.
4. If anyone smite a male or female slave, he shall bring this one also and give one person, he shall let him or her go to his home.
5. If anyone slay a merchant of Hatti, he shall give one and a half pounds of silver, he shall let it go to his home.

6. If anyone blind a free man or knock out his teeth, formerly they would give one pound of silver, now he shall give twenty half-shekels of silver. . . .

8. If anyone blind a male or female slave or knock out their teeth, he shall give ten half-shekels of silver, he shall let it go to his home. . . .

10. If anyone injure a man so that he cause him suffering, he shall take care of him. Yet he shall give him a man in his place, who shall work for him in his house until he recovers. But if he recover, he shall give him six half-shekels of silver. And to the physician this one shall also give the fee. . . .

17. If anyone cause a free woman to miscarry, if it be the tenth month, he shall give ten half-shekels of silver, if it be the fifth month, he shall give five half-shekels of silver.

(continued)

(continues)

18. If anyone cause a female slave to miscarry, if it be the tenth month, he shall give five half-shekels of silver. . . .

20. If any man of Hatti steal a Nesian slave and lead him here to the land of Hatti, and his master discover him, he shall give him twelve half-shekels of silver, he shall let it go to his home.

21. If anyone steal a slave of a Luwian from the land of Luwia, and lead him here to the land of Hatti, and his master discover him, he shall take his slave only. . . .

24. If a male or female slave run away, he at whose hearth his master finds him or her, shall give fifty half-shekels of silver a year. . . .

31. If a free man and a female slave be fond of each other and come together and he take her for his wife and they set up house and get children, and afterward they either become hostile or come to close quarters, and they divide the house between them, the man shall take the children, only one child shall the woman take.

32. If a slave take a woman as his wife, their case is the same. The majority of the children to the wife and one child to the slave.

33. If a slave take a female slave their case is the same. The majority of children to the female slave and one child to the slave.

34. If a slave convey the bride price to a free son and take him as husband for his daughter, nobody dare surrender him to slavery. . . .

36. If a slave convey the bride price to a free son and take him as husband for his daughter, nobody dare surrender him to slavery. . . .

98. If a free man set a house ablaze, he shall build the house, again. And whatever is inside the house, be it a man, an ox, or a sheep that perishes, nothing of these he need compensate.

99. If a slave set a house ablaze, his master shall compensate for him. The nose of the slave and his ears they shall cut off, and give him back to his master. But if he do not compensate, then he shall give up this one. . . .

170. If a free man kill a serpent and speak the name of another, he shall give one pound of silver; if a slave, this one shall die. . . .

173. If anyone oppose the judgment of the king, his house shall become a ruin. If anyone oppose the judgment of a lord, his head shall be cut off. If a slave rise against his master, he shall go into the pit. . . .

191. If a free man picks up now this woman, now that one, now in this country, then in that country, there shall be no punishment if they came together sexually willingly. . . .

194. If a free man pick up female slaves, now one, now another, there is no punishment for intercourse. If brothers sleep with a free woman, together, or one after the other, there is no punishment. If father and son sleep with a female slave or harlot, together, or one after the other, there is no punishment. . . .

Asia and the Pacific

~ Kautilya: excerpt from the *Arthashastra* (ca. 250 B.C.E.) ~

BOOK III, CHAPTER 13, RULES REGARDING SLAVES AND LABORERS

The selling or mortgaging by kinsmen of the life of a Shudra who is not a born slave, and has not attained majority, but is an Arya in birth shall be punished with a fine of twelve panas; of a Vaisya, twenty-four panas; of a Kshatriya, thirty-six panas; and of a Brahman, forty-eight panas. . . . Any person who has voluntarily enslaved himself shall, if he runs away, be a slave for life. Similarly any person whose life has been mortgaged

by others shall, if he runs away twice, be a slave for life. . . . Deceiving a slave of his money or depriving him of the privileges he can exercise as an Arya, shall be punished with half the fine levied for enslaving the life of an Arya. . . . Employing a slave to carry the dead or to sweep ordure, urine, or the leavings of food; or a female slave to attend on her master while he is bathing naked; or hurting or abusing him or her, or violating the chastity of a female slave shall cause the forfeiture of the value paid for him or her. Violation of the chastity

of nurses, female cooks, or female servants of the class of joint cultivators shall at once earn their liberty for them. Violence towards an attendant of high birth shall entitle him to run away. . . . When a man commits or helps another to commit rape with a girl or a female slave pledged to him, he shall not only forfeit the

purchase-value, but also pay a certain amount of money to her and a fine of twice the amount of sulka to the government. . . .

From: Kautilya, *Kautilya's Arthashastra*, 2nd ed., trans. R. Shamasastri (Mysore, India: Wesleyan Mission Press, 1923).

Greece

≈ Aristotle, excerpt from "On Slavery"
(from *The Politics*, ca. 330 B.C.E.) ≈

Let us first speak of master and slave, looking to the needs of practical life and also seeking to attain some better theory of their relation than exists at present. . . . Property is a part of the household, and the art of acquiring property is a part of the art of managing the household; for no man can live well, or indeed live at all, unless he be provided with necessaries. And so, in the arrangement of the family, a slave is a living possession, and property a number of such instruments; and the slave is himself an instrument which takes precedence of all other instruments. . . . The master is only the master of the slave; he does not belong to him, whereas the slave is not only the slave of his master, but wholly belongs to him. Hence we see what is the nature and office of a slave; he who is by nature not his own but another's man, is by nature a slave; and he may be said to be another's man who, being a human being, is also a possession. And a possession may be defined as an instrument of action, separable from the possessor.

But is there anyone thus intended by nature to be a slave, and for whom such a condition is expedient and right, or rather is not all slavery a violation of nature? There is no difficulty in answering this question, on grounds both of reason and of fact. For that some should rule and others be ruled is a thing not only necessary, but expedient; from the hour of their birth, some are marked out for subjection, others for rule. . . . Again, the male is by nature superior, and the female inferior; and the one rules, and the other is ruled; this principle, of necessity, extends to all mankind.

Where then there is such a difference as that between soul and body, or between men and animals (as in the case of those whose business is to use their body, and who can do nothing better), the lower sort are by nature slaves, and it is better for them as for all inferiors

that they should be under the rule of a master. For he who can be, and therefore is, another's and he who participates in rational principle enough to apprehend, but not to have, such a principle, is a slave by nature. Whereas the lower animals cannot even apprehend a principle; they obey their instincts. And indeed the use made of slaves and of tame animals is not very different; for both with their bodies minister to the needs of life. Nature would like to distinguish between the bodies of freemen and slaves, making the one strong for servile labor, the other upright, and although useless for such services, useful for political life in the arts both of war and peace. But the opposite often happens—that some have the souls and others have the bodies of free men. And doubtless if men differed from one another in the mere forms of their bodies as much as the statues of the gods do from men, all would acknowledge that the inferior class should be slaves of the superior. It is clear, then, that some men are by nature free, and others slaves, and that for these latter slavery is both expedient and right.

There is a slave or slavery by law as well as by nature. The law of which I speak is a sort of convention—the law by which whatever is taken in war is supposed to belong to the victors. But this right many jurists impeach, as they would an orator who brought forward an unconstitutional measure: they detest the notion that, because one man has the power of doing violence and is superior in brute strength, another shall be his slave and subject. Even among philosophers there is a difference of opinion. The origin of the dispute, and what makes the views invade each other's territory, is as follows: in some sense virtue, when furnished with means, has actually the greatest power of exercising force; and as superior power is only found where there

(continued)

(continues)

is superior excellence of some kind, power seems to imply virtue, and the dispute to be simply one about justice (for it is due to one party identifying justice with goodwill while the other identifies it with the mere rule of the stronger). If these views are thus set out separately, the other views have no force or plausibility against the view that the superior in virtue ought to rule, or be master.

Others, clinging, as they think, simply to a principle of justice (for law and custom are a sort of justice), assume that slavery in accordance with the custom of war is justified by law, but at the same moment they deny this. For what if the cause of the war be unjust? And again, no one would ever say he is a slave who is unworthy to

be a slave. Were this the case, men of the highest rank would be slaves and the children of slaves if they or their parents chance to have been taken captive and sold. Wherefore Hellenes do not like to call Hellenes slaves, but confine the term to barbarians. Yet, in using this language, they really mean the natural slave of whom we spoke at first; for it must be admitted that some are slaves everywhere, others nowhere. The same principle applies to nobility. Hellenes regard themselves as noble everywhere, and not only in their own country, but they deem the barbarians noble only when at home, thereby implying that there are two sorts of nobility and freedom, the one absolute, the other relative.

► social collapse and abandonment

INTRODUCTION

Throughout the world archaeologists discover the remains of human settlements that were abandoned at some point in ancient history. These remains include homes, artifacts, middens (that is, trash piles), piles of shells, figurines, household objects, tombs, and public buildings. After studying their discoveries, archaeologists and historians conclude that the peo-

ple who lived there either abandoned the settlement or died. Even great empires such as the Roman Empire at some point collapsed. While the Romans themselves continued to exist on the Italian peninsula, their empire around the Mediterranean Sea shattered, and the civilizations they had conquered gained their independence from Rome.

Social collapse and the abandonment occurred for various reasons. A common cause was a catastrophic natural disaster, such as an earthquake, volcanic eruption, flood, fire, or tsunami (in coastal regions). Perhaps the most famous example is the eruption of Mount Vesuvius in 79 C.E., a volcano whose ash and lava buried the Roman cities of Pompeii and Herculaneum, entombing people almost literally in their tracks. Natural disasters also include plagues, which often took hold during times of warfare and social unrest. In response, people from the surrounding countryside fled their villages and hamlets to take refuge in nearby cities. The cities, however, were not equipped to handle a large influx of people. Hunger became commonplace, since rural people were no longer producing food. Conditions often became crowded and unsanitary so that disease was easily spread. A plague of this nature killed a quarter of the population of ancient Athens, severely weakening the Greek empire.

Sometimes social collapse and abandonment was a gradual process, often brought about by climatic change. As a region became colder or warmer, rainfall amounts changed dramatically, affecting the flora and fauna of the region. Good examples are provided by parts of Egypt and Mesoamerica, where lush, green areas turned into harsh desert over relatively short periods of time, forcing people to move. Even comparatively minor cooling or warming could play havoc with agriculture, leading to crop failures that forced people to abandon their settlements in search of new farm-

land. When such changes occurred over a wide region, entire peoples could disappear. Some of these changes were caused by human activity. When farmland was overworked or forests were cleared, the result was soil erosion, flooding, and other disruptions that wiped out communities. Of course, these changes worked in the other direction; as land formerly covered by glaciers warmed and the glaciers receded, new communities of people moved in.

Warfare, too, often led to the collapse of societies. For nearly 3,000 years, Egypt stood at the summit of human civilization. But beginning in the Late Dynastic period Egypt could no longer defend its empire. Successive wars and occupations by the Assyrians, Persians, and finally Greeks led to the end of dynastic rule and the collapse of Egypt as a major world power. The Romans suffered a similar fate when their empire split under the weight of its own sheer size and finally collapsed when it could no longer fend off Germanic peoples from the north.

AFRICA

BY MICHAEL J. O'NEAL

The peoples of ancient sub-Saharan Africa lived primarily as hunter-gatherers until about the second century B.C.E. Accordingly, they did not form cities or permanent settlements that expanded into empires or dominant civilizations. Housing and other structures were built with temporary material, such as mud and wattle, rather than the stone and brick used by some other cultures. Thus, little can be known in detail about the collapse and abandonment of settlements in the ancient sub-Saharan, although social scientists can make inferences about the processes that led them.

One such process was probably environmental degradation. Although the sub-Saharan was rich in resources that allowed people to subsist and even thrive as hunters and gatherers, it was inevitable that as the population of a given area increased, resources were strained, particularly the food supply. As game animals became scarcer and native plants were exhausted for their food value, communities would simply pick up, abandon the region they inhabited, and move on to a new region, where the process began again.

Similar processes affected the ironworking cultures of the sub-Saharan. This region was unique in that it seems to have skipped the Bronze Age that was so important to the development of other world cultures and passed directly from the Stone Age to the Iron Age. Iron smelting, however, requires high heat in furnaces. The most common fuel used to fire these furnaces was wood—and wood in massive amounts. The result was deforestation in the area immediately surrounding an ironworking community. As time went on, firewood had to be brought to the site from farther and farther away. This deforestation led to soil erosion and the disappearance of game, making it increasingly difficult for surrounding populations to feed themselves.

Another process that led to social collapse and abandonment was climate change. The most noteworthy example in

ancient Africa had to do with the Sahara. For thousands of years this vast region has been a harsh, forbidding desert. It was not always this way. Until about 3000 B.C.E. much of the Sahara was fertile grassland that supported populations of people. In the area that is modern-day Mauritania, for example, an early Berber culture called the Bafour survived by farming and grazing herds. Then the climate began to change, the rains disappeared, and the desert grew relentlessly southward (overcultivation and overgrazing of the land may have contributed to its decline). The Bafour had to abandon the region. Many people simply moved to urban centers, including those of Egypt, where they and their descendants forged a new kind of life. Historians believe that the descendants of the Bafour include the Imraguen, who became fishermen on the African coasts; the Toucouleur, who moved to Senegal; and the Wolof peoples, who settled in Gambia, Senegal, and Mauritania. All three of these ethnic groups survive in the 21st century. The process was intensified as the Berber people from the north, themselves facing environmental degradation and political turmoil, expanded southward in the third and fourth centuries C.E., driving out surviving members of the indigenous groups. This example illustrates the complex movement of peoples as they faced crisis, abandoned their communities, and were absorbed into other cultures.

Disease and famine, too, contributed to the collapse of ancient African civilizations. A noteworthy example is the Nok civilization, which emerged in modern-day Nigeria in about 500 B.C.E., survived into the Common Era, and then mysteriously disappeared. The Nok were an advanced civilization best known for ironworking and, especially, terra-cotta sculptures. Historians do not know with any certainty why the Nok simply disappeared, but they speculate that famine or disease led to a sharp decline of the population and the merger of the Nok with the Yoruba people. Famine and disease are mutually reinforcing; food shortages make hungry people more susceptible to disease, and as people die, less and less food can be produced. A civilization weakened in this way could not survive.

Finally, warfare and the desire for empire led to the collapse of African civilizations. A good example is provided by Kush, a region just south of the Egyptian Empire. The Kushites developed a flourishing culture between about 1700 and 1500 B.C.E., primarily because Egypt was under the control of the Hyksos, a Semitic people from Asia. However, when the Egyptians expelled the Hyksos, they set their sights on Kush, wanting control of the region not only as a buffer to protect their southern border but also as a trading colony. Then, in about 1000 B.C.E., the Kushites again asserted their independence, unified their kingdom, moved their capital city upriver (that is, to the south, since the Nile River flows south to north) to Napata, and became a major power in the region. They had access to rich gold mines and grew so strong that they attacked and conquered Egypt for a time.

However, this power was not destined to survive. Kush came under attack from the Assyrians and later the Persians.

When Napata finally fell in the fourth century B.C.E., the Kushites abandoned it and moved their capital farther south, to Meroë. They survived for the next several hundred years as traders. Meanwhile, a new power in the region emerged, the kingdom of Axum, which lay to the Kushites' east. In the second century C.E. Axum conquered Kush, and the Kushite civilization for all intents and purposes disappeared.

Warfare also contributed to the decline and disappearance of the Carthaginian culture along Africa's northern coast. Carthage had been founded in the ninth century B.C.E., and over time it developed into a major trading power, supported by a sophisticated agricultural system. Protecting its large mercantile fleet in the Mediterranean Sea was a massive navy. However, Carthage was a threat to the Roman Empire, and Rome concluded that Carthage had to be subdued. A series of three wars began in 264 B.C.E. Although the outcome of the first war was indecisive, the treaty the two powers signed forced Carthage to pay huge indemnities to Rome, depleting its treasury and beginning the process of collapse. At the end of the third war, in 146 B.C.E., Rome decisively defeated the Carthaginians; sacked the capital city, Carthage; and effectively wiped out Carthaginian culture and society.

EGYPT

BY MARIAM F. AYAD

The Egypt of the pharaohs lasted more than 3,000 years. The wonderful monuments preserved at Luxor, Saqqara, and other archaeological sites testify to the greatness this civilization enjoyed. Except for those magnificent ruins, however, little remains of this ancient culture.

Egypt's long history is divided into Old, Middle, and New Kingdoms, spanning the period from about 2575 to 1070 B.C.E. These periods of prosperity, expansion, and massive construction projects are interrupted or followed by times of weakened royal authority and even chaos known as the First, Second, and Third Intermediate Periods, respectively. The Second (ca. 1640–ca. 1532 B.C.E.) and Third (ca. 1070–ca. 712 B.C.E.) Intermediate Periods witnessed foreign domination over parts of Egypt; the First Intermediate Period (ca. 2134–ca. 2040 B.C.E.) is unique in that internal rather than external factors seem to have caused the collapse.

The First Intermediate Period survived in literary works long after stability was restored to the land. More than any other period of Egyptian history, it affected the Egyptian collective psyche. For centuries after its end Egyptians viewed it as a time of social collapse in which fundamental notions of justice and social order were overturned. Several literary works, including *The Complaints of Khakheperre-sonb* and *The Admonitions of Ipuwer*, vividly describe the social conditions prevalent during the First Intermediate Period.

In *The Complaints of Khakheperre-sonb* we read of a land destroyed and broken up, where “order is cast out,” chaos ruled, and the temples are deprived of their regular rations. This text describes a general state of mourning, distress,

inequity, and crime. It paints a picture of reversed social norms wherein the rulers become ruled. *The Admonitions of Ipuwer* describes similar conditions. The author imparts a sense of overarching futility and infertility: “Lo, . . . the women are barren, none conceive.” Several passages explicitly refer to bloodshed: “There’s blood everywhere. . . . Lo, the river is blood.” Others mention that there was “no shortage of dead,” that “many dead are buried in the river,” and that “the stream [became] the grave, the tomb became stream.” *The Admonitions of Ipuwer* has been cited as evidence of an Egyptian civil war.

Another text, known as *Instructions to Merikare*, written sometime in the Middle Kingdom, may also contain references to a civil war, such as in a warning that “troops will fight troops.” Traces of the name “Khety” preserved in *Merikare* and written within the royal cartouche (the oval that typically encircles the king’s name in ancient Egyptian writings) may indicate that the events referred to took place in the First Intermediate Period, as “Khety” could conceivably be another way to write Akhtoy, a name held by several rulers during that difficult time. Yet another text, known as the *Prophecy of Neferti*, suggests that Egypt’s rulers were “many” during this period and that the land was in “turmoil” and “uproar.” People “seize[d] weapons of warfare,” the son becoming as enemy, “the brother as foe,” and “a man slaying his father.”

Scattered references in *The Admonitions of Ipuwer* and in the *Prophecy of Neferti* as well as in other texts suggest an extended severe drought. In the *Prophecy of Neferti*, “Dry is the river of Egypt. One crosses the water on foot; . . . The land is bowed down in distress.” This text also describes the land as “ruined” and “shrunk,” “bare” and “deprived of produce” and “lacking in crops.” Indeed, it has been suggested that toward the end of the Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) a series of low Niles and the ensuing economic decline may have directly contributed to the collapse of centralized power so characteristic of the First Intermediate Period.

Literary and autobiographical texts as well as archaeological evidence indicate that the Second Intermediate Period witnessed a massive wave of Asiatic infiltration into the Nile delta. Whereas early scholars have assumed that an outright invasion resulted in the Hyksos rule in Egypt (Hyksos being a Greek version of the Egyptian *heqa khasut*, “rulers of foreign lands”), it is now believed that the Hyksos infiltrated the delta gradually but massively at the end of the Middle Kingdom. What exactly caused this mass immigration is not known, but possibly it resulted from a period of drought in western Asia. The Second Intermediate Period ended with the military expulsion of the Hyksos through campaigns initiated by a series of Theban rulers of the Seventeenth Dynasty (ca. 1640–ca. 1550 B.C.E.), leading eventually to the establishment of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.) and the New Kingdom.

The Third Intermediate Period shares some similarities with the first two. Like them, it was characterized by much

Sarcophagus of Nectanebo II, the last native ruler of Egypt, from Alexandria, Thirtieth Dynasty, around 343 B.C.E.; Nectanebo's reign was ended by the second Persian occupation of Egypt, and it is said that he fled to Ethiopia. (© The Trustees of the British Museum)

internal conflict and long periods of foreign domination. Competing claims over the Egyptian throne at the beginning of the Twentieth Dynasty (ca. 1196–ca. 1070 B.C.E.) undermined the royal authority, and toward the end of the dynasty a series of weak kings ruled, often only briefly. Inevitably, weakened royal authority led to a drastic rise in the influence and power of prominent figures of the priesthood, who added military titles with civic duties to their priestly roles. One such figure was Herihor, a high priest of the god Amun who assumed royal titles and enclosed his name in the royal cartouche even while Ramses XI, the last pharaoh of the Twentieth Dynasty, still ruled.

With the death of Ramses XI the New Kingdom ended, and an era of “foreign” dominion began. Because of its rulers’ foreign names, the Twenty-first Dynasty (ca. 1070–ca. 945 B.C.E.) is often characterized as Libyan. Although Libyan by origin, these rulers had been assimilated into Egyptian society. Some had been members of the Egyptian court or army and had used their positions to gain power. The Twenty-second through Twenty-fourth Dynasties (945–712 B.C.E.) were also Libyan in origin and often contentious, with various dynasts claiming royal titles even though they controlled only small areas. The resulting competition divided Egypt into warring fiefdoms. It may be that the Libyans’ decentralized approach to rule was their cultural heritage as people who had led a tribal, nomadic existence. Texts from earlier periods of Egyptian history often mention wars with the “Libyan tribes” along Egypt’s western border.

The Libyan period ended in the second half of the eighth century B.C.E. when invaders from Nubia to the south of Egypt took power in Memphis. The Nubians claimed to be restorers of order who wanted to reunify Egypt and purify it of sacrilegious Libyans. In 664 B.C.E. Necho, a ruler from the western delta city of Sais, formed a military alliance with the Assyrians and with their help drove the Nubians out of Egypt. Necho’s son Psamtik I (r. 664–610 B.C.E.) became the

first ruler of the Egyptian Twenty-sixth Dynasty, which lasted until the Persian invasion of Egypt in 525 B.C.E.

During the Twenty-sixth Dynasty contacts with other Mediterranean and Near Eastern countries strengthened, and Egypt became increasingly involved in the politics of the region. Egypt was invaded twice by the Persians, in 525 B.C.E. and 343 B.C.E., and then by Alexander the Great’s Macedonian troops in 332 B.C.E. After Alexander’s death in 323 B.C.E. one of his generals, Ptolemy, declared himself ruler of Egypt. His descendants reigned for almost 300 years, during which Egyptian culture became increasingly Hellenized. After Cleopatra VII’s defeat at the battle of Actium in 30 B.C.E., Egypt was annexed to the Roman Empire, and its distinctive pharaonic culture gradually disappeared.

THE MIDDLE EAST

BY FRANS VAN KOPPEN

The ancient Near East offers a historical record of unparalleled length, continuity, and complexity for the development of human society over time. From the beginning of urban culture in late prehistory up to the Middle Ages, this record is replete with evidence for episodes of social collapse after periods of relative stability. These episodes typically involved settlement desertion on a regional scale, changes of subsistence strategies, and political fragmentation. Evidence for these events comes primarily from archaeological surveys using landscape investigation to determine the growth and decline of regional settlement systems. Excavations, climatic data, and ancient texts shed further light on social collapse and help reveal the complex interplay of socioeconomic and environmental factors that lay at the root of it.

Differences in landscape, rainfall, and temperature divide the Near East into distinct environmental zones, each of which accommodated specific forms of human subsistence: sheep and goat herding in the semiarid and mountainous regions, trade and crafts along the interregional routes, dry farming and small-scale cattle herding in the low-rainfall zones, and intensive cereal cultivation in the floodplains, again in combination with herding away from the rivers and fields. Maximum population density occurred near the rivers, and the Mesopotamian floodplains, in particular, exhibited the greatest size and number of settlements throughout the millennia.

Ancient agriculture was, however, always a dangerously fragile system operating under critical social and environmental constraints and therefore susceptible to abrupt fluctuations. Strong central control coincided with agricultural expansion and an increase in settlement, while disruptions of the political order were typically characterized by a reversion to local self-sufficiency and the abandonment of villages and smaller rural towns. In the face of such fluctuations the rural population maintained a spectrum of subsistence options and moved back and forth between village-based farming and other economic strategies such as herding, relocating if necessary to neighboring environmental zones.

A typical cycle of rural settlement and abandonment includes some or all of the following elements: Expansion is instigated by the urban centers, the seats of elite governments and their trappings of symbolic identifications on which regional states are founded. Growing demand in the center stimulates agriculture and settlement of the countryside, including ecologically marginal areas. Maximal growth is contained in order not to cross the threshold of the environmental carrying capacity, but the system at its greatest expansion is vulnerable when this threshold drops—for example, if yields diminish because of minor shifts in rainfall or river levels. Political demands for surplus remain constant, and pressure on the rural producers therefore increases, leaving them no alternative but to grow more on their land, which compounds the problem of diminishing returns by increasing soil poverty and salinity. Once producers start fleeing the oppression of their urban landlords, the agricultural infrastructure can no longer be maintained, and the downward spiral accelerates, ending with the desertion of rural settlements and the decline of the urban political center, usually resulting in dynastic collapse.

Ancient Mesopotamian texts show that sequences of political growth and waning and the associated expansion and contraction of settlement were thought to obey universal cyclical patterns. The Mesopotamian word for “dynasty” designates any temporary term of public duty, and dynastic collapse was considered an inevitable shift in office. Political discontinuity sometimes occurred well before expansion en-

dangered the resilience of the rural economy—for example, when the last indigenous Mesopotamian dynasty fell and the land was integrated in the Persian Empire (535 B.C.E.)—but more often dynastic change took place when the fragility of the rural social and ecological systems had already eroded the state’s economic foundations. Under these circumstances even relatively minor external pressure, such as an attack by rival powers, could topple dynasties.

Major cities suffered during phases of settlement reduction and agricultural decline but usually survived. Cities were the custodians of divine worship, high culture, and learning, institutions that were quickly revitalized by new contenders to power who sought to be recognized and took up the traditional seats of rule. Nevertheless the archaeological record contains ample evidence for crises that disrupted a region’s urban centers over and beyond its rural settlements. In many cases large cities were permanently abandoned, often with telltale signs of destruction in their final moments. Extreme instances reveal widespread breakdown—for example, the great collapse that occurred around 1200 B.C.E. when the Hittite capital, Hattusha, and the Syrian cities Emar and Ugarit (as well as many centers of Mycenaean Greece and Cyprus) were abandoned, never to be reoccupied. This and similar episodes clearly represent major disruptions in the development of human society. A comparable cycle of urban decay occurred at the transition from the Early to the Middle Bronze Age (ca. 2200–2000 B.C.E.).

Many of the theories proposed to account for collapses of this scale attribute them to external forces. Two factors, in particular, are often brought into the debate: abrupt climatic deterioration, leading to droughts and famines; and foreign invasion. Current consensus is that no single factor was decisive and that combinations of a variety of causes—external as well as internal—could lead to societal breakdown. Economic interdependency through trade networks explains how episodes of collapse could simultaneously affect large areas of the Near East and beyond.

Despite the fragility of the Near Eastern environment, agriculture, and settlement, ancient societies were remarkably successful in preserving their civilizations over time, an endurance that can be credited to the cities and their palace and temple resources. Only when the collapse of a state involved the total destruction of its urban centers—for example, during the fall of Assyria in 614–612 B.C.E.—was it possible to fully eradicate an ancient Near Eastern civilization.

ASIA AND THE PACIFIC

BY FRANCIS ALLARD

Asia and the Pacific region make up a large and culturally diverse area with a history marked by the rise of numerous states and empires, some of which display continuity with present-day nations. Less well known are the many archaeological cultures and polities that emerged as culturally and politically distinct entities but eventually collapsed or underwent trans-

Basalt relief of a gazelle, Neo-Hittite, ninth century B.C.E., from Carchemish, southeastern Anatolia (modern-day Turkey); after the collapse of the Hittite Empire around 1200 B.C.E., Hittite culture survived in places such as Carchemish that had once been under Hittite control. formation. Early instances of social collapse in Asia are evident in various areas and periods and exemplify some of the reasons scholars have proposed for collapsed societies, including environmental disturbances, social upheaval, military defeat, and even peaceful contact with other regions. It is important to note that the nature of the evidence—solely archaeological in the case of prehistoric cultures and archaeological and textual for the more historical polities—affects the type of interpretation proposed, with military conflict more likely to be advanced as the trigger to collapse for polities discussed in written sources. Also worth noting is the likelihood that the various names given by archaeologists to successive periods and cultures may not necessarily reflect dramatic instances of social collapse, concealing instead more gradual, but nevertheless significant social and political transformations.

The prehistory of the Korean peninsula and Japanese archipelago provides evidence of the long-term impact of external forces on local cultures, transformations that witnessed the abandonment of sites and undoubtedly challenged their social and political structures, although the details of such strains are difficult to identify in the archaeological record. In Korea the 6,000 years of the Chulmun (ca. 6000–ca. 1500 B.C.E.) and Mumun (ca. 1500–ca. 300 B.C.E.) periods were characterized by the presence of village life, the use of pottery, and a reliance on the products of fishing, hunting, and gathering. By the third millennium B.C.E. millet cultivation had been introduced from northeast China. Further reflecting the diffusion of ideas, skills, and even materials (for example, bronze daggers, and mirrors) from China, the Mumun Period is marked by intensification of agriculture, megalithic tombs, and greater social and political differentiation.

In Japan the Jōmon Period (13,000–300 B.C.E.) is similarly characterized by villages, pottery, a reliance on wild (nonagricultural) resources, and incipient agriculture. The succeeding Yayoi Period (300 B.C.E.–300 C.E.) points to a significant transformation of Jōmon society as the arrival of immigrants, styles, and ideas from the Korean peninsula was associated with the intensification of wet-rice agriculture, metallurgy, defensible sites, objects imported from the mainland (like mirrors), and an increasingly hierarchical society.

The Neolithic Period of mainland China, typified by the highly distinctive archaeological cultures known as Hongshan (ca. 4500–ca. 3000 B.C.E.) and Liangzhu (ca. 3200–ca. 2100 B.C.E.), provides clearer instances of apparent social and political collapse, though the absence of texts renders interpretations of the archaeological data highly tentative. Centered in northeast China, the Hongshan culture is characterized by what are believed to have been ceremonial centers (including so-called temples and altars), female figurines and statues, and large complex tombs. The grave goods include finely crafted jades (representing birds, clouds, turtles, and “pig dragons”) that suggest the presence of elites. It is significant that by the middle of the third millennium B.C.E. these features had disappeared, and the number and size of residential sites had decreased.

Located along the coastal regions of central China, the Liangzhu culture shares with the Hongshan culture the presence of ceremonial centers and wealthy tombs whose exquisite jades (tubes, discs, bracelets, and pendants) point to control of production by an elite. At the end of the period Liangzhu residential sites, which were concentrated on riverbanks, were abandoned. The succeeding Maqiao culture (ca. 2100–ca. 1300 B.C.E.) is marked by a dramatic reduction in the number of sites and an almost complete disappearance of Liangzhu traits.

Explanations proposed to account for the collapse of Hongshan and Liangzhu include climatic change (associated with flooding in the case of Liangzhu) and an inability to manage economic resources efficiently. In addition, the elite of both cultures may have lost the support of their respective populations when workers felt they were not adequately rewarded for their efforts at producing the elite’s symbols of power.

Instances of social growth and collapse become easier to chart over the course of the first millennium B.C.E., when increasingly detailed texts become available. This is especially true of the region encompassed by present-day China. During that region’s Warring States Period (453–221 B.C.E.) numerous small states (Zhao, Shu, Chu, Yue, Han, Wei, Qi, Song, Lu, Yan, and Qin) emerged and suffered subsequent defeat through military conquest. The Qin Dynasty (221–207 B.C.E.), the eventual victor of this period of instability, was led by China’s famous “First Emperor,” an autocratic and firm ruler whose harsh treatment of detractors and forced conscription of laborers (used, for example, in the building of the Great Wall) led to popular uprisings and the downfall of the dynasty. The succeeding Han Dynasty (202 B.C.E.–220 C.E.) proved highly successful at expanding China’s territory to reach close to its present-day borders, an increase in territory that, like the contemporaneous Roman Empire, led to contact with sometimes powerful foreign cultures. In the end the Han Dynasty would fall victim to internal rebellions and the problem of maintaining control over distant regions of its empire.

Not surprisingly, the territorial expansion of the Han Dynasty in eastern Asia was associated with the collapse of a number of preliterate and culturally distinctive polities, events that the Chinese recorded in their historical texts. Two examples pertaining to the Han’s southern periphery illustrate this. First, the Dian culture (third century B.C.E. to first century C.E.), centered in southwestern China’s Yunnan Province, is known for its highly distinctive and elaborate material culture, which includes bronze drums and cowry shell containers. Although the Chinese texts relate the defeat of the Dian by Han forces in 109 B.C.E., burial evidence points to the survival of Dian cultural traits for another century following its incorporation into the Han Dynasty. The second example is the Dongson culture, located in present-day North Vietnam and noted for its large bronze drums. The Dongson culture survived through much of the first millennium B.C.E.,

finally succumbing to the Han in 43 C.E. after an earlier defeat in 111 B.C.E. It is significant that Chinese cultural traits had already infiltrated Dongson culture by the second century B.C.E. The histories of the Dian and Dongson cultures signal the need to distinguish between military defeat and cultural decline in reference to “collapse.”

Centered on the Indus Valley of Pakistan and northwestern India and represented by the large sites of Harappa and Mohenjo Daro, the Indus civilization (3000–1600 B.C.E.) provides a dramatic example of a flourishing South Asian

A burial jade carved with faces, from southern China, Neolithic Period, Liangzhu culture, around 2500 B.C.E.; tombs rich with jade objects were characteristic of this culture, whose sites were abandoned in the mid-third millennium B.C.E. (© The Trustees of the British Museum)

culture as well as a fitting illustration of the complexities of societal collapse and transformation. Although the absence of clear textual references to the Indus civilization limits an understanding of its political structure and religious life, it nevertheless displays a range of features common to other civilizations of the ancient world, including urbanism (centers with streets, specialized quarters, amenities, public structures, and populations numbering in the tens of thousands), a writing system (as yet undeciphered), a system of weights and measures, long-distance trade (with Mesopotamia, among other regions), and craft specialization (bead making, metallurgy, shell working, weaving, and the like).

By the beginning of the second millennium B.C.E. it appears that both Harappa and Mohenjo Daro had stopped functioning as urban centers, a change paralleled by a reduction in the number of sites in a large sector of the region encompassed by the mature phase of the Indus civilization. This transition might represent a migration out of this area or a restructuring of the settlement pattern or both. The possible forces behind this change remain open to debate. They include the destruction of the civilization by invading Aryan peoples (mostly rejected, owing to an absence of clear evidence for such destruction at the sites themselves), the drying of the large Ghaggar-Hakra River, the decline of the trade system, and the flooding of a large area resulting from the formation of a natural dam.

Population and urban decline apparently characterized only a portion of the area encompassed by the Indus civilization, with some sectors experiencing continued growth during the second millennium B.C.E. Moreover, certain features of the Indus civilization appear to have been maintained throughout later periods. For example, Hinduism has retained some of the civilization's customs, such as ceremonial bathing, the importance of bulls and elephants, and Yogic positions. This illustration of the maintenance and transformation of cultural features over long periods underscores the need to disentangle the many strands subsumed under the term *societal collapse*.

