CONTRIBUTORS

Saheed Aderinto is a Ph.D. student at the Department of History, University of Texas at Austin. Some of his most recent publications include “Prostitution and Urban Social Relations” and “Policing Urban Prostitution: Prostitutes, Crime, Law and Reformers in Colonial Nigeria” in *Nigeria’s Urban History: Past and Present* (2006) and “Discrimination in an Urban Setting: The Experience of Ijebu Settlers in Colonial Ibadan, 1893–1960” in *Inter-group Relations in Nigeria during the 19th & 20th Centuries* (2006). His writings have also appeared in *IFRA Special Research Issue, Ethnic and Third World Review of Books, African and Asian Studies Journal*, and *The Encyclopedia of Prostitution and Sex Work* (2006).

Olutayo Charles Adesina, Ph.D., teaches at the Department of History, University of Ibadan, Nigeria. He is the author of “The Underground Foreign Exchange Market in Ibadan during Devaluation” in *Money Struggles and City Life: Devaluation in Ibadan and Other Urban Centres in Southern Nigeria, 1986–96* (2002) and “Teaching History in Twentieth Century Nigeria: The Challenges of Change” in *History in Africa: A Journal of Method*, vol. 33 (2006).

David Otieno Akombo, Ph.D., teaches music education and world music at Wabash College of Indiana. He is the author of *Music and Healing across Cultures* (2006).

Francis Allard, Ph.D., teaches in the Department of Anthropology at Indiana University of Pennsylvania. His research interests include the archaeology of early China and Mongolia. He has contributed articles to *Archaeology of Asia* (2005) and *Beyond the Steppe and the Sown: Proceedings of the 2002 University of Chicago Conference on Eurasian Archaeology* (2006).

Miguel Arisa is finishing his doctoral studies in art history at the Graduate Center, City University of New York. He teaches at Technical Career Institutes and is a regular lecturer at the

Cloisters and a docent at the Metropolitan Museum of Art, New York.

Mariam F. Ayad, Ph.D., teaches graduate-level classes on Egyptian language and literature at the University of Memphis, where she is the assistant director of its Institute of Egyptian Art and Archaeology. Her main research interests focus on the role of women in ancient Egyptian temple ritual and the selection and transmission of funerary texts in post-New Kingdom Egypt. Her book on the God's Wife of Amun is under contract with Routledge.

Heather D. Baker, D.Phil., is a researcher at the University of Vienna, Austria, specializing in Babylonian history, society, and culture. She has published widely on Babylonian and Assyrian history and is writing a book to be titled *The Urban Landscape of First Millennium BC Babylonia*.

Robin Barrow, Ph.D., FRSC, is professor of philosophy of education at Simon Fraser University, Canada. His most recent books include *Plato* (2007) and *An Introduction to Moral Philosophy and Moral Education* (2007). He is the author of *Athenian Democracy* (2001) and *Greek and Roman Education* (1996).

László Bartosiewicz, Ph.D., D.sc., teaches archaeozoology at the Loránd Eötvös University in Budapest (Hungary) and the University of Edinburgh (United Kingdom). He is the author of *Animals in the Urban Landscape in the Wake of the Middle Ages* (1995) and principal author of *Draught Cattle: Their Osteological Identification and History* (1997) and has published more than 200 scholarly articles.

Kirk H. Beetz, Ph.D., emeritus, has published over two dozen books and more than 900 articles. His books span topics from endangered mammal species to children's literature, including *Exploring C. S. Lewis' "The Chronicles of Narnia"* (2000). His recent writings have focused on the history and culture of ancient Japan.

Craig G. R. Benjamin, Ph.D., teaches world and ancient Eurasian history at Grand Valley State University. He is the coeditor of vols. 2 (1998), 4 (2000), and 6 (2002) in the Brepols Silk Roads Studies series and the author of *The Yuezhi: Origin, Migration and the Conquest of Northern Bactria* (2007).

Uffe Bergeton, Ph.D., is in the Ph.D. program in the Department of Asian Languages and Cultures at the University of Michigan. He is the author of *The Independence of Binding and Intensification* (Ph.D. dissertation, University of Southern California) and various articles on theoretical phonology and syntax.