EUROPE

BY JUSTIN CORFIELD

Throughout Europe traces exist of ancient settlements long ago abandoned. Sometimes the reason for this abandonment is known, but often it is not. Mobile hunter-gatherers lived in a spot for several weeks or months and then moved on, but they often returned to the same locations. Neolithic farmers lived in farmsteads and hamlets for decades. Sometimes they needed to shift their settlement locations owing to changes in their agricultural systems. Some archaeologists have speculated that settlements were abandoned when a lineage died out and no longer had an attachment to a particular location. Resource depletion of the surrounding countryside is another possible reason for abandoning ancient farming settlements. Occasionally warfare and raiding may have driven out the

inhabitants of local settlements. Given the relatively simple organization, based on households and hamlets, of societies in Europe before about 2000 B.C.E., it is not really possible to speak of true social collapse on any large scale.

Rural farmsteads were the prevailing settlement form during the Bronze Age (ca. 2800–ca. 700 B.C.E.) and Iron Age (ca. 1000 B.C.E.–ca. 500 C.E.) in most of Europe, though some larger sites arose that could be considered villages. The settlement at Biskupin in Poland, built between 750 and 720 B.C.E., was inhabited by several hundred people but abandoned after several decades. The two major theories have been advanced for the abandonment of Biskupin and similar sites nearby. One is that rising water levels in the lakes that surrounded the peninsulas on which these sites were built forced the residents to leave. The other is that the local population was driven out by marauders, possibly Scythians from lands to the east, since some of the sites show traces of fire and Scythian-type arrowheads have been found in the archaeological deposits.

Farther north there have been studies of Iron Age settlements in Denmark. Some of these settlements may well have been more densely populated in ancient times than today. Many other sites appear to have been abandoned when the food supplies ran out or when the population increased to such a level that a new settlement had to be established.

Inhabitants of Bronze Age and Iron Age Britain and France built numerous hill forts. Very many of them are located in the southeast of England at sites that have never been populated since and that were clearly abandoned in ancient times. Because these settlements had low population densities and good agricultural land, it seems unlikely that they suffered from a lack of food crops. A more probable reason for their abandonment is social collapse following the emergence of a more powerful local group or federation. For example, the Celtic hill fort at Danebury, on the South Downs, England, near the river Test, was built from the sixth century B.C.E. and abandoned around 100 B.C.E. after what appears to have been an enemy attack—there is archaeological evidence that the east gate was burned down, and the remains of bodies were found in charnel pits.

On a much larger scale the Roman invasion of Gaul (which consisted essentially of present-day France, Belgium, and Germany and the Netherlands west of the Rhine River) under Julius Caesar in 58–51 B.C.E. brought widespread destruction of villages and towns. Many communities were wiped out. As a large number of those killed were men, many groups lacked the ability to collect the harvests, leading to collapse of their societies, with the result that Gaul remained the most quiescent of Roman provinces until the fall of Rome itself in the fifth century C.E. Similarly, military campaigns in Spain as part of a Roman civil war despoiled some of the country in 46–45 B.C.E. The civil war, which pitted Caesar against other powerful Romans and their armies, led to the destruction, temporarily, of many other cities across Roman-held territory, such as Massilia (modern-day Marseilles, France).

In Germany the Romans managed to seize the lands west of the Rhine, but even in the areas they did not control the Roman legions destroyed much of the infrastructure. In 9 C.E. the campaigns of the Germanic tribal leader Armin (“Arminius” to the Romans) and the Roman commander Varus spread mass destruction, though Armin and his forces all but annihilated three Roman legions at the battle of the Teutoburg Forest. Fighting continued for the next four years and then recurred sporadically from 17 until about 200 C.E.

In eastern Europe fighting between the Romans and such peoples as the Dacians and the Goths and later wars with the Bulgars led to the abandonment of many inland settlements, but a number of coastal ones remained, suggesting that the more isolated places were perhaps harder to defend and the coastal ones more easily reinforced or rebuilt. Certainly in Roman Britain, when the cities of Camulodunum (Colchester), Londinium (London), and Verulamium (Saint Albans) were destroyed during the revolt of the Iceni under Queen Boudicca in 60 C.E., the three cities were easily rebuilt on the same foundations; archaeologists have found a layer of ash in many places representing the destruction. Other cities flourished under the Romans but after the fall of the Western Roman Empire in 476 C.E. never regained their former wealth and size. Although most Roman cities have been built over and massively enlarged in the last 2,000 years, there are still some, such as Cirencester (Roman Corinium) in England, where the old city walls extend well beyond the current size of the town.

GREECE

BY SPYROS S. SIROPOULOS

Greece had never been a rich country. Small-scale agriculture, including the cultivation of olive trees, along with animal keeping and fishing were the basis of its population’s nutrition. The scarce natural resources were balanced by a favorable climate that allowed the Greeks to remain outdoors for most of the year to cultivate the earth and to engage in trade and seafaring. To make most of the natural resources, large parts of the country’s population did not inhabit the famous civic centers of antiquity but instead lived permanently in the countryside. In a typical city-state the polis, or city, was the decision-making center; a relatively small agricultural area called the *chóra* lay outside the polis and included a number of smaller settlements called *kómai*. A fine balance was formed between the city and the *kómai*: The civic way of life and the stability and growth of the civic community were sustained and secured by the provisions from the agricultural settlements.

This delicate balance could easily be upset in the ancient world. The mass desertion of rural settlements, with all the catastrophic repercussions for neighboring cities, could occur for various reasons, including natural causes, economic or political causes, and war.

Because people depended upon the climate to produce the maximum of the land’s potential, any unpredicted natu-

ral catastrophe, such as a flood, prolonged draught, fire, or earthquake, could drive the people to abandon the countryside and move to cities to earn a living. Civic communities were not always prepared to handle such events. It was easy for agricultural problems to become social problems if the city could not compensate the devastated farmers or provide alternative ways to incorporate them into the broader social mechanism. In some cases extreme situations called for extreme solutions. The Greek historian Herodotus (ca. 484–ca. 425 B.C.E.) describes the case of the small island of Thira in the fourth century B.C.E. Unable to provide for the needy farmers or to handle the political and social tension created by the dissatisfied citizens, the state of Thira sent a large population to colonize another territory. The state released a decree that prohibited the colonists from returning to Thira before five years had elapsed. In this case the successful colony of Cyrene was founded in northern Africa. Between 750 and 550 B.C.E. colonization became a common way to diffuse internal social tension and to divert the surplus of a city's male population outside the society.

The economic and social organization of the city-states were closely connected to the way a given city handled the economic and political crises that manifested toward the end of the Homeric Period (ca. 1600–ca. 1100 B.C.E.). Rapid population growth and the inability of city governments to redistribute land satisfactorily led to social unrest. Sparta tried to solve this problem by waging war on other regions to gain more land, the Athenians encouraged trade, and most cities turned to colonization. The demand for greater amounts of raw materials or agricultural products and the heavy taxation of farmers often drove farming communities to desperation. In the Hellenistic Period (323–31 B.C.E.) the abandonment of the countryside (a phenomenon the Greeks called *anahorisis*) became an economic and political problem for the Ptolemaic Dynasty of Egypt. The first rulers of this dynasty tried to expand their power by rapidly developing their naval economy; for this they demanded heavy taxes from farmers. Consequently, the farmers deserted the countryside and sought guidance and protection at the local temples, thereby upsetting both the local Greek economy and the intentions of the Ptolemaic kingdom.

War is an obvious reason for the abandonment of rural settlements. Farmers, woodsmen, goatherds, and inhabitants of small fishing villages often were forced to seek protection behind the walls of a nearby city with the advent of war. This was bad for the city in two ways. First, the city was deprived of the replenishment of natural goods upon which the civic population depended for sustenance. This was the intended result of a prolonged siege on a strong, fortified city: to exhaust the resources and compel the citizens to surrender.

Second, other practical problems arose from an unpredicted overpopulation. The Greek historian Thucydides (d. ca. 401 B.C.E.) describes how a plague was added to the problems of the Athenians during the Peloponnesian War (431–404 B.C.E.). Pericles (ca. 495–425 B.C.E.), the leader of the

democratic party in Athens at the time, had thought that the famous “long walls,” the fortification that connected Athens with Piraeus, would secure the country's population. He also thought that the walls would enable the city to communicate undisturbed with the vital harbor of Piraeus during the siege, thereby replenishing its products and withstanding the Spartans' siege. But Pericles had not provided for proper housing for all of these refugees. In 430 B.C.E. the inevitable pestilence, caused by a lack of elementary hygiene and the concentration of thousands of people, wiped out more than a quarter of the population of Athens. Among the victims of the pestilence were Thucydides' family and Pericles himself.

War puts a stop to the development of a society in more than one way. In the western plain of Boeotia there was a marshy lake called Copais that was a source of illnesses. The Minyae, a native people of the 13th and 14th centuries B.C.E., had tried to drain the lake to provide arable land for the local farmers. This ambitious plan was stopped because of a war with Orchomenus.

Some historians see a definite connection between the collapse of the Mycenaean society around 1100 B.C.E. and the formation of cities. When the Mycenaean civilization, also known as the Palace civilization, collapsed and the Dorians colonized Greece, many important social changes took place. People ceased being dependent upon the prosperity of palaces and stopped living in small settlements around them. This and the repopulation of the countryside led to the formation of the first cities, marking the beginning of a new social and political era for Greece. The interdependence between social order and the agricultural economy of Greece was a defining factor in the development of Greek cities throughout antiquity.

ROME

BY CHRISTOPHER BLACKWELL

The third century C.E. was a time of social crisis for the Roman Empire even as the emperors completed some of the most striking and enduring monuments to Roman greatness. From 193 to 312 C.E. the Column of Marcus Aurelius, the Arch of Septimius Severus, the Baths of Caracalla, the Aurelian Walls, and the Basilica of Maxentius were added to the splendor of the city of Rome. Also during this period the death of the emperor Commodus (r. 180–192 C.E.) led to the chaotic “Year of Four Emperors” (193 C.E.), the emperor Severus (r. 193–211 C.E.) died campaigning in Britain, Ardashir I (r. 224–241 C.E.) took the throne of Iran and began a war with Rome that would continue for 400 years, and Rome and its provinces suffered invasions from Goths, Heruli, and other Germanic groups. The entire Mediterranean world suffered from a recession in trade, and prices soared. Despite the *Constitutio Antoniniana*, or Constitution of Antoninus (r. 211–217 C.E.), issued in 212 C.E.—a law that granted universal citizenship to all free men living under Roman rule—the population of Rome was neither growing nor harmonious;

birthrates declined, and communities were wracked by official and unofficial persecutions of the Christians, a new but growing religious minority.

By 280 C.E. these pressures came close to destroying Rome, but a new and strong emperor, Diocletian (r. 284–305 C.E.), took office in 284. For the 23 years of his reign and the 31 years of his successor, the emperor Constantine (r. 306–337 C.E.), imperial policies both averted immediate collapse and perhaps ensured that it would eventually occur.

Diocletian attempted to take control of the economic crisis by putting strict control on the prices of certain goods, which prompted farmers, artisans, and merchants simply to stop dealing in those goods. When Constantine tried to increase trade and commerce by distributing gold from the Roman temples, inflation increased even more dramatically. Under Diocletian the bureaucracy of the Roman Empire was split in two, east and west, and Constantine reacted to the pressures of foreign invasion by virtually eliminating the authority of the Senate, thereby putting all power into the emperor's hands, and by building up the army. These changes did allow Rome to ward off invasion, but they also had immediate consequences for Roman society.

Diocletian's splitting of the empire doubled the weight of bureaucracy. Always prone to corruption, the now more numerous civil officials became generally more rapacious. Citizens found themselves subject to extortion or required to pay bribes to secure basic services such as protection under the law. In succeeding years, the emperors' various efforts to crack down on corruption only made matters worse. Officials came to realize that they could lose their jobs at any time, and they reacted by trying to amass as much illicit profit from their positions as they could before being caught.

New laws against usury, which began during Constantine's reign, had a similarly paradoxical effect. These laws forbade lending money at exorbitant interest, and they were passed as the result of influence from Roman Christians. But citizens still needed to lend money, and bankers continued to make loans. Under the new laws, however, a lender could not expect the courts to support claims against debtors who defaulted on loans. This increased the risk to the lender, which led creditors to charge ever-higher rates of interest. The common citizens suffered accordingly.

Constantine's efforts to consolidate military power under the emperor and to defeat the invasions of groups from northern Europe, while largely successful, held long-term consequences for Roman society. In Constantine's army increasingly more legions, and eventually all of the most effective legions, were composed of soldiers from the very Germanic peoples that Rome was resisting. These soldiers served and became Roman citizens, some of them reaching high military and civil office, and introduced new cultural elements into Roman society.

The rise of Christianity had other effects on Roman culture. For example, in the middle of the fourth century C.E. the Greek prelate Gregory of Nyssa (ca. 335–ca. 394 C.E.) pub-

Coins from the Hoxne hoard, Roman Britain, buried in the fifth century C.E. and found in Hoxne, Suffolk; the hoard is thought to have been buried for safekeeping during difficult times for the Roman British, who were left without any help from the Roman Empire to defend themselves from the attacks of the barbarians. (© The Trustees of the British Museum)

lished tracts arguing, from a Christian perspective, against the institution of slavery. While enslaved people revolted numerous times and earlier philosophers had argued against the cruel treatment of slaves, Gregory is the earliest example of any writer from the Greco-Roman world suggesting that slavery was, in itself, an evil institution. The economic consequences of a rejection of slavery, by the late Roman Empire, may not have been great, but such a radical rethinking of a universal social institution was destabilizing. Similar Christian arguments against capital punishment and aggressive wars drove wedges between the Christian and non-Christian populations.

As the official institutions of Rome became dominated by Christians and, after Constantine, officially Christian, divisions within the faith continued to disrupt society at all levels. Starting in the fourth century C.E. a series of schisms between Orthodox Christianity (whose definition changed decade by decade) and various alternative sects, branded heretical by defenders of orthodoxy, often brought legislation to a standstill and repeatedly sparked riots in all the major cities of the Roman world. Nestorians, Monophysites, Donatists, Monothelites, and Arians all differed in theology (sometimes only by exceedingly fine points of doctrine), but each claimed to represent true Christianity. Each sect argued, legislated, and fought against the others whenever and wherever they could.

During the fourth and fifth centuries imperial power grew weak and dispersed. The city of Rome itself became less hospitable as the mouth of the river Tiber silted up and became a malarial marsh. The center of political activity in Italy moved to Ravenna and Milan. Constantinople, the splendid new capital, became less involved in affairs to the west and increasingly Greek in its language and customs. New generations of

THE DEATH AND REBIRTH OF THE LATIN LANGUAGE

Augustine of Hippo (354–430 C.E.) and Jerome (ca. 347–419 or 420 C.E.) were the last two masters of the classical Roman literary tradition. Both of these writers, while writing on Christian topics, were steeped in the Latin of Cicero (106–43 B.C.E.), Virgil (70–19 B.C.E.), and other writers of classical Latin. As early as the fifth century C.E., however, the Latin language had begun to split apart. In some quarters people tried to preserve the classical language by continuing to write in an elaborate style; works such as those of Martianus Capella (fourth to fifth century C.E.), a Vandal writing in Carthage around 470, are full of allusions to classical literature. In other quarters, local dialects became more pronounced, beginning as early as the fourth century C.E. Egeria, a woman who made a pilgrimage from Spain to Jerusalem in 384 C.E., left a diary that shows a version of Latin that would have been hard for a classical Roman to understand.

The elaborate system of Latin grammar became simplified, and its verbs became more regular. By the seventh century the language of Italy resembled medieval Italian more than classical Latin. In the eighth century in formerly Roman parts of France, the definite article (*the*) first appears as *lo*, *la*, *lis*, moving toward modern French's *le*, *la*, *les*.

In the western part of the former empire Latin survived as a tool that allowed scholars and church officials to communicate with each other. As a means for communicating with the common people, it died by the ninth century when, in 813 C.E., a decree from the bishop of Tours forbade sermons in Latin, which the common people could no longer understand.

rulers, while considering themselves Roman, were more likely to be Gothic or Germanic in ethnicity and culture. For ordinary people, the Roman Empire was no longer the organizing institution, upholder of laws, or guarantor of security. Ecclesiastical institutions (churches and monasteries) and ecclesiastical officers (priests, monks, abbots, and bishops) were more likely to take over local government and play central roles in local economies.

So, for example, Apollinaris Sidonius (ca. 430–487 or 488 C.E.), from Lugdunum in Gaul, grew up in an aristocratic Roman family and married a Roman woman whose father, Avitus (r. 455–456 C.E.), would eventually become a Roman emperor. But his political career ended when Avitus was killed and Apollinaris Sidonius became bishop of Auvergne. There he dedicated his life to writing histories of Roman emperors. His numerous letters reveal, however,

that he was not, in fact, preserving a corner of Rome (as he believed) but governing a small, independent fragment of a collapsed empire.

THE AMERICAS

BY KEITH JORDAN

Several episodes of cultural and political change in the ancient Americas fit modern definitions of social collapse—the breaking down of a complex (by modern Western standards) sociopolitical arrangement into what look like simpler or more chaotic systems. We must be careful, however. *Collapse* carries a negative connotation, but ancient peoples may not necessarily have experienced these changes as negative or as forced upon them. Nor can we cling to discredited theories of cultural evolution, claiming that societies develop toward greater complexity (often defined in Western terms) and that a change in the opposite direction constitutes disaster. Finally, since we lack written records for any of these developments in the ancient Americas, our reconstructions from archaeological data are always speculative and tentative and may be invalidated when the next major find is unearthed.

In the North American Midwest the Hopewell culture (200 B.C.E.–400 C.E.)—more accurately described as a ritual and burial complex linked by trade networks—seems to have vanished by 400 C.E. No more Hopewell burial mounds or ceremonial centers were constructed, and the trade networks linking areas as distant as the Rocky Mountains and the Gulf Coast ceased to bring exotic materials to Ohio and Illinois sites. Pottery decoration became less elaborate and objects included in graves simpler and scantier. Societies seem to have become more egalitarian: No longer do burials include a very few with especially rich items, suggesting the existence of an elite.

Some archaeologists once believed that a shift toward cooler weather in the Midwest around 300 C.E. spurred the decline of the Hopewell phenomenon by making it difficult to grow the corn on which the culture supposedly relied for food. However, we now know that Native Americans in the Hopewell areas did not start growing corn on a large scale until five centuries after Hopewell culture disappeared, and there is no firm evidence for the alleged climate shift. On the contrary, in the centuries following the Hopewell “collapse” the peoples of eastern North America became more dependent on corn agriculture, leading to growing populations, bigger settlements, and ultimately the rise of the complex Mississippian cultures (900–1600 C.E.) with their huge towns, massive mounds, and powerful chiefs.

Other proposed reasons for the disappearance of the Hopewell include economic factors. In one theory trade networks collapsed because Native Americans in the southeast started to work local copper deposits instead of relying on copper mined in the Lake Superior region. But the archaeological evidence indicates that Lake Superior copper was mined and widely traded up to the European invasion in the

17th century. Another factor implicated in the Hopewell decline is increased warfare. War does seem to have become more common after roughly 500 C.E., but this may be the result of the increase in population and rise of chiefs with the adoption of corn farming after Hopewell's demise, rather than being the cause of that demise. Some late Hopewell structures once thought to be forts are now regarded as ritual centers. Similarly, although use of the bow and arrow became more common after 500 C.E., we cannot say that its introduction increased warfare and led to the Hopewell decline—the weapon may have been used for centuries before this time. Ultimately the disappearance of the Hopewell culture remains a mystery.

Another mystery confronts us near the Gulf Coast of southern Mexico, where the Olmec political and religious center of San Lorenzo flourished between 1500 and 1200 B.C.E. Its rulers erected monumental images of themselves and conducted trade in exotic materials with other ruling groups across Mesoamerica. Around 1200 B.C.E. the creation of monumental sculpture seems to have ceased, and the palaces of the rulers were abandoned. Although San Lorenzo itself was not abandoned at that time, its influence over the Gulf Coast and other parts of Mesoamerica ended. When the site was excavated in the 1960s, finds of broken statues seemed to suggest destruction by foreign invaders or by a revolution of local farmers against their kings, whose statues they purposely smashed. However, more recent excavations reveal that the broken statues simply represent the recycling of the monuments of previous kings into new ones by artists working for their successors. Recent geological evidence indicates shifts in the courses of the rivers surrounding the site, possibly as a result of silt buildup from erosion after the Olmec cut down forests to clear land for agriculture. These changes may have damaged the local environment and interfered with trade and travel.

Whatever the reason for San Lorenzo's decline, La Venta, to the east, succeeded it as the dominant Olmec center. La Venta flourished from 1200 B.C.E. to around 400 B.C.E.—after which it, too, collapsed and was abandoned. At this same time Olmec civilization itself began to fade, developing into the so-called Epi-Olmec culture (ca. 400 B.C.E.–250 C.E.). Like San Lorenzo's demise, La Venta's may have been related to the silting of adjacent rivers, whether due to natural factors (even a volcanic eruption) or to the effects of agriculture. But that would not explain why the culture itself disappeared or why the population of the eastern half of the Olmec Gulf Coast dropped drastically around the same time. Nor can we say that the Epi-Olmec culture represents a decline. This culture created sophisticated art and played an important role in the development of hieroglyphic writing and the calendar in Mesoamerica, influencing the Maya. It was hardly decadent, as some archaeologists have described it.

A third mystery of social collapse and abandonment exists in South America. Sometime around 2700 B.C.E. inhabitants of the Peruvian coast began building huge ceremonial

structures in U-shaped arrangements. They continued this practice for more than 2,000 years. Then, in the early first millennium B.C.E., it came to an end. Few new large coastal cities were built between about 900 B.C.E. and 600 B.C.E., and construction at many existing sites ground to a halt. Large settlements were abandoned, sometimes reoccupied by small groups of squatters who left their rubbish in the deserted temples. Where new construction took place, as on the north-central coast, the old U-shaped pyramid groups were replaced by labyrinthine arrangements of smaller structures, and fortifications became increasingly common. Meanwhile, religious influences from the highland site of Chavín de Huántar made their appearance, supplanting the long-dominant coastal traditions.

The mechanism for these changes remains poorly understood. The religious system that led to the creation of the U-shaped enclosures suddenly lost its influence and prestige, but why is unclear. Invasions from the highlands have been suggested as a cause, but there is no solid evidence for this. Conflict might have broken out between priestly leaders and their followers in the relatively egalitarian coastal cultures—especially if those leaders tried to emulate the new class of hereditary nobles that seems to have arisen in highland cultures at the same time. Finally, there is evidence that an El Niño climatic event in the middle of the first millennium B.C.E. created catastrophic flooding and killed off much of the cool-water marine life on which coastal folk depended for much of their food supply.

► social organization

INTRODUCTION

The topic of social organization speaks in many ways of why people study ancient history. It speaks of the vast possibilities of the human imagination, revealing that there have been and still are many solutions to the problems human beings have faced over their existence. Some solutions have been successful, helping cultures survive for hundreds or thousands of years, while other solutions have been unsuccessful, resulting in the decline and extinctions of some cultures.

The sheer variety of social organizations is in itself an attraction to modern readers, but there are practical reasons for looking at ancient ways societies organized themselves. One reason is highly personal, belonging to each individual student of ancient life: Ancient social organizations can help tell people why they are here and why they are living as they are. Many problems the individual person faces in modern society are not new. For instance, when a modern Western woman wonders why she faces social barriers in the business world, she may wonder about the truth of the common notion that her biology has fated her to a difficult career. She need only study the ways of ancient Sumer to see that a society in which women could have equal opportunities with men is possible, because it has existed. Further, she can discover how civilizations evolved to restrict her opportunities. Knowing why she is where she is can be spiritually liberating—reason enough to study ancient social organizations. Beyond that, there may be clues to why the culture of Mesopotamia changed from one where women were social equals with or even superior to men to one in which women were treated as less than human, as in the Neo-Assyrian culture. From that understanding can come ideas for solutions to her modern difficulties, because she will have learned that society changes and that creative minds can be the agents of change.

When human societies began to form, they were almost certainly kinship groups, composed of parents, their children, siblings, and cousins. Even within such close groups, there had to be rules of conduct. For instance, the young had to learn to be respectful of their elders for the very good reason that they would die without their parents' knowledge of how to survive. The larger social organizations that emerged with larger groups of people probably had that imperative: survival. In ever-larger social groups there are greater opportunities for the young to learn from their elders and a better chance of being cared for if sick or injured. Still, larger social groups mean more chances for conflict among people. Many ancient social organizations were created in part to find ways in which people could conduct their lives without harming or being harmed by others in their groups.

With the development of agriculture, the need for social rules that were organized in a manner that most people could understand became more important. Agriculture gave human beings an enormously greater opportunity to survive childhood by making the food supply more reliable and regular

than it had been previously. The chances for survival increased even more if people found ways to manage their harvests so that they could eat well during seasons when food would normally be scarce, and those chances could increase further if they found a way to manage their harvests so that they did not starve during years of drought or other disasters that caused poor harvests. Such management of harvests required progressively more complex rules for storage and distribution of food. Some societies became very successful at management of food supplies. For instance, Egypt's granaries kept its people fed through lean times as well as fat times for thousands of years. Cultures that mismanaged food or kept food supplies to a small minority of elites faced uprisings, as China did, or collapse of their economies, as the ancient Maya did.

It is perhaps part of human nature that people, whatever their stations in their societies, wish to share in the benefits of their cultures. Good clothes, good food, and good schooling seem to be desired in almost any culture, yet rarely are there enough supplies of anything that everyone can share in. To deal with the problem, cultures have devised various solutions. In many cultures outright repression holds society together, with those in charge of the armies controlling the benefits of society. In others, it is religion. In ancient India religious doctrine developed in such detail that every person could know what he or she was supposed to do throughout life. Who shared in which benefits was determined by birth and explained by a doctrine that held that people were born into certain social groups because of the good and evil they had done in previous lives. The hope for a better life lay in fulfilling one's duties in the present life, providing motivation for one to contribute to society in the role allotted. The notion of being able to improve one's life has been a safety valve for many cultures.

When reading about social organization, look for how rigid the organization was as well as for the ways in which it was flexible. This requires thought, because a culture might, in theory, have very strict rules for organization but, like ancient India, be somewhat flexible in how the rules were actually applied. Then, too, look at how much a society allowed for social mobility. Even for someone who had no realistic chance of improving his or her life, just having the possibility for improvement could be a powerful motivator, one that could encourage people to be industrious and faithful to the organization of their society because the organization gave them hope. It can be enlightening to see how cultures with long histories, such as ancient Egypt and China, organized and reorganized themselves to cope with changes in environment, technology, and their neighbors. Perhaps some of what they did still has value for the modern age.

AFRICA

BY LEAH A. J. COHEN

Many factors contributed to the forms of social organization in ancient Africa, including environmental and cli-

matic conditions that affected animal and plant resources as well as social, political, and livelihood characteristics. Common social structures during this ancient period in history grouped people by family, lineage, kinship, clan, and tribe. Later there were social structures based on caste or trade (occupation). The political systems that existed in ancient Africa are often categorized into three distinct forms: stateless societies, centralized city-states, and centralized kingdoms or empires (although not all human groups fit so neatly in these three categories). People in early ancient Africa lived primarily by hunting and gathering or fishing and harvesting of aquatic resources. Changes in the climatic conditions over time led to mass migrations and changes in ways of surviving that resulted in the widespread development of societies based on pastoralism, agriculture, and eventually skilled trades.

NOMADIC HUNTER-GATHERER GROUPS

Around 10,000 years ago (at the start of the Holocene), the climate was becoming increasingly moist as much of Africa entered a humid period that would last until around 4,000 years ago. At least during the early part of this humid phase most human groups in Africa were engaged in nomadic hunting and gathering activities in which they occupied no single location permanently. This ancient wetter African landscape, which included the Sahara, provided ample resources to support this lifestyle. Furthermore, population densities were low, meaning that there was relatively little competition for animal and plant resources.

While the specific characteristics of social structure for hunter-gatherer groups certainly varied based on culture and location, the archaeological record indicates some common structures. Hunter-gatherers were generally organized into small bands. Given the existing archaeological evidence, it is difficult to know the size of these ancient groups; modern hunter-gatherer groups range from 20 to 60 people. Although there was a richer natural resource base, which might have affected the size of these groups, ancient groups would nevertheless have been relatively small because of their need to move from place to place, at least seasonally, to follow the water, plant, and animal resources that sustained them. Physical evidence from burial sites shows a lack of material objects, since the nomadic lifestyle left little time for the accumulation of material wealth. This evidence is interpreted as indicating that there was little social or political stratification within ancient hunter-gatherer groups compared with later, more settled or sedentary agricultural and pastoral groups.

In contrast, burial sites of the elite class in more hierarchical societies, such as ancient Egypt, are bigger, more elaborate, and filled with more nonessential items compared with those of non-elite members of society. Archaeological records also show few differences in size and condition of individual homes in ancient hunter-gatherer sites (unlike more socially hierarchical societies), and this lack of difference indicates little social stratification.

One problem with archaeological evidence is that while it can speak about the material characteristics of ancient hunter-gatherers, material wealth might not be the only basis for social stratification. There might have been ancient hunter-gatherer societies in which social hierarchy was based on hunting skill or the ability to communicate with deceased ancestors rather than on material objects, but these bases for status are more difficult to detect in the archaeological record.

To supplement archaeological evidence, travel records of European, Arab, or Mediterranean explorers and traders have been used to shed light on ancient human groups. However, these records describe the social situations of African groups only after foreigners entered Africa (around the fifth century C.E. for Arabs and the 15th century C.E. for Portuguese), and they were certainly colored by the worldview of the writers. In addition, many assumptions made about social organization of ancient hunter-gatherer groups are based on the study of modern hunter-gatherer groups. If modern groups can be used as a window into the life of ancient hunter-gatherers, a much more complete picture of social organization can be painted. One criticism of this commonly accepted technique of exploring the lives of ancient hunter-gatherers is that many aspects of life for ancient hunter-gatherers—for example, climate and available resources—were too different to make accurate assumptions.

Ethnographic studies of modern hunter-gatherers indicate that labor is divided according to gender and age, a feasible division for ancient hunter-gatherers as well. Based on these studies of modern groups it is thought that women were primarily responsible for gathering the wild roots, tubers, berries, and plants that made up the majority of the daily diet, and men were responsible for hunting to provide meat on a periodic basis. Because women carried young children long distances and breast-fed them for long periods (which often served to limit population growth), there were probably long periods of time between the birth of each child that allowed the women to do the gathering.

Hunter-gatherer bands were composed of several families often related by lineage (descendants of one common ancestor). Lineage systems are a more specific type of kinship group in which individuals and families are organized by bloodlines, often traced back to the group's founding ancestor. Today these lineages are most commonly patrilineal (familial connections and lines of descent recognized through the father's bloodline) or matrilineal (familial connections and lines of descent recognized through the mother's bloodline), although there are rare cases today where social systems recognize both lines of descent. In more hierarchical lineage systems, individuals with closer links to the founding ancestor are often granted more decision-making power. In a lineage system a council of elders is often responsible (to varying degrees) for the group decisions. It is difficult to know what importance lineage had for early hunter-gatherers and how strongly it influenced the system of hierarchy they lived within.

Lineages have often been the basis by which individuals have access to resources and groups. In traditional hunter-gathering bands, lineage determines whether individuals remain with their birth group or migrate to another group. When young men leave their parents' group to find their mates, the culture is called matrilineal; when young women leave their parents' group to live with their mates' band, the culture is referred to as patrilineal. This kind of social organization serves to diversify the gene pool and keep bands small. Bands also might have split in ancient Africa once a critical threshold for population was reached, a threshold possibly created by whether resources were available.

Although lineage is a type of kinship system, not all kinship systems are necessarily based on genetic descent. Hunter-gatherer and later agro-pastoral groups could have also been organized based on more generalized kinship relations not necessarily rooted in blood relations. In some kinship systems, subgroups have differential degrees of influence over the entire society. All societies have underlying kinship groups, but the degree to which they are the basis of organization and structure varies considerably.

Early hunter-gatherer groups often are referred to as acephalous societies, meaning they had no centralized, specialized political leader, such as a chief or a king. Informal leaders might have emerged based on skill and accomplishment, but these leaders are thought to have had little absolute control and to have led more by group support than coercion, force, or intimidation. Decisions might have been made on a consensus basis by all group members or with heads of families having a stronger vote. Consensus-based decision making was possible because of the small size of the groups.

EMERGENCE OF SEDENTARY SOCIETIES

At some point in the ancient period human groups began to experiment with domestication of animals and plants in northern Africa. The exact dates for the origins of farming and herding are not certain, since many of the early steps toward domestication of animals and plants are not detected in the archaeological record. What is detectable in the record is that increased reliance on agriculture led to more sedentary lifestyles, since agriculture requires farmers to remain in one location for at least one crop season. Once humans started manipulating the land, they realized the benefits of staying in one spot and were able to improve their ability to grow the food they needed where they needed it.

One of the earliest examples of sedentary villages is the site of Nabta Playa (western deserts of southern Egypt), some 62 miles west of the Nile River. Nabta Playa is the site of a village with permanent houses from as early as 8,000 years ago that were formally organized around a "street." This village had wells and granaries to store food; although in the beginning the majority of their diet still came from wild animals and plants, evidence of domestic animals appears as early as 7,000 years ago, and agriculture may have been adopted as early as 6,500 years ago. There are some who believe that hu-

man groups may have experimented with agro-pastoral activities in the Nile Valley prior to the Holocene.

Although many (but not all) human groups would eventually rely mostly or only on farming or herding, the transition from hunting and gathering to farming and herding was gradual, and there were long periods during which human groups continued to rely on all of these activities simultaneously. Changes in climatic conditions were instrumental in the spread and eventual dominance of herding and farming activities. Around 4,000 years ago the African continent began to dry out, which forced human groups to migrate out of the increasingly dry Sahara region into the Sahel and the oases around rivers and lakes. When people moved out of the desert areas, more and more people were compressed into smaller and smaller areas, which further encouraged development of herding and farming activities as the climate change brought a decrease in wild animals and plants. Adoption of herding and farming moved south and east, eventually reaching southern Africa around 2,000 years ago with the mass migration of the Bantu farmers across the continent that started around 1000 B.C.E. In general, in the densely forested areas of central Africa, hunting and gathering persisted much longer.

This change in livelihood strategies had profound effects on the population and organization of human groups. When human groups became more sedentary and skilled in herding and farming, populations grew even more, and people had the opportunity to accumulate material objects and build permanent structures. The increased importance of a specific area of land led to ownership of property, which in turn led to the development of rules and laws to enforce ownership rights. Over time, increases in population densities and accumulation of material possessions led to labor specialization and more and more complex social organization. Competition for resources, wealth, and social status started to increase in importance and affect social organization through the dictation of alliances based on a variety of relationships, not just family, lineage, and kinship.

Anthropologists, using more modern human groups to draw conclusions about ancient cultures, often apply E. E. Evans-Pritchard's term *segmentary societies* (coined in 1940 for his study of groups in southern Sudan) to ancient agricultural human groups. This term is commonly used to describe societies that are subdivided into groups based on kinship that are relatively equal in status. Segmentary societies are often led by elders, and participation in the collective decisions and activities is accomplished through relationships with these elders.

Another ancient system of governance and stratification was based on the power an individual was granted as a result of the size of the group loyal to him or her (that is, patron-client relationships). Kinship-based societies might have had this type of organization, which brought more (but not necessarily absolute) power over decisions affecting the entire society to individuals who had larger families or more "clients" that pledged loyalty to them.

CENTRALLY ORGANIZED HIERARCHICAL SOCIETIES

The ancient civilization of Nubia in present-day Sudan and part of southern Egypt (also known as Kush during certain periods) formed around 3100 B.C.E. This area came under Egyptian rule between 2000 and 1000 B.C.E. and as such is outside the terms of this discussion, but for much of its history it was autonomous from Egypt. (Nubia even governed Egypt from around 800 to 700 B.C.E.) From about 900 B.C.E. this civilization was based on a divine kingship, which developed from a loosely related collective of locally governed human groups. This might have been partly due to the nature of their livelihoods as nomadic pastoralists and the low population density of the region. Women appear to have had an important role in Nubian culture. Nubian queens were depicted in art as defending the nation's interests, and in religion the cult of the goddess Isis was widespread. The Nubians developed a system of writing and were also known for their skilled warrior bowmen.

The great African kingdom of Axum (present-day Ethiopia, northeastern Africa) emerged as a city-state during the first century C.E. and dominated trade in the Red Sea by around the third century C.E. This state was another centrally organized, hierarchical, sociopolitical system. The king was the leader of the political, military, and religious systems. Axum was founded in the Ethiopian highlands, which at the time was fertile ground where agricultural innovations such as terracing and the ox-drawn plow increased productivity. This civilization developed an indigenous written script, engaged in extensive trade with Arabia, and issued its own coinage. Axum gained control over other lands (including ancient Nubia) and, at the height of the empire, there was a firmly established elite class whose members surrounded themselves with luxury goods from Axum and beyond.

LESS CENTRALLY ORGANIZED AND LESS HIERARCHICAL SOCIETIES

Urban societies that appear from archaeological evidence to have been less centrally governed also existed in Africa. One example is the settlement of Jenne-jeno, which appeared sometime in the third century B.C.E. in Mali (West Africa) near the modern town of Djenné. (It reached its height around 900 C.E. in the medieval period.) Despite the apparent lack of centralized governance and rigid hierarchy, the city grew to be very densely populated with houses situated very close together, and there may have been a centralized marketplace. Households were often organized based on trade (farming, metallurgy, fishing, and ceramics). Other than the location of housing, dedication to a specific craft did not seem to indicate any hierarchical status.

It is thought that many of the pastoralists, agriculturists, and fishermen in the region around Jenne-jeno had moved from the drying-out Sahara. West African rice became an important agricultural product. Houses were made of mud bricks. Despite numerous human groups in the region and

different ethnic backgrounds, centralized, rigid hierarchical political systems did not prevail in the Niger delta. Archaeologists typically look for evidence of monumental architecture as one of the main signs of a political system ruled by one person or a relatively small group of wealthy individuals. Sites in the Niger delta offer no such evidence (with the exception of the wall surrounding the city of Jenne-jeno, which has been interpreted somewhat tentatively as a defensive structure to protect the city from floods).

In other areas of ancient Africa many nomadic and semi-nomadic pastoral groups (for example, some of the Berber—also known as Amazigh—groups) in northern Africa near the Nile delta during the first millennium B.C.E. were organized into segmentary societies characterized by social and political systems that often did not have a specified leader but that placed individuals within a series of progressively larger networks such as family, lineage, clan, and tribe. These networks played a primary governing role only when it was necessary to settle disputes with opposing networks.

The archaeological record is not as complete yet for social organization in ancient southern Africa, but it is known that around 300 to 400 C.E. sedentary groups that relied on agriculture and herding lived in villages. Many of these villages engaged in trade for goods from at least as far away as the eastern Africa coast.

ANCIENT SOCIAL ORGANIZATION IN LIGHT OF MODERN SYSTEMS

The term *chiefdom* is applied to societies in which one individual holds the decision-making power and in which his or her authority is related to his or her relationship to an important ancestor of the group (often the founder); ability to communicate with the ancestors; success in wielding the power and maintaining or improving living standards; or obtaining loyalty in a patron-client relationship through a large following. There were African chiefdoms in western Africa that were connected by a council of chiefs who shared power among many leaders representing their respective chiefdoms. Many of the southern African Bantu societies that were observed by the first European travelers (after 1400 C.E.) were organized into chiefdoms where successive chiefs inherited their position based on their lineage back to previous chiefs. Another feature of these societies was the categorization of clans in which some were less definitively associated with the royal lineage but were recognized as related enough to allow clan members to be part of the higher leadership community. In this way a system of hierarchy was established based on clan membership. However, there is little evidence from ancient times that tells when human groups developed into chiefdoms, what their social and political organization had been prior to that development, or if they had always been organized into chiefdoms.

Colonialists may have created the concept of tribe, which has been applied to African societies from the ancient past (as well as today). A tribe has been defined as a society larger

in number than a band (hundreds of individuals) that is composed of subgroups united by associations or social constructs, such as councils of elders who are members of the same age set, secret societies, warrior societies, and religious cults. Tribes often have a lead headman or less commonly headwoman, although this person may not be occupied with the task of leadership full time. The application of *tribe* and other terms to describe the social organization of human groups has often served as the focus of strife and conflict and may not be useful. These terms can hide unifying characteristics between groups and overly accentuate irrelevant differences. So although the perception of Africa as a multitude of competing tribes seems to be one that has stuck to the concept of Africa's ancient history, it is difficult to assess the accuracy of this picture.

The age-set system (known as *gerontocracy*) draws lines of distinction based on gender and age. It is a social, political, and economic system in which elders hold power. Among the modern Masai in East Africa, one age set is responsible for cattle and community safety. The individuals that carry out this service are supervised by the elders, who are male. Individuals move from one age set to another as a group, often in a very ceremonious fashion known to anthropologists as a rite of passage. For many ethnic groups in African history circumcision has been a manifestation of movement from one age set to another. Most commonly, the consensus of the entire age set determined those individuals who would emerge as leaders to act on behalf of the age set. In this system, which was and is widespread in sub-Saharan Africa, age is highly respected. This system balanced a system in which family lineage might concentrate power in a way unrelated to individual skills recognized by the group. Despite the fact that upon European contact with Africa there were many examples of this type of social organization, it is not known whether this system dominated the social organization of ancient sub-Saharan African human groups or how far back it dates.

EGYPT

BY WILLIAM H. PECK

The social structure in ancient Egypt, like almost every other aspect of Egyptian life, underwent changes over 3,000 years of history. However, the general structure of the society can be visualized as a pyramid, with the ruler at the top supported by progressively larger groups underneath. Directly below the ruler were the royal family and kin and then, in progressively larger groups, the high-level administrators, middle-level functionaries, supervisors of labor and crafts, specialized craftspeople, and finally the peasant class, made up mainly of agricultural workers, who were the base of the pyramid. This multilevel society reflected the complex bureaucracy that had begun to develop in the country as early as the emergence of a unified Egypt and was well established by the beginning of the Old Kingdom (ca. 2575–ca. 2134 B.C.E.)

KING, GOVERNMENT, AND EXTENDED FAMILY TIES

The concept of kingship is central to any discussion of Egyptian society and Egyptian civilization. The king was the absolute monarch, supreme ruler, considered a personification of a god on earth and inheritor of his position by divine right. He was not only chief executive, head of state, and commander of the military but also the chief priest and main intermediary between humankind and the gods. The king was considered responsible for guaranteeing the cosmic order of the universe by his continued attention to the gods. He ensured that the gods were pleased by the uninterrupted sacrifices and offerings made to them and the rites carried out for them in all the temples of the land. In theory, the king led all of the activities in the country, both civil and religious. In actual fact, a large bureaucracy and well-organized civil service shouldered these responsibilities as his appointed representatives. The social structure of the country was dependent on the complexities of the bureaucracy and cannot be examined without reference to the levels of governance.

In the Old Kingdom the upper level of the administration was largely based on close family relationships such that most important posts were occupied by the ruler's closest relatives. As an example, the person responsible for overseeing the construction of the Great Pyramid, King Khufu's burial monument at Giza, was Hemiunu, a cousin or nephew of Khufu. This tradition of family ties was somewhat modified and gradually relaxed as history progressed, but the king's family continued to be appointed to important posts. In the Nineteenth Dynasty (ca. 1307–ca. 1196 B.C.E.), as a further example, sons of Ramses II filled a number of key positions. One was commander in chief of the army, another was high priest of the god Ra at Heliopolis, a third was the overseer of the royal vineyards at Memphis, and a fourth was the administrator of the entire Nile delta region.

On other levels many posts and positions were hereditary, evidenced by fathers and sons who had the same titles and ranks of office. This allowed for considerable continuity and probably increased overall efficiency. The training received by a son who learned his job as an apprentice and assistant to his father was more personalized and specialized than an organized education along academic lines could be. Although family relationships played an important part in the rule and administration of the country, ambition and talent could also be rewarded. From the biographies found on the walls of tombs it is possible to trace the careers of functionaries as they rose through the various levels of the bureaucracy. While these biographies were more in the nature of a tribute or eulogy than a real life story, they did detail important accomplishments and virtually every title that the deceased might have held during his lifetime. They give a good idea of the key events in a person's career and also illustrate how mobile the society might have been.

Although the upper classes were originally created from the family and relatives of the ruler, it was still possible for

talent and ambition to be recognized. A prime example of social mobility is illustrated in the career of Senenmut, an official in the reign of Queen Hatshepsut of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.). His family origins were undistinguished, but Senenmut rose through the ranks from a relatively low position, when he may have been Overseer of the Royal Seals or Overseer of the Audience Chamber, to an appointment as tutor to the queen's only daughter. During the period when Hatshepsut reigned alone, he became the chief Steward of the Temple of the god Amun at Karnak and thus one of the most powerful and influential men of his time. He was also chief adviser to the queen and is credited as being the chief architect of Hatshepsut's mortuary temple at Deir el-Bahri. On the other hand, a reversal of fortune was also possible. In the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.), when the office of nomarch (semi-autonomous provincial ruler) was abolished, those officeholders were demoted and stripped of their rank by royal decree.

CLASS STRUCTURE

Within the pyramidal structure of Egyptian society there were essentially two clearly delineated classes for which designations in the Egyptian language have survived. The wealthy and privileged (usually termed “nobility” or “elite” in the modern literature) were the leaders in every aspect of life; the lower class included workers, farm laborers, and servants. From the few examples of communities that have been preserved, it is possible to study the evidence of this division in the arrangement of villages and towns. These arrangements generally reflect the stratification of Egyptian society into two main parts. The archaeological excavation of sites clearly shows class difference, as at el-Lahun, a village built for those constructing a pyramid in the Middle Kingdom, and at Deir el-Medina, the settlement inhabited by the artisans who excavated and decorated the tombs in the Valley of the Kings. At el-Lahun the class distinction is unmistakable because the town was divided in two by a wall that separated the district with the large and lavish villas of the administrators from the much smaller row houses of the workers.

At Tell el-Amarna in Middle Egypt, the capital built by Akhenaton during his religious revolution, about 10 percent of the dwellings are large, many-roomed structures, while the workers' houses are much smaller and simpler. But that does not necessarily mean that all the family activities took place in limited, cramped quarters. In the climate of Egypt it was possible to cook out of doors and sleep on the roof for relief from the heat as well as to sit and congregate in the narrow streets. Although the family was the basic unit of society, interaction with neighbors and community was obviously necessary for day-to-day activities and for the mutual support provided by a community.

The two basic classes, the elite or nobility and the workers or commoners, were sharply divided not only in privileges but also in responsibilities. The nobles were the administrators and governors, the members of the priesthoods, and the offi-

cers of the military. These duties brought the usual rewards of material goods, social position, and community respect. The workers were for the most part free laborers, but there is some indication of a serflike arrangement where the workers were tied to the land they cultivated. The class of individuals who were actual slaves generally consisted of enemies captured in battle, convicted criminals, and debtors. Slavery was not so common in Egypt until the New Kingdom (ca. 1550–ca. 1070 B.C.E.) when more foreign conquests made it practical to employ the growing number of captives as slaves. These defeated foreigners were used at the will of the king. Slaves captured in battle could be employed on state projects or awarded to outstanding members of the military as reward for service. The old fiction that the pyramids were built by slave labor generally has been discounted. The workers on the pyramids were essentially field hands employed generally during the period of the annual flooding of the Nile, when they were not needed to sow and reap the crops.

ORGANIZATION OF WORK AND ECONOMY

A system of *corvée* (or drafting) of workmen for state projects was used throughout Egyptian history. Members of the general population were called to duty for service in the military, for work in mines and quarries, and on state construction projects, such as the building of temples or pyramids. Drafted crews were also used to work on roads, canals, and the complex irrigation systems. This draft was so much a part of Egyptian life that a tradition of substitute figures to be buried with a workman developed for use of the spirit in the afterlife. The *shabiti*, mummy-shaped statuettes equipped with symbolic tools and baskets, were intended to magically answer for the deceased if he was called on to do any kind of draft labor in the next life.

The economy of Egypt was essentially based on agriculture. The largest landholders were the state and the temples, and a system of taxation on these lands, worked by tenants, provided the means to pay the employees of the governmental and religious institutions. All of the land of Egypt was in theory the domain and possession of the king. The system of tenant farming, where free individuals were allowed by contract to work the fields of royal or religious (temple) establishments, was vital to the national economy. In the New Kingdom, as the powers of the temple priesthoods became stronger and the temple holdings larger, tenant farming was one obvious solution to the management of temple estates. Since most of the economy was organized and controlled by the government, the workers in state institutions were dependent on rations provided for them. Many of these employees were also able to supplement their incomes by other activities carried on privately. Members of the upper class enjoyed the privilege at the pleasure of the king of owning property and estates and profiting from the produce of them. It was also possible for free men who were not members of the elite to own land and cultivate crops that could be used to sustain their families or traded for other goods. These landowners

had the possibility of moving up in the administrative ranks to offices of responsibility. This was one of the avenues of upward mobility for those not born to rank.

Coinage as it is known today did not exist in ancient Egypt until very late in its history. Weights and measures were standardized, and some metals, such as gold and silver in bars and rings, were used as one medium of exchange. Far more common was a system of barter. The basis of this trade was generally wheat so that workmen who were paid in wheat could make bread from part of it and exchange the rest for other needs. Therefore the chief measure of wealth was land and other possessions rather than some bankable instrument of exchange.

Much of the information about the material display of wealth comes from the tombs. This evidence is either in the form of the actual objects preserved for the use of the spirit in the next life or represented in wall paintings, relief carvings, or models. Lists of estates owned by the deceased with their locations occur as part of the offerings depicted in the tomb. Models of activities to benefit the spirit suggest the wealth necessary to provide the services of the craftspeople depicted in the models. In one case, the grave of a mayor of Thebes, 15 model boats were included, giving some indication that a person of his rank would be well equipped for travel on the Nile. One additional measure of wealth, in life and in the tomb, was the possession of large quantities of cloth. This could be in the form of garments or simple sheets. In the Old Kingdom there are a small number of offering reliefs that include a "linen list" detailing great quantities of linen cloth of different types and quality. In some tombs piles of folded linen have been found, giving added evidence of the use of cloth as an indication of affluence.

Craftsmen—sculptors, painters, and furniture and jewelry makers—were generally in the service of the state or the religious establishment. They enjoyed regular employment and income and were able to pass their craft occupations on to their sons. Where it was possible or desirable, they lived together in a community of others who were similarly employed. Deir el-Medina on the West Bank at Luxor was inhabited by the workers who made and decorated the tombs in the Valley of the Kings. It is the best example of a village especially intended for workers and craftsmen. As such, excavations there have produced a great deal of information about the organization of this specialized labor, the worker's family relationships, and their day-to-day activities.

NUCLEAR FAMILY, WOMEN, AND MARRIAGE

The basic nuclear family was the most important societal unit in ancient Egypt. The ancient Egyptians were especially proud of family and lineage. The family was a close-knit group of father, mother, and children not usually extended to a larger organization such as a clan. Inscriptions on statues of individuals often give parentage and sometimes grandparentage with details about the rank and title of these forebears. However, a modern understanding of the relationship

within the family is complicated because the same words in the Egyptian language were used to designate different members of the family. The word for *brother* could also be used to identify the husband, just as *sister* could also designate a wife. *Father* could easily mean a grandfather or an ancestor. Teachers were also sometimes called "father" and coworkers might be termed "brother," not signifying an actual relationship but another close affiliation or other bond. This somewhat ambiguous use of language caused earlier scholars to believe that there was a general tradition of brother-sister marriage in Egypt, but this was not the case and can rarely be proved. This confusion of language still occasionally leads to difficulties in clearly understanding of family structure.

There were exceptions to the general rules against brother-sister marriage, however. Kings sometimes did marry their sisters, and marriage with their daughters is also attested, but this was rare and had to do with providing an heir of royal blood. Likewise, only royalty enjoyed the custom of multiple wives, though commoners could have concubines as well as a wife.

Adulthood was considered to begin for women at the start of menses and for men with circumcision, performed in adolescence. For the most part, daughters lived with the family until marriage, but it was possible for sons to join others of their age group and live outside the family home. Newlywed couples might live for a time with either partner's parents, but generally this was not considered an ideal arrangement. Marriage usually took place when the man had the means to establish his own separate household. Unmarried, divorced, or otherwise single female members of the family, such as widowed mothers, divorced sisters, or maiden aunts, might live with their sons, nephews, or other close male relatives. For reasons not completely clear, two households could be joined so that two families shared living arrangements. This kind of extended family, though it was not the norm, was not unusual.

Since the family was a close-knit group, its members might be held responsible for the actions of one another. This meant that punishment might be applied for a crime committed by one to others or that family members could be held hostage to ensure the loyalty of others. It also meant that heirs could be forced to make good the debts of deceased family members. The obligations of family membership extended not only to resolving the matters of inheritance but also to securing the proper burial rites for the dead. One of the most important obligations an Egyptian had was to provide parents with the guarantees of continued life after death. This included not only the traditional preparation of the corpse (mummification) and the tomb or burial place but also the maintenance of continued rites and offerings for the spirit of the deceased.

Even though the importance of the family in Egyptian society is clear, no evidence for a formal marriage ceremony is known, and there is also no evidence that government records were registered or kept. Marriage can be characterized

as a social contract, not a legal one. It is also not clear how matches were arranged or how partners were chosen. Some marriages were arranged by parents, but there is no strong indication that the arrangement could be forced on the participants. Marriage was essentially a private affair, to which the husband and wife both agreed. Both members brought property to the union, and it was possible for the wife to maintain title to her portion. Divorce was possible, and the penalties were carefully spelled out, at least there is evidence that this was regularized in the later centuries of Egyptian history. Even though society in Egypt was clearly male dominated, women held a position unequalled in any other ancient culture. Women could own property and slaves, could manage their own affairs to a certain extent, and were even able to institute legal suits. They could also conduct businesses and engage in trade. The weaving of cloth was just one example of a home-based industry carried out by women for profit. Women also had a part in the temple cults, but those responsibilities were generally limited. There are some records of women with the title “priestess” in the service of a god, but generally the title found is “chantress” or ritual singer, attached to a particular temple.

VOCATIONS, EDUCATION, AND SOCIAL MOBILITY

Craftspeople in Egypt enjoyed occupations that were relatively secure and respected. Since coinage did not exist until late in Egyptian history, they were paid in grain and sometimes cloth or other products that could be used for barter for other necessities. On the level of the trades and crafts there is a clear gender division. Women are seen in representations of spinning and weaving, in the textile crafts. Occasionally they were also employed as potters, but sculptors, painters, carpenters, boatwrights, chariot makers, metalworkers, and jewelers are almost exclusively male.

The priesthood in Egypt was not an exclusive vocation as it is in many other cultures and in modern religious institutions. The position of priest was a rotating one, where an individual would serve for a prescribed length of time, continue to occupy his secular positions, or return to his other duties after his service was finished. Priests could also serve in several different capacities, devoted to different deities, at the same time. It was only with the growth of the power of the priesthoods in the New Kingdom that the temples became important economic powers, owning vast tracts of farmland and collecting the income from estates. With this added influence the higher levels of the clergy became managers similar to the executives of large corporations. The career of Nebwenenef, high priest of the god Amun in the early years of the reign of Ramses illustrates both service in multiple cults and concurrent civil duties. He served as high priest in the cult of the god Anhur and the goddess Hathor, Lady of Dendera, before being appointed to the priesthood of Amun. His several secular titles included “overseer of the Double House of gold and silver” (the treasury) and “chief of all the craftsmen of Thebes.” He exemplified the ability of individuals to occupy the top

levels of power and influence in Egyptian society in both the religious and governmental spheres.

In a society that had an estimated literacy rate of 1 to 5 percent, the training to acquire the ability to read and write was very important, especially where a premium was put on record keeping. Scribes were vital to every aspect of life, from the simplest duties of letter writing and keeping accounts to the greater responsibilities of serving as administrator, emissary, or ambassador. Scribes were held in high esteem, and the initial training was sought after by bright and able young people. It was mainly the children of the elite who were able to study to be scribes, but there are examples of students from the lower classes finding access to scribal schools. The subject matter was essentially designed to prepare students for practical applications and consisted of the basics of reading, writing, and applied mathematics. The scribes’ education took place in the palace or temple precincts, and its method consisted essentially of repetition and rote learning, which included the copying of classic texts. Many of the important literary texts that have been preserved, often in several versions, were copied by apprentice scribes.

There is a preserved document called “The Satire on the Trades,” a glorification of the occupation of the scribe, which is written in the form of a father’s advice to his son. In it the father describes many of the other occupations, with their obvious drawbacks, in contrast to the life of the scribe. He tells his son that other jobs are dirty or smelly or otherwise undesirable but not the life of the scribe. “You never see a sculptor sent as an emissary, but scribes are always chosen for such tasks”—a typical observation intended to make the young person devote himself to his studies. It is clear that the person with scribal training enjoyed a privileged position.

Most scribes were attached to governmental or temple service, but there is some indication that there was also a class of independent literate individuals whose services were available for hire. However, the importance of keeping accurate state records and managing the system of taxation required large numbers of specialists who were well trained. Tomb paintings and funerary models attest to the varied activities of the scribes, mainly keeping accounts of the produce of the fields for tax purposes. They are almost always depicted in twos and threes at the same work, suggesting a system of careful accounting.

THE SOCIAL ORGANIZATION OF DEATH

The stratification within Egyptian society can be illustrated with a variety of examples. A simple and obvious illustration is the size (or even the existence) of a tomb. Certainly only the well-to-do had the resources to construct or carve out tombs for burial. The very fact that an individual was buried in a tomb automatically demonstrates that he or she had wealth and influence. The ability to plan, commission, and carry out the preparation and decoration of a tomb of any size implies considerable wealth. The quality of the tomb furniture, including the mummy cases and ritual vessels, gives a

good indication of disposable capital. Even the differing sizes of private tombs imply differences in rank and status. This evidence serves to correct the notion that everyone in ancient Egypt was mummified at death and accorded a lavish burial. The truth of the matter is quite different. The remains of ordinary people were treated simply. A grave furnished with a few personal possessions was all that the lower classes could expect. The relatively small number of tombs preserved from all periods in proportion to population estimates offers yet another example of the separation between the small upper class and the much larger lower classes.

When the unlimited expenditure used for a royal burial is compared with the simple preparation for a common grave, the disparity between the two major classes in ancient Egypt becomes even clearer. The often-cited example of the material from Tutankhamen's tomb includes one coffin of solid gold that weighed 300 pounds. In contrast, the grave of a workman might have contained a bronze razor or a mirror. It is hardly necessary to add that Tutankhamen was a minor ruler who died young and was buried in a tomb prepared for someone else. It is difficult to imagine what would have accompanied such great kings as Amenhotep III or Ramses II in their burials, a reminder of the pyramidal structure of society in ancient Egypt with the supreme ruler at the apex and a gradual lessening of responsibility and wealth at each wider level below.

THE MIDDLE EAST

BY KIRK H. BEETZ

There are large gaps in modern knowledge of the ancient societies of the Near East, partly because many did not leave relics in durable materials such as stone, partly because on occasion entire peoples were wiped out with few traces of their having existed and partly because much of the modern Near East has been and still is very dangerous for archaeologists, with many important sites having been out of their reach for decades at a time.

ÇATALHÜYÜK

One ancient people whose existence was forgotten for thousands of years lived at Çatalhüyük, in south-central Turkey. The ruins of this large village or small town—its population was perhaps 5,000 to 8,000—lay undiscovered until 1958. The earliest structures so far excavated date to before 7200 B.C.E., predating sites in Mesopotamia that were long thought to be the oldest urban areas in the world. The people at Çatalhüyük seem to have left no written language, so their social organization has to be deduced from physical remains.

Çatalhüyük consisted of mud-brick houses built side by side with no streets or passageways between them, making it look somewhat like a beehive. It had no defensive walls, but attackers would have had to fight house by house to get into and through it. In effect, the houses themselves were walls. They had no doorways and rarely had windows. People

moved about by climbing through trapdoors in their ceilings and walking from roof to roof, sometimes using ladders when the roofs were uneven.

Many, perhaps even most houses had shrines in them, suggesting that religious ritual was an important part of everyday life. Some houses were much bigger than others, and the burials that are richest in goods tend to be under the floors of the larger houses, suggesting that some members of society ranked higher than others, perhaps forming a social elite group. The people of Çatalhüyük often buried their dead in their homes, under large platforms on which people could sit. Paintings on walls of headless people being picked at by vultures suggests a custom of leaving corpses out to be cleaned by scavenging birds, but many burials were of completely intact bodies, which seems to contradict the idea that corpses were picked clean before burial. Perhaps there were divergent burial customs; perhaps the paintings have another meaning. The dead were segregated by gender into separate graves, with women typically having the larger coverings and the better burial goods, suggesting that Çatalhüyük had a matriarchal society, meaning a society in which women were dominant over men. Many archaeologists believe that early societies in the region of Turkey were matriarchal.

The dwellings of Çatalhüyük are rich in manufactured products such as ceramic vessels. Excavations have revealed that these objects were created in homes. A section of each house seems to have been designated for craft work. At present, archaeologists suspect that every member of society was expected to know basic crafts such as basket weaving and home building. Çatalhüyük was abandoned sometime around 5600 B.C.E. The cause for its desertion is unknown. Some of the skeletons that have been recovered show signs of a mosquito-carried disease that may have killed many people, but this evidence does not necessarily mean that the settlement was afflicted with an epidemic. Instead, some residents may simply have come from marshlands to the south, where the disease and mosquitoes were more likely to be found.

JERICHO

Among very ancient remains are those of Jericho, in what was later known as Palestine. In about 8000 B.C.E. people built a large stone wall and a 30-foot-tall tower at this location. Archaeologists disagree over what the tower was for, with some insisting it was a watchtower, others supposing it was used for astronomical observations, and still others believing it was a defensive structure intended to protect either stored grain or a spring, or both. The tower has a sophisticated design and is not just a pile of rocks. It had an interior stairway, and its stones were fitted carefully together. The skill shown in the construction suggests that even earlier stone walls and towers must have existed somewhere in the area, since the builders at Jericho clearly were sure of their techniques.

The wall and tower are associated with human skulls that were apparently cleaned and then covered with clay sculptures of human faces, with seashells for their eyes. This treat-

ment may indicate that the builders of the wall and tower worshipped their ancestors and that the skulls represented dead leaders or priests who could be consulted by the living. An alternative possibility is that people thought they could capture and hold prisoner the spirits of the dead, forcing the spirits to do as they were ordered. Some art historians think that the tradition of realistic depictions of human beings found in such places as Egypt and ancient Greece derives from a similar ancient tradition begun in Jericho.

ERIDU

Most archaeologists point to ancient Sumer, in what is now southern Iraq, as the first broadly influential culture of the Near East, starting in the 4000s B.C.E., when city-states arose. The ancient Mesopotamians believed the city of Eridu was the oldest in the world and that it stood on the very spot where the world was created. Ancient Mesopotamian writers claimed that Eridu was founded before 72,000 B.C.E. Although it is not nearly that old, the city does seem to be the oldest yet discovered in the region of the Tigris and Euphrates rivers. At the bottommost layer of Eridu is a small shrine, which may mean that the city was built on a site already considered sacred as well as that the builders were very religious. Eridu was part of

a region archaeologists designate as southern Mesopotamia, the lands approximately south of the Diyala River, a tributary of the Tigris. Northern Mesopotamia, encompassing lands mostly near the north of the Tigris, did not come into cultural prominence until about 1900 B.C.E.

Many archaeologists dispute whether Eridu should be considered a real city, because its population probably did not exceed 9,000. To them Uruk just to the north, which at its peak in about 2700 B.C.E. had a population of at least 50,000, was the first true city. In the 4000s B.C.E., however, Eridu was the by far the largest settlement in a region in which villages of 250 or so people were regarded as notable, and it must have seemed crowded and metropolitan to the people of its era. It also represented a more complex social organization than would have been found in the villages of Mesopotamia. It did not become a capital of an empire or kingdom, and it was not even a great economic power, but it was the focus of religion for the Sumerian culture, and it therefore remained an example for the Sumerian cities that followed.

Many archaeologists have assumed that cities could not have been built without centralized leadership—for example, a king—because of the large public works projects required for building and maintaining an urban center. For the ancient

cities of Sumer these projects included streets, irrigation canals, and walls to guard against invading armies, but Eridu and other Sumerian cities until about 3000 B.C.E. probably did not have monarchs. Instead, they developed an institution that was called the *lugal*, which translates as “great man.” In a crisis such as a great flood or a war, an assembly of free citizens chose a leading fellow citizen to take charge until the crisis was over. It is possible that at some point crises came so frequently that a *lugal* was able to stay in power permanently.

Some historians call the earliest Sumerian city-states simple democracies because people in them supposedly had equal civil rights. Individual cities varied in how they organized themselves around the concept of free, socially equal citizens, but in general no one person was supposed to be born superior to another. These societies may have been matriarchal in outlook, with female ancestry being more important in identifying a person’s heritage than male ancestry and with priestesses dominating religious rituals, but gender rights seem to have been equal in matters of social standing, control of land, marriage, and divorce. Much about the social organization of Eridu’s era, about 5000 to 4000 B.C.E., is vague because of the absence of written records.

THE URUK PERIOD

The Uruk Period (ca. 4000–ca. 2900 B.C.E.) is somewhat clearer because written documents exist both from that time and from soon afterward. The period is named for the dominant city of the age, Uruk, known as Erech in the Bible. During this period men and women shared civic duties, with a man called *en* and a woman called *nin* holding chief administrative powers over a bureaucracy, each serving a term of one year. Divisions of labor seem to have been developing between the genders, with women in charge of the textiles industry, which was important to a city’s wealth through trade. Wool was the primary material.

Although some archaeologists believe that there was no social differentiation in Uruk, with all free people being equal, there is evidence of an elite group of government workers who organized and directed group activities. Governments combined civil administration and religious practices, making public service an act of faith. Although the *en* and the *nin* supposedly controlled both government activities and religious rites on behalf of the general population, the existence of a permanent bureaucracy indicates that those who knew procedures and rituals well could manipulate the short-term administrators.

Archaeologists sometimes point to physical evidence that Uruk had an egalitarian society, meaning a society in which no one had special privileges by right of birth. They note that the temples and government buildings were open, airy places with numerous large doorways that were open to the outside, so that anyone passing by could see what was taking place inside. This free access implies that the government was open to public scrutiny. Citizens could know all they wanted about government and religious business merely by observing from

a doorway or simply strolling in among the government and religious officials. From this point of view, the *en*, the *nin*, the bureaucrats, and the priests and priestesses were all accessible to any citizen and were accountable to the public for what they did.

The institution of the assembly, even though it lingered for hundreds of years after kings and dynasties appeared, is another indication of egalitarianism. The assembly originally consisted of all free people, probably including women (but excluding slaves). At some point women lost their right to vote in the assembly; exactly when this happened is unknown, and possibly they retained their right to vote in some cities long after they lost it in others. By 3200 B.C.E., however, the egalitarian aspects of Sumerian society had begun to fade. Cities had not only *ens* and *nins* as well as the occasional *lugal* but also governing boards composed of wealthy landowners. Previously burials had shown no difference in status between rich and poor, but this began to change as landowners asserted their economic power to influence society. Even so, an assembly of citizens could overrule the governing board if someone, perhaps an *en* or a *nin*, brought a board decision to a public vote, which was typically held outside in a courtyard or other large, open public space.

DYNASTIC PERIOD

During the Early Dynastic Period (ca. 2900–ca. 2340 B.C.E.) in southern Mesopotamia, permanent kingship developed, but the kings had an uneasy relationship with their subjects, who retained many of the rights they had held during the Uruk Period. Perhaps the most interesting and most unaccountable change during this period was the loss of civil rights for women. They still had some legal protections, but by and large they were owned by the men in their lives, with their wealth always controlled by a male family member.

Social organization was dominated by the *oikos*. Archaeologists use this Greek word, which means “household,” to refer to an extended family of close relatives who jointly own land and perhaps workshops. An *oikos* always had a male as its head, whose responsibilities included using family funds to support infirm family members, provide dowries, and pay fines for criminal convictions of relatives; possibly it was also his responsibility to carry out court orders for punishments of family members. One of his most important duties was to find mates for the unmarried men and women of his *oikos*. Marriages were arranged on the basis of wealth, although discrimination based on social class seems to have been rare.

By the time of Babylon’s King Hammurabi (r. 1792–1750 B.C.E.) society had divided itself into three groups: the *awilum*, the *mushkenum*, and the *wardum*. The *awilum* were landowners. They had the most political power, and as the centuries passed they came to possess most of a city-state’s wealth. They tended to hold the highest posts in government and religion, and they expected the best government jobs to go to their family members. The *mushkenum* were free people but did not own land. They retained the right to assemble in

public places, and they could vote during assembly meetings. In most places women were now excluded from these rights. The *wardum* were slaves. They consisted mostly of prisoners of war who were forced to work for the government in public works projects or were sold to private citizens. Sometimes free people were sold into slavery. The head of an *oikos* could sell family members for money; a father could sell his children or his wife or even himself to escape poverty or debts. Slaves had few rights, and everything they made belonged to their owners. In a social practice that continued at least through the Old Babylonian Empire of about 2000 to 1600 B.C.E., members of one of these classes could move to another. A member of the *awilum* could join the *mushkenum* by selling all his land, and a member of the *mushkenum* could become part of the *awilum* by purchasing land. Slaves had to be freed first but then could join either of the classes of free people.

Women held on to one principal source of power, religion. In what was probably a relic tradition of the past, certain rituals had to be performed by women. In a practice that lasted at least through the Old Babylonian Empire, women could join a *gagum*. A *gagum* was a cloister for women whose lives were devoted to the priesthood. In the Uruk Period, if these women gave birth to children it probably would have been seen as a blessing, a sign of their fertility in service to the gods and therefore a good omen for the city. After women had lost most of their civil rights, however, members of a *gagum* were forbidden to have children. In a patriarchal culture, denying them the right to bear children was a means of symbolically taking away their creative power in religious life. A member of a *gagum* who even visited a tavern was put to death because taverns were where people often met to find partners for sexual relations. The women of the cloisters may have had a small victory over their oppressors, however: They were avid writers and many, possibly most, of the writings surviving from the Old Babylonian Empire are theirs and reflect their view of their society.

Sexuality was an important part of civic life in southern Mesopotamia. Every city was believed to be sacred, and the cities themselves were worshipped. One way to increase the health of a city was to have sexual relations in it. This was considered to be a joyful activity, and people were discouraged from having sexual relations in private. Indeed, some ancient writers bemoaned the antisocial behavior of young lovers who had sex in private rather than out in the street as proper people did. On the other hand, childbirth was an occasion for anxiety because only about one in two babies lived long after birth. Women giving birth were subjects for artists, probably because giving birth was an affirmation of life in the city and among its people.

THE HITTITES

Archaeologists disagree greatly about when the Hittites migrated from southern Europe into Anatolia (modern Turkey), dating it to between 2750 B.C.E. and 1700 B.C.E. In any event, by the 1600s B.C.E. the Hittites were expanding their domain,

attacking their neighbors and raiding deep into the lands of Babylon. Their kings were remote and usually inaccessible to ordinary people, with a large bureaucracy between them and commoners. The king's palace was its own community within the broad community of the empire, with its own priests, physicians, craftspeople, and animal tenders. Princes lived within the palace's compound but in a house separate from the king's residence.

The apex of society was the king and queen. If the king died, the queen became the ruling monarch. Even while he lived, she exercised considerable control over the government bureaucracy and public ceremonies. Possibly this queenly power was a legacy of earlier matriarchal cultures in the Anatolian region, adopted by the Hittites in order to provide stability for their government: If a king died prematurely, he was succeeded by someone who already had experience of rule. Beneath the monarchs in social standing were nobles and beneath them government officials. Next in line came craftspeople and tradespeople: manufacturers of ceramics, blacksmiths, weavers, carpenters, sculptors, and the like. Farmers ranked below the craftspeople and tradespeople, and below them were slaves.