Amy Hackney Blackwell has degrees in history from Duke University and Vanderbilt University and a J.D. from the Uni-

versity of Virginia. Her books include *Mythology for Dummies* (2002), *LSAT for Dummies* (2004), *The Everything Irish History and Heritage Book* (2004), and *Essential Dictionary of Law* (2004). She has contributed to the *Encyclopedia of World Nations and Cultures* (2006), *Alternative Energy* (2006), and *Chemical Compounds* (2006).

Christopher Blackwell, Ph.D., teaches classics at Furman University. He is the author of *In the Absence of Alexander: Harpalus and the Failure of Macedonian Hegemony* (1999) and various protocols and software applications for building digital libraries, and he serves as technical editor for the Center for Hellenic Studies of Harvard University.

Amy Bogaard, Ph.D., teaches prehistory and archaeobotany at the Department of Archaeology, University of Nottingham, United Kingdom. She is the author of *Neolithic Farming in Central Europe* (2004).

Peter Bogucki, Ph.D., is an archaeologist who is associate dean for undergraduate affairs of the School of Engineering and Applied Science at Princeton University. He has studied prehistoric settlements in Poland and has a particular interest in the spread of farming in Europe. He is the author of *The Origins of Human Society* (1999) and the editor (with Pam J. Crabtree) of *Ancient Europe 8000 B.C.–A.D. 1000: An Encyclopedia of the Barbarian World* (2004).

Larissa Bonfante, Ph.D., professor of classics at New York University, is the author of several books on Etruscan and early Roman culture as well as publications on ancient dress and nudity, including *The World of Roman Costume*, co-edited with Judith Sebesta (1994).

Charlotte Booth is a Ph.D. student at the University of Wales, Swansea, and teaches Egyptology for Birkbeck College and other institutions in the United Kingdom. She is the author of *People of Ancient Egypt* (2007), *The Hyksos Period in Egypt* (2005), and *The Role of Foreigners in Ancient Egypt* (2005).

Lisa R. Brody, Ph.D., teaches Greek and Roman art history at Queens College, City University of New York. Her research interests include Greek iconography and cult, ancient lamps and their decoration, children in antiquity, and representation of ethnicity in Greco-Roman art. She compiled the revised edition of David Sacks's *Encyclopedia of the Ancient Greek World* (2005) and is author of *Aphrodisias III: The Aphrodite of Aphrodisias* (2007).

David Brown, Ph.D., is researching the interactions of the pre-Islamic astral sciences of Mesopotamia, Greece, India, Egypt, Iran, the western Semitic world, and China at the Free University of Berlin. He is the author of *Mesopotamian Planetary Astronomy-Astrology* (2000) and *The Interactions of Ancient Astral Science* (forthcoming).

Deborah N. Carlson, Ph.D., teaches in the Nautical Archaeology Program of the Department of Anthropology at Texas A&M University. She also directs the Institute of Nautical Archaeology's shipwreck excavation of a Roman marble carrier off the Aegean coast of Turkey at Kizilburun and is preparing the final publication of the Classical Greek ship excavated by the Institute of Nautical Archaeology at nearby Tektas Burnu.

Jeffrey S. Carnes is associate professor of classics at Syracuse University. He is the author of *The Uses of Aiakos: Pindar and the Aiginetan Imaginary* (forthcoming) as well as articles on Greek lyric poetry, gender studies, literary theory, and Plato.

Julia Marta Clapp is pursuing her doctorate in art history at the Graduate Center, City University of New York. Her research interests include modern and pre-Columbian Latin American art.

Wendy E. Closterman, Ph.D., teaches ancient history and Greek at Bryn Athyn College. Her research focuses on Athenian burial and funerary ritual. She is the author of "Family Members and Citizens: Athenian Identity and the Peribolos Tomb Setting" in *Antigone's Answer: Essays on Death and Burial, Family and State in Classical Athens*, edited by C. Patterson (forthcoming).

Leah A. J. Cohen is an independent writer and editorial consultant with a master's degree in geography from the University of Florida. She specializes in Africa area studies and food security. She was a senior author for the *Encyclopedia of African History and Culture*, volumes 4 and 5 (2005).