ARABIA AND ISRAEL

While the Hittites were building their empire in the northwestern Near East, another culture was making itself felt in the south. These were the people of the Arabian Peninsula. By 1154 B.C.E. the Arabs had become a significant distraction to the Kassite Dynasty (ca. 1530–ca. 1155 B.C.E.) of Babylon. The Kassite kings devoted so many resources to coping with the Arabs that the kingdom of Elam was able to invade Babylon and overthrow the Kassites.

The peoples of Arabia were nomads, herders of sheep. They raided their neighbors for food and wealth. Sometime before 1000 B.C.E. one of these groups, known as the Sabeans, settled in the region of modern-day Yemen. (The biblical place-name Sheba is derived from *Sabea*.) The Sabeans were a mercantile people, specializing in being go-betweens for the shipping of goods from Africa and the Near East to southern Asia, especially India, as well as for the return trade. They formed part of the kingdom of Axum, named for its capital city in eastern Africa.

Little is known about the social organization of the Sabeans, partly because their written language has yet to be translated and partly because during the 20th century their buildings and canals in Yemen were dismantled, the stones and bricks being used for modern house building. They had a long tradition of rule by queens and seem to have been a fairly open society for women, allowing them to become merchants as well as members of the ruling elite. Ethiopian oral tradition says that around 955 B.C.E. this legacy was abandoned when Queen Makeda was succeeded by Menelik, her son by King Solomon. Thereafter, so the oral tradition says, only men could rule. Women seem to have been limited to officiating in the worship of female gods.

King Solomon of Israel was probably viewed as something of an upstart at that time. Israel had been a backwater dominated by the Sumerian culture. Israel had a social organization similar to that of southern Mesopotamia. Women were severely limited in what they could do and were probably excluded from most religious rituals. Although Solomon's kingdom had a strong military force, merchants tended to dominate social life. Government officials seem to have been preoccupied by tasks intended to smooth trade within Israel and with other nations. The many wives of Solomon were part of the effort to gain protection for Israeli traders; the wives tended to be political brides, the marriages intended to cement goodwill between Israel and the kings and queens who were their parents. This was a common practice among Near Eastern rulers of the time. Among Israel's commoners polygamy tended to be reserved for political leaders and the rich. Enslaved women were often kept as concubines.

NEO-ASSYRIAN EMPIRE

The culture of the Near East suffered a significant upheaval with the rise of the Neo-Assyrian Empire of 934–612 B.C.E. in northern Mesopotamia. Assyria of the Old Assyrian Period (ca. 1813–ca. 1365 B.C.E.) had been primarily a trading empire with customs derived from Sumer, but the new empire was a military state in which warriors were the elite of society. Women were reduced to the status of nonhumans. They were forced to wear garments that covered them entirely, not for the sake of modesty but to symbolize their utter lack of worth. Further, the garments made clear that the women belonged to certain men, who were the only ones allowed to see them without their coverings. Female babies were often killed at birth because only male babies were valued. A woman's duties consisted of bearing male babies to supply the army and obeying her husband, father, or brothers in all matters. The Neo-Assyrian social practices toward women influenced all of the Near East and much of central Asia, even pervading some Hindu sects in India. The Neo-Assyrians created such loathing among their subject peoples that after their overthrow they were hunted down and killed for another 10 years, until they were exterminated, but the status of women in the Near East never recovered from their suppression under the Neo-Assyrian regime.

PERSIA

During the reign of Cyrus the Great from 559 to 529 B.C.E., Persia (modern-day Iran) conquered much of the Near East. The Persian government typically allowed conquered peoples to continue to live their lives as they had before, provided they paid their taxes and supplied soldiers for the Persian army. Thus, even at this late date, Sumerian customs continued to be practiced in much of the Near East. Most of what is known about Persian social customs comes from Greek writers, who tended to be very biased in their accounts because Greece and Persia were bitter enemies. From these Greek authors comes the image of the decadent oriental potentate, based on their

depictions of Persian courts as places of idle luxury and lazy nobility. One Greek historian who provided an alternative view was Herodotus, in the 400s B.C.E. According to him, the Persians were courageous fighters and intelligent statesmen.

The Persian monarch kept himself remote from his subjects, surrounding himself with impressive buildings and elaborate rituals intended to awe outsiders. He employed many artists and craftspeople who decorated his public works. The Persian social order is not clear to modern historians, but it seems that after the king came nobles, who were born to their high status. After them came governors of conquered territories and then officials who ran the day-to-day operations of the government. Among the latter were probably the generals of Persia's large armies. Persian rulers were much occupied with enhancing communications and trade within their empire, which suggests that merchants were important members of society. There were many slaves, mostly prisoners of war.

Greeks already had settled in parts of the Near East near the Mediterranean Sea, and they had made themselves nuisances to the Persians, sparking wars that made Persians and Greeks long-term enemies. From 336 to 323 B.C.E. the Macedonian king Alexander the Great conquered and occupied most of the Near East, bringing Greek culture all the way into India. Out of Alexander's conquests arose the Seleucid Kingdom (ca. 311–ca. 140 B.C.E.). Although they were Greek in outlook, the Seleucid monarchs imitated the trappings of a Persian court.

PARTHIANS

The Parthian Empire began in about 250 B.C.E. in northeastern Iran, and under Mithridates I (r. 174–136 B.C.E.) the Parthians supplanted the Seleucids through most of Mesopotamia. Although the Parthians had migrated into Iran from central Asia and had used Iran as their base for conquering much of the Near East, they made their capital city of Ctesiphon in Mesopotamia, near modern-day Baghdad, and they ruled their empire as if it were a Mesopotamian one. The first Parthian dynasty, the Arsacids, ruled from about 250 B.C.E. until they were overthrown in 226 C.E. by people from western Iran. The newcomers founded the Sassanid Dynasty, which lasted until an invasion by Arabs in the 600s C.E. Although it is sometimes confusingly called the Persian Empire, the Sassanid Dynasty had little in common with the original Persian Empire. Like the Arsacids, the Sassanids ruled as a Mesopotamian culture from Ctesiphon.

The official language of the Parthians was Greek. They derived their laws and social customs from the Near Eastern peoples they conquered, and little is known of their native customs, which had been replaced by those of Mesopotamia. Women had few rights, children were expected to follow the professions of their parents, and local cultures were compelled to provide the Parthian military with troops. The preoccupation of Parthian monarchs was war, and they often fought Greeks and Romans in the west and nomads from central Asia in the east. Despite the emphasis on military con-

quest, trade was essential to life of the empire, with numerous trade routes extending as far as China and Africa. This activity brought the rise of a merchant class whose members used their wealth to climb the social ladder by buying their way into government. Government officials, like nobles, ranked higher than ordinary members of society.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

INDIA

The earliest-known civilization in India was that of the Harappans, named by modern archaeologists for a place near one of their major cities. Although the Harappans had a written language, it survives mostly on seals, meaning that it is in fragments, and it has not yet been translated. The ancient Sumerians made only a few written references to the Harappans. Therefore, the social organization of the Harappans must be deduced from their physical remains, which consist of two or three cities and numerous towns and villages scattered throughout the valley of the Indus River, with some farther south and others farther west or north.

Mohenjo Daro seems to be the best preserved of the cities. The city was well planned, with a grid pattern for streets, a well-maintained sewer system, and separate areas for public gatherings and residences. The residential areas are divided distinctly into sections with big houses with brick walls that were laid in decorative, abstract patterns and sections with small houses with little or no fancy brickwork. To some archaeologists, these divisions mean that the Harappans had class distinctions between rich and poor. Archaeologists infer that those with small houses were oppressed by those with big houses. Nevertheless, all residential areas had the same sort of narrow streets and the same high-quality sewers, with manholes giving access to sewer repair workers in all areas. This evidence suggests that while there may have been a difference in wealth among the Harappans, the poorer Harappans had access to civic services equal to richer Harappans. Further, public areas seem to have been accessible to all.

There was a large public swimming pool, perhaps for ritual bathing. There were large buildings that may have been used for worship. Archaeologists have also discovered foundations to a long building, with air ducts to keep its interior dry, which was a huge facility for storing grain. The existence of this structure implies that food was collectively owned by the community, in turn implying that the land on which the grain was grown was collectively owned by the community. From this information, some archaeologists surmise that the Harappans had a social elite who owned all the means of production and that most people were slaves or serfs who worked the land for the benefit of the elite. Other archaeologists think the evidence indicates that the grain was kept in public trust and belonged to all.

Exactly when the Harappan culture began is not known, but it was thriving by 2600 B.C.E. and began to decline between 1900 and 1700 B.C.E.; it was eclipsed by Aryan invaders by 1500 B.C.E. These Aryans were nomadic cattle herders from central Asia who overwhelmed the Harappans, who had already been weakened by natural disasters. The era from about 1500 to about 600 B.C.E. is known as the Vedic because of the Vedas, sacred works of the Hindus that began as an oral tradition telling of the events of the Aryans' migration into northern India.

The Vedic peoples were slow to settle, preferring for hundreds of years to move their herds across the land, especially the grassy plains near the Ganges River, which ran northwest to southeast across northern India. Their culture mingled with the local cultures to become the Brahmanic social order, the basis of Hinduism. Much of the history of India is the story of the Vedic culture spreading ever southward over thousands of years. The Vedic people brought with them the caste system of social organization. A caste was a class based on birth that restricted the professions, civil rights, and marriage possibilities of people born into it. How many castes the Vedic peoples originally had is not known, but by the fourth century B.C.E., when the Vedas were written down, there were four. The top caste was that of the Brahmans, followed by Kshatriyas, Vaishyas, and Shudras. After these came the people without caste.

People born into the Brahman caste were priests and were expected to be spiritual leaders. They could not be punished for many crimes and could not be put to death or physically harmed. Even to annoy a Brahman was a crime. Sometimes, however, even a Brahman could commit a crime so vile that it had to be punished, in which case the knot of hair on the head—which in Brahman tradition was tied at the age of three years old—was cut off. This act made a Brahman a nonperson. It cut off a Brahman from all family and friends and denied a Brahman any social rights.

Many Brahmans lived off donations from members of other castes. It was considered a social obligation for members of lower castes to make gifts to Brahmans. Social customs and religious laws forbade someone to give his family's entire wealth to a Brahman, but Brahmans often received houses, even whole villages, as gifts. Giving gifts to Brahmans was thought to improve a person's karma, the spiritual energy that governed how many times a person would have to be reincarnated before becoming one with the universal spirit. Many Brahmans worked at professions that were supposed to be outside their caste. Brahmanic laws allowed them to take such jobs if they were in distress, a rule that applied to members of other castes as well.

The Kshatriyas were the caste of high government officials and warriors. Kings and nobles belonged to this caste. Such was the power of India's social organization that even at the end of the ancient era, kings were bound by the rules of their caste and usually followed the rules. Not to do so could invalidate their right to rule, but if they followed the rules

carefully, no one had the right to depose them. In actual practice, however, kings were often deposed, sometimes by their own sons.

Kshatriyas were supposed to devote themselves to the good of the nation. As warriors, they were expected to serve their king and to strive to increase the power of their king. As government officials, they were supposed to be honest and impartial when making decisions. As court officials, they were expected to be above bribery and other inappropriate influences. Brahmans did not have to pay taxes because they were expected to improve the welfare of the public through their piety, but the Kshatriyas were expected to pay taxes. Their taxes were lower than those of the lower castes, a circumstance that inspired resentment among members of lower castes. Even so, members of the lower castes were expected to be respectful toward Kshatriyas.

The Vaishyas were merchants, moneylenders, and farmers. They were expected to pay extra high taxes because under Brahmanic law it was their duty to support the Brahmans and the Kshatriyas. Even so, some Vaishyas managed to become wealthy. The Vaishyas, Kshatriyas, and Brahmans were all allowed to learn the holy writings of the Vedas, and they were twice-born, meaning that as children they underwent rituals that resulted in a spiritual birth. Shudras were barred from reading most religious works and were not allowed to be spiritually reborn. They could not participate in public religious rituals, only private ones.

Craftspeople, servants, laborers, wage earners, and minor government officials were Shudras. Some historians believe that when the Aryan nomads invaded India, they made the local peoples members of this fourth caste. The Shudras tended to be paid poorly and usually worked for the same employer from one generation to the next. The Shudras were subdivided into three groups: pure, unexcluded, or excluded. The pure Shudras could hope to read minor religious works. The unexcluded and excluded Shudras were treated with disdain. Beneath them were outcastes. Outcastes were expected to do the work that would defile members of the four castes, such as hunting, fishing, butchering live animals, executing human beings, and carrying the dead. They were not allowed to walk on roads but had to walk to the sides of roads. A Brahman could kill an outcaste with little or no penalty.

There were two kinds of outcastes that were treated better. One included people who had detached themselves from society to live as hermits, forsaking most of the pleasures of life. Such people could be respected and could even become considered holy and were often treated well. The other kind consisted of foreigners. Foreigners could be treated well, though their lack of caste meant that they could not be accepted to meals; Brahmans often could not let foreigners into their homes. There was a feast day on which foreigners and Indians were allowed to dine together, and sometimes foreigners were absorbed into castes, with foreign dignitaries joining a high caste.

Women were protected by laws, but those of lower castes could be abused by those of higher castes. A woman's word could not be taken over that of a man of her caste or higher. In matters of law, women were not to be subjected to the same severity of tortures and punishments as men. On the other hand, if they were wives or daughters of a man sent to prison, they were sent to prison as well and suffered as he suffered. A woman's testimony was usually unacceptable in court proceedings. Women often earned their own money, but those who belonged to the Brahman or Kshatriya castes were not supposed to work at menial jobs. Sometimes they had to, and they then usually worked at home weaving cloth, which they could sell to a factory. The workers at the factory were not allowed to look at the women while the transactions took place.

Rebellion against Brahmanic laws came in the form of new, rival religions. One such religion was Buddhism, which began as just a sect within the Brahmanic tradition. Buddhists rejected the caste system, holding as a tenet of their faith that any person could attain enlightenment through good deeds, religious rituals, and prayers. Some parts of India became primarily Buddhist. In those places even Brahmans had to have jobs to support themselves, and they took jobs under the rule of duress that allowed people to work outside their caste if they had to do so.

Although the rules of ancient Indian social organization sound very strict, the Brahmanic rules were not followed as scrupulously as they are now followed by many Hindus. For instance, in the ancient world marriages between castes were common, and a stigma was attached to the marriage for two generations but no more. It was possible to find Brahmans doing jobs of any of the other castes, and they were sometimes important government officials. Clever Shudras could become rich and influential.

CHINA

Knowledge of the social organization of China before the Han Dynasty (202 B.C.E.–220 C.E.) is sketchy at present. Emperor Qin Shi Huangdi (r. 221–210 B.C.E.) tried to have the records of previous governments destroyed and even had Confucian scholars executed so that they could not transmit their knowledge to later generations. He did so because he wanted history to begin with him. He wanted to eradicate bad influences from the past, and he wanted the system of legalism to replace all previous systems of government. Legalism advocated laws to govern every action a person took, even trivial actions.

For a long time the Shang Dynasty (ca. 1500–1045 B.C.E.) was thought to be a myth, the primary records of existence being the transcription of histories from the memory of a 90-year-old scholar who survived Qin Shi Huangdi's purges. Archaeological discoveries have revealed the existence of the Shang, including their written language, but most of their known writings come from bamboo sticks that were used for magical records. Much about their society must be deduced from their physical remains.

Peasants made up the vast majority of Shang society. They lived primarily in the region of the Yellow River, and the food they produced kept the empire fed. When there were public works projects, such as building roads or city walls, peasants were conscripted to do the work. They formed the bulk of Shang armies and were often forced into war. Those who marched to a part of the empire far from home rarely returned. It seems that the Shang rulers learned that they were dependent on the peasants and may have made some efforts to care for the peasants, at least well enough to keep the peasants healthy and working. A peasant was expected to devote his or her life to work, laboring every moment possible.

Like the Shang, the Zhou were warlike. Much of society during their dynasty (1045–256 B.C.E.) is still a mystery. As with the Shang, nearly everyone was a peasant. The Zhou placed nobles in charge of provinces, creating a feudal system in which the nobles had principal authority within their provinces. The lives of peasants were very hard. Nobles often took their land away from them, forcing them to pay rent for the land or to work the land as sharecroppers—people who have to give a share of their harvest to the landowner in order to be allowed to farm the land. Occasionally, a Zhou emperor would redistribute the land to the peasants, but the nobles would retake the land, often by making loans to peasants that the peasants could not repay, forcing them to forfeit their lands. During the second half of the Zhou Dynasty, the emperors had little military power and could not enforce their edicts, ending their ability to care for the peasants. The lives of peasants became so dire that some archaeologists and historians refer to their being slaves, but for all their miseries, peasants were not considered slaves. In fact, they were far higher on the social scale than were slaves.

During the Zhou Dynasty much of the pattern for Chinese social organization was set. At the top of society was the royal family, with the emperor ruling because he had been blessed by the gods. Below him were the nobles, who held their stations from the authority granted to them by the emperor. This situation meant that the nobles needed to keep the emperor even after the emperor had lost almost all his power because the nobles were accepted by the rest of the Chinese only as a result of the authority supposedly derived from a divinely appointed emperor. After the nobles came warriors, most of whom were minor nobility. After them came the peasants. During the Han Dynasty these would be the only true people of the nation. Everyone else, wealthy or not, was not socially recognized, including traders, craftspeople, servants, and slaves.

Perhaps the most socially significant change during the end of the Zhou Dynasty was the elevation of government officials in social standing. The period from 453 to 221 B.C.E. is known as the Warring States Period. During that time China's provinces had been combined into several large provinces, each competing with the others to rule all of China. The governors of these provinces took to calling themselves kings. One of these rulers was King Zheng of the Qin province in

the western part of China. Qin had already adopted legalism as its philosophy of government. In its harsh organization of life, legalism had become the tool of scholars, men educated in the intricacies of running a government with complex rules. Some of these scholars traveled through China looking for sponsors; in Qin they had attained a standing below only that of King Zheng himself.

King Zheng became Qin Shi Huangdi, and his enforcement of legalism throughout China made him hated by nearly everyone. His government officials were loathed. Legalism sought to reorganize society so that no one except the emperor was exempt from the law. People would be persuaded to behave according to legalist principles by severe punishments for violating the rules and by rewards for obeying the rules. In theory, anyone could climb the social ladder by obeying the rules. In practice, legalism was corrupt, with people unable to avoid breaking at least a few laws every day, giving the emperor an excuse to send millions of unfortunate people into slave labor camps working on the Great Wall or other construction projects as punishment for their crimes. The legalist government officials became devoted to betrayal and political scheming.

When rebellion finally came, rebels slaughtered the entire royal family, even after the emperor surrendered. It is to Liu Bang's credit that when he finally emerged as emperor in 202 B.C.E., he did not continue the bloodbath, and he did not slaughter government scholars. He was a rough man with little respect for scholars, but he did see the good sense of having educated people run government. He chose Confucians. He often made fun of them, but he allowed them to reform the laws of the empire.

Liu Bang (r. 202–195 B.C.E.) founded the Han Dynasty, and the basic social organization of the Han remained the organization of Chinese society through civil wars and new dynasties throughout the rest of the ancient era. The basic social order was the emperor, then the nobles, then government officials, and then peasants. When disasters struck, these were the people who were to be saved because they were deemed essential to the survival of the nation. Although being a peasant was still usually miserable, the Han instituted new opportunities for social mobility. One of these was the institution of 20 ranks within society. Peasants had access to the first eight, while the others were reserved for members of higher social standing. Through contributions to community welfare, hard work, and acquisition of wealth, a peasant could ascend the first eight ranks, gaining prestige and rights with each rank. Whether the government officials who devised the 20 steps intended this result or not, the system was a powerful motivational tool because it gave hope to people in a culture where respect mattered greatly. A peasant at the eighth level was a significant member of his community. Further, the ranks allowed for downward mobility. A person in the highest ranks could lose so many ranks as punishment for a crime that he fell below the eighth level and could end up beneath the peasants he had once dominated.

Another opportunity for social advancement was through education. Schools open to boys from many walks of life began in 145 B.C.E. in the province of Shu, where modern Sichuan is, when Governor Wen Weng (ca. 1231–ca. 1135 B.C.E.) opened schools to boys from throughout the province because he needed a pool of educated people from which to hire government officials. The schools of China were Confucian, and students were expected to learn the principles of the philosopher Confucius (551–479 B.C.E.) and become skilled in the sciences and the law. If a student passed tests given by the government, he could gain a government job and rise through the ranks of government, acquiring higher social rank as he did.

Girls could become educated, too, but they had to be educated in private, usually by other women. This practice limited the opportunities for education to daughters of the wealthy, nobles, and government officials. Some women were marvelously gifted and even became influential advisers to emperors. Even so, they complained about restrictions placed on them because of their gender. The women of ancient China were notable for their industriousness and contributed greatly to the economy, but they were expected to submit to the authority of men. When they rose in rank, they did so usually because their husbands rose in rank. They may have found their greatest opportunities in trades and crafts because tradespeople and craftspeople were outside official recogni-

tion, but even a woman who made herself wealthy might find that her money was not her own if she married.

JAPAN

In Japan people did not begin building an agricultural economy until about 300 B.C.E. Even in the third century C.E. they had not yet learned to irrigate their farms; they did not plant rice as seedlings and, in fact, just scattered rice seed in wet areas, such as marshes. When they first formed governments is not known, but the earliest ruler for whom there are written records, mostly Chinese, is Queen Himiko (fl. third century C.E.), who ruled a nation called Yamatai, whose people the Chinese called Wa. This culture existed in the late second century and third century C.E. The Wa lived in more than 50 small chiefdoms. It is possible that Himiko ruled by the consent of the chiefs. That she was a sorceress suggests that women held high rank in religion. Although her being the monarch implies a matriarchal society, the effort to replace her with a man after her death suggests that male chiefs wanted a male leader.

Ceramic sculptures left by the Wa indicate that they had a society with many crafts because the sculptures portray many people in everyday work. It is easy to suppose that ceramic makers were highly respected because the people of Japan had produced magnificent pottery for thousands of years.

Jōmon Period pottery, Japan (about 13,000–300 B.C.E.); the development of production techniques and decoration of this style of pottery over such a long period suggests that the country was stable and enjoyed a continuity of social organization. (© The Trustees of the British Museum)

CENTRAL AND NORTHERN ASIA

Most of what has been recorded about the peoples of central and northern Asia was written by people who hated them. Historical records are of raids by central and northern Asians on farms and towns, of rampant slaughter of civilians and theft of a year's harvest as well as of valuable goods. However, the people of those parts of Asia were among the world's greatest explorers. Several times they crossed from Asia to North America, and their descendants populated two unfamiliar continents. Many in the far north of Asia followed nomadic animal herds, as some still follow reindeer. There is little record of these far northern Asians being warlike or raiding others. They seem to have had their societies organized around the herds they followed, which were regarded as owned by everyone in the society.

Those who raided the settled peoples of Asia had ethics so different from those of the settled areas that their points of view seemed almost incomprehensible to the settled peoples. In general, such groups as the Xiongnu, who lived north and northwest of China, regarded other peoples as prey. Their societies were organized around taking what they needed to survive, either from herds of sheep or cattle or from people who grew crops and manufactured goods they wanted. Efforts to reason with them by the Chinese and Indians failed for lack of a common ground of understanding.

The Xiongnu had kings, men selected from among many tribal chiefs. Their authority was limited because chiefs would sometimes choose to disobey them. Both men and women were trained from birth to be expert horsemen, and both genders held responsibility for carrying and raising tents, providing food, and defending their camps. Within a traveling group, there seems to have been social ranking, with some people owning more cattle or horses than other people. One way for someone to raise his or her social standing was to steal horses or cattle from another tribe.

Some nomads of central Asia moved into settled territories in order to find pasture for their herds. Central Asia had been drying out for centuries when Aryans moved into India and Iran to find new grazing areas. A growth in population may have provided additional pressure to move south into new lands. The best records of their societies known to exist are the Hindu religious works the Vedas, based on the ancient oral history of the Aryan invasion of India.

OCEANIA

Very little is known of the social organization of ancient Oceania. Thus, archaeologists and historians study the customs of people of Oceania of recorded history, from the 18th century C.E. to the present, and make inferences about social behavior. Sometimes they make assumptions about social organization that lack scientific foundation, based on what they know of similar societies in other parts of the world. Thus, much that is thought to be true of ancient Oceania is subject to sometimes radical change when new evidence is discov-

ered. In general, the peoples of the ancient Pacific probably organized themselves by family relationships, with immediate relatives being the smallest social unit, followed by membership in a clan. The peoples of Tonga may have been organizing themselves into a larger social unit, a nation, during the last couple of centuries of the ancient era, when they were likely moving toward creating a monarchy and a kingdom. In Australia people probably moved across the landscape in family groups, forming larger groups only for religious observances. Elsewhere the social dynamics are murky. For instance, Indonesia almost certainly had cultures in which loyalty to one's clan was being replaced by loyalty to a monarch, but what form this change took is unknown. During the medieval era powerful kingdoms emerged on Java, suggesting that society was already organized and developing as distinct groups or nations earlier, during the ancient era.

EUROPE

BY AMY HACKNEY BLACKWELL

Although social organization is very difficult to determine from nonwritten sources, archaeologists use information from settlements and burials to infer how the ancient people of Europe structured their social relationships. The ice age hunter-gatherers before 10,000 B.C.E. were organized into bands that had only a loose connection to kinship and were based more on friendship and trust. Such groups may have coalesced at some times of the year and split apart at other times to take advantage of seasonal conditions for hunting and collecting. It is difficult to tell whether the family was a central element of social life at this time. The establishment of farming communities across Europe between 7000 B.C.E. and 3000 B.C.E. brought the emergence of distinct households, residential groups related by kinship and probably organized in a family structure. Such households were the basic building blocks of Neolithic society. Differences in status, power, and wealth were transient, and no lasting hierarchies appear to have formed.

Social structure changed in the late Neolithic and the Bronze Age, when we see for the first time clear differences in status, power, and wealth that persisted across generations. Farming households were still the fundamental basis for social structure, but starting in about 3000 B.C.E. in southeastern Europe and 2000 B.C.E. in northwestern Europe, there began to be rich burials and the accumulation of goods that marked social differences. Many archaeologists believe that the societies at this time took the form of what anthropologists call "chiefdoms," in which a small group of elite individuals and families were in control of a larger population of commoners. On the other hand, it is also possible that the lines of authority and status were not so hierarchical at first, and while some individuals may have been leaders in some spheres of activity (such as trade), others may have had leading roles in other activities (such as warfare and ritual). It is clear, however, that the complex social organization of Celtic and Germanic Europe

that is known to us from written records emerged from these formative periods centuries and millennia earlier.

Most of what is known in written sources about ancient European social organization comes from the Celtic and Germanic peoples. The Celts, or more precisely the Celtic languages, spread through Europe during the first millennium B.C.E., radiating out from the Alps of Central Europe. By 400 B.C.E. most of the people in northwestern Europe and the British Isles spoke Celtic languages. The Germanic-speaking peoples appeared in northern Germany and southern Scandinavia around 500 B.C.E. and migrated throughout Central Europe over the next 1,000 years. Although there were other language groups and accompanying cultures, Celtic and Germanic peoples predominated in non-Mediterranean Europe.

Almost every ancient European culture was organized around a tribal structure. Both Celts and Germans organized their societies around two principles: family and war. Kinship determined tribal membership and battle companions. Family relationships and skill in battle also determined an individual's position in the social hierarchy. Social institutions were designed to help people behave within the hierarchy and to maintain the peace within a warlike society.

Ancient European social organization was also largely determined by the fact that Celtic and Germanic peoples moved around frequently. The Romans observed that the Celts and Germans sometimes wandered for generations at a time, loading their wagons with their worldly goods and traveling from place to place in the forests of Central Europe. They occasionally settled in small villages and farmed the surrounding land, but they often abandoned these settlements and wandered around. Social mores facilitated this frequent movement. For example, both Celtic and Germanic people would kill old people or newborn infants if keeping them around would slow down the group too much. By the time of the Roman Empire, Celtic and Germanic societies had become fairly civilized. People lived in cities and traded with people from several nations. In this period social organization was influenced by Roman and Greek practices.

CELTS

The Celtic peoples who occupied most of Europe by the fifth century B.C.E. had a loose social structure that revolved around family and warfare. Tribes, clans, and families were the primary social groupings. The largest grouping was the tribe, or *tuath* in Irish. This group provided people with their ethnic identity. Within the tribe, people belonged to a clan, an extended family that was the real source of social organization. Nuclear families formed the smallest social group but were less significant than clans.

Celts seem to have thought of themselves first as soldiers. The chiefs of Celtic tribes were expected to be extremely brave in battle to show an example to their soldiers. Soldiers grew very close to their comrades in arms and were expected to sacrifice their lives for one another or to avenge their fallen companions. It went without saying that clan members would

rally to the aid of their fellow clansmen. If a Celtic man was insulted or murdered by someone from another clan, his kinsmen would all assume the responsibility of avenging him. This practice resulted in extended feuds between families throughout the Celtic world.

Because feuds were so common, Celtic societies created a class of men who arbitrated disputes. These men were experts in the complex body of laws (called Brehon laws in Ireland) used throughout Europe in Celtic communities. Historians believe that these laws originated among European Celtic peoples during the Bronze Age, between 2300 and 900 B.C.E. For centuries Celtic legal experts memorized the body of laws so that they could interpret them and resolve disputes. One of the main purposes of Celtic laws was to prevent the frequent blood feuds from resulting in a never-ending string of murders by forcing murderers to compensate the families of their victims. This compensation would effectively end a feud, allowing the rival clans to resume peaceful relations.

Celtic society was organized into a number of different classes. Kings and noblemen sat at the top. These men were wealthy and counted in their clans large groups of powerful kinsmen who could support them in battle. Nobles often functioned as chiefs of their tribes. The people in the clan of a nobleman's tribe owed him allegiance. The nobleman himself might owe allegiance to a higher nobleman or a king. In Ireland a number of lesser kings would owe allegiance to a single high king. Anyone who owed allegiance to someone else was required to pay that nobleman tribute every year, in the form of grain, livestock, and military assistance.

Below the noble classes there were two classes of free people (as opposed to slaves). Members of the higher class owned some movable property, such as cattle, but they did not own land. Below them were free people who owned nothing. These freemen rented land from nobles, paying rent in the form of crops and fighting for their landlords during wartime. Below the free classes were slaves captured from other tribes and free clansmen who had somehow lost their tribal rights.

Celts also ranked themselves within classes, according to age, birth, and skill and courage in battle. This social ranking helped Celtic people know how to relate to one another. They knew who owed what to whom, who could own land and who could not, and who could testify in court. Social rank determined which crimes were prosecuted and how they were punished. It even determined the sort of funeral a person would receive; chiefs were often buried with chariots and weapons as well as gold jewelry.

Two categories of Celts operated somewhat outside the usual system of rankings. Priests, called Druids, maintained the calendar and determined the dates of festivals. Druids also memorized the body of mythology and taught it to people. They served as advisers to the kings and officiated at rituals. Professional poets, or bards, composed and memorized long poems describing mythical or historical events. Nobles and kings kept bards at their courts to serve as official historians and entertainers. Bards were allowed to travel more

freely than other people and were often welcomed as visitors because they offered entertainment. Although Celtic society was patriarchal and kinship was traced through male lines, women had a fairly high position in society. They could own property, and they fought alongside men in battles.

During the first millennium B.C.E., settlement patterns varied from place to place. Many early Celts lived in small settlements that might house several extended families who farmed and hunted in the surrounding area. In the British Isles people lived in and around hilltop forts. Others lived in larger groups in towns. The people of the Hallstatt culture (1200–500 B.C.E.) lived in towns and in hill forts. Some Gallic tribes were large, amorphous groups of migrating warriors and families. They seem not to have believed that they had a homeland of their own and were willing to move long distances.

Several kings appear to have taken advantage of Celtic military skill and lack of national ties by buying their services as mercenary soldiers. In the days of the early Roman Republic (509–27 B.C.E.) the Gauls encroached on the Mediterranean world several times. Gauls of the Senones tribe, led by the chief Brennus (fourth century B.C.E.), attacked Rome in 387 B.C.E. and then immediately left; some historians believe that Brennus was hired by Dionysius of Syracuse (r. 405–367 B.C.E.) to attack Rome. In the late third century B.C.E. several thousand Gauls wandered through Thrace and were invited into Asia Minor by King Nicomedes I (r. 278–250 B.C.E.) of Bithynia, who wanted them to help him fight his brother. These Gauls settled in central Anatolia, where they became known as the Galatians.

Celtic people seem to have been trading with one another and with other Europeans long before the Romans arrived. Archaeologists have found prehistoric roads in Ireland and Germany that might have been used to transport goods from place to place. Celtic smiths used a variety of metals that had to come from other places. Celtic goods made their way throughout the Mediterranean region. Most trade among Celtic peoples was done by barter and exchange, and its primary purpose was the cementing of kinship ties and military alliances. Cattle were a particularly important form of wealth, and attempting to steal the cattle of enemies was apparently a fairly common enterprise among Celtic nobles.

The Celts did make some coins during the Roman Period, but these were of limited use, and most people preferred to hold their wealth in more tangible forms, such as gold jewelry, weapons, chariots, cloth, slaves, and livestock. As time went on and the Roman Empire grew, however, Celts became increasingly Romanized in their behavior and trading practices.

GAULS

By the time of the Roman Republic, the Celts in France and Belgium, known as the Gauls, had developed a complex society with defined territories and military alliances. Julius Caesar (r. 49–44 B.C.E.) wrote a lengthy description of Gallic life in his account of the Gallic Wars. Caesar describes three

main groups of Gauls: the Aquitani, the Galli or Celtae, and the Belgae. The Belgae appear to have been at least part Germanic, though historians do not know much about them. They were particularly warlike because they lived far from the Mediterranean world.

According to Caesar, the Gauls of his time organized themselves into tribes, which were subdivided into *pagi*. Each *pagus* was a subdivision of the tribe's overall territory; the Romans also used the term to refer to the individuals who lived in a given *pagus*. Every tribe was led by a council of elders and a single leader, either a hereditary king or an elected official. The Aeduii tribe called their king Vergobret. These kings ruled together with the councils, preventing the kings from taking complete control of their tribes.

Tribes were also organized into larger groups that contained several tribes. Although these organizations, called "*civitates*" by the Romans, encompassed large amounts of territory and had large populations, they were not equivalent to nations. The Gallic tribes occasionally united to fight a common enemy, but generally they did not get along well enough to stay together for long. The chief Vercingetorix (d. 46 B.C.E.) of the Avernii led a union of Gallic tribes in battle against the Romans in 52 B.C.E. Vercingetorix had enough authority to make alliances with other Gallic tribes and to hold supreme command of all the Gallic armies. He engineered an overarching defense strategy that would have been impossible with a looser arrangement. However, he was captured by Caesar, and the union of the tribes dissolved.

The Romans knew of numerous tribes. Gallic tribes included the Allobroges of the region near Geneva; the Aquitani of southwestern France; the Carnutes from modern Chartres, France; the Helvetii of Switzerland and southwestern Germany; the Nervii, a Belgic tribe from northern France; the Parisii, who lived on the site of modern Paris; and many others. Many of these tribes were "half-civilized," according to Roman estimations. They lived in well-organized towns and traded with their neighbors, but they did not value education as Romans did, and their governments were disorganized by Roman standards.

The Gauls who lived near the Mediterranean lived in cities, many of them elaborately fortified to serve as safe havens in battle. Gallic towns were often built on top of hills, the better to defend themselves. These cities were home to large numbers of people. Caesar calls these towns *oppida*. Each tribe might have several cities, but one would be more important than the others and serve as a capital of the tribe's territory. The Avernii were centered in a city called Gergovia. The tribe known as the Mandubii called their capital Alesia. Alesia, in particular, left behind good archaeological remains, where historians have found evidence of a thriving town that traded with outsiders, including Romans. There were many large buildings, including a number of public buildings constructed during the Roman period. Contemporary writers mention the fine metalwork produced by smiths from Alesia, and archaeologists have found artifacts confirming this account.

GERMANS

The best source on Germanic social organization is the Roman historian Tacitus (ca. 56–120 C.E.), who describes the people in his work *Germania*. Tacitus observes that family and kinship formed the strongest ties among German people. Clans and families organized themselves into tribes. Male relatives fought together. Military squadrons were composed of clans and families instead of random groups of strangers, a bond that Tacitus claims gave the Germans great courage in battle. To add to the power of family, German women and children came to watch their men fight in battle, cheering on the brave and tending the wounds of the injured. Germans were said to have dreaded being taken captive and especially to have feared having to give noble women to enemies who beat them in battle.

German government was very loose, and the Germans had nothing that could be called a state. The only time they organized into large groups was during wartime, when large numbers of Germans might fight together under a single leader. This arrangement was very flexible, allowing them to adapt to threats as necessary; some historians believe it was this flexibility that helped the Germans avoid being conquered by the Romans.

According to Tacitus, the Germans had three types of leaders: chiefs or kings, generals, and priests. Kings were hereditary; the sons of a king could hope to become kings themselves. Kings were expected to provide a good example for their people, especially in battle, but their power was quite limited. They could make certain minor decisions on their own, but for major matters the entire tribe had to participate and make a group decision. Chiefs were required to be excellent soldiers and to lead the charge in battle. Their followers, who were also their male kinsmen, were expected to defend the chiefs with their lives. It was considered a disgrace for a chief to show cowardice or for a follower to walk away alive from a battle in which his chief had fallen.

Generals were chosen based on their ability. Soldiers who proved themselves in battle and who combined courage with intelligence and energy could win the admiration of their peers and thus become military leaders. Generals, like kings, lacked arbitrary power over their soldiers and civilians.

Tacitus wrote that German priests had the most real power. Priests alone were allowed to punish people by reprimand or flogging, typically for cowardice or other error in battle. Religion was the foundation of much of German social activity. Priests organized numerous festivals. Divination was a primary method of making decisions. Priests would perform various rituals to see what the future was likely to bring, and the Germans would base their decisions on the results.

German society was hierarchical, organized roughly according to birth, age, and military might. The various chiefs were ranked by birth and military prowess, so there was a chief of the chiefs. The highest-ranking chief was the man with the most followers. The followers themselves knew their respective ranks, determined by the nobility of their lord,

their age, and their skill in battle. Young men vied to fight at the side of a chief because doing so was one of the best ways for them to advance. These young men would also walk around with a chief during peacetime because it was considered an honor for a chief to be surrounded by a large group of faithful soldiers. Chiefs solidified their power by giving large feasts for their followers. They also gave presents to their soldiers and to fellow chiefs.

Chiefs made minor decisions by themselves. For major matters, the entire tribe would consider the matter and make final decisions that the chiefs would respect. Tacitus notes that German tribal meetings were somewhat disorganized. The Germans did not have an accurate means of accounting for days and nights, so it was difficult for them all to assemble at once. Instead, they would take two or three days to assemble in one place. Then they would sit down, still wearing their weapons, and the priests would order everyone to be silent. The tribe members were then allowed to speak in order of rank, starting with the king or chief. The other participants ranked themselves by age, family, prowess in battle, or speaking ability, all of which were considered important and worthy of distinction.

According to Tacitus, German men had little to occupy themselves when they were not fighting. He wrote that they spent most of their free time either hunting or lying around sleeping. The women and old men were responsible for the daily care of the home and the production of food. Each German family had a nominal male head, usually the father, who could make decisions about family members, deciding who should marry whom and who would live where. German families lived in close quarters. Children had the run of the local clan area, whether they lived in a village or were in the midst of travels. Uncles, aunts, and other relatives were expected to help care for children. The relationship between men and the sons of their sisters was especially close; these men considered their nephews as important as their own sons. Germans also solidified family ties through the practice of fosterage, in which children went to live with relatives for a time.

The Germans had no cities. They did not even really have towns. Their villages sprung up with no plan, arising simply because groups of people all chose to build houses around the same site. Their homes were roughly built of timber, though the Germans were known to live in caves if they were convenient.

The Germans did not use actual currency, but they did have forms of wealth that allowed them to distinguish rich from poor. Germans loved gold and silver, which they wore as jewelry. Chiefs wore the best jewelry. Chiefs also used jewelry as a form of reward for faithful followers. Fine weapons were also appreciated. When couples married, they exchanged gifts of oxen, weapons, and horses.

Like the Celts, the Germans kept slaves. Slaves were typically prisoners taken in war. German slaves were allowed to live in their own homes and have families. They functioned more as tenants of their masters than as household servants.

By the end of the ancient period, the Germanic peoples had divided into numerous groups, including the Franks, the

Goths (who split into the Visigoths and the Ostrogoths), the Alamanni, the Vandals, the Suebi, and the Burgundians. The Visigoths and the Ostrogoths organized themselves into actual kingdoms in the third century C.E. Their social organization was heavily influenced by Roman culture over the next century. The two groups of Goths had kings and genuine governments and adopted Christianity, which added a church hierarchy to their society.

THRACIANS

The region north of Greece was home to various peoples who spoke Thracian languages. This area encompassed modern Bulgaria, Serbia, Romania, Ukraine, Hungary, and Slovakia. Homer wrote about the Thracians in the *Iliad*, describing Thrace as including the region bordered by the Black Sea and Hellespont to the east and the Vardar River to the west. According to the ancient Greeks, the people who lived in Thrace organized themselves into tribes led by kings or chiefs. These tribes were defined by kinship, military power, and geography.

Most people in Thrace lived in small villages and did not venture far from home. Thrace had no cities or large social groups. The region is mountainous, and travel was very difficult during ancient times. Therefore, groups of people were isolated from one another. The Greeks thought that the mountain tribes were the most warlike and uncivilized of the Thracian peoples. Thracians who lived in lower, flatter areas close to Greece were more peaceful and better informed about the larger world than those who lived in the mountains.

The only organized Thracian nation was the Odrysian Kingdom, which existed in Bulgaria, Romania, northern Greece, and the European portion of Turkey between the fifth century B.C.E. and the third century B.C.E. Its first capital was located in Edirne, Turkey. This kingdom was formed by King Teres (r. 480–440 B.C.E.), who gathered several tribes together in a rough union. Not all Thracian tribes joined the union, and though contemporary Greeks occasionally mentioned kings of Thrace, these kings did not control all tribes living in the region. Kings tried to unify the tribes, to increase both their own power within the kingdom and the power of the Thracians against kingdoms to the south, such as the Macedonians, but they had little success. In the fourth century B.C.E. the Thracian Kingdom divided into three smaller kingdoms. These smaller kingdoms proved easier for rulers to run. One of them moved its capital to Seuthopolis, Bulgaria, where its rulers kept it together for the century. The Greeks and Romans gradually colonized the area, influencing social structures. By 400 C.E. Thracian languages had disappeared, and the tribal structure had been replaced by Greek and Roman customs and styles of administration.

GREECE

BY JEFFREY S. CARNES

Greek societies were hierarchical, with clearly marked social classes and kinship groups. The place of an individual

within society was defined by birth and family connections, property or other wealth, and status, particularly with respect to citizenship. Social structures varied from one polis (city-state) to the next but tended to fall into certain basic categories; they were, moreover, subject to manipulation and change over time; as always, ideology (of class, equality, or freedom) could cover over the actual social conditions under which people lived.

FREEDOM AND SLAVERY

The most basic social distinction at all times in ancient Greece was between the free person and the slave. Greeks prided themselves on freedom, and this freedom was defined by contrast with those who lacked it: slaves in Greek cities and the inhabitants of other, non-Greek nations. Slaves made up a large percentage of the population during the Classical Period (fifth and fourth centuries B.C.E.), perhaps as high as one-third in Athens and somewhat lower elsewhere. Inscriptions show the categories of liberty that the slave was denied: freedom to live where one chooses (including the possibility of migrating to another polis), freedom to act on one's own behalf in legal matters, freedom from arbitrary capture or seizure, and freedom of action. Greeks believed that other peoples, in particular, the Persians, also lacked such freedoms. It was common to portray the inhabitants of the vast Persian Empire as slaves to the Great King while the Greeks were their own masters.

As is always the case with ideological constructs, the simple free-slave, Greek-barbarian dichotomies masked a more nuanced reality. *Eleutheria* (freedom) became the rallying cry of Sparta in its imperialist struggles with Athens, despite the fact that citizens of Athens enjoyed far greater personal liberty than did Spartans. Nor was the distinction between slave and free always hard and fast. In addition to chattel slavery, a variety of types of limited servitude existed (such as debt bondage and serfdom). As Aristotle points out, the Greek ideal of freedom also included not having to work for the benefit of another person; however, a relatively small percentage of the population could make this claim, and many free laborers must have led lives more difficult and more constrained than those of some slaves (and in some instances may even have enjoyed lesser social status). In addition, the freedoms denied slaves were also denied women, and women of higher status were more subject to male scrutiny and control and thus enjoyed less freedom than did lower-class women.

SOCIETY IN THE HOMERIC AGE

The poems of Homer (ca. ninth to eighth centuries B.C.E.) present a vivid, if idealized picture of early Greek society as it existed in the years prior to the eighth century B.C.E., told from the viewpoint of the upper classes (though with a great deal of sympathy for others). The *Odyssey* shows a world in which the self-sufficient household (*oikos*) is the basic social and economic unit. Landholders with relatively large estates dominate the political and social landscape; Odysseus, as the

largest of these landholders, is the king (*basileus*) of Ithaca. Other noble landholders compete for honor and power within Ithaca, but there exists as well the ethos of *xenia* (guest friendship), which governs relations between members of different households and different communities. *Xenia* demands that strangers be treated with respect and provides them protection, since it is viewed as a sacred bond protected by Zeus Xenios, the god of strangers. Moreover, *xenia* forges reciprocal bonds of friendship and obligation that last from one generation to the next. When a man of high status travels to a distant land, he will call upon other noblemen to provide him with shelter; the exchange of guest presents, often quite lavish ones, is customary. His descendants will be governed by the same obligations of *xenia*. The most striking example of this practice is in the *Iliad*, in which Glaukos and Diomedes meet on the battlefield. Upon learning that their grandfathers had entertained each other as *xenoi*, the two warriors refuse to fight each other and exchange armor in a gesture of mutual friendship. (Homer remarks that Diomedes gets the better of the exchange, receiving gold armor in return for bronze; this observation is perhaps a commentary on the rivalry and craftiness that might lurk behind the practice of gift giving).

The actual practice of *xenia* was perhaps less important than its ideological significance. For the upper classes it marked a way of life that set them apart from those below them. Contempt for merchants and those who make their living by trade is evident in the *Odyssey* and shows up in pro-aristocratic sources centuries later. Nevertheless, the Homeric worldview also exhibits sympathy for those of lower status. Those who overstep the limits of their class (the common soldier Thersites in the *Iliad* and the beggar Iros in the *Odyssey*) are treated harshly, but in general slaves and beggars are accorded sympathy. Being a wanderer or an exile is considered one of the worst possible fates (thus the poignancy of Odysseus's plight), especially for those who lack the safety supplied to the upper classes by the practice of *xenia*. Slavery was a condition to which anyone might be subject (piracy and warfare being common), and Homer expresses compassion for those who were subject to it. (The poems' dominant ruling-class ideology is reflected, however, in the expectation that slaves be loyal to their masters' interests.)

THE ARCHAIC PERIOD

In the eighth century through the sixth century B.C.E. the poems of Homer became the central texts for the Greeks' conception of themselves as a people (or group of peoples). During this time interest in genealogy grew, with oral or written genealogies becoming a way for noble families to trace their descent from the great heroes of the past as well as a foundation for the kinship systems that formed the basic social structures of archaic Greece. The poems of Hesiod (fl. ca. 800 B.C.E.) reflect the importance of heroic genealogies: Descent from a heroic or divine ancestor guaranteed the prestige of a particular group, whether a city or a family, and intercity alliances were made and unmade on the basis of such gene-

alogies. It was during this time that the distinction between Dorians and Ionians solidified. Greeks had always spoken a variety of dialects (Doric and Ionic among them), but it was during the early Archaic Period that these dialects took on an ethnic and political dimension. Thenceforward states could claim solidarity based on ethnicity and distant kinship, so that the fifth century B.C.E. conflict between the Spartan and Athenian Empires could be portrayed as a Dorian versus Ionian struggle.

The structure of Greek society was permanently altered by the events of the Archaic Period. A combination of factors led to material prosperity and expansion, in both colonization and trade. The influx of new wealth challenged the older aristocratic order, and colonization allowed more Greeks to possess more land, which remained the main source of wealth throughout antiquity. In many cities tyrants arose to champion the newly prosperous classes against the aristocracy; in others reforms kept the cities free from one-man rule. Material culture reveals a tendency toward equality. The rich tended to avoid ostentatious displays of wealth, and taste in art and handicrafts became relatively uniform throughout society. Literary sources reveal a flourishing debate on the nature of citizenship, wealth, and power. Some poets, such as Archilochus (seventh century B.C.E.), claim to represent the voice of the common soldier or citizen, while others, such as Theognis (sixth to fifth century B.C.E.), take a reactionary viewpoint, expressing disdain for poorer citizens' claims to social and political equality. This point of view was represented even into the fifth century B.C.E., with the odes of Pindar (ca. 522–ca. 438 B.C.E.) expressing a preference for inherited excellence over acquired skill and using the language of older aristocratic institutions such as *xenia* in an era in which they had long since lost their original significance.

The reforms of the statesman Solon (ca. 630–ca. 560 B.C.E.) in Athens illustrate the social developments of the Archaic Period. A rapidly changing economy led to a situation in which many small farmers had become heavily indebted to their landlords or even enslaved for debt. Solon abolished debt slavery, gave the tenant farmers ownership of their land, and divided the citizen body into four property classifications, with varying degrees of citizen rights. The top two classes, for example, could hold the major elected offices. The third could hold minor offices and the fourth none. All four classes could participate in the Assembly. Solon thus reestablished land ownership as the basis for citizenship, a tendency that continued throughout antiquity in many Greek states and was removed in Athens only with the advent of the democracy in 508 B.C.E. Land, however, remained the main source of wealth for citizens even in Athens, and various measures were enacted to prevent the concentration of land in too few hands.

PHRATRIES

The most significant kinship groups were the phyle (tribe) and the phratry. Membership in a phratry was determined by heredity and was normally linked to a particular place. Its

members were *phrateres*, a word derived from the Indo-European root meaning “brother.” The names of phratries normally used the patronymic (name derived from the father’s name) ending *-idai* (thus Demotionidai, “sons of Demotion”), and while membership was inherited, the phratry was thought of as a larger unit than the family; “clan” is sometimes used to translate the term. Phratries were probably in existence in Mycenaean times (ca. 1600–1100 B.C.E.) but are first mentioned in the *Iliad* and existed in many Greek cities, both Dorian and Ionian. For citizens of the Ionian cities (including Athens), phratry membership was an essential component of their Ionian identity. The creation of the phratries was traced to Ion, the hero for whom the Ionians are named, and virtually all Ionian cities celebrated a festival known as the Apatouria, which was devoted mainly to enrolling new phratry members. In some instances, phratries seem to have been subdivisions of phylae, though in most cities it seems that the two institutions were separate and overlapped.

Membership in a phratry was a necessary condition of citizenship in Athens, even after the reforms of Cleisthenes (ca. 570–after 508 B.C.E.); this practice seems to be true for other Ionian cities as well. Their functions generally reflect the notion of phratry as brotherhood or extended family. They were responsible for enrolling citizens (usually young men coming of age and occasionally naturalized citizens) and oversaw questions of legitimate descent and inheritance. The Draconian law on homicide, which dated from the 620s B.C.E. and was the only one of Draco’s (seventh century B.C.E.) laws reenacted in the fifth century B.C.E., provided that in a case of homicide, the victim’s fellow *phrateres* were responsible for supporting his family and were to take on the responsibilities of his family (including prosecuting the alleged killer) if he had no family.

Phratry membership evolved with the changing needs of the polis. In the early days phratries may have been strongholds of aristocratic privilege (though the link of phratry membership to citizenship makes this theory somewhat less likely). Phratries could split up into smaller phratries or merge (whereas the number of demes, or local communities, and phylae were fixed). In democratic Athens phratries were themselves democratic: All members voted by secret ballot, and an official called a phratriarch was elected to a one-year term. There were perhaps 30 phratries in Athens, subdivided into *genē*, whose function is less clear. Not all citizens belonged to *genē*. They seem to be self-identified groups, claiming descent from a common ancestor. In some cases priesthoods were reserved for members of a particular *genos*.

PHYLAE

Later to develop than the phratry but ultimately more important was the phyle, or tribe. Unknown in the Homeric poems, phylae were in place by the eighth century B.C.E. in most but not all Greek cities. There were two main sets of phylae in the Archaic Period: the Dorian, consisting of the Hylleis, the Dymanes, and the Pamphyloi, and the Ionian, consisting of

the Geleontes, the Hopletes, the Argadeis, and the Aigikoreis in Athens and including the Oinopes and the Boreis in other Ionian cities. The names common to various cities most likely owe to the development of Dorian and Ionian ethnic identity, thus establishing the relatively late origin of the phylae.

Phylae often served as military units or as voting constituencies. Each tribe would be responsible for providing a certain number of soldiers or entitled to elect a certain number of magistrates. Like the phratries, phylae often had subdivisions—in some cases phratries themselves, or *genē*, but more often numerical subdivisions, such as thirds, hundreds, or thousands. Phylae were less stable than phratries, perhaps because they were viewed as more strictly political divisions, lacking some of the phratries’ religious aura. Almost all cities for which we have evidence had altered their basic tribe structure by the start of the fifth century B.C.E. In some cases new tribes were added to accommodate an increase in population or an influx of immigrants; in others a political upheaval or a consolidation of several smaller communities (a process known as synoecism) provided the impetus for realignment. The Greek historian Herodotus (ca. 484–between 430 and 420 B.C.E.) tells the story of Cleisthenes (r. ca. 600–ca. 570 B.C.E.), who became tyrant of Sicyon and gave the local Dorian tribes insulting names (such as Hyatai, “pig-men”) while naming his own tribe Archelaoi (“rulers of the people”).

The best-known tribal reform is that of the Athenian Cleisthenes (grandson of the Sicyonian tyrant), which was effected in the years immediately following the establishment of the democracy in 508 B.C.E. The system was both complex and central to civic life. Attica (Athens and its surrounding territory) is one of the larger areas controlled by a polis, some 930 square miles. There existed within Attica a number of formerly independent cities (such as Marathon) that had been brought together via synoecism during the early Archaic Period. As a result, there were many local communities known as *demoi* (demes), representing villages or neighborhoods within the city. The demes were grouped into three main divisions: city demes, coastal demes, and hill demes (the inland parts of Attica), which had developed rivalries based on their perceived differences in economic interests. Cleisthenes made 30 groups (known as *trittyes*) out of contiguous demes (10 in each division), then formed 10 phylae by taking one *trittys* from each of the three divisions. The phylae were named after local heroes—Erechtheis for Erechtheus, Kekropis for Kekrops, and so on—thus distinguishing them from the older Ionian tribes (whose use was kept only for certain limited religious contexts) and marking them as a uniquely Athenian institution. The distribution of demes irrespective of geographic location had the effect of breaking down rivalries within the city so that any Athenian citizen would find himself sharing civic duties with citizens from far-flung parts of Attica.

A citizen in Athens, then, would find himself a member not only of a phratry but also of a deme, a *trittys*, and a phyle. The deme as a small-scale political unit had a substantial degree of autonomy; more important for social organization

was its status as the basic unit of citizenship. Young men were enrolled at age 18 in their deme registers, thus becoming citizens; thereafter they would be known in formal contexts by name, father's name, and deme affiliation. Thus, the statesman Pericles (ca. 495–429 B.C.E.) was known as *Perikles Xanthippou Cholargeus*, “Pericles, son of Xanthippus, of the deme Cholargos.” Although it was geographic in origin, deme affiliation was inherited and did not change if a citizen moved from one locality to another. In practice, few did move unless compelled by circumstance. The Greek historian Thucydides (d. ca. 401 B.C.E.) speaks of the forced evacuation of the countryside during the Peloponnesian War (431–404 B.C.E.) as a time when citizens felt they were leaving their own native cities to move into Athens.

The *trittys* was by far the least important of the social units. It does not seem to have had an elected governing body or officials, although *trittyes* seem to have played some part in the organization of the navy and perhaps the army. The *phylae*, however, were central to civic life, and most state institutions were organized along tribal lines. The Boule, or Council, was composed of 500 citizens, selected by lot, 50 from each tribe; the 6,000 jurors for the law courts were selected in a similar way. The tribes became the basis for military organization, and the *strategoï* (generals) who led the army and became the de facto leaders of the city, were elected annually, one from each tribe. Civic competitions (in athletics, dancing, or singing) were contested according to tribal divisions; even the great tragic festivals chose their judges with equal representation from each tribe.

STATUS AND IDEOLOGY

There existed throughout the democratic era in Athens a strong ideology of equality, which emphasized that all citizens had an equal share in the government, enjoyed equal protection of its laws, and possessed an equal right to speak freely. The typical Athenian citizen believed himself to be *metrios*, “in the middle,” neither extremely rich and powerful nor extremely poor or cut off from the governance of the city. The word does not exactly describe an economic middle class. Even well-off Athenians could be *metrioi* if they lived without extravagance or obvious arrogance. Rather, the term suggests a habit of equality and civic competence. The vast majority of Athenians were deemed capable of running the state (and, in fact, did so in turns, thanks to the large numbers of offices that were filled by lot). The free and equal status of the citizen was taken very seriously indeed. *Hubris* was the term used for the deliberate and gratuitous personal insult to a citizen's dignity, and such an insult was punishable by law. Those who committed certain crimes could be punished with *atimia* (loss of citizen rights), while those who were found guilty of making a false claim of citizen status could be taken and sold into slavery.

Officially, wealth brought obligation (higher taxes, usually in the form of expensive public services known as liturgies) rather than privilege; officially, noble birth like-

wise counted for little. Nevertheless, the rich and well-connected were, even in Athens, overrepresented in public life and enjoyed more comfortable lives. It is an open question as to what extent the rich were really in control of the state; certainly the ideology of equality guaranteed high status for middling Athenians, and most scholars believe that the common people really did have a large share in the running of the polis.

The ideology of equality among citizens was found in most other cities as well, though its practice varied greatly from one location to the next. In particular, cities with oligarchic constitutions (government in which a small number of people were in control) might restrict full citizenship to those who met certain property qualifications (often tied to their ability to undertake and pay for their own military service); in other instances, descent from some particular ancestral group was a requirement. In Sparta there was a radical social and economic equality among citizens, who were known as *homoioi* (equals). Together they owned the best land in Sparta, which could not be transferred to outsiders and which was worked by a subservient group known as helots (“the captured ones”). Spartan men devoted their lives to military training and service. After a rigorous and austere upbringing, they became members of *syssitia* (eating groups), to which each contributed produce from his ancestral land. Power was by no means equally shared. Two hereditary kingships, a body of elders, and a small group of annually elected officials essentially ruled the city, with the Assembly of Citizens having little more than veto power. Nevertheless, the Spartans viewed themselves as having an equal share in the state and remained a relatively harmonious political unit for several hundred years.

Sparta shows with particular clarity the ways in which citizenship and social status were defined in opposition to those on the outside. For Sparta to have its military society, a nonfree class of helots was necessary; in addition, there was a group called *perioikoi* (“surrounding inhabitants”), who, while free, lacked a voice in the governance of the polis. Indeed, every Greek city had in its midst a large number of non-citizens—slaves, women, local but disenfranchised freemen, and Greek and non-Greek foreigners. In the modern world, citizenship is a matter of birth or naturalization, and virtually every inhabitant of the planet is a citizen of one country or another (and sometimes more than one). For the Greeks, to be a citizen was a special and privileged status, one that entitled its possessor to a share in his government (a frequent turn of phrase in the ancient texts) and that guaranteed four basic abilities: to vote, to hold office, to fight for the polis, and to own land.

Greek cities marked out resident noncitizens in a variety of ways, often using the term *metic* (Greek *metoikos*, “dweller among”); the status of metics varied from place to place, and, as usual, Athens provides the best evidence. Any foreign residents in Athens who stayed longer than a month were required to register as metics—as such they had to pay a special

tax of one drachma per month and needed to be sponsored by an Athenian citizen. The metic enjoyed the privileges of residence at Athens—admission to theaters and festivals as well as economic opportunity—but was also liable for military service or (if wealthy enough) for expensive liturgies, without the opportunity to have a voice in making the policies that might send him to war. Most metics were of modest means—traders and craftspeople, both male and female, Greek and non-Greek—who had come to Athens to make a better living. A few were wealthy and prominent, including the orator Lysias (ca. 445–after 380 B.C.E.), whose father had come to the city to set up a large shield factory. The literary sources show wealthy metics moving easily among the upper crust of Athenian society.

The status of women in Greek society presents several paradoxes. Women were excluded from citizenship and were thus automatically of lower political status than men, yet upper-class women enjoyed not only a comfortable standard of living but also privileges appropriate to their class. The chorus of women in Aristophanes' (ca. 450–ca. 388 B.C.E.) *Lysistrata* provides an example of the privileges enjoyed by wellborn women, mainly holding certain religious offices and fulfilling specific roles in the city's religious festivals. They go on to make a further point: Women contribute sons to the city and therefore have a share in the city's well-being. The language used is similar to that for citizenship and is designed to counter the argument (found in a variety of sources dating from the time of Hesiod) that women are an economic burden to the men who are responsible for them.

Indeed, women in Athens were treated as perpetual minors, unable to own property or exercise basic legal rights and in need of a legal guardian if not under the control of a husband or a father. However, while women could not be citizens, it makes sense to speak of women of citizen class, particularly in light of Pericles' citizenship law of 451 B.C.E. Under this law citizenship was restricted to those born of two freeborn Athenian parents; thus, women were capable of passing on citizenship to their sons but could not possess it themselves. Needless to say, one effect of this law was to give all metic women—who ranged in wealth and status from the poorest vegetable seller to the most celebrated entertainer or courtesan—the same permanent outsider status as male metics. And, as noted, both women and slaves were characterized by a lack of the basic freedoms that even the lowest freeborn male took for granted.

ROME

BY MICHAEL J. O'NEAL

Rome began its existence as a small settlement on the banks of the Tiber River. The possibility that it would rule a territory that stretched across the Mediterranean Sea and northward into Europe was remote. Still, over a period of a millennium, Rome would come to shape the culture, politics, and social organization of a vast empire.

THE LEGENDARY PERIOD OF KINGS (753–509 B.C.E.)

Historians often refer to the time from 753 B.C.E., the fabled year of the founding of Rome, to 509 B.C.E., the beginning of the Roman Republic, as Rome's "legendary period." This period of Roman history is not very well documented. Most of what is known about the kings who ruled during this period comes from the later writings of the Greek historian Herodotus (ca. 484–ca. 430 B.C.E.). While much of the history of this period is based on legend, including the story of the founding of Rome by the twin brothers Romulus and Remus, archaeological evidence suggests that at least some of what Herodotus and others wrote was true.

The social organization of the earliest Romans was strongly influenced by the Etruscans, who occupied a large portion of the western coast of the Italian peninsula and swatches of territory extending northward. Not much is known about the origins of the Etruscans, but they interacted with the earliest Romans and exerted considerable social influence on them. The Etruscans were ruled by kings, and cities were controlled by nobles. Etruscan women occupied a place of equality relative to men. In the fifth century B.C.E., as Rome was extending its reach throughout the peninsula, it defeated the Etruscans in a major sea battle, and the distinct Etruscan culture began a slow decline as it was assimilated into Rome.

During this early period Rome was principally an agrarian society. The pillars of its society were family and religion. Just as an absolute monarch ruled the state, so too the early Roman family was ruled by the senior male, the *paterfamilias*, who wielded absolute power (*patria potestas*) for life. Children and the fruits of their labor on a farm were regarded as belonging to the father. A father had the legal right to kill a son or sell him into slavery if he was guilty of disloyal behavior, and fathers frequently practiced infanticide when children were born with deformities or illnesses. The father was, in effect, the chief priest of his clan, and one of his major roles was to foster worship of the gods. Romans during this period tended to be conservative, frugal people who lived simple lives.

Despite the absolute power of the *paterfamilias*, evidence suggests that families in early Rome were bound by strong ties of loyalty and warm feelings. The family and clan were the basic units of social organization. Divorce was uncommon, and women enjoyed privileges that were denied to women in Greece, Rome's rival but also its role model at the time. Daughters inherited property equally with sons, and after they married, they managed the household with a level of authority that rivaled that of their husbands. Households of the affluent were likely to include slaves, usually people who were captured in war or who were in severe debt. Slaves were relatively well treated. They could save their own money and in many cases buy their freedom. Slaves who were freed were granted citizenship, and many

stayed with the family that had owned them to work for pay in the fields or in the household.

THE ROMAN REPUBLIC (509–27 B.C.E.)

Historians refer to the period after 509 B.C.E. as the Roman Republic because in that year the monarchy came to an end and families of leading citizens ruled Rome. According to the Roman historian Titus Livius (ca. 59 B.C.E.–17 C.E.), better known to modern readers as Livy, the last of the Roman kings was Lucius Tarquinius Superbus (“Tarquin the Proud”). His son, Sextus Tarquinius, raped a Roman noblewoman named Lucretia (an event memorialized in William Shakespeare’s long poem *The Rape of Lucrece*). She told her kinsmen what had happened and demanded justice before she committed suicide. Her husband and brother led a popular uprising that expelled the ruling house and established a republican form of government with elected magistrates.

The end of the Roman Republic and the beginning of the Roman Empire is a modern distinction that the Romans themselves did not make. Modern historians variously date the beginning of the empire at 44 B.C.E., when Julius Caesar was granted complete authority as emperor; 31 B.C.E., when Octavian defeated Marcus Antonius in the Battle of Actium; or 27 B.C.E., when Octavian was granted the title *Augustus*. The precise date is not important. What is important is that over a 500-year period, Rome grew in size and influence, primarily through military conquest.

The growth in the power and military prowess of Rome is relevant to its social organization. Repeated military victories lent a great deal of prestige to Rome’s most important families and to its senators. Booty seized during military campaigns gave many Roman ambassadors and generals, who all served in the Senate, a great deal of wealth. With this wealth came a major shift in values and growing divisions and antagonisms in the social structure of the republic.

During the legendary period Romans valued frugality, modesty, public service, family, and worship of the gods. Among women, the ideal was the Roman “matron” who ruled her household and labored at crafts such as weaving. As the Roman Republic grew wealthier from conquest, a large class of nobility and statesmen became more arrogant and ostentatious. Many had traveled in the East, where they came into contact with the Greeks. They tried to imitate the Greeks by building large, elaborately decorated homes and massive public buildings. They seemed to compete with one another over who could hold the most lavish banquets or otherwise display their wealth. Women, too, began to imitate the Greeks by creating lavish lifestyles, often using inheritances from husbands or fathers who had died in warfare. This kind of ostentation got so out of hand that laws were passed allowing the state to confiscate excessive jewelry and gold.

During the Roman Republic considerable friction grew between the wealthy elites in the cities and the nation’s rural population. Many men from the countryside were recruited into the military, meaning that they were not able to tend

their fields. Then the republic embarked on a series of wars, called the Punic Wars, with the Carthaginians. During the Second Punic War, the Carthaginians’ leading general, Hannibal (247–182 B.C.E.), led an army over the Alps from Spain into the Italian peninsula, laying waste to the countryside as he went. Meanwhile, Rome was cutting down the peninsula’s forests to build ships for its navy. The result was that rural Rome was devastated. Its farms became far less productive, forcing the Romans to rely more heavily on imported grain from such places as Sicily. Many people tried to convert their farms into vineyards and olive orchards, but these types of operations required a large financial investment and years of work before they paid off.

With farm prices plummeting, many members of the Roman elite purchased land in the countryside. They used this land in part for recreational pursuits such as hunting and fishing. They also took over tracts of land that had been seized when Rome subdued other areas of the peninsula. In many cases they farmed this land, adding to their wealth, using thousands of slaves they had captured in war. Because of the greed of these landlords, the slaves were treated cruelly. The result was a series of slave revolts beginning in 135 B.C.E. The most famous of these revolts was the one led by Spartacus in 73 B.C.E.

Many rural Romans were unable to compete with the absentee Roman landlords whose land was worked by slaves. Many were forced off their land into the cities, where they could get jobs. Because of the immense amount of building taking place, jobs were plentiful, at least for a while. Most jobs were in the construction trades, as wealthy Romans built large homes and the government funded the construction of public buildings, aqueducts, and the like.

This new class of workers enjoyed the attractions that city life offered, but their relocation caused another problem for the republic: increasing difficulty finding military recruits. During the time of the Roman Republic a man had to own property to serve in the military, in part because he had to provide his own weapons and horses. As men left the countryside for the cities, they were no longer property owners, so the pool of potential military recruits was shrinking, and, given the farm crisis, those who remained on the land were reluctant to leave it for military service. The quandary for Rome was that this difficulty in manning the army came when Rome was essentially living off tribute (money paid by foreign rulers for protection and as a sign of submission) and booty seized in war. Making matters worse, Rome had to maintain armies of occupation in conquered territories. The result was a strain on the economy—Rome essentially spent its entire yearly revenue—and growing friction between social classes.

This friction between social classes not only affected the relationship between city elites and people in the countryside. It also affected social classes within the cities, especially the city of Rome itself. Two major social classes existed, the patricians and the plebeians. The patrician class included

those who could trace their ancestry back to the first Roman Senate at the beginning of the republic. They were the aristocrats, the people who enjoyed wealth, status, and political influence. The plebeians consisted of everyone else (excluding slaves). During the early centuries of the republic, only patricians could hold public office. Intermarriage between patricians and plebeians was against the law. In general, patricians thought of plebeians as a mob, as the dregs of society who in many respects were barely human. In fact, however, many plebeians were themselves landowners, and some were fairly wealthy in their own right.

Over a period of some 200 years, conflict often erupted between the patricians and the plebeians (often called plebs). According to some historical accounts, this conflict led to a number of developments, including repeal of the laws barring plebs from holding public office and intermarrying with patricians. Further, the plebs frequently threatened, in effect, to go on strike and secede from Rome. Their interests were represented by the Plebeian Council (or Plebeian Assembly), which claimed the power to pass laws, giving rise to the modern word *plebiscite*, referring to a measure voted on by the population as a whole rather than its legislature. Collectively, these developments and threats are referred to as the Conflict of the Orders; the primary source of information about this conflict is Livy and his history of Rome, *Ab urbe condita* (From the Founding of the City).

Over time, the patrician class met many of the plebs' demands so that by the early third century B.C.E., the distinction between the two classes was eroding. In fact, many members of the patrician class were falling on hard times and petitioned the government to be reclassified as plebeians so they could reduce their tax bill. (Patricians, because of their alleged wealth, paid far higher taxes.) They also tried to reclaim their fortunes by marrying into plebeian families that had become affluent through trade and commerce. The political distinctions between the two classes diminished in the later years of the republic, though the social distinction between the two survived as a matter of prestige rather than law.

It should be noted that some historians dispute Livy's account of the Conflict of the Orders. While they agree that changes took place in the republic's social order, they maintain that nothing like an organized "conflict" took place and that the plebs never threatened to secede from the republic. Historians continue to dispute the exact nature of the events that took place.

THE ROMAN EMPIRE (27 B.C.E.–476 C.E.)

During the period referred to as the Roman Empire, Roman society remained exceptionally hierarchical, though historians know more about the lives of upper-class Romans than they do about the lower classes. It is known that "Rome" was a diverse entity difficult to define. It included not only descendants of Rome's founders and earliest citizens but also large numbers of people from conquered territories who were granted citizenship, slaves and former slaves who had

been able to buy their freedom and gain citizenship, rural immigrants who came to the cities for economic opportunity, people in conquered territories who were granted some citizenship rights, and large numbers of "easterners" from Greece and elsewhere who made Rome a cosmopolitan city. While aristocratic Romans looked down their noses at foreigners, former slaves, and rural immigrants, many Romans welcomed the mix of people, seeing it as a source of strength and vitality. Many of the legal distinctions between patricians and plebeians had been eliminated, but this did not mean that social distinctions ceased to exist.