John Collis is professor emeritus in the Department of Archaeology, University of Sheffield, where he taught for over 30 years. He has had a major role in the development of university and professional training in archaeology in Britain, and is secretary of the European Association of Archaeologists' Committee on Training and Education. He is author of several books and excavation monographs, including *Digging Up the Past* (2004) and *The Celts: Origins, Myths and Inventions* (2004).

Constance A. Cook, Ph.D., directs the Asian Studies program and teaches Chinese language and literature courses at Lehigh University. She is the author of *Death in Ancient China: The Tale of One Man's Journey* (2006) and coeditor of *Defining Chu: Image and Reality in Ancient China* (1999).

Susan Cooksey, Ph.D., is the curator of African art, Harn Museum of Art, University of Florida.

Justin Corfield, Ph.D., teaches history and international relations at Geelong Grammar School, Australia. He is the co-author of *Historical Dictionary of Cambodia* (2003) and

has written extensively on Asia, Australia, and European colonial history.

James A. Corrick, Ph.D., is a full-time editor and writer with 25 books to his credit. His most recent titles are *The Early Middle Ages* (2006), *The Byzantine Empire* (2006), and *The Renaissance* (2007).

Arden Decker is a Ph.D. candidate in the history of art at the Graduate Center, City University of New York. Her research interests include Mesoamerican art as well as modern and contemporary art of Mexico.

Leo Depuydt, Ph.D., teaches Egyptology at Brown University and is curious about everything relating to ancient Egypt in its Near Eastern and Mediterranean context, especially the area's languages and history. He wrote *Civil Calendar and Lunar Calendar in Ancient Egypt* (1997) and *The Other Mathematics: Language and Logic in Egyptian and in General* (2007).

Haig Der-Houssikian, Ph.D., is professor emeritus (2003), linguistics, at the University of Florida, Gainesville. His research and publication interests are in morphology, Creolization, and sub-Saharan Africa.

Christine End, M.A., works on the Giza Archives Project at the Museum of Fine Arts, Boston. Her main interests of research are Middle Kingdom funerary iconography, material culture, burial practices, and mummification. As a researcher and illustrator, her work has appeared in Egyptological publications and documentaries.

Linda Evans, Ph.D., specializes in ancient Egyptian art at Macquarie University, Sydney, Australia. She recently completed her doctoral dissertation on the representation of animal behavior in Egyptian tomb paintings and has published several papers on the role and depiction of animals in the ancient world. She has also contributed chapters to *Egyptian Art: Principles and Themes in Wall Scenes* (2000), *The Encyclopedia of Animal Behavior* (2004), *Egypt: The Land and Lives of the Pharaohs Revealed* (2005), and *Historica* (2006).

Stephen M. Fabian, Ph.D., is an anthropologist and currently teaches seminars on religion, myth, and ritual at Princeton University. He is the author of *Space-Time of the Bororo of Brazil* (1992), *Clearing Away Clouds: Nine Lessons for Life from the Martial Arts* (1999), and *Patterns in the Sky: An Introduction to Ethnoastronomy* (2001).

Erin Fairburn is a graduate student in the Department of Egyptology and Western Asian Studies at Brown University. She has contributed to *The City and Urban Life* (forthcoming).

Alessia Frassani is a Ph.D. candidate at the Graduate Center of the City University of New York. Her research interests in-

clude the art and civilizations of ancient Oaxaca and issues surrounding the cultural interaction between the Old and New Worlds.

Markham J. Geller is professor of Semitic languages at University College London, in the Department of Hebrew and Jewish Studies. He has recently published a text edition of cuneiform medical texts, *Renal and Rectal Disease Texts, Babylonisch-assyrische Medizin VII* (2005).

J. J. George is working on his Ph.D. at the Graduate Center, City University of New York. His research area is pre-Columbian art and architecture.

Wolfram Grajetzki, Ph.D., wrote his dissertation at the Humboldt University of Berlin and has taught Egyptology there. He has excavated in Egypt and Pakistan and was principal archaeologist and author for the online learning project Digital Egypt for Universities (University College London). He is preparing the catalogue of Egyptian coffins in the Fitzwilliam Museum, Cambridge. His publications include *Burial Customs in Ancient Egypt* (2003) and *The Middle Kingdom in Ancient Egypt* (2006).