The imperial court was the center of power and influence during the empire. Senators and knights were among the most important people at court. Historians estimate that at any given time there were about 600 senators and perhaps 30,000 knights, often referred to as equestrians, or *equites*. Numerous other people, including actors and astrologers, hung around the court seeking patronage and influence. The result was a kind of feudal system, where senators and knights rewarded the loyalty of their followers and retainers with offices and money, while the followers themselves often had a train of dependents who relied on them for their living.

So rigid was this sense of hierarchy that the Roman census actually divided people into six classes based on the amount of property they owned. The senatorial class (which did not necessarily mean that a person was a member of the Senate) required ownership of at least a million sestertii, referring to a silver or bronze coin. (A sesterti was equal in value to one-fourth of a denarius. It is difficult to attach a modern value to a sesterti, but using the price of bread as a standard of value, it was equal roughly to \$5.00.) Membership in this class was based on estate ownership, and a person in this class was not allowed to engage in trade or commercial activity. The next class included the *equites*, who could engage in business and had to be worth at least 400,000 sestertii. These two were the most influential classes. Below them were three additional classes of property owners, followed by the *proletarii*, who owned no property. These census classes were important because they determined voting rights, with more voting power, of course, going to the higher classes than to the lower ones. Further, voting took place from the top down, and as soon as a majority was attained, the result was announced. Therefore, the *proletarii* rarely got to vote.

Social relationships were often based on the concept of patron and client. A patron (*patronus*) was typically a person of higher wealth, rank, status, or talent. In return for special attention and services from people of lower status, he provided them with benefits, which could include jobs or loans at low rates of interest. These patron-client relationships did not involve a single patron and a single client. These relationships formed a network, so the same patron would have numerous clients—a large retinue of clients was a sign of social status—and an individual client could have more than one patron. This social system emerged rooted in the belief that a network of mutual obligations based on status created a stable social order, one in which everyone knew their place.

The elite in Rome did not have to work. Because many owned large estates in the countryside, their source of income was secure, so they turned to public service. When they could, they lived in large villas on these estates. The elite received preferential treatment in many ways. They were able to eat fresh game meat and fish from the Mediterranean or specially stocked fishponds at lavish banquets and at everyday meals, while the diet of commoners consisted largely of beer, bread, lentils, processed fish sauce, and occasionally vegetables and bits of fruit. The elite often got away with criminal offenses and, unlike commoners, could not be tortured by the authorities if they were arrested. Even those convicted of a capital crime such as murder received preferential treatment. Commoners were thrown to beasts, crucified, or burned alive, but aristocrats were put to death relatively humanely with swords—assuming they were convicted. Among the top of the elite, the emperor heard cases and would probably have been reluctant to pronounce a death sentence on a member of his imperial court.

It has been estimated that the population of the city of Rome was about 500,000, but many scholars believe that the number was closer to a million, including a large population of slaves. An elite family lived in a single-story dwelling called a *domus*. Such a house typically had several rooms and a central courtyard. But as much as a quarter of the city of Rome was taken up with public buildings, so masses of commoners had to live in apartment buildings called *insula*. These buildings were a constant danger. The upper stories were supported by wooden beams that sometimes collapsed, and the threat of fire was ever present. Additionally, the streets were dark at night, making them dangerous and not just because of criminals. Commoners frequently discarded objects or emptied chamber pots through windows onto the street, often to the dismay of people walking below. Conditions were similar in other Roman cities, where aristocratic elites held power and commoners lived in less comfortable conditions.

Privilege among the upper classes extended to the education of children, especially boys. Early in the Roman Republic there was no system of education. Children learned what they needed to learn, usually farming, at home. But during the Macedonian Wars with Greece (215–148 B.C.E.), many Romans gained exposure to Greece and the system of education it had for its sons. Because many Romans wanted to imitate the lifestyle of the Greeks, they began to believe that Rome needed a similar education system as a means to a successful public career as an administrator or even a senator.

Wealthy Romans hired tutors for their children. For the less wealthy, private schools provided instruction in reading, writing, and arithmetic; the teachers in these schools were often Greek or Greek-speaking slaves. At the age of 12 or 13, talented students went on to attend a *grammaticus*, where they continued their studies in rhetoric, philosophy, history, literature, music, astronomy, geometry, and the Greek language. The very best students completed their studies in Athens, studying Greek oratory. In the wealthiest homes, books

were highly valued and slaves were often employed as copyists to produce a copy of a book for the home.

The lower classes of the Roman Empire consisted of a diverse set of people. They included, of course, poor citizens, but also noncitizens, slaves, and freedmen, or people who had formerly been slaves. Manual laborers were regarded as lower class, but so too were large classes of people who in modern life would be regarded as professionals. These people included craftspeople, actors, musicians, and philosophers. Many people even scorned doctors as members of the lower classes. Doctors were often hated because they did not pay taxes.

To represent their interests, members of the lower classes joined *collegia*. These were similar to modern-day fraternal lodges. They gave poor people a place where they could find social relationships. They also functioned as burial societies to ensure that poor people received proper burials. They were often under the patronage of a wealthy citizen, who provided money for banquets and other activities. Patrons also gave members of a *collegium* some measure of legal protection. In return, the *collegium* honored the patron with prayers and respect. *Collegia* were open to slaves and freedmen as well as poor citizens.

Slaves were the lowest class of Romans. Estimating the number of slaves is difficult, but historians put the number between two million and 10 million, with as many as a half million living in and around the city of Rome. Slavery was an odd institution in ancient Rome. Slavery was never based on race or ethnicity. Slaves were prisoners of war, people in debt, or people who voluntarily sold themselves into slavery as a way of escaping debt or crushing poverty to a way of life that at least provided them with shelter and food. Many people treated their slaves with great kindness; others, especially in the countryside, were cruel. A slave had no legal status and was regarded as property. A male slave was responsible for his master's welfare to the extent that if the master was murdered, the slave was put to death for failing to protect him. Yet slaves could testify in court. Many were able to save their own money and eventually buy their freedom. Perhaps the oddest thing of all was that some Roman slaves themselves owned slaves.

Slaves served their masters in many capacities. The largest class included agricultural laborers. Many slaves worked on construction projects in and around cities. Still others worked in Roman households. Many slaves were relatively well educated and had talents that led to work as barbers, schoolteachers and tutors, accountants, secretaries, hairdressers, carpenters, messengers, goldsmiths, and even doctors. The most talented and educated slaves served as architects, business managers, and civil servants in the empire's bureaucracy. Owning slaves was a mark of status. While many Romans owned just one or two slaves, with 10 or fewer being a common number for middle-class people, others owned huge numbers; the historian Pliny claimed that one slave owner he knew owned 4,000 slaves.

Freedmen were slaves who had gained their freedom. In some cases, slave owners freed slaves for meritorious

service. Some earned their freedom through service in the military. Still others were able to buy their freedom. Many freedmen continued to work for their former masters. The political rights of freedmen were limited in the early years of the empire, but their children were often able to enjoy all the rights of Roman citizenship, and the political rights of freedmen expanded later during the empire period. In some cases, the transformation from slave to prominent citizen took only one generation. Publius Helvius Pertinax, who became Rome's emperor in 193 C.E., was the son of a former slave. Many freedmen became quite wealthy through commerce, often wealthier than many members of the patrician class. Still others became wealthy through bribery and fraud in civil service jobs.

The experiences of women in ancient Rome were mixed. They did not have direct political power. While other nations in the region were at one time or another ruled by women, Rome never had a woman emperor. In some cases, such as that of Augustus and his wife, Livia, women served as advisers and could exert a great deal of indirect influence over public matters. Additionally, women could own property, including estates and commercial enterprises, giving them some measure of economic power. Otherwise, women were expected to serve primarily as managers of the home and family, which often included not only their own children but also the children's spouses and children. Women were highly visible in public; in contrast to Greece, they were never sequestered from life in public. Overall, upper-class women were expected to live up to the ideal of the virtuous, dignified Roman matron. In upper-class families, girls were given some measure of education, but they did not take part in advanced studies alongside men. Little is known about the lives of lower-class women, though archaeological evidence strongly suggests that many worked as midwives, food sellers, and nurses and in crafts production, including jewelry, leatherwork, and textiles.

THE AMERICAS

BY MICHAEL J. O'NEAL

Archaeologists and historians generally agree that the first human inhabitants of the Americas arrived about 30,000 years ago, possibly earlier. At that time the earth was much colder than it is today. Large glaciers, often a mile thick, had pushed southward as far as present-day Ohio and Indiana. Because so much of the world's water had turned to ice, sea levels were much lower than they are now. As the seas fell, a large bridge of dry land opened between the eastern tip of Asia and the western tip of Alaska in North America. That bridge is now submerged under the Bering Sea.

Historians speculate that the first Americans were Siberian hunters who were simply following game across the land bridge—entirely unaware that they were the first humans to set foot on a new continent. (Because the land bridge was roughly 1,000 miles wide from north to south, they would

not have thought of it as a “bridge” at all, but as a vast stretch of open country.) In time other hunters followed, and by about 8000 B.C.E. humans had migrated as far as the southern tip of South America. Clearly, when Christopher Columbus “discovered” America, he was only establishing contact between Europe and the Americas, which had been inhabited for thousands of years.

When the first migrants arrived, the Americas were entirely uninhabited. Groups of people were able to spread out and live in nearly total isolation from one another, although occasionally trade and barter took place between nearby groups. The result was the existence of a large number of distinct cultures and language groups, including the many tribes of Native Americans in what are now Canada and the United States and similar bands in present-day Mexico and Central America and South America. (In contemporary usage *Native American* refers to the tribes that inhabited, and still inhabit, the United States, such as the Apache, Sioux, and other familiar groups. In a larger historical context, though, the term refers to any of the many groups of people who occupied North, Central, or South America before the European contact—including, for example, the Maya and the Toltec.) Historians estimate that northern Mexico alone was home to between 300 and 350 distinct language groups. Because of the immense diversity of social groups any general statement about their social organization has to be supplemented with more specific statements about the organization of any particular group.

THE AMERICAS IN PREHISTORY

Unfortunately for historians, the archaeological record for the vast majority of early Native American groups is either sparse or nonexistent. Before about 12,000 B.C.E. most of the social groups of the Americas were hunter-gatherers. They moved from place to place following sources of food and left behind only the sparsest evidence of their presence—for example, burial sites, bones, and a few stone tools. Almost everything they made with nondurable materials has long since decayed and disappeared. They had no writing systems.

From 12,000 to about 5000 B.C.E. the record holds a little more detail, giving historians a somewhat better picture of how people lived and enabling them to offer a few generalizations about social organization among ancient Americans. They believe that Americans in these years lived in hunter-gatherer bands of perhaps up to 100 members. The bands were based on kinship, and their members assumed that they all had a common ancestor. Occasionally, when they felt threatened by natural conditions or by aggression from other groups, several bands would forge alliances with one another, forming a loose community of perhaps 1,000 people. Neighboring bands sometimes traded with each other, and they also cemented alliances through intermarriage, primarily because each band wanted to maintain a rough equivalence in the number of men and women. Only in this way could they ensure the bearing of children to sustain the population

and continuity of the band. For the most part, however, individual bands were self-sufficient.

The social organization of these bands was essentially egalitarian, meaning that no person or group of persons held a higher status or social position than others because of birth, though, of course, a person could achieve status through greater skill as a hunter. Because the groups were constantly on the move, following food supplies and seasonal changes, opportunities to accumulate possessions were few. People lived in caves or built temporary shelters out of perishable materials, and for the most part they owned only what they could carry.

Accordingly there was little sense of caste or social class within these bands. Men typically hunted, often leaving the settlement for days at a time (but carefully avoiding encroachment on the territory of other bands). Women stayed

near the settlement to rear children and to gather plant foods. In coastal communities or those near major bodies of fresh water fishing and the collection of shellfish were important sources of food. (Parts of ancient Mexico and the southwestern United States were much cooler and wetter than they are in modern times, so the region contained larger and deeper inland bodies of water.)

To say that a culture is egalitarian does not mean that status differences do not exist. In what is today the southwestern United States along the Rio Grande there lived numerous Pueblo peoples. One of these groups made up the ancestors of a culture that came to be called the Tewa. The ancestral Tewa were an egalitarian society, and yet status differences were part of their culture. The Tewa identified levels of earthly beings, as well as levels of inhabitants of the spirit world. The top rung of earthly people, for example, included the *patowa*,

HOW DO ARCHAEOLOGISTS KNOW?

How can archaeologists detect something as abstract as an “egalitarian ethic” in a society with no written historical records and only a sparse and incomplete archaeological record? How can they look at bones or tools or pieces of pottery and make statements about the social relationships and organization of people who lived thousands of years ago?

In the case of a hunter tribe one specific technique that archaeologists use is to examine such objects as arrowheads and spear points. These points, made of stone, have survived through the millennia, while the wooden spear shafts, arrows, and the like have long since decayed and disappeared. These stone objects may not be writing, but they can tell a story about the people who made them in much the same way that a written account can.

In examining points used on hunting weapons, archaeologists are interested in at least three different things. First they examine the style of each point they find, looking for points that were probably made by the same person. An arrowhead or spear point is like a small sculpture, with a style unique to the person who made it. Such matters as size, shape, and the way the sharp edge was formed come into play. Archaeologists can sort the points found in an area according to the individual styles in which they were made.

Second, archaeologists try to determine how many people in a community made points for hunting weapons. Sometimes they find a number of points, but all seem to have been made by the same person or perhaps by just two people. In other cases they find a variety of styles, suggesting that numerous people made points and perhaps even that each hunter was responsible for making his own.

Finally, archaeologists are interested in where the points are located. If they find points made by a particular hunter in a narrow geographical zone, they can infer that use of those points was restricted to the hunter who made them, along with perhaps a limited number of others in his band. If the points are found over a wider geographic zone, they can infer that the points were used by a wider range of people in the band and perhaps even in other bands.

In Mexico’s Oaxaca Valley, for example, archaeologists have discovered that the same small band of hunters made use of six or seven distinguishable styles of points. This tells them that each hunter in the band was responsible for making his own points; a smaller number, perhaps one or two, would suggest that one or two people had responsibility for making points for all the members of the hunting group.

In other societies the existence of unique points, each made by an individual hunter, suggests that a point could be used to identify the hunter who made the kill; this in turn could determine who got the meat. Among the people of the Oaxaca Valley, however, the existence of six or seven unique points found over a relatively wide geographic area strongly suggests that points were exchanged with friends and relatives. Points, then, could not have been used to identify the successful hunter, since several hunters may have been using the same point. For the same reason, the points could not have been used to determine who could lay claim to the meat. The effect was to diffuse meat distribution. Put simply, it did not matter who made the kill; the meat was equally distributed to everyone. Archaeologists can infer that the social organization of the band was egalitarian, with no one person seen as deserving more game meat than any other because of higher social status.

or “Made People.” These were ritual leaders who earned their position through their skills and service to the community. They served as intermediaries between the earthly and spiritual realms. These people achieved their position by climbing through ranks or orders, starting with the “scalp” society and continuing through the “hunt,” “warm clown,” and “bear medicine” societies. These “societies” were in the nature of fraternal orders. At the bottom of the social order were the Dry Food People. These were ordinary citizens who had no official position. The Made People could choose to select ritual assistants from among the Dry Food People. While serving as assistants these people acted as mediators between the Dry Food People and the Made People. The key point is that rank and prestige were earned by service and skill, not birthright.

MESOAMERICAN SOCIETY

The most extensive archaeological record in the Americas exists for the people of Mesoamerica (Mexico and parts of Central America) beginning about 2500 B.C.E., although the roots of these civilizations extended even farther back in time. Some Mesoamerican civilizations were highly advanced. They built immense cities—cities larger than were, for example, Paris or London at the time the first Europeans arrived in the Americas—and had many of the characteristics usually thought of as belonging to modern societies, including government bureaucracies, systems of writing, calendars, sophisticated art and architecture. Because of the depth and detail of the historical and archaeological record, historians know more about the social organization of the Mesoamerican cultures than they do about those of other ancient American civilizations.

Between roughly 5000 and 2500 B.C.E. life in Mesoamerica began to change dramatically. The major change was a shift from hunter-gatherer societies to societies whose major source of food was cultivated plants. Plant cultivation required an entirely new way of life, for agriculture demands that people remain in one place for all or much of the year, rather than roaming from one place to another in search of game.

When people settle to grow food and tend plots of land, they form communities, and some of these communities eventually grow into cities. The cities, however, cannot provide their own food, so they come to rely on the surplus grown by surrounding rural areas. This surplus supports a larger and growing class of priests, artists, engineers, civil servants, and others who are not directly involved in the production of food. Further, it supports the existence of an elite that holds power, making decisions for the community as a whole. The result in the ancient Americas was the development among these cultures of a social order that differed from that of their hunter-gatherer ancestors, a social order that included a high-level class or ruling elites, a middle class of artisans and craftsmen, and a lower class of farmers and peasants.

Historians are not certain why this change took place. One theory emphasizes population growth: A larger number of people rendered hunting and gathering no longer practical, for

Double-spout-and-bridge vessel with pelican and fish, Nasca culture of Peru (ca. 200 B.C.E.–ca. 600 C.E.); birds played an important role for Nasca people, and bird feathers were used as ornaments for people of high social rank. (© The Trustees of the British Museum)

hunter-gatherer bands would be stumbling across one another, leading to competition and to the depletion of game. Others attribute the shift to ecological change. Much of the Mesoamerican region became more arid at this time, requiring people to find ways to produce and store their own food supply and to domesticate plants that could survive in the more desertlike climate. The best example is corn, which was developed from a wild plant (though botanists are not sure which plant). Over time people experimented with seeds from corn plants, developed varieties that could grow in the area’s unique conditions, and turned corn into a major subsistence crop.

In discussing ancient Mesoamerica, historians conventionally identify three major periods. The first, the Preclassic, extended from about 1800 B.C.E. to about 150 C.E. (The Classic and Postclassic Periods came later and gave rise to the great civilizations of the Aztec and the Maya.) The Preclassic Period itself is typically divided into three subperiods: the Early Preclassic, from 1800 to about 1200 B.C.E.; the Middle Preclassic, from 1200 to 400 B.C.E.; and the Late Preclassic, from 400 B.C.E. to 150 C.E. These dates are approximate, and each Mesoamerican culture underwent changes at its own pace. The divisions, though, enable historians to make meaningful generalizations about the social organization and other characteristics of Mesoamerican culture.

During the Early Preclassic Period social organization remained much as it was during the region’s prehistory. Cultures tended to be egalitarian, without any rigid social order

or inherited social power. People lived in tribal communities consisting of hamlets of perhaps 20 or so huts built near the fields the inhabitants tended. No one's hut was much better or worse than anyone else's. Much of the society's activity centered on agriculture and seasonal changes in the weather. Most communities were entirely independent, but some contact and trade occurred as one community, because of ecological factors, was able to produce a commodity useful to a neighboring community that was unable to produce it for itself.

It was during the Middle Preclassic Period that a social order began to develop. Throughout Mesoamerica important changes took place, particularly in agriculture. People began to control the environment by building bridges, dams, and canals to store and channel water. They began not only to grow and harvest larger crops but also to grow a greater variety of crops. Further, they began to specialize. Each microregion increasingly focused on the crops that were best suited to the local conditions and then traded with other communities for crops that were better suited to those communities' environments. Ultimately, a greater abundance of food enabled some people to specialize in nonagricultural activities, such as pottery making.

Along with this increased prosperity and technical innovation came social stratification, meaning that a social hierarchy began to develop. (The word *stratification* comes from the Latin *strata*, meaning "layers.") For example, archaeologists studying the Olmec civilization of the Gulf Coast of Mexico have discovered that this society was the first in Mesoamerica to bury some people in more elaborate tombs, filled with richer funerary offerings, than they buried most of the population. Surviving art depicts people wearing sumptuous clothing, and it appears that the elite came to place high value on clothes made from exotic materials, often imported from far-flung locations. Further, archaeologists have discovered a considerable number of artifacts that could have been owned only by higher-class, wealthier people. These artifacts include ceramics made with rich and various colors, mirrors made with exotic minerals, figurines made of greenstone, cinnabar powder (used as a pigment), and jewelry made of semiprecious stones, shells, and bones.

Historians have offered many theories about why social stratification took place. Most of the theories have to do with the control of precious resources. Some people may have achieved a higher status because they had better access to valued resources. Others may have acquired special skills that had value as populations became larger and denser. Others may have possessed particular knowledge about agriculture or waterworks or some such useful subject. Still others may have acquired control over networks for trade and exchange with other communities, becoming the Americas' first entrepreneurs and business moguls. Finally, some belonging to a priestly class may have been thought to have special divine or supernatural powers.

No matter what the cause, it is likely that kinship groups played a role, as families acquired resources or means of so-

cial control that were passed down through the generations. Thus power and social status were now inherited rather than earned, as they had been in earlier societies. Another important factor was the development of writing systems. The ability to write—and therefore to record history, myth, and political information—placed power and prestige in the hands of an educated few.

THE ZAPOTEC

The shift toward stratified societies is illustrated by the Zapotec people of the Oaxaca Valley of Mexico, whose civilization began to flourish in about 600 C.E. and who built a number of large cities. The Zapotec believed that there was a genealogical connection between people and the spirit world. In other words, they believed that certain people had divine origins. This belief was rooted in the Zapotec cosmology—the branch of thought that deals with the history and origins of the universe.

The Zapotec believed that there were two realms, that of the earth and that of the sky. The earth was generally kind, but it occasionally expressed anger, primarily through earthquakes. The celestial realm, too, was generally kind, but it expressed anger through bolts of lightning and thunder—a thunder roll was called "lightning's earthquake." Highly stylized images depicting earthquakes and lightning began to appear on the earliest Zapotec pottery. These images appear on burial pottery, but only for males—suggesting to archaeologists that the Zapotec believed that the earth and sky were the ancestors of some male descent groups.

Other evidence supports the notion that Zapotec civilization was marked by status differences. One is called the "mat" motif. It is believed that the civilization's rulers showed their status by not allowing their feet to touch the ground. Unlike ordinary people, the elite wore sandals rather than going barefoot; they sat on benches, thrones, or stools, and they placed reed mats on the floors when they held an audience with others. Pottery illustrates all of these behaviors.

Burial position also can provide clues about social status. Archaeologists have excavated a number of Zapotec cemeteries, and their findings shed light on the status of the people buried there. In one cemetery most of the people were buried in a prone position with a jade bead in the mouth and a modest collection of pottery in the tomb. Their arms were at their sides. However, six people, all men, were buried in a kneeling position. Archaeologists believe that these men, as well as people in other cemeteries who were buried in a sitting position or with their knees drawn up (perhaps seated on stools that have since decayed), were of higher status and probably rulers. Those buried prone were in a subordinate position. Similar differences in burial practices have been found in other parts of Mesoamerica. In Panama, for instance, the bodies of chiefs were first dried out in a smokehouse and then buried in common graves.

Cranial deformation, or reshaping of the head, is another mark of social status. In human infants the cranium

(skull) is pliable and flexible. Among the Zapotec, cranial deformation was regarded as a sign of nobility. Typically, a few days after being born a noble infant was placed on a bed and its head was tightly compressed with boards. This gave the head an elongated appearance. The key point about this practice is that it shows hereditary rank. Clearly, an infant is not able to achieve high status through skills or service, so cranial deformation was practiced only on highborn children. Cranial deformation is easily spotted in skeletons found in tombs.

Differences in housing also suggest differences in status. Excavations of Zapotec hamlets have uncovered different types of houses. Some of the houses were modest; they were not very well made, the poles supporting them were slender, and walls were not covered with whitewash. Artifacts found in these structures suggest a simple life and include sewing needles, a few modest ornaments, and little in the way of minerals, pottery, and so on that would indicate affluence. Some other houses were larger, more elaborate, and more solidly constructed and had whitewashed walls. Some had lean-to roofs similar to the roof covering a deck or porch on a modern house. More important, artifacts found in these houses suggest a more affluent life. These artifacts include articles for use in crafts, such as minerals, basket-weaving tools, imported pottery, mother-of-pearl, jewelry, ceramic masks, shells, jade beads, and so on. Through their skill in crafts, the people who lived here occupied a higher status and thus had more comfortable and elaborate houses.

THE MAYA

One of the best-known ancient American civilizations is that of the Maya, whose roots extended back into the first millennium B.C.E. but who flourished from the fourth through about the tenth centuries C.E. For a long time archaeologists and historians believed that the Maya lived in an egalitarian society. They thought that Mayan rulers assumed positions of leadership on a rotating basis and that heredity was not a

source of power. That view, however, changed after excavation of a major Maya site at Tikal, in modern-day Guatemala. The archaeological evidence strongly suggests that Mayan society was rigidly organized, with an elite class of rulers, a servant class, middle classes of artisans and civil servants, and a lower class of laborers and peasants.

Archaeologists discovered, for example, marked differences in housing, with elites commanding more space and privacy provided by stairways, screens, and gates. They also discovered elaborate royal residences. Burial practices, too, were stratified, with the elites buried in larger tombs, often engineered to keep earth from seeping in, and the tombs containing a larger number of decorative artifacts.

The skeletons of people buried in these tombs also reveal indications of class differences. Working much like the scientists who examine evidence at crime scenes, archaeologists have found differences in wear and tear on joints, differences in bone length, and cranial deformation, all suggesting an elite royal class that enjoyed a better diet, less physical labor, and longer life. Evidence of certain inherited diseases and other physical conditions suggests that certain families intermarried, indicating, in turn, that these were elite families who used intermarriage as a way of preserving power and status.

~ Herodotus, excerpt from *The Histories* (ca. 430 B.C.E.) ~

BOOK IV

The Libyans dwell in the order which I will now describe. Beginning on the side of Egypt, the first Libyans are the Adyrmachidae. These people have, in most points, the same customs as the Egyptians, but use the costume of the Libyans. Their women wear on each leg a ring made of bronze; they let their hair grow long, and when they catch any vermin on their persons, bite it and throw it

away. In this they differ from all the other Libyans. They are also the only tribe with whom the custom obtains of bringing all women about to become brides before the king, that he may choose such as are agreeable to him. The Adyrmachidae extend from the borders of Egypt to the harbor called Port Plynus. Next to the Adyrmachidae are the Gilligammae, who inhabit the country westward as far as the island of Aphrodisias. . . . The customs

(continued)

(continues)

of the Gilligammae are like those of the rest of their countrymen.

The Asbystae adjoin the Gilligammae upon the west. They inhabit the regions above Cyrene, but do not reach to the coast, which belongs to the Cyrenaeans. Four-horse chariots are in more common use among them than among any other Libyans. In most of their customs they ape the manners of the Cyrenaeans. Westward of the Asbystae dwell the Auschisae, who possess the country above Barca, reaching, however, to the sea at the place called Euesperides. In the middle of their territory is the little tribe of the Cabalians, which touches the coast near Tauchira, a city of the Barcaeans. Their customs are like those of the Libyans above Cyrene.

The Nasamonians, a numerous people, are the western neighbors of the Auschisae. In summer they leave their flocks and herds upon the sea-shore, and go up the country to a place called Augila, where they gather the dates from the palms, which in those parts grow thickly, and are of great size, all of them being of the fruit-bearing kind. They also chase the locusts, and, when caught, dry them in the sun, after which they grind them to powder, and, sprinkling this upon their milk, so drink it. Each man among them has several wives, in their intercourse with whom they resemble the Massagetae. The following are their customs in the swearing of oaths and the practice of augury. The man, as he swears, lays his hand upon the tomb of some one considered to have been preeminently just and good, and so doing swears by his name. For divination they betake themselves to the sepulchers of their own ancestors, and, after praying, lie down to sleep upon their graves; by the dreams which then come to them they guide their conduct. When they pledge their faith to one another, each gives the other to drink out of his hand; if there be no liquid to be had, they take up dust from the ground, and put their tongues to it. . . .

Above the Nasamonians, towards the south, in the district where the wild beasts abound, dwell the Garamantians, who avoid all society or intercourse with their fellow-men, have no weapon of war, and do not know how to defend themselves. These border the Nasamonians on the south: westward along the sea-shore their neighbors are the Maceae, who, by letting the locks about the crown of their head grow long, while

they clip them close everywhere else, make their hair resemble a crest. In war these people use the skins of ostriches for shields. . . . Adjoining the Maceae are the Gindanes, whose women wear on their legs anklets of leather. Each lover that a woman has gives her one; and she who can show the most is the best esteemed, as she appears to have been loved by the greatest number of men.

A promontory jutting out into the sea from the country of the Gindanes is inhabited by the Lotophagi, who live entirely on the fruit of the lotus-tree. The lotus fruit is about the size of the lentisk berry, and in sweetness resembles the date. The Lotophagi even succeed in obtaining from it a sort of wine. The sea-coast beyond the Lotophagi is occupied by the Machlyans, who use the lotus to some extent, though not so much as the people of whom we last spoke. . . .

The next tribe beyond the Machlyans is the tribe of the Auseans. Both these nations inhabit the borders of Lake Tritonis, being separated from one another by the river Triton. Both also wear their hair long, but the Machlyans let it grow at the back of the head, while the Auseans have it long in front. The Ausean maidens keep year by year a feast in honor of Minerva, whereat their custom is to draw up in two bodies, and fight with stones and clubs. They say that these are rites which have come down to them from their fathers, and that they honor with them their native goddess, who is the same as the Minerva (Athena) of the Grecians. If any of the maidens die of the wounds they receive, the Auseans declare that such are false maidens. Before the fight is suffered to begin, they have another ceremony. One of the virgins, the loveliest of the number, is selected from the rest; a Corinthian helmet and a complete suit of Greek armor are publicly put upon her; and, thus adorned, she is made to mount into a chariot, and led around the whole lake in a procession. . . . These people do not marry or live in families, but dwell together like the gregarious beasts. When their children are full-grown, they are brought before the assembly of the men, which is held every third month, and assigned to those whom they most resemble.

Such are the tribes of wandering Libyans dwelling upon the sea-coast.

From: Herodotus, *The History*, trans. George Rawlinson (New York: Dutton and Co., 1862).

Asia and the Pacific

~ Arrian, excerpt from *Anabasis Alexandri*
(*Campaigns of Alexander, second century C.E.*) ~

BOOK VIII (INDICA)

XI. The Indians generally are divided into seven castes. Those called the wise men are less in number than the rest, but chiefest in honour and regard. For they are under no necessity to do any bodily labour; nor to contribute from the results of their work to the common store; in fact, no sort of constraint whatever rests upon these wise men, save to offer the sacrifices to the gods on behalf of the people of India. Then whenever anyone sacrifices privately, one of these wise men acts as instructor of the sacrifice, since otherwise the sacrifice would not have proved acceptable to the gods. These Indians also are alone expert in prophecy, and none, save one of the wise men, is allowed to prophesy. And they prophesy about the seasons of the year, or of any impending public calamity: but they do not trouble to prophesy on private matters to individuals, either because their prophecy does not condescend to smaller things, or because it is undignified for them to trouble about such things. And when one has thrice made an error in his prophecy, he does not suffer any harm, except that he must for ever hold his peace; and no one will ever persuade such a one to prophesy on whom this silence has been enjoined. These wise men spend their time naked, during the winter in the open air and sunshine, but in summer, when the sun is strong, in the meadows and the marsh lands under great trees; their shade Nearchus computes to reach five plethra all round, and ten thousand men could take shade under one tree; so great are these trees. They eat fruits in their season, and the bark of the trees; this is sweet and nutritious as much as are the dates of the palm. Then next to these come the farmers, these being the most numerous class of Indians; they have no use for warlike arms or warlike deeds, but they till the land; and they pay the taxes to the kings and to the cities, such as are self-governing; and if there is internal war among the Indians, they may not touch these workers, and not even devastate the land itself; but some are making war and slaying all comers, and others close by are peacefully ploughing or gathering the fruits or shaking down apples or harvesting. The third class of Indians are the herdsmen, pasturers of sheep and cattle, and these dwell neither by cities nor in the

villages. They are nomads and get their living on the hillsides, and they pay taxes from their animals; they hunt also birds and wild game in the country.

XII The fourth class is of artisans and shopkeepers; these are workers, and pay tribute from their works, save such as make weapons of war; these are paid by the community. In this class are the shipwrights and sailors, who navigate the rivers. The fifth class of Indians is the soldiers' class, next after the farmers in number; these have the greatest freedom and the most spirit. They practise military pursuits only. Their weapons others forge for them, and again others provide horses; others too serve in the camps, those who groom their horses and polish their weapons, guide the elephants, and keep in order and drive the chariots. They themselves, when there is need of war, go to war, but in time of peace they make merry; and they receive so much pay from the community that they can easily from their pay support others. The sixth class of Indians are those called overlookers. They oversee everything that goes on in the country or in the cities; and this they report to the King, where the Indians are governed by kings, or to the authorities, where they are independent. To these it is illegal to make any false report; nor was any Indian ever accused of such falsification. The seventh class is those who deliberate about the community together with the King, or, in such cities as are self-governing, with the authorities. In number this class is small, but in wisdom and uprightness it bears the palm from all others; from this class are selected their governors, district governors, and deputies, custodians of the treasures, officers of army and navy, financial officers, and overseers of agricultural works. To marry out of any class is unlawful—as, for instance, into the farmer class from the artisans, or the other way; nor must the same man practise two pursuits; nor change from one class into another, as to turn farmer from shepherd, or shepherd from artisan. It is only permitted to join the wise men out of any class; for their business is not an easy one, but of all most laborious.

Europe

~ Julius Caesar, "The Germans," excerpt from
De bello Gallico (The Gallic Wars, ca. 51 B.C.E.) ~

21. The customs of the Germans differ widely from those of the Gauls; for neither have they Druids to preside over religious services, nor do they give much attention to sacrifices. They count in the number of their gods those only whom they can see, and by whose favors they are clearly aided; that is to say, the Sun, Vulcan, and the Moon. Of other deities they have never even heard. Their whole life is spent in hunting and in war. From childhood they are trained in labor and hardship.

22. They are not devoted to agriculture, and the greater portion of their food consists of milk, cheese, and flesh. No one owns a particular piece of land, with fixed limits, but each year the magistrates and the chiefs assign to the clans and the bands of kinsmen who have assembled together as much land as they think proper, and in whatever place they desire, and the next year compel them to move to some other place. They give many reasons for this custom—that the people may not lose their zeal for war through habits established by prolonged attention to the cultivation of the soil; that they may not be eager to acquire large possessions, and that the stronger may not drive the weaker from their property; that they may not build too carefully, in order to avoid cold and heat; that the love of money may not spring up, from which arise quarrels and dissensions; and, finally, that the common people may live in contentment, since each person sees that his wealth is kept equal to that of the most powerful.

23. It is a matter of the greatest glory to the tribes to lay waste, as widely as possible, the lands bordering their territory, thus making them uninhabitable. They

regard it as the best proof of their valor that their neighbors are forced to withdraw from those lands and hardly any one dares set foot there; at the same time they think that they will thus be more secure, since the fear of a sudden invasion is removed. When a tribe is either repelling an invasion or attacking an outside people, magistrates are chosen to lead in the war, and these are given the power of life and death. In times of peace there is no general magistrate, but the chiefs of the districts and cantons render justice among their own people and settle disputes. Robbery, if committed beyond the borders of the tribe, is not regarded as disgraceful, and they say that it is practiced for the sake of training the youth and preventing idleness. When any one of the chiefs has declared in an assembly that he is going to be the leader of an expedition, and that those who wish to follow him should give in their names, they who approve of the undertaking, and of the man, stand up and promise their assistance, and are applauded by the people. Such of these as do not then follow him are looked upon as deserters and traitors, and from that day no one has any faith in them.

To mistreat a guest they consider to be a crime. They protect from injury those who have come among them for any purpose whatever, and regard them as sacred. To them the houses of all are open and food is freely supplied.