Lyn Green, Ph.D., has taught at several Canadian universities and for the Royal Ontario Museum. She has contributed to several encyclopedias, including *The Oxford Encyclopedia of Ancient Egypt* (2000) and the *Encyclopedia of the Archaeology of Ancient Egypt* (1999) as well as *The Royal Women of Amarna* (1996). Currently she is devoting her time to her duties as president of the Society for the Study of Egyptian Antiquities, which has over 400 members and subscribers internationally, and to writing.

Angela Herren, Ph.D., teaches pre-Columbian art and architecture as an assistant professor in the Department of Art and Latin American Studies at the University of North Carolina at Charlotte. A specialist on painted manuscripts from central Mexico, she completed a 2005 dissertation entitled "Portraying the Mexica Past: A Comparative Study of Accounts of Origin in Codex Azcatitlan, Codex Boturni, and Codex Aubin."

David B. Hollander, Ph.D., teaches ancient history at Iowa State University. He is the author of *Money in the Late Roman Republic* (2007).

Brooke Holmes, Ph.D., is an assistant professor of classics at the University of North Carolina, Chapel Hill. She is at work on a book about the symptom in early Greek medicine and classical Greek literature.

Michael Allen Holmes is a freelance editor and writer who recently contributed to *Shakespeare for Students*, 2nd edition (2007). He has also written an unpublished novel.

John W. Humphrey, Ph.D., is professor of Greek and Roman studies at the University of Calgary. A veteran of many seasons of archaeological excavation in Turkey and Greece, he is the author of *Greek and Roman Technology: A Sourcebook* (1998, with J. P. Oleson and A. N. Sherwood) and *Ancient Technology* (2006).

Keith Jordan, M.Phil., is a Ph.D. candidate in pre-Columbian art history at the Graduate Center of the City University of New York. He is currently finishing his doctoral dissertation, entitled "Stone Trees Transplanted? Central Mexican Stelae of the Epiclassic and Early Postclassic and the Question of Maya 'Influence.'"

Amr Kamel is an Egyptologist in the Rare Books and Special Collections Library at the American University in Cairo, Egypt.

David Kelly is an instructor of English writing and literature at Oakton Community College in Illinois. He has written over 100 published literary analyses and wrote the instructor's manual for the *Exploring Poetry* computer program. His short fiction has been published in *The Rockford Review*, *Grub Street*, and *The Iconoclast*, among other places.

Panagiotis I. M. Kousoulis, Ph.D., is a lecturer in Egyptology at the Department of Mediterranean Studies of the University of the Aegean. He is the author of *Moving across Borders: Foreign Relations, Religion and Cultural Interactions in the Ancient Mediterranean* (2007) and *Ancient Egyptian Demonology: Studies on the Boundaries between the Demonic and the Divine in Egyptian Magic* (2007).

Philippa Lang teaches ancient science and related subjects, with research interests in ancient medicine and philosophy, in the Classics Department of Emory University, Atlanta. She is the editor of *Re-Inventions: Essays on Hellenistic and Early Roman Science*, *Apeiron* special issue vol. 37 (2004).

Russell M. Lawson, Ph.D., is associate professor of history and chair of the Division of General Studies at Bacone College in Oklahoma. He is the author of *Science in the Ancient World* (2004), *The Land between the Rivers: Thomas Nuttall's Ascent of the Arkansas, 1819* (2004), and *Passaconaway's Realm: John Evans and the Exploration of Mount Washington* (2002, 2004).

Anne Mahoney, Ph.D., teaches Greek and Latin linguistics and literature at Tufts University. She is the author of *Plautus: Amphitryo* (2004) and *Roman Sports and Spectacles: A Sourcebook* (2001). She is also the editor of revised editions of *Allen and Greenough's New Latin Grammar* (2001), *Morice's Stories in Attic Greek* (2005), and *Bennett's Essentials* (2007).

Susan Malin-Boyce, Ph.D., serves as deputy director of the Regime Crimes Liaison Office, Mass Graves Investigation

Team, in Baghdad, Iraq. She has contributed to *Ancient Europe 8000 B.C.–A.D. 1000: Encyclopedia of the Barbarian World* (2004) and to publications addressing Early and Late La Tène settlement in Bavaria, Germany.

Renee McGarry is a student in the Ph.D. program in art history at the City University of New York Graduate Center. Her research interests include Aztec sculpture of the natural world and religious manuscripts from the post-Conquest period.

Paul McKechnie, D.Phil., is a senior lecturer in classics and ancient history at the University of Auckland, New Zealand. He is the author of *First Christian Centuries: Perspectives on the Early Church* (2002) and *Outsiders in the Greek Cities in the Fourth Century B.C.* (1989).

John M. McMahon, Ph.D., teaches at Le Moyne College in Syracuse, New York, where he directs the classics program. He is author of *Cave Paralysis: Impotence, Perception and Text in the Satyricon of Petronius* (1998) and numerous articles on the intersection of ancient literature and natural history. His most recent work includes nine entries in the forthcoming *Biographical Encyclopedia of Astronomers* (2006).

Jianjun Mei, Ph.D., teaches the history of science and technology at the University of Science and Technology Beijing. He is the author of *Copper and Bronze Metallurgy in Late Prehistoric Xinjiang: Its Cultural Context and Relationship with Neighbouring Regions* (2000).

James E. Meier, Ph.D., is assistant professor in the Department of Humanities and Social Sciences at Central Florida Community College. He is a contributor to the *Encyclopedia of African History and Culture* (2005).

Francesco Menotti, Ph.D., is a lecturer in European prehistory at the Institute of Prehistory and Archaeological Science, Basel University, Switzerland. He is the author of *Living on the Lake in Prehistoric Europe* (2004).

Melissa Moore Morison is associate professor of classics and classical archaeology at Grand Valley State University. She has extensive experience in archaeological fieldwork in Greece, Turkey, and the United States. Her research interests include Roman provincial archaeology, Greek and Roman pottery, and ceramic technology.

Penny Morrill, Ph.D., teaches pre-Columbian and early colonial Mesoamerican art at Hood College, Frederick, Maryland. She has an essay, "The Queen of Heaven Reigns in New Spain: The Triumph of Eternity in the Casa del Deán Murals," in a Brill anthology, *Woman and Art in Early Modern Latin America* (2006). She has authored several books on modern Mexican silver: *Mexican Silver: 20th Century Hand-*

wrought Silver Jewelry and Metalwork (4th ed., 2007), *Silver Masters of Mexico: Héctor Aguilar and the Taller Borda* (1996), and *Maestros de Plata: William Spratling and the Mexican Silver Renaissance*, a catalog for a traveling exhibit (2002–2004).

Julian M. Murchison, Ph.D., teaches in the Department of Sociology and Anthropology at Millsaps College. His work in cultural anthropology examines the intersections of medicine and religion in East Africa. He recently published a chapter examining stories about a cure for HIV/AIDS in *Borders and Healers* (2005).

Caryn E. Neumann, Ph.D., teaches history in Ohio Wesleyan University's Black World Studies Department. She is a former managing editor of the *Journal of Women's History*.

Emily Jane O'Dell, is a Ph.D. candidate at Brown University and has taught at Brown University in both the Department of Egyptology and Ancient Western Asian Studies and the Department of Literary Arts. She has been the chief epigrapher of the Cairo-Brown University Abu Bakr Epigraphic Survey in the western cemetery of the Great Pyramids in Giza, Egypt, for the past five years.

Simon O'Dwyer is founder and researcher for Prehistoric Music Ireland, author of *Prehistoric Music of Ireland* and prehistoricmusic.com, and contributor to *The Encyclopedia of Music in Ireland* and *The Encyclopedia of Ireland*. He has published four papers for the International Study Group on Music Archaeology.

Penelope Ojeda de Huala is a Ph.D. candidate in art history at the Graduate Center of the City University of New York, where she studies pre-Columbian to contemporary art of Latin America. Her research focus is Guatemala and Peru, particularly the enduring thoughts and practices of indigenous cultures as manifested in art.

Michael J. O'Neal, Ph.D., is a writer who lives in Moscow, Idaho. He is a frequent contributor to reference and educational books, including *Lives and Works: Young Adult Authors* (1999), *The Crusades* (2005), and *America in the 1920s* (2006).