► sports and recreation

INTRODUCTION

The word *recreation* suggests the idea of “re-creating,” or “creating again.” In turn, this suggests that recreation serves to reinvigorate and strengthen people so that they can face life’s trials. Sports and recreation in the ancient world were in many senses forms of “re-creation.” Sports, for example, often served ceremonial purposes. Sporting events were frequently held in conjunction with religious festivals. Sometimes these events were staged to symbolize the creative powers of the gods. In other cases they reaffirmed the power and authority of a ruler and reinvigorated him to continue his rule. In some cultures, sporting events were held in connection with funerals as a way of honoring the dead. In the ancient Americas a ball game that bore characteristics of soccer and basketball held a ceremonial purpose. The participating teams were engaged in a literal life-and-death struggle, for the losing team might be ritually sacrificed to the gods.

While cultures throughout the world used balls for games, the ancient Americans, having discovered rubber, were the only ones to use rubber balls. In other parts of the world, balls were typically either stone or made by wrapping an animal skin around straw or a similar material. The ancient Chinese developed a game in which balls were hit with sticks into holes in the ground, a precursor of golf.

Sports and recreation were also regarded as a way of training a person for such activities as hunting and military service. The ancients knew what modern people know: that running, rowing, and other strenuous activities build muscle and increase endurance. Running, for example, was a necessary part of the training of couriers, who carried news of the progress of battles to commanders. Indeed, the modern 26.2-mile marathon recreates the legend (which is probably untrue) that an Athenian ran 26 miles to carry the news from Marathon to Athens that the Greeks had defeated the Persians in the Battle of Marathon in 490 B.C.E. In many cultures young men being initiated into the adult community had to prove their mettle by taking part in long races and similar challenging activities.

Some ancient cultures developed the concept of the spectator sport—that is, a sporting event people watched but in which they did not participate. In this regard the Romans led the way. In the Roman Empire people gathered in arenas that closely resemble modern football stadiums to watch mock hunts, contests between gladiators, chariot racing, animal exhibitions, and even brutal executions of criminals (suggested by the common phrase “throwing him to the lions”). For private recreation ancient Roman and Egyptian men went to gyms, often with the chief purpose of associating with other men.

Common sports in the ancient world included horse racing, boat racing, wrestling, track-and-field events (such as foot races and discus and javelin throwing), boxing, and archery. People who lived near bodies of water swam for sport and recreation. Other forms of entertainment included board

games, dice, gambling, dancing, and bathing at public baths, where people could relax in the company of others.

AFRICA

BY KIRK H. BEETZ

In ancient Africa sports and games seem to have been important. What is known about African sports in earlier centuries, however, can be gleaned only from tenuous hints, some of which linger in the customs of modern Africans. For example, wrestling seems to have been a favorite pastime for some ancient Africans, because old wrestling traditions survive into modern times among some Bantu-speaking peoples. How prevalent wrestling was in ancient Africa and how important it was to society probably cannot be known. Still, it is apparent that young men in some places tried to prove their strength and social worthiness by grappling with others. Like ancient African warfare, wrestling matches could be very stylized events, with opponents moving as if choreographed by a set of rules designed to display their skills. Blood probably was rarely shed, and pinning an opponent’s shoulders to the ground was enough for victory. It is possible that some groups—particularly those in which women chose their mates—used ritualized wrestling to show off marriageable men to marriageable women.

Racing was possibly a sport in ancient Africa; in North Africa especially, racing horses, camels, and elephants might have been popular. Among the ruins of ancient Kush, a kingdom along the Nile River south of Egypt, there is a large complex of buildings that may have housed elephants. The elephants would have been a type more easily trained than the African elephants from farther south. Near the ruined buildings is an area where these elephants may have been raced.

Most ancient African games involved numbers. Traders and nomads of North Africa, in the Sahara and along the steppes south of the desert, seem to have had games involving guesses at how long it would take to reach a certain place and word games involving the counting of words, perhaps to form a particular phrase. Number systems and number patterns were sometimes used in rituals for foretelling the future, and number and word games may have been played for the amusement of seeing what sort of predictions could be made with them.

Most ancient African games that modern people know anything about involved mathematics. There seems to have been a general cross-cultural fascination with mathematics that attracted people from all sorts of walks of life in almost all parts of Africa. Other sorts of games probably existed, but of those only game boards without rules remain, and it is possible that even boards that do not imply mathematical contests nonetheless involved mathematics. Boards from Kush and Axum are sometimes beautifully inlaid with ivory and variously colored woods. An interesting aspect of these boards is that even though their rules are long forgotten, the tradition of gaming with boards is so deep within modern

cultures that a person seeing a relic from ancient Africa could easily recognize it as something people played games with.

Some African mathematical games were very simple, so lacking in complexity that whoever started first was the probable winner. Such games may have been used to teach children how to count and how to do simple addition and subtraction. Other games may have been intended to teach multiplication and division. Others involved such complex reasoning that they may have kept adult minds sharp for the complicated business of trading with outsiders, which could require people to keep in mind several different quantities of different goods along with how much they were asking or offering for the goods. Successful bargaining often depended on all the involved traders understanding and agreeing on numbers derived from hours of negotiations.

One of the oldest games is now called morabaraba. Its origins are obscure, but it spread through herding communities in northern, eastern, and southern Africa. It may be the ancestor of the European game called nine-man Morris. According to tradition, it was a way for African elders to teach young people how to steal livestock, especially cattle. The basic idea is to capture an opponent's cattle while moving one's own cattle toward the opponent's edge of the board. A cow is captured by lining up in a straight line three of one's own cattle in front of a cow of the opponent.

An interesting aspect of morabaraba and other ancient African games is that a game board could be drawn on the ground. All the players needed was a fairly flat, open area of sufficient size for both them and the board. Even when boards were fashioned from stone, clay, or wood, these materials were readily available, so play could begin at almost any time—an indication of how much some ancient Africans loved their games. Some boards were made to fold up to hold game pieces and be easily carried.

One of the most popular types of games in Africa is the sowing game, so named because its premise is planting seeds for crops. The general name for all such games is mancala. Although sometimes a game is sold in the Western world as mancala, the word actually was meant to refer to all sowing games. The name derives from *naqala*, which is Arabic for “to move.” Sowing games probably originated in eastern Africa, perhaps in the ancient kingdom of Axum. They spread through most of Africa, along southern Asia to Indochina, and along the Mediterranean coast to southern Europe. In ancient Africa both men and women played these games avidly.

The games were probably originally played on the ground, with holes dug in rows and stones, seashells, or seeds used for playing pieces. Ancient boards made of stone and clay indicate that there were several variations of play, because holes would be arranged in different patterns on different boards. In general, the objective of the game was to force an opponent into a position in which no move was possible or to have more game pieces than one's opponent at the end of play.

Numerous variations evolved over many centuries, but a sowing game was usually played by two people, each con-

trolling one side or end of a game board. Game pieces, called seeds, were usually gathered in a starting hole. A player could move seeds from his hole into neighboring holes, which usually meant that he controlled those holes and could, during a later turn, move seeds from them into other holes. Often a player was allowed to move to capture a hole controlled by her opponent, with the rules for how to capture a hole varying greatly depending on the variation of the game. A player's turn often ended when he ran out of moves, which could happen when he reached a hole he could not take. Moving seeds, choosing how many to move and where to move them, often involved complex thinking, requiring a player to have the ability to foresee an opponent's reactions to her moves, as well as the ability to thwart her opponent's strategy.

EGYPT

BY EMILY JANE O'DELL

Ancient Egypt was not all work and no play. In fact, there are many examples of sports and games from ancient Egypt. We know of the recreational habits of ancient Egyptians from surviving game pieces, written texts, and temple and tomb carvings. Although the ancient Egyptians had nothing like the Olympics of the ancient Greeks, they did participate in athletic and recreational activities that included throwing, running, wrestling, archery, boating, and board games.

We do not know very much about organized sports activity in ancient Egypt, but we do know that the pharaoh had a recurring athletic event that symbolically and magically rejuvenated him for the kingship. During the sed festival, a jubilee that traditionally occurred after 30 years of rule and thereafter every three years, the king was required to run around a special courtyard in front of his courtiers and the public. Such a court can still be seen at the step pyramid of the pharaoh Djoser (r. ca. 2630–ca. 2611 B.C.E.) at Saqqara. Relief carvings show royal guards running alongside kings' chariots, and some soldiers held the title “swift runner.” However, we do not have evidence of competitive running until the time of King Taharqa (r. ca. 690–664 B.C.E.), when a stela (a carved standing stone) at Dashur records a government-sponsored footrace by units of the army, with prizes awarded to the best runners.

Many people associate horses and chariotry with ancient Egypt, but neither existed there until the Hyksos, a western Asian people who ruled much of Egypt during the Fifteenth and Sixteenth Dynasties (ca. 1674–ca. 1567 B.C.E.), introduced them, along with powerful new composite bows. These new elements of sport and war were quickly assimilated into ancient Egyptian culture. While target archery had been around since the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.), the addition of the composite bow and moving chariots made the sport that much more difficult and exciting. King Thutmose III (r. ca. 1479–ca. 1425 B.C.E.) claims on his stela in Armant to have pierced copper with his arrows, but the most famous example of such archery boasts comes from his son Amenhotep II (r. ca. 1427–ca. 1401 B.C.E.): Known as the most

athletic of the kings, having been trained since childhood in many athletic pursuits, Amenhotep II claimed not only to have pierced four copper targets “as thick as a man’s palm” while riding full-speed in a chariot but to have cleaved each target in two.

Wrestling appears in Egyptian art from the First Dynasty (ca. 2920–ca. 2770 B.C.E.) onward. During the Old Kingdom (ca. 2575–ca. 2134 B.C.E.) servant statues—statues buried with the dead to serve and entertain them in the afterlife—often depicted wrestlers. Naked boys who are wrestling are carved in relief in the tomb of Ptahhotep (a philosopher and high government official in the 24th century B.C.E.) at Saqqara. The most famous scenes of ancient Egyptian wrestling come from the Twelfth Dynasty (ca. 1991–ca. 1783 B.C.E.) tombs at Beni Hasan, which house more than 100 depictions of wrestlers. There is debate as to whether these figures are of recreational wrestlers or simply Egyptians fighting each other in one of the many civil conflicts of that time. However, at nearby Bersheh similar art clearly depicts sports wrestlers, as they are shown with a referee. During the New Kingdom (1550–1070 B.C.E.) wrestling became incorporated into royal ceremonies in which Egyptians wrestled foreign opponents. Art at Medinet Habu portrays stick fighting as another part of these competitions, with the fighters wearing shields on their forearms and padding on their faces.

Ancient Egyptians also played ball sports, and original balls from some of these games have survived. They were generally made by sewing a leather cover around a filling of clay or tightly packed straw, hair, papyrus, palm leaves, or yarn. In Twelfth Dynasty tombs women are shown juggling balls and throwing them back and forth, sometimes while sitting on the shoulders of other people. Some Egyptologists have read mythological meaning into the juggling games, but this explanation is speculative and not universally accepted. There are a few examples, however, of balls being used ceremonially and magically to stave off chaos. For example, during the Late Period (ca. 712–332 B.C.E.) the king would hit a ball with a stick as if he were striking the eye of Apophis (the god of evil and darkness), and in the edifice of Taharqa at Karnak the king is shown throwing four balls, each toward one of the four cardinal points of the compass. Apart from royal sports activity tomb art at Beni Hasan shows ancient Egyptians using a ball and long sticks in a manner that resembles field hockey.

In addition to juggling, ancient Egyptian art portrays women dancing and contorting in many different poses in gymnastic activity. For example, a painting from 2000 B.C.E. shows one woman doing a full backbend and another doing a front handspring or front walkover. Further, at Beni Hassan there are examples of ancient Egyptians holding certain yogic positions, including one in a headstand. Ancient Egyptians also had a unique form of weightlifting: They used bags full of sand that could be raised with one hand, much like dumbbells, to work their arm muscles.

Because most ancient Egyptians lived near water—along the Nile and its tributaries, as well as the Red Sea and Medi-

terranean—it seems probable that many people knew how to swim. The *Biography of Khety*, from the Eleventh Dynasty (ca. 2040–1991 B.C.E.), mentions swimming lessons given to the royal children. Both the Old Kingdom and the Middle Kingdom (ca. 2040–1640 B.C.E.) provide many carved depictions of men, women, and children fishing and hunting birds with throw sticks along rivers, and in some of these scenes men on papyrus rafts on the water are trying to push each other overboard with poles. Although there is no direct evidence of boat races, they must have occurred, as boating was part of daily life for people living on the Nile. Further, in the Late Egyptian text *The Contendings of Horus and Seth* the gods Horus and Seth compete against each other in a boat race, indicating that there must have been real-life precedents for such events.

Game pieces from ancient Egypt survive to this day. Egyptologists have identified four board games, but it is likely that more existed. The most popular was *senet*, played from the very earliest times all the way down to the Roman conquest. Besides recreational value, it had magical and religious significance: A person had to play a game of *senet* in the afterlife in order to proceed toward eternal happiness and peace. Thus, in effect, one played *senet* for one’s life. The game appears in the Egyptian Book of the Dead, and a scene of the queen playing it for her life is beautifully painted in vibrant colors in the Tomb of Nefertari in the Valley of the Queens at Luxor. *Senet* was played by two players on a rectangular board of 30 squares (10 by 3). Each player had seven pieces, and flat two-sided dice sticks determined the moves that could be made. Much as in checkers, a player could jump the opponent’s pieces to remove them and reach the opposite end of the board.

Another game, *men* (from the word for “endurance”), was contested by two players on a long narrow board divided into 13 or more sections. Not much is known about this game, but it seems that each player controlled five pieces and moved them according to throws of stick dice as in *senet*. After *men* disappeared at the start of the Old Kingdom, a somewhat similar game played with pegs became popular and lasted for 2,000 years. Players moved carved pegs on boards that had two tracks of 30 holes each. It is not known whether the peg game developed from *men* or was something new, perhaps imported from the Near East.

In the Old Kingdom tomb of the physician and scribe Hesy-Ra there is a depiction of a game called *mehen*, “serpent,” named for the serpent god Mehen, who protects the sun as it sails across the sky. The board for the game is in the shape of a coiled snake and divided into six compartments, each holding six marbles of one color and a lion-shaped piece. In the tomb of King Reshepses at Saqqara four people are shown playing. The game, however, disappeared sometime around 2000 B.C.E., possibly because worship of the serpent god Mehen died out. A game called “20 squares” (for the number of squares on the board) became popular in the Seventeenth Dynasty (ca. 1640–1550 B.C.E.) and may have been introduced by the Hyksos. It was played by two people, each using five pieces.

In addition to board games children in ancient Egypt played with assortment of tiny figurines carved from wood and clay. Many such figurines and toys are found in the Cairo Museum. Children also played with hoops and sticks, engaged in jumping and whirling contests, and competed in tug-of-war.

THE MIDDLE EAST

BY MARK ANTHONY PHELPS

Defining what constitutes sports in the context of leisure activities in the ancient Near East is difficult before the advent of Greek colonization in Asia Minor and the later Hellenization of the region. What passes for sport by modern definition generally constituted three classes in the ancient Near East: children's games, military training, and professional acrobatics. All this changed after the conquest of the Greek king Alexander the Great (r. 336–323 B.C.E.), as sports and theater became a major component of social life.

Wrestling is the most widely depicted sport in Mesopotamian texts and artwork. The wrestlers are shown naked except for a type of belt. It seems that the belt was a necessity, owing to its ubiquitous artistic representation and its appearance in texts. It is not clear whether this equipment functioned as a grip for wrestling moves or served something in the capacity of a modern athletic supporter. The most famous literary image of the wrestler in Mesopotamia actually occurs as a simile in one of the earliest-known epic poems, wherein Gilgamesh, the legendary king of Uruk, and his foe Enkidu fight “like wrestlers.” A copper vase from the third and fourth millennia B.C.E. shows the sculpted image of two wrestlers grasping each other's belts while balancing large vases on their heads.

Boxing is the next most commonly presented sport in iconography and textual evidence. A votive tablet from around 3000 B.C.E., found at Khafaje (in modern-day Iraq), shows a pair of boxers along with two pairs of wrestlers. Boxers almost universally wear the same belt as wrestlers, leading one to wonder if there was indeed always a strong division between the activities. Other representations show boxers wearing typical skirts with some sort of binding on their wrists, probably functioning in the same fashion as modern taping for strengthening the joint.

Life-and-death duels served as a spectator sport, if the Egyptian story of Sinuhe is to be believed. Sinuhe, stranded in Palestine, becomes adopted into a kin group and manages to become chief. He then is forced to encounter a “strong man from Retenu” (referring to Syria-Palestine), doubtless for the political control of a kin group. Challenged to single combat, he fights with his challenger before spectators, including women. The crowd initially roots for the man they thought was the underdog, the Egyptian, who soon proves his worth by killing the challenger.

This practice is in line with a scene depicted in the Hebrew Bible (2 Samuel 2:12–17). In this event, 12 representa-

tives each of the armies of David and Ishbaal, Saul's son and successor, meet near the pool at Gibeon to determine which army is favored by Yahweh, the Israelite deity, to rule Israel. These two dozen pair off, grab each other by the hair, and kill each other with the flint knives all were carrying. Divine favor unrevealed, open warfare begins. The story of David and Goliath, told in 1 Samuel 17, is also one of representational combat to the death through the use of weapons.

Sinuhe and the biblical examples are certainly not sport by modern definition, but the need for witnesses to validate the outcome of these life-and-death struggles for political supremacy finds some parallel in the “death for entertainment” context of gladiatorial shows. The fact that all ancient Near Eastern competition was a reflection of military training might suggest that these episodes may well be understood as sports writ large.

A Phoenician vase depicting runners, a Hittite tablet making reference to races at a New Year's festival, and references to the New Year's festival in Babylon call attention to another sport in the ancient Near East. The Bible (Ecclesiastes 9:11) states that “the race goes not to the swift,” a reference in all probability to distance running. It is hard to fathom that there were no horse or chariot competitions, especially given the Hurrian manu-

Game of 58 Holes, made of ivory inlaid with gold and blue paste, from Megiddo, Palestine, Late Bronze Age, 13th century B.C.E. (Courtesy of the Oriental Institute of the University of Chicago)

als translated into Hittite for horse training from the 13th and 14th centuries B.C.E. Likewise, there probably existed competition that involved lifting or throwing objects.

The king engaged in leisure pursuits that were calculated to increase his majesty. Domination over wild predators spoke well of his ability to deal with human adversaries. For example, Assyrian palaces were covered with scenes of the king killing lions for the benefit of the vassal delivering tribute. The ritualization of actual hunts by the king would involve animals that were typically captured or raised and then placed, perhaps bound, in a context that would present no actual danger to the ruler. A relief depicting a hunt by the Assyrian king Ashurnasirpal II (r. 883–859 B.C.E.) shows a lion being released from a cage. The depictions of hunting scenes on vessels used by individuals points to the hunt as being the activity of the elite as well. It is impossible to determine whether there was any influence of Egypt upon such activities as boxing, wrestling, or hunting. Although these activities doubtless developed independently of each other, the rules, social contexts, and individual moves could have been influenced from either cultural realm to the other.

Astragali, animal knucklebones, were an integral part of gaming. They functioned as four-sided dice, as each edge was distinct. These bones were also used in divination. Imitation astragali were made of stone, metal, or glass. Game boards, some with holes or depressions, have been discovered as well. One Babylonian game board included the signs of the zodiac. Among the best-known influences of Egypt upon leisure time is the presence of the board game *senet*, found throughout Syria and Palestine beginning in the Neolithic Period (ending ca. 3800 B.C.E.). The game board has been found from Cyprus to Iran and most points in between.

Musicians, dancers, jugglers, and acrobats are depicted in literature and artwork. Music was ubiquitous at work (as work songs), at festivals (as religious or wedding songs), and in daily life (as perhaps lullabies or taunts). Dancing accompanied many festivals. Watching acrobats and jugglers perform is probably as close to viewing spectator sports as the bulk of the population could come.

With the coming of the Hellenistic world, the face of ancient Near Eastern sports and leisure changed dramatically. Athletic competitions and theatrical performances became an integral part of the social life of at least some strata of the cities of the region. Hippodromes, gymnasiums, palaestrae (facilities for sports practice), and amphitheaters appear throughout the ancient Near East. Athletic competitions were spectator sports in this era, a big business that in turn spawned other affiliated businesses, such as concessions and prostitution. Fans of chariot racing arose in the provinces as well as the Roman heartland, evidenced by graffiti extolling both green and blue factions at Alexandria.

In addition to spectator sports and theater, the coming of the Greeks and Romans also provided for new types of games, new music, and other novel entertainment staples. Along with sports, the presence of public baths presented a

cultural challenge throughout the ancient Near East as public nudity was nearly a universal mark of shame in the region.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

In ancient Asia and the Pacific sports and games served not only as entertainment but also to train players in physical and intellectual skills they needed to survive. Two sports, wrestling and archery, were common in most cultures. In China wrestling matches could attract large audiences in cities and were often part of celebrations staged by the rich and powerful. By the time of the Han Dynasty (ca. 202 B.C.E.–ca. 220 C.E.) the sport had become ritualized, taking a form similar to modern Japanese sumo wrestling. In India victors in even one tournament sponsored by a king not only became famous but indeed made their fortunes for the rest of their lives. These contests took place outside the gate to the king's palace, and individual wrestlers often were sponsored by nobles. The opponents began the contest by grasping each other around the waist, with their chins resting on each other's shoulder. Each then tried to force the other down or to break his hold, either of which brought victory.

Archery was a popular sport. In China nobles took excursions into the countryside to hunt game, usually birds, with their bows. These hunting parties could be extremely elaborate, with the nobles or kings accompanied by professional hunters and large retinues of servants. It was long the rule in Chinese society that no hunter take more than one of every two animals he killed, but during the Han Dynasty many of the rich or the nobility slaughtered every game animal they could find, ruining once-healthy forests. Hunting as a sport was open to people of every walk of life in China, with even poor peasants being able to show off their prowess occasionally with a bow. Archery contests, by contrast, were usually formal affairs, sponsored by a king or a provincial ruler, in which aristocratic participants shot at targets.

In India archery as a sport was reserved for the nobility. Only kings and nobles actually hunted for sport. By the Gupta Empire (ca. 320–ca. 600 C.E.) kings had hunting parks stocked with animals captured by professional hunters in the wild. A king's hunt was an elaborate undertaking, with the king riding a chariot, a horse, or an elephant, surrounded by dancing girls and assisted by servants and game wardens. Archery contests were open to nobles. A target was placed atop a tall pole. The winning archer received a prize, sometimes even marriage to a daughter of the king.

Spectator sports in China included horse racing, dog racing, and cockfighting. All involved gambling, with people wagering on the outcomes. The Chinese officially regarded gambling as a vice because it meant that people were gaining money without contributing anything worthwhile to society. High-stakes betting was particularly scandalous and sometimes resulted in even nobles being punished by the king or

Ceramic Liubo players, from China, Eastern Han Dynasty, first to second century C.E.; the board is marked with divination symbols, and the game pieces show the animals of the four directions. (© The Trustees of the British Museum)

emperor. Nevertheless, gambling was prevalent. One very popular betting game was *liupo*, which may have meant “six dice.” It was a board game played by two or four people who shook six marked bamboo sticks in a cup and then spilled them out. Players moved pieces on the board according to what the sticks displayed. The pieces consisted of five pawns and one general, the objective of the game being to capture the opposing general. The board’s design was meant to represent the universe. The game was played with much shouting and gesturing.

India had numerous games of chance, all condemned by the predominant religion, Brahmanism, because money changed hands without producing anything of social value. Governments regulated gambling, and players were forbidden to use their own dice. Gambling dens paid 5 percent of the value of their property in taxes, and both dice and stakes were taxed. Dice were sometimes made from seashells or the five-sided nut of the *vibhitaka* fruit or were sometimes cubes of ivory or wood. The game of *vibhitaka*, named for the dice that were used, called for a player to grab a handful of dice from a heap of them and declare how many he had grabbed while throwing them onto the ground. The number declared had to be a multiple of four. The player won when the number he or she shouted matched the total number of dice thrown. If more than one player guessed correctly during a round, play continued until only one correct guesser was left. Another popular game was *pasaka*, which used four-sided oblong dice. Gamblers agreed beforehand on a number, as well as on their bets, and winners were those whose throws resulted in the dice matching the agreed-upon number.

Board games in India dated from Harappan times (ca. 2600–ca. 1500 B.C.E.). Harappan boards were made of stone with grids etched on them. Playing pieces looked like mushrooms and towers. The most famous game of ancient India was *caturanga*, the ancestor of chess. Intended to teach people to think like military strategists, it was played by four people who sat around a board or a tabletop marked with a grid. Each player had four pawns and four other pieces representing a king, a horse, an elephant, and either a ship or a chariot. These last four pieces represented the traditional divisions of four corps in an army. Two dice were rolled to determine which moves could be made. *Caturanga* called for strategy and deception, with each player contending against three others, which required alertness and an ability to keep track of movements from multiple directions. Other ancient Indian board games include ones similar to modern backgammon and Parcheesi.

China had an ancient military strategy game of its own, called *yi* during the Han Dynasty but later called *weiqi*, ancestor of Chinese checkers and Go. Its first mention in surviving documents is from 559–548 B.C.E., but its origins probably extend back to the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.), and it was played avidly throughout ancient times. Ancient Chinese tradition held that the game was invented in the 2300s B.C.E., during the legendary Xia Dynasty by the emperor Yao, as a way to teach his son how to think. The game was typically played on a wooden board etched or painted with a grid of black lines. Playing pieces were usually circular bits of stone or wood. The object of the game was to surround an opponent’s playing pieces with one’s own. It was easy to learn but could involve very complex strategy. A game between masters of *yi* could last several hours. In China emperors or nobles sometimes commissioned tournaments in which almost anyone, whether peasant or emperor, could participate. By the end of the ancient era the popularity of the game was spreading to Japan and Southeast Asia.

Little can be said with certainty about sports and recreation in the rest of Asia and Oceania during the ancient era. During the medieval era, counting games like those found in Africa became popular in Southeast Asia, but it is unlikely these games had as yet made their way along the southern coast of Asia to Southeast Asia before the ancient period ended. It is possible that Indian games made their way into Funan and that Chinese games made their way into Vietnam, but evidence for this is scant. The game of Go and sumo wrestling both had their origins in China, but documentary evidence for their existence in Japan before the medieval era is lacking. That the ancient Japanese played games is probable. Given the nearly universal popularity of wrestling, it probably existed in various forms throughout Asia and the Pacific. Surfing, the best known Polynesian sport, probably was not invented until after the ancient era, because the Polynesians had yet to colonize those islands where it seems to have emerged.

EUROPE

BY JUSTIN CORFIELD

The archaeological record of prehistoric Europe tells us very little about recreation and sport, and indeed these concepts as they are familiar to us in the modern Western world may not have existed. People probably found small amusements frequently in the course of their everyday life, but they may have involved telling stories, making music, or joking. Sports as competition in games and recreation as involving sport seem to have been relatively late developments in the human story; until modern times they seem to have been unknown in many parts of the world. At the Neolithic settlement at Skara Brae in the Orkney Islands of Scotland, a number of small well-carved stone balls have been found. Were they used in a game possibly similar to marbles, or did they play some ceremonial function? We can only guess.

Throughout Europe during the Bronze Age and the Iron Age many sports may have been connected with training boys and men for battle. Although there is little direct evidence for them, competitions in archery, javelin throwing, horse riding, and swordplay would have been natural accompaniments to training in these activities. It also seems probable that the Celts in Gaul and Britain engaged in chariot racing. Certainly their agility in battle, which Julius Caesar commented upon, meant that they had much practice, and it is reasonable to surmise that the development of these skills might have had a recreational aspect to it prior to their employment in combat.

A number of games and sports were limited to specific peoples or areas. Many Celts, for example, took part in games such as shinty, which seems to have been popular from the start of the Iron Age. Players on two opposing teams used

sticks to hit a hard ball into a goal, much as in field hockey. A modern version of *shinty* is still played in Scotland, and hurling, a related sport resembling lacrosse, is still popular in Ireland. The ancient Celts seem to have believed that such sports provided good training for men and boys who were going to serve in battle.

In Scotland many men engaged in weight sports such as tossing the caber, which was popular among the Picts and remains a feature of present-day Highland games, as a test of strength. The sport, highlighting accuracy and skill rather than distance, consisted in throwing a long, tapered length of wood such that it turned over in the air and landed pointing at the thrower. In the Balearic Islands boys were trained intensively from a young age to use the sling.

As to indoor games and recreations, it seems likely that dice were used—certainly many dice have survived in Roman settlements, and it seems likely that enterprising traders would have sold dice to the Celts. Celts also played games with knucklebones as well as a form of chess.

In the area of music Europeans had been playing instruments such as flutes, drums, lyres, and cymbals for many centuries, and by around 1000 B.C.E. they were making bronze trumpets, as indicated by numerous finds in northern Germany, Denmark, Scandinavia, and especially Ireland. In addition to music there was spoken entertainment. Celtic bards, in particular, had a reputation for being able to recite stories of ancient times, former kings, and valorous deeds. During Roman times poetry reading and oratory became more important in cities throughout the Roman Empire.

Eating and drinking at large communal feasts was a popular recreation both in the Celtic world and after the Romans took control of Gaul and Britain, with some references in Roman works to similar events taking place in Germany, and archaeological evidence in Denmark also pointing to the use of large halls for eating. Feasts of this kind often provided a venue for dancing, music, and the telling of old stories. Women and girls danced for their own pleasure and also for the entertainment of others.

Large-scale spectator sports seem not to have existed in most of Europe before the Romans brought their gladiatorial shows, which became popular in larger cities throughout the conquered lands. Ancient Europeans attended these events as onlookers, and many who had been captured in war and enslaved fought in them as gladiators, with particular dress codes for those who were Germans, Celts, Thracians, and so on. A glass cup found at Colchester, England, clearly shows two gladiators fighting.

Other blood sports of the period included badger-baiting, bull-baiting, cockfights, and hunting. While much of the hunting was to provide food, there was also an element of sporting prowess, with trophies such as horns or the heads of the animals being displayed after the hunt. There are also descriptions of bullfighting taking place in Spain, with men in Baetica, Andalusia, in about 220 B.C.E. attacking bulls with a lance or an ax in an arena, after using a cloak or skins to confuse the bull.

Bronze group of a bull and acrobat, Minoan, about 1700–1450 B.C.E., from Crete; bull jumping is frequently shown in Minoan art and was thought to be a sport associated with ritual activity. (© The Trustees of the British Museum)

GREECE

BY JOHN THORBURN

The Greeks were one of the few ancient cultures to engage in athletic activity for purposes other than religious ritual or training for either war or hunting. With few exceptions athletic competitions were limited to men, but some women (especially those from Sparta) did exercise for recreation or physical fitness. Although Greek athletics may originally have been connected with war, hunting, or worship, eventually people began to engage in sports for the joy of competition and the desire to display their *aretê* (“goodness” or “excellence”).

The earliest evidence for athletic activity in the region near Greece comes from wall paintings found on the islands of Thira (modern-day Santorini) and Crete. The fresco from Thira (ca. 1650–1500 B.C.E.) shows two children boxing; the Cretan fresco (ca. 1500 B.C.E.) shows a person leaping over a bull, an activity that may have had some religious significance.

The next significant evidence for athletic activity among the Greeks comes from two epic poems attributed to Homer, the *Iliad* and *Odyssey*. First written down during the eighth century B.C.E., these poems contain several descriptions of athletic events. The competitions described in the *Odyssey* occur in Phaeacia, which cannot be identified with certainty as a Greek land, but the events—running, wrestling, jumping, discus throwing, and boxing—are comparable to those described in the *Iliad* where the hero Achilles honors a dead companion with athletic competitions: chariot racing, boxing, wrestling, running, sparring in battle gear, throwing the quoit (similar to a discus), and archery.

Although the historical accuracy of the *Iliad* and *Odyssey* is uncertain, about the same time they were written down the first athletic games took place at Olympia, in southwestern Greece (in 776 B.C.E.). By 500 B.C.E. several other athletic festivals were being held regularly: the Pythian Games at Delphi, the Isthmian Games near Corinth, the Nemean Games at Nemea, and the Greater Panathenaea at Athens. In each case these games honored a divinity, and except at the Panathenaea the victors received crowns of vegetation (for example, the olive crown at Olympia).

For the first five decades of the games at Olympia a foot-race, the *stadion*, was the only event. The name (the source of the modern word *stadium*) referred both to the setting in which the race occurred and to the distance it covered (a stade). The length of the *stadion* varied somewhat from site to site, but at Olympia it was about 210 yards. As with most Greek athletic events, the athletes competed in the nude.

At Olympia and at the newer festivals other events were gradually added. A second running event, the *diaulos*, was named after a Greek musical instrument with a double pipe because the race covered two lengths of the *stadion*. The course was straight, not oval or circular, and it is uncertain how the runners turned at the race’s midpoint. Apparently they started out in individual lanes and then turned around a single post at the opposite end of the *stadion*.

The *dolichos* and the *hoplitodromos* were grueling events. As the name *dolichos* (“long”) indicates, this was a distance race. Its length differed at the various festivals; at Olympia it was 24 stades, or just under 3 miles. In the *hoplitodromos* (“running in armor”) the athletes competed in military gear.

Hockey game, found in the Themistoclean wall, Athens (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

Ancient vase paintings show runners carrying shields and wearing helmets and other armor. The *hoplitodromos* appears to have been from 2 to 4 stades in length.

The Greeks also engaged in boxing, wrestling, and the *pankration* (“all fighting”), which combined boxing and wrestling. The opponents neither fought in a ring nor had rounds lasting for any specific time. Unlike their modern counterparts, Greek boxers, wrestlers, and pankratiasts, though divided into different age classifications, could be matched against opponents much heavier than themselves. Greek boxers and pankratiasts did not wear gloves but wrapped their hands in leather thongs. They won by either knocking out the opponent or having him give up. Wrestlers won when the opponent gave up or when a certain number of falls, probably three, occurred. What determined a fall is not completely clear, but causing an opponent’s back or shoulders to touch the ground seems to have counted as one.

The Greeks also competed in a pentathlon (javelin, discus, jumping, *stadion*, and wrestling). An athlete who won three of the five events obviously would claim the prize, but otherwise the pentathlon’s scoring system is debated. The javelins used in athletic competition seem to have been about 6 feet long. Unlike in the modern event, Greek athletes wrapped the shafts of their javelins with a strap that they looped around one of their fingers. The strap apparently caused a rifling effect that made the throws more accurate and possibly longer than they would have been without it.

Other events in the pentathlon also differed somewhat from their modern counterparts. Whereas the men’s discus in the modern Olympics weighs 4.4 pounds, the Greeks threw disks whose weight probably varied from location to location. Modern competitors in the event whirl around two and three-quarters times before releasing the discus, but the Greek discus throwers apparently made only a single three-quarters turn. Meanwhile, Greek jumpers seem to have engaged in a standing broad jump rather than taking a running start. The most unusual feature of this event was that the jumpers held weights in their hands. Apparently swinging the weights forward and then dropping them after takeoff increased the distance of the jump.

Besides track-and-field events various equestrian competitions occurred. Greek riders, who had neither saddles nor stirrups, made six laps around an oval track about three-quarters of a mile long. The competition was divided into races involving horses either less or more than a year old. Chariot racing made the same age division but also had races for chariots drawn by two or four horses. Chariot races were twice as long as the horse races.

ROME

BY ANNE MAHONEY

In ancient Rome spectator sports and individual exercises were distinct: The games people played on their own were not the same ones they watched other people playing. Spec-

tator sports included gladiator combat, wild-animal shows, and chariot races. Few Roman citizens participated in these events except as onlookers.

Gladiator combats began at least as early as the third century B.C.E. The Latin word for such a combat was *munus*, “duty,” because at first they were held only at funerals, as an offering for the dead person. In about 50 B.C.E. Julius Caesar held a memorial service for his daughter Julia that featured gladiators, even though this was not her actual funeral. From then on gladiator shows were no longer necessarily connected with funerals. Most gladiator fights were between two combatants. A showy, expensive *munus* would involve several pairs fighting one after another. There were several styles of fighting, each with its special weapons and equipment. For example, a *hoplomachus* used the heavy armor and weapons of a Greek infantry soldier or “hoplite.” A *retiarius* used a net (from Latin *rete*).