Dianne White Oyler, Ph.D., teaches African history at Fayetteville State University. She is the author of *The History of the N'ko Alphabet and Its Role in Mande Transnational Identity: Words as Weapons* (2005) as well as articles in the refereed journals *Research in African Literature*, *the Mande Studies Journal*, and the *International Journal of African Historical Studies*.

Katie Parla is an art historian and archaeological speleologist working in Rome and Naples as a docent leading didactic seminars of archaeological sites. She consults for the History

Channel and will appear in their 2007 series *Cities of the Underworld* as an expert on underground Rome and Naples.

Marie Passanante is a doctoral candidate in the Department of Egyptology and Ancient Western Asian Studies at Brown University.

William H. Peck teaches at the College for Creative Studies, Detroit, and the University of Michigan, Dearborn. He was for many years the curator of ancient art at the Detroit Institute of Arts and is at present a member of the Brooklyn Museum excavations in Egypt at Karnak. He is the author of *Drawings from Ancient Egypt* (1987) and numerous contributions to reference books and encyclopedias on the ancient world.

David Petechuk is a freelance writer specializing in educational texts focusing on the sciences, literature, and history. The former director of publications for the health sciences at the University of Pittsburgh, he is the author of *The Respiratory System* (2004), *LSD* (2005), and *Health & Medical Issues Today: Organ Transplantation* (2006).

Mark Anthony Phelps is taking a leave after teaching continuously since 1994 (primarily at Drury University, in five different departments) to finish his dissertation at the University of Arkansas entitled "Sewage from the Orontes: Roman Elite Attitudes toward Ecstatic Religion in the 3rd and 4th centuries C.E." This degree in ancient Mediterranean history augments his graduate degrees from Harvard and Johns Hopkins in Hebrew Bible and ancient Near Eastern languages and cultures. His research interests reflected in his writings are widely eclectic, spanning Paleolithic to contemporary society and including the disciplines of archaeology, linguistics, cultural anthropology, physical geography, historical geography, classical history, ancient Near Eastern history, medieval history, modern history, religion, and biblical history.

Jen Piro is a Ph.D. candidate in anthropological archaeology at New York University. Her dissertation research focuses on the development of pastoral economies in Early Bronze Age Transcaucasia.

Karen Radner, Ph.D., is lecturer in ancient Near Eastern history at University College, London. She specializes in the Assyrian Empire and is the author of *Die neuassyrischen Texte aus Tall Seh Hamad* (2002), *Das mittelassyrische Tontafelarchiv von Giricano/Dunnu-sa-Uzibi* (2004) and *Die Macht des Namens: Altorientalische Strategien zur Selbsterhaltung* (2005).

Judith A. Rasson, Ph.D., teaches in the Department of Medieval Studies, Central European University, Budapest (a post-graduate American-accredited university). Her research interests lie in southeastern Europe (especially the countries

of the former Yugoslavia) and focus on Neolithic and historic archaeology and ethnographic material culture.

Kelly-Anne Diamond Reed, Ph.D., teaches ancient Egyptian history and archaeology at Villanova University's Department of History. She is investigating early Egyptian funerary rituals and burial customs.

Duane W. Roller is professor of Greek and Latin at Ohio State University. Trained as an archaeologist, he has over 30 years' experience in field archaeology in numerous Mediterranean countries. He is the author of *The Building Program of Herod the Great* (1998), *The World of Juba II and Kleopatra Selene* (2003), and *Through the Pillars of Herakles* (2006) as well as many other publications in history, classics, and archaeology.

Kelley L. Ross, Ph.D., teaches philosophy at Los Angeles Valley College. He specializes in Kantian epistemology, metaphysics, and ethics, with emphasis on members of the Friesian tradition—Jakob Fries, Leonard Nelson, Rudolf Otto, Sir Karl Popper, and others. Since 1996 he has been the publisher and editor of the online philosophy journal *Proceedings of the Friesian School, Fourth Series*.

Edward M. W. A. Rowlands, M.Phil., has research interests in Mycenaean political geography, trade, and religion.

Lucas G. Rubin, Ph.D., develops master of science programs for Columbia University. He was previously administrator of the university's Center for Archaeology, where he managed multiple excavations and projects. His research and scholarship have focused on fires and firefighters in ancient Rome.