Gladiators were almost always slaves. The person putting on a *munus* hired the troop of gladiators from its owner. Fights might or might not end with the death of the loser. Sometimes the audience was asked whether the winner should kill the loser, and the spectators would shout and gesture their opinions. We know that they could give thumbs-up or thumbs-down, but the ancient evidence does not tell us clearly what these gestures meant.

Wild-animal shows included exhibitions, combats, and public executions. There were no permanent zoos in Rome, but travelers sometimes brought back exotic animals and showed them off. For example, Pompey the Great (Gaius Pompeius Magnus, 106–48 B.C.E.) showed elephants in his games of 55 B.C.E. celebrating the dedication of a theater he had paid for. More exciting were animal fights and staged hunts. In the hunts armed slaves called *venatores* (“hunters”) chased down and fought various dangerous animals. *Venatores* were not as skilled as gladiators, and theirs was a less prestigious kind of combat.

Gladiator shows and animal shows took place in an amphitheater or arena much like a modern football stadium. The Colosseum in Rome is one such amphitheater, and others still exist in several former cities of the Roman Empire. A day at the arena might start with a staged hunt in the morning and finish with gladiators in the afternoon. In between there might be public executions. Criminals were often executed by wild animals in a spectacle much like the staged hunts except that the humans were not armed. Another form of execution was to perform a story from mythology with the condemned criminal in the role of a character who dies brutally. For example, the Roman historian Suetonius (ca. 69–ca. 130 C.E.) tells us that someone was made to act out the story of Icarus, the boy who in myth flew too close to the sun, which melted his artificial wings. Suetonius adds that the condemned man playing Icarus splashed the emperor with his blood when he fell.

Chariot races were the other major spectator sport. In these events chariots, usually pulled by two or four horses, raced around a track. The stadium was called a *circus*, “circle,” although the track was an oval; the Circus Maximus (“biggest

DYRRHACHIUM

The Roman amphitheater in the port city of Dyrrhachium (Durrës), in Albania, is the largest in the Balkans, the city being a Roman stronghold in their wars with the kings of Macedon. During the Roman civil war between Julius Caesar and the Roman Republic, Caesar's rival general Pompey used Dyrrhachium as his base, with a series of engagements fought there in 49–48 B.C.E. The famed orator and statesman Cicero had lived in the city 10 years earlier when he was exiled from Rome. However, it was not until the reign of the emperor Hadrian (r. 117–38 C.E.) that construction of the amphitheater began on the side of the rocky hill that overlooks the city. Although the city was formerly Greek, there is little trace of Greek design in the architecture of the building, which was primarily for gladiators, and the showing and killing of wild animals—a popular Roman pastime.

The amphitheater could hold some 15,000 to 20,000 spectators and was no doubt popular with the many landless, discharged Roman soldiers settled in the region. The whole of the structure has not yet been excavated, with some later buildings occupying the east and west sides of the arena, where many of the people would have sat during the gladiatorial performances. The amphitheater was used until 1081, when the town was attacked by the Normans, and then the stones became a source for building elsewhere in the city. Work did not begin on the excavation of the amphitheater until 1966, when Albania made great play of the Roman use of slaves and prisoners as gladiators. They opened up the underground tunnels where gladiators and wild animals had been held. The animal chambers were found to have neatly rounded corners to prevent the animals from injuring themselves when they charged out into the arena to be killed.

circle”) in Rome was the most famous example. The charioteers belonged to four different teams or “factions”—Blue, Green, White, and Red—which were part of an organization that covered the entire Roman world. (The emperor Domitian created Gold and Purple “expansion teams” in the late first century C.E., but they did not last.) A race might involve one chariot of each color, or there might be two or four of each color, which allowed for team tactics in the race. Charioteers were generally free or freedmen, not slaves; they got a share of the purse for races they won, and the best became fairly wealthy. Chariot races took place at the civic or religious festivals called *ludi* (“games”) along with theatrical performances and other entertainments. They were a standard part of the major annual *ludi* and were also typically included

in games given in celebration of military victories or other special occasions.

At Roman sporting events, unlike most Greek ones, the audience included both men and women. Elaborate rules dictated who could sit where, with the best seats reserved for senators and the wealthiest equestrians (also known as *equites*, just below patricians in the Roman social order). Most cities in the provinces had amphitheaters and chariot racetracks: Gladiator combats and chariot races were popular throughout the Roman world. Although some intellectuals found the games boring or unsophisticated, most Romans seem to have enjoyed them. The emperor Augustus (r. 27 B.C.E.–14 C.E.) included the games he sponsored in his list of major achievements, and Suetonius in his biographies of the first 12 Caesars always tells us what kinds of spectacles they staged.

The sports and games that Romans played on their own were far less dramatic. Upper-class men might go to a Greek-style gymnasium or a palaestra (wrestling school) to exercise and socialize. The public baths were another place for recreation, open to Romans of all classes and both sexes. In all these places people would talk, have snacks, and play games. Mosaics from Ostia, Sicily, and Pompeii show people playing with balls ranging in size from softballs to large exercise balls. Although we do not know the rules of the games, the pictures and literary references indicate that there were throwing games and kicking games. Adults and children, men and women all played ball games.

The Romans also played games much like modern board games. There were gambling games with dice and games

Roman terra-cotta sculpture of two gladiators fighting, first to second century C.E. (© The Trustees of the British Museum)

similar to backgammon and checkers. The dice were typically made from the small bones of animals' knuckles but also could be blocks of wood or ivory like present-day dice. Game pieces varied from simple pebbles to elaborately carved figures. Romans played these games almost anywhere, in the baths, in taverns, and at home.

THE AMERICAS

BY RENEE MCGARRY

People in the ancient Americas played a variety of sports and games. Many of these larger-scale sports, such as the ball game and the popular foot races, served ritual purposes. Other, smaller games often served the purpose of diversion and were leisure activities. Many games were played universally across the Americas, although the rules and practices of each varied greatly from civilization to civilization and group to group.

The ancient ball game is the oldest game known in the Americas. It originated about 1200 B.C.E. with the Olmec civilization and spread throughout Mesoamerica and even into the Caribbean islands. By about the year 1290 B.C.E. it was common for artists to dress figurines of Olmec rulers in ball-court costume, demonstrating the importance of the sport in society. Many ancient ball courts are still in existence, and scholars have used these courts and ancient figurines to determine the purposes, rules, and play of the ball game. While these remaining ball courts are principally located in areas where people played the game most frequently and extravagantly, archaeological evidence indicates that civilizations as far north as Arizona played less elaborate versions of the ancient ball game.

The Maya story of creation, the Popol Vuh, dates to the sixth century B.C.E. and illustrates the divine beginnings of the ancient ball game. In the story the gods known as the Hero Twins prove themselves to be extraordinary ball players, defeating even the Lords of the Underworld in a ball game. This early story establishes the game as more than simply a sport but indeed a contest of life and death, with the losing team ultimately suffering sacrifice to the gods.

The purpose of the ball game has been difficult to decipher. Many scholars believe that it was a fertility ritual that began as a simple game and evolved into a ceremony. This correlates with the blood sacrifice of the game, as many Mesoamericans believed that to perpetuate human life societies must take lives as offerings to their gods. These sacrifices could serve as a representation of a keeping of cosmic order, the victory of the sun over darkness, or an agricultural ritual.

The rules of the game varied by location, but many elements remained consistent across distance. Remarkably, each game was played with a rubber ball, a material entirely unique to the Americas in this period of history. Mesoamericans began harvesting and using rubber in approximately 1600 B.C.E., thousands of years before Europeans were familiar with the material. This rubber ball weighed 5 to 8 pounds and was bounced rapidly up and down the ball court during the game.

Stone hacha, Classic Veracruz, possibly as early as 300 C.E.; hachas were ax heads related to the Mesoamerican ball game and thought by some to be used as ball court markers. (© The Trustees of the British Museum)

In each culture the ball game was played with formalized teams and protective gear. From both depictions of the game and Spanish accounts, it is clear that neither the hands nor the feet were allowed contact with the ball. The body parts used to transport the ball varied across civilizations, though the manner of scoring points was rather consistent. A team scored a point with the use of two central hoops, or goals, midfield. Ball courts were generally large structures, complete with seating and a central field. Walls were decorated with depictions of the civilization's gods and often contained depictions of the ritual sacrifice at the end of the game.

The ball game was not the only sport played in the ancient Americas, but it is the one with the most remaining evidence. Foot races were perhaps the most popular and exciting sports for Native Americans. These races evolved out of a long tradition of running for transportation, but because little archaeological evidence exists there is no way to date the origin of the races. Much like the ball game, foot races have mythological origins. Several groups believed that races between their gods and the animals shaped the world, providing an explanation for constellations and the differentiation between species.

In advance of foot races participants took care to train and prepare themselves accordingly, which included such extreme measures as tying weights to their ankles for the weeks before the race. Runners also painted their bodies to identify themselves in the race and for ritual purposes. In many races

wagering also became an important element, piquing interest in the sport.

Indigenous inhabitants of the southwestern United States and northern Mexico often participated in kick-ball races, long-distance races that involved kicking a ball for more than 25 miles at a stretch. Both men and women participated in these races, although women used a stick to toss a hoop ahead of them as they ran. Children began training for the kick-ball race when they were young, as it was seen as a religious ritual as well as a sporting event. Ceremonies were held the night before and the morning of the race, and there was a strong belief in supernatural intervention in these races. Many groups even believed that they were able to run faster while kicking the ball than without, as if a supernatural force were pulling each member of the team forward.

In Peru foot races were often included in the initiation of a boy reaching puberty. With other rituals, these foot races established each boy as a member of the adult community by showing his mental and physical fortitude. Foot races in North America were also run as part of growing up. Nations living in the Great Plains and along the Mississippi often viewed these races as preparation for future warfare.

For North American Indians in snowy climates, such as the ancestors of the Iroquois and Seneca nations (who can be traced to these regions to 4000 B.C.E.), the snow-snake game used the weather to its advantage. The object of the game was to toss an object called a snake (most commonly a pole) the farthest on ice or in snow. The lanes intended for the snow-snake were long and free from obstruction, but there were no specific rules about the paths or the snake itself. Snow-snake was generally an individual sport, although it could be played in teams, with each member tossing a snake and each team accumulating points for the longest throws. The game did not attract the attention of either the ball game or the races, nor did it have a supernatural or spiritual component. This game, then, seems to have been played simply for diversion and leisure activity.

Sports and games, then, did serve a purpose outside of a ritual one, particularly games of chance that originated in prehistoric times. In fact, the ancient dice playing of North American Indians can be traced back nearly 2,000 years using archaeological remnants of dice found in the southwestern United States. This prehistoric game did not use skill or

calculation. Rather, each player relied on chance to win the game. As was the tradition with such games of chance, Indians often placed wagers on who would win. Some players were certainly luckier than others, and it was believed that those players had a special relationship with the gods or themselves had supernatural powers.

The dice that have been uncovered in Arizona, Utah, and Colorado are referred to as two-sided dice and are very unlike the six-sided dice of modern times. These dice resembled sticks and were decorated on each side, using light colors on one and dark colors on the other. As with most games of chance, the goal was to guess a number or a series of numbers involving the dice. The dice game has been found in more than 100 distinct groups in North America and is generally considered universal to nations in North America. As with the kick-ball race and the ball game, the rules and means of playing the game varied from nation to nation. Both men and women played the game in all nations, but they generally did so separately. Score was kept either with another set of sticks or using an abacus.

Ancient games were also played among children, and one of the best known is the skin or blanket tossing game of the Eskimo. In this game a large animal hide was spread, and a child climbed on it. When the hide was pulled taut, the child was thrown into the air. The object of this game was for each boy to land on his feet. Oftentimes the children were doing so after having been thrown more than 20 feet in the air.

Children all over the Americas also played with dolls, which were most frequently made using the most convenient materials. Those living in the region now occupied by the Chippewa used cattails in making their dolls, and clay figures were used in other parts of the Americas. Children often made their own dolls out of cornhusks where corn was most prevalent. Children played with dolls in much the same way as they do today, and these dolls were used by boys and girls alike.

Greece

~ Pindar, *Olympian Odes* (ca. 470 B.C.E.) ~

No. 9

Fit speech may I find for my journey in the Muses' car; and let me therewith have daring and powers of ample scope. To back the prowess of a friend I came, when Lampromachos won his Isthmian crown, when

on the same day both he and his brother overcame. And afterwards at the gates of Corinth two triumphs again befell Epharmostos and more in the valleys of Nemea. At Argos he triumphed over men, as over boys at Athens. And I might tell how at Marathon he stole

from among the beardless and confronted the full-grown for the prize of silver vessels, how without a fall he threw his men with swift and coming shock, and how loud the shouting pealed when round the ring he ran, in the beauty of his youth and fair form and fresh from fairest deeds.

No. 10

Ample is the glory stored for Olympian winners; thereof my shepherd tongue is fain to keep some part in fold. But only by the help of Zeus is wisdom kept ever blooming in the soul. Son of Arcestratos, Agesidamos, know certainly that for your boxing I will lay a glory of sweet strains upon your crown of golden olive and will have in remembrance the race of the Locrians in the west.

No. 11

Who then won to their lot the new-appointed crown by hands or feet or chariot, setting before them the prize of glory in the games, and winning it by their act? In the foot-race down the straight course of the stadion was Likymnios' son Oionos first, from Nodea had he led his host: in the wrestling was Tegea glorified by Echemos: Doryklos won the prize of boxing, a dweller in the city of Tiryns, and with the four-horse chariot, Samos of Mantinea, Halirrhotos' son: with the javelin

Phrastor hit the mark: in distance Enikeus beyond all others hurled the stone with a circling sweep, and all the warrior company thundered a great applause. Then on the evening the lovely shining of the fair-faced moon beamed forth, and all the precinct sounded with songs of festal glee, after the manner which is to this day for triumph.

No. 13

Also two parsley-wreaths shadowed his head before the people at the games of *Isthmus*, nor does *Nemea* tell a different tale. And of his father Thessalos' lightning feet is recorded by the streams of *Alpheos*, and at *Pytho* he has renown for the single and for the double *stadion* gained both in a single day, and in the same month at rocky *Pan-Athenaios* a day of swiftiness crowned his hair for three illustrious deeds, and the *Hellotia* seven times, and at the games of *Poseidon* between seas longer hymns followed his father Ptoiodoros with *Terpsias* and *Eritimos*. And how often you were first at *Delphi* or in the *Pastures of the Lion*, though with full many do I match your crowd of honors, yet can I no more surely tell than the tale of pebbles on the sea-shore.

Rome

~ Suetonius, excerpt from *The Divine Augustus* (ca. 120 C.E.) ~

43. In the number, variety, and magnificence of his public spectacles, he surpassed all former examples. Four-and-twenty times, he says, he treated the people with games upon his own account, and three-and-twenty times for such magistrates as were either absent or not able to afford the expense. The performances took place sometimes in the different streets of the city, and upon several stages, by players in all languages. The same he did not only in the forum and amphitheatre, but in the circus likewise, and in the *Saepta* and sometimes he exhibited only the hunting of wild beasts. He entertained the people with wrestlers in the *Campus Martius*, where wooden seats were erected for the purpose; and also with a naval fight, for

which he excavated the ground near the Tiber, where there is now the grove of the Caesars. During these two entertainments he stationed guards in the city lest, by robbers taking advantage of the small number of people left at home, it might be exposed to depredations. In the circus he exhibited chariot and foot races, and combats with wild beasts, in which the performers were often youths of the highest rank. His favorite spectacle was the Trojan game, acted by a select number of boys, in parties differing in age and station; thinking that it was a practice both excellent in itself, and sanctioned by ancient usage, that the spirit of the young nobles should be displayed in such exercises. Gaius Nonius Asprenas, who was lamed by a fall in this diversion, he presented

(continued)

(continues)

with a gold collar, and allowed him and his posterity to bear the surname of Torquati. But soon afterwards he gave up the exhibition of this game, in consequence of a severe and bitter speech made in the senate by Asinius Pollio, the orator, in which he complained bitterly of the misfortune of Aeserninus, his grandson, who likewise broke his leg in the same diversion.

Sometimes he engaged Roman knights to act upon the stage, or to fight as gladiators; but only before the practice was prohibited by a decree of the senate. Thenceforth, the only exhibition he made of that kind, was that of a young man named Lucius, of a good family, who was not quite two feet in height, and weighed only seventeen pounds, but had a stentorian voice. In one of his public spectacles, he brought the hostages of the Parthians, the first ever sent to Rome from that nation, through the middle of the amphitheatre, and placed them in the second tier of seats above him. He used likewise, at times when

there were no public entertainments, if any thing was brought to Rome which was uncommon, and might gratify curiosity, to expose it to public view, in any place whatever; as he did a rhinoceros in the Saepta, a tiger upon a stage, and a snake fifty cubits long in the Comitium. It happened in the Circensian games, which he performed in consequence of a vow, that he was taken ill, and obliged to attend the Thensae [procession] reclining on a litter. Another time, in the games celebrated for the opening of the theatre of Marcellus, the joints of his curule chair happening to give way, he fell on his back. And in the games exhibited by his grandsons, when the people were in such consternation, by an alarm raised that the theatre was falling, that all his efforts to reassure them and keep them quiet, failed, he moved from his place, and seated himself in that part of the theatre which was thought to be exposed to most danger.

The Americas

Excerpt from the Popol Vuh (oral tradition, unknown date)

II. CHAPTER 2

THE messengers of Hun-Camé and Vucub-Camé arrived immediately.

“Go, Ahpop Achih!” they were told. “Go and call Hun-Hunahpú and Vucub-Hunahpú. Say to them, ‘Come with us. The lords say that you must come.’ They must come here to play ball with us so that they shall make us happy, for really they amaze us. So, then, they must come,” said the lords. “And have them bring their playing gear, their rings, their gloves, and have them bring their rubber balls, too,” said the lords. “Tell them to come quickly,” they told the messengers.

And these messengers were owls: Chabi-Tucur, Huracán-Tucur, Caquix-Tucur and Holom-Tucur. These were the names of the messengers of Xibalba.

Chabi-Tucur was swift as an arrow; Huracán-Tucur had only one leg; Caquix-Tucur had a red back, and Holom-Tucur had only a head, no legs, but he had wings.

The four messengers had the rank of Ahpop-Achih. Leaving Xibalba, they arrived quickly, bringing their message to the court where Hun-Hunahpú and Vucub-Hunahpú were playing ball, at the ball-court which was called Nim-Xob-Carchah. The owl messengers went directly to the ball-court and delivered their message exactly as it was given to them by Hun-Camé, Vucub-Camé, Ahalpuh, Ahalganá, Chamiabac, Chamiaholum, Xiquiripat, Cuchumaquic, Ahalmez, Ahaltocob, Xic, and Patán, as the lords were called who sent the message by the owls.

“Did the Lords Hun-Camé and Vucub-Camé really say that we must go with you?”

“They certainly said so, and ‘Let them bring all their playing gear,’ the lords said.”

“Very well,” said the youths. “Wait for us, we are only going to say good-bye to our mother.”

And having gone straight home, they said to their mother, for their father was dead: “We are going,

our mother, but our going is only for a while. The messengers of the lord have come to take us. "They must come," they said, according to the messengers."

"We shall leave our ball here in pledge," they added. They went immediately to hang it in the space under the roof-tree. "We will return to play," they said.

And going to Hunbatz and Hunchouén they said to them: "Keep on playing the flute and singing, painting, and carving; warm our house and warm the heart of your grandmother."

► storage and preservation

INTRODUCTION

Hunter-gatherers in prehistoric times paid minimal attention to long-term food storage and preservation. Their way of life dictated that they move about in search of food supplies and then consume what they found as they found it. Food typically would not have been preserved for more than a few days or perhaps weeks, depending on how long it would keep. Meat and fish, of course, had to be consumed within days, while plant foods could be kept on hand for a period of weeks.

It was with the advent of agriculture that ancient peoples turned more attention to longer-term food storage and preservation. Agriculture offered the possibility of making a community's food supply more consistent and predictable over time. By storing and preserving food, people could measure out their food consumption over the year and eliminate the need to pick up and move when food supplies ran out. Accordingly, they developed a number of techniques for storing and preserving food.

At the household level, food was stored primarily in such containers as woven baskets and clay pots; pots were also used for storing beverages. Grains (often ground into meal and flour), beans, and rice could be stored in this way for long periods of time. Foods more susceptible to spoilage were preserved principally by drying. The food was spread out on the ground or on racks and placed in the sun or over a fire. When its moisture content was low enough, it would be suitable for storage because microorganisms would not grow in it. In this way ancient peoples preserved fruits, berries, corn, vegetables, and especially meat and fish.

Smoking was another common method for preserving meats and fish. The smoke coated the food's cells with substances that inhibit the growth of microorganisms. Similarly,

freezing was a good way to preserve food in cold-weather climates. North Americans, for example, killed game late in the fall and then allowed the meat to freeze, often grinding it up and mixing it with other foods such as berries. Another major way of preserving meat and fish was by salting them. Salt, inexpensive and taken for granted in the modern world, was a highly valued commodity in the ancient world, necessary not only for nutrition but for food preservation. In addition to salt, certain herbs and other plants were found to have preservative properties, particularly in discouraging insects and rodents. Enzymes from cow stomachs and some plants enabled people to preserve dairy products in the form of cheese. Pickling, too, used acids to preserve vegetable crops.

Larger, more advanced communities needed to find ways to preserve and store large quantities of food. The ancient Egyptians, for example, developed highly sophisticated techniques for growing grain in the silt left behind by the floodwaters of the Nile River. After the waters receded, millions of acres of grain crops were planted and then irrigated with water stored in a complex system of fields, dikes, dams, and sluices. Annual crop yields amounted to millions of tons, most of which was stored in community granaries for later distribution. On a smaller scale, some ancient peoples developed underground storage silos for grain, sealing the silos off from the air to prevent rotting, molds, and pest infestations.

AFRICA

BY KIRK H. BEETZ

Archaeological evidence for ancient African storage and preservation is patchy, known only from a smattering of sites scattered across the continent. Archaeologists have used physical evidence, records from ancient historians such as Herodotus (ca. 484–ca. 425 B.C.E.), and the practices in historical times of ancient ethnic groups to reconstruct a little of how ancient Africans stored food and valuables. There are hazards in using the practices of people in the present day to reconstruct what their ancestors may have done, because even a very traditional culture may change some of its practices over a period of thousands of years.

Even so, what little is known about storage and preservation in ancient Africa offers clues to the matters of ancient relationships among cultures and the diffusion of knowledge in ancient times. Grass-lined pits have been discovered in West Africa and in the central Sahara in which food, probably millet, would have been stored, and the peoples around ancient Lake Chad had silos made of mud bricks, possibly for storing grain. The pits of West Africa may date from about the early 4000s B.C.E., around the same time as similar ones found in Egypt, whereas the pits and silos of Chad date from about 1800 to 400 B.C.E. Some archaeologists take these finds as evidence of a shared culture that predated the ancient Egyptian culture and probably developed in the Sahara, then spread into the region of the Nile. Others suggest it is evidence that storage practices spread either from the newly agricultural

peoples of the lower Nile region to the west or from central or western Africa to the region that became central Egypt.

Archaeological work in Chad is especially interesting because it is one of the few places in Africa where archaeologists have been able to begin constructing a record of continuous cultural development. Very early, people built villages near the shores of Lake Chad, which was much bigger before the Sahara dried. As the shores of the lake receded, people moved their homes to remain near the vital source of water. This has allowed archaeologists to go from one site to another, progressing ever more recently in history as they move ever closer to the modern lake. Thus there is evidence for the development of storage practices from about 1800 to 400 B.C.E.

The most significant finds have been pits. Some pits were dug to remove clay for building homes. Others were dug to provide clay for building defensive walls around villages. Still others are of a more mysterious purpose. Some probably stored valuables such as pottery and metal objects. Some of the pits may have stored food, especially cowpeas. Not yet securely dated are the silos, which were probably built after 1800 B.C.E. They were for grain, probably pearl millet, a type of grain that was durable when stored. The silos are taken as an indication that the ancient villagers were able to have surpluses of crops from their harvests and had the social organization to store the surpluses for periods of poor harvests. Given that pearl millet was a summer crop and that winters could be very dry, the silos and pits at least may have provided storage of food for use during the winter. People in the region still use storage pits, and archaeologists draw some of their conclusions about pits being used for storing food from the similarity of the ancient pits to the modern ones.

As the Sahara and much of northeastern Africa dried in ancient times, storing and preserving water became more and more important. Evidence for how this was done in the Sahara comes mostly from ancient rock paintings dating to about 8000 B.C.E. onward. Many of the paintings depict ordinary life, which has allowed archaeologists to trace some of the developments in Saharan culture as the climate changed. During the period from 2780 to 600 B.C.E. residents of the Sahara drew water from wells. One painting shows what appears to be a leather bucket being hoisted from a well. The belief that it is leather is based on the artist's depiction, which makes it look like animal hide, and the fact that the Saharans were longtime herders of cattle. From this it may be inferred that leather bottles were used to store and transport water much as the peoples of the Sahara have done in historical times.

In the kingdom of Kush (ca. 900 B.C.E.–ca. 300 C.E.), south of ancient Egypt, water management seems to have been more sophisticated. Cisterns made of stone have been found in Kush's towns and cities. Archaeologists debate about the use of the cisterns, suggesting that they were swimming pools, baths, or storage for drinking and cooking water. They tend to be located in or near homes, and the ancient Kushites boiled food extensively, both of which suggest that the cisterns were intended to store water for consumption.

South of Kush, along the coast of East Africa, lived people who seemed to put water to another use. According to the Greek geographer Strabo (64 or 63 B.C.E.–after 23 C.E.), fishermen of the region stored shellfish and fish in pools of water near the shore to keep for eating later, perhaps when catches were poor. This is a logical practice, and Strabo took greater pains than most ancient geographers to make his accounts accurate. A later development was the use of baskets to catch fish and keep them in water. This use of baskets was also found among Bantu-speaking peoples of West Africa.

The Bantu speakers were farmers, and by 200 C.E. they were advancing east and south out of West Africa, using their iron tools to carve out farms from forests. How they stored their harvests is not entirely clear, but inferences can be made from the recorded practices of their descendants. One is that their granaries were elevated above the ground on posts made of tree branches. This helped protect the grain not only from pests such as rats but also from flooding, a common problem in central Africa and parts of eastern Africa south of Kush. Another practice was that of making granaries out of walls of woven mats and conical roofs of long rushes that ran lengthwise from the peaks down to the edges, thus making rainwater flow out and away from the granary. Much of this inference is speculative because archaeologists have not made much progress in researching in Africa's forests; the central regions are remote and therefore hard to reach, and the region has been very dangerous for scientists because of bandits and warfare.

EGYPT

BY KATHARINA ZINN

Most food in ancient Egypt was not produced or consumed daily, and to be kept longer it had to be preserved. Methods of storage and preservation were designed to solve this problem and to accommodate the growing population of the region. Stored or preserved food could include grain, fruits, vegetables, meat, fish, poultry, and wine. The storage facilities in ancient Egypt showed a wide range of types and extended from single storage jars or basketwork containers for domestic use to large storeroom complexes. Meat, fish, and poultry were stored in pottery vessels. Plates or bowls were used to hold offerings (it was necessary to offer food to the deceased daily), and tightly closed jars were used for long-term storage. Oil, fat, and suet were stored in stoneware jars. Grain was stored in small domestic pits or jars as well as large-scale granaries controlled by the state or a temple, such as the Ramesseum (a mortuary temple in Thebes dedicated to the Egyptian king Ramses II [r. 1290–1224 B.C.E.]) and Medinet Habu (dedicated to Ramses III [r. 1194–1163 B.C.E.]). Store-rooms for grain and other agricultural products were named *shenut* (“barns”) and had a specific administrative structure devoted to their maintenance. Precious goods, such as herbs, spices, and salt, were kept in small leather or linen bags. Of further importance was the form of rations for food supply.

In a society without money, rations had a special significance; food had to be stored within the food circle from harvest or slaughtering to ration distribution.

Grain was stored in large quantities at the local, provincial, and state level in granary silos whose maximum capacity was calculated by scribes. Some silos are partly excavated, while others have been depicted in artwork or as model granaries in tombs. Depictions of stored grain or models placed in tombs were meant to guarantee a supply of food for the dead. Scenes portray people sacking up and carrying the grain from fields to the granaries, sometimes using donkeys. Grain was put directly into storage facilities after winnowing, sieving, recording, and measuring by scribes. At the granary porters carried the baskets up the stairs to the charging hole, where the grain was poured in. The process was supervised by a scribe or administrator who recorded intakes, storage, and removal. All harvested goods belonged not to the farmer but to the king or to the temples or nobles who had received the land as a gift from the king.

The first small-scale granaries were pits with basketry linens and a total yield of about 7.5 pounds. In El Faiyûm, a large oasis, Egyptologists have found well-preserved wheat and barley from the Neolithic Period (dating to about 5200 B.C.E.). This shows the long tradition of storage that preceded dynastic times. Other early examples are in El Badâri in northern Upper Egypt about 4500 B.C.E., where postholes, pits, and storage jars were found. The oldest large granaries were cones with round bases and domed tops that were made of mud brick or seasoned wood and sometimes plastered. The larger ones had steps or a ladder leading to a hole at the top

Painted wooden model of a granary, from Aswân, Egypt, Sixth Dynasty, around 2200 B.C.E. (© The Trustees of the British Museum)

where the grain was poured in. Another opening at the bottom was used to remove the grain. This structural form existed until the beginning of the Greco-Roman Period in 332 B.C.E. and was supplemented by trapezoidal structures used for storing cereals to be used for sowing in the next season. Quadrangular chambers, filled through small holes on the ceiling, also are evidenced by models and drawings. Sometimes terms for the contents were written on the models.

The Egyptian temples were given estates and royal endowments as offerings to the gods. The priesthood, in turn, received food and other offerings through an elaborate allocation formula called the Reversion of Offerings. Holding and redistributing the offerings required the use of large storage facilities, which belonged to the temples. The best-preserved set of large storage facilities is attached to the Ramesseum, which could support about 3,400 families (about 17,000 to 20,000 people) for a year with grain. The temple storehouses consisted of long mud-brick, barrel-vaulted halls of varying size with filling holes at the top, erected in groups with a shared vestibule. The temples built up substantial reserves for grain and other goods. From these or state granaries each farmer got his grain for sowing, again recorded by scribes. The granaries housed the food that was used as payment for the army, workers on building projects, and other citizens.

Egyptian houses, including palaces, also contained storerooms and granaries. Some of the houses of the planned towns in El-Lahun, Tell El-Amarna, and Medina had a row of storerooms. El-Lahun shows evidence of several locations within the town rather than a central granary. Large estates had large private storerooms, while those who lived in the country had smaller, mostly conical ones that stored nearly everything in the Egyptians' diet.

As a form of preservation, most food was dried in air and sunlight. There is little evidence for smoking, probably for lack of wood. Pickling with brine, oil, or salt was common as salt draws out liquid. The use of vinegar is assumed but not evidenced. Meat and poultry were preserved through the use of fat, honey, or beer.

If meat was not consumed immediately after hanging, it was cut, wet- or dry-salted, dried in sun and air, possibly smoked, and cured in jars. As the food cooled inside the jars, a sort of vacuum was created that kept the food from spoiling. Some of these jars were made of marl clay, which kept their contents cool. The food was later cooked before it was eaten, which killed most bacteria in the process.

Another perishable food was fish. Much of the catch was cleaned, gutted, and dried in the sun on wooden frames. It sometimes was salted or pickled in oil. Roe was dried or pickled in salt and then pressed and dried. Drying, salting, and pickling were methods of preservation for small birds, too. Dairy products such as cheese were salted and sometimes preserved in oil, dried, and hardened. Dates, figs, olives, or grapes could be dried, ground, pickled, or pressed. Storing grain in spikelet form, rather than threshed, helped to protect it from attacks by insects or other pests. Herbs such as

coriander, black cumin, and fenugreek were added as insecticides, as evidenced in a model granary of the Egyptian king Tutankhamen (r. 1333–1323 B.C.E.) containing emmer with other seeds.

THE MIDDLE EAST

BY LYN GREEN

The first permanent settlements appeared in the ancient Near East during the Neolithic Period. They were small and usually clustered around sources of water, as all later towns would be. These most ancient farmers tended to settle particularly along rivers, where alluvial soil carried by the water spread out and made fertile, easily cultivated agricultural land. Their houses and probably storage buildings were made of the same unbaked river mud. The crops grown by these earliest farmers did not have a high yield, since they were still essentially wild forms of the plants. The farmers, therefore, would not have been able to put aside large quantities of food between growing seasons. To supplement the grains and pulses such as barley, einkorn, emmer, lentils, peas, chick peas, and bitter vetch, they also ate wild fruits and nuts, fish, birds, and game. Because storage facilities did not need to be large or to keep food for extended periods of time, the earliest-known storage facilities (from the Pre-Pottery Neolithic A Period, perhaps as early as 8500 B.C.E.) were small bins and silos and probably baskets or sacks. The latter have not survived because they would have been made of rushes, reeds, or hide.

Later civilizations of the area, such as the Halaf culture (dating to as long ago as the sixth millennium B.C.E.), practiced agriculture and stored grain in beehive-shaped communal granaries. Many centuries later, granaries of the same shape were built at the sites of Arad and Beth Yerah. The Halaf storage facilities were small and shared only among a few dwellings. By contrast, the Bronze Age (ca. 3500–ca. 1200 B.C.E.) granaries of Arad and Beth Yerah were much larger and served whole communities. They rested on stone foundations and were usually from 13 to 30 feet in diameter. All of these storage buildings were built above the ground, but farmers of the fifth millennium B.C.E. in the Negev desert stored their food in below-ground chambers linked to each other and to the living quarters by a series of subterranean tunnels. Within the underground storerooms were pits where grain, lentils, and other foodstuffs were stored. Underground storage in the desert was both cool and dry and proved so effective that these farmers continued to store grain underground even after they began to build their houses on the surface.

The earliest storage containers of the ancient Near East, dating to the early Neolithic Period, differ markedly from all later forms of storage because they appear before pottery was made. All later civilizations depended heavily on pottery storage jars in all sizes and shapes. These pottery pieces were almost always of undecorated fired clay, though they could be covered with a thin clay coating called a slip. Slip makes

the surface of the pot less permeable to air and moisture and helps prevent the contents from spoiling. By the Chalcolithic Period (also known as the Copper Age, ca. 4500–ca. 3300 B.C.E.) pottery was becoming a specialized craft, and pots could be made in a variety of sizes and shapes. These new shapes became necessary because Near Eastern farmers from the Chalcolithic Period onward were experimenting with new ways of preserving foodstuffs. Around this time they began to crush grapes and olives for wine and oil, which obviously required quite different storage containers from whole olives or dried grapes (raisins). Scholars believe that around this time the farmers also began to dry figs and dates, though it is possible that in a hot, dry climate this sort of preservation would have been happening all along.

After the Chalcolithic Period centralized government arose in the Fertile Crescent, first in the form of city-states and later as kingdoms and even empires. It is often said that developments in food technology, including storage, are inseparable from this change. The evidence of texts and of archaeology makes it clear that the structures of the ruling elite were economic centers as well as residences or temples. In early Sumer, for example, where the priesthood often ruled the cities, storehouses were often located close to the temples. These government storehouses served multiple purposes: They provided long-term storage for grain and other foodstuffs for seed and as a guard against famine, and they were used as shorter-term storage for goods to be traded or redistributed as rations or wages.

Many different types of food were now being kept for a longer term, and this necessitated new preservation techniques. For example, while yogurt may have been made in the Chalcolithic Period, by Sumerian times the milk of sheep, goats, and cattle was preserved by being made into cheese and ghee (clarified butter). Grapes and dates were dried or pressed for their juice, which could be left to ferment into either wine or vinegar. The grape and date juice itself could also be boiled down until it became a synthetic form of honey. (Real honey was expensive and probably mostly imported.) The concentration of sugars caused by boiling down the juice inhibited the growth of bacteria, so the syrup would keep without spoiling. Pomegranates, another widely grown fruit, would keep without processing if stored carefully.