Michael M. Sage, Ph.D., teaches classics and ancient history in the Classics Department at the University of Cincinnati. His main areas of study are historiography and military history. He is the author of *Cyprian: A Biography* (1975) and *Warfare in Ancient Greece: A Sourcebook* (1996).

Rick Schulting, Ph.D., is a lecturer in scientific and prehistoric archaeology at the University of Oxford. His current research interests lie in understanding the Mesolithic-Neolithic transition in western Europe, emphasizing the use of radiometric dating and stable isotope analysis, and in skeletal evidence for interpersonal violence in earlier prehistoric Europe.

David R. Sear, a fellow of the Royal Numismatic Society in London and the American Numismatic Society in New York, has authored an extensive range of numismatic books over the past four decades, aimed at collectors and students of ancient Greek, Roman and Byzantine coinage. He has been a resident of Los Angeles for the past 25 years and operates a research service authenticating ancient coinage. His

numerous publications include *Roman Coins and Their Values* (1964; rev. ed., 2000–2005), *Byzantine Coins and Their Values* (1974, rev. ed., 1987), *Greek Coins and Their Values* (1978–1979), and *The History and Coinage of the Roman Emperors, 49–27 B.C.* (1998).

Robert Shanafelt, Ph.D., teaches courses in anthropology, religion, and Africana studies at Georgia Southern University. He has published a number of articles on different aspects of life in southern Africa, among them, “Crime, Power, and Policing in South Africa” in *Democratic Policing in Transitional and Developing Countries* (2006).

Alison Sheridan, Ph.D., is head of early prehistory in the National Museums Scotland, Edinburgh, specializing in the British and Irish Neolithic and Bronze Age. Exhibition work includes *Heaven and Hell—and Other Worlds of the Dead* (2000), for which she was lead curator and book editor. Other books include *From Sickles to Circles* (with A. M. Gibson, 2004) and *Vessels for the Ancestors* (with N. M. Sharples, 1992).

Spyros Siropoulos is senior lecturer of Greek philology and history at the Department of Mediterranean Studies, University of the Aegean, Greece. He has published various articles in three books: *Unlike a Woman: Gender and the Social Function of the Athenian Tragedy* (2003), *The Goat’s Skin: The Other Side of Alexander the Great’s Power* (2003; in Greek with English summary), and *The Things after Alexander: The Centrifugal Potencies of the Hellenistic Kingdoms* (2005, in Greek).

Bradley Skeen, M.A., has taught at the University of Minnesota, Webster University, and Washington University. He is a specialist in magic, religion, and philosophy in late antiquity and has contributed to research in that field in *Die Zeitschrift für Papyrologie und Epigraphik*, among other journals.

Christopher Smith, D.Phil., is professor of ancient history at the University of Saint Andrews in Scotland. He is the author of *Early Rome and Latium: Economy and Society c 100–500 B.C.* (1996) and *The Roman Clan: From Ancient Ideology to Modern Anthropology* (2006) as well as editor of several collections of essays, including *Trade, Traders and the Ancient City* (with Helen Parkins, 1998); *Sicily from Aeneas to Augustus* (with John Serrati, 2000), and *Religion in Archaic and Republican Rome and Italy: Evidence and Experience* (with Edward Bispham, 2000). He is engaged in work on Roman historiography and oratory.

Nancy Shatzman Steinhardt is professor of East Asian art and curator of Chinese art at the University of Pennsylvania. She is author of *Chinese Traditional Architecture* (1984), *Chinese Imperial City Planning* (1990), *Liao Architecture* (1997), and *Chinese Architecture* (2002) and more than 60 scholarly articles.

Tom Streissguth is a freelance author, editor, and journalist who has published more than 70 nonfiction and reference books. His most recent titles include *Clay v. United States*, *Genghis Khan’s Mongol Empire*, *Library in a Book: Hate Crimes*, *Eyewitness History: The Roaring Twenties*, and the *Greenhaven Encyclopedia of the Middle Ages*.

Ananda Cohen Suarez is a Ph.D. student at the Graduate Center of the City University of New York, specializing in pre-Columbian and colonial Latin American art history. She is particularly interested in cross-cultural encounters, vernacular religious art, and manuscript production in the early colonial Americas.

Frank J. Swetz, D.Ed., is professor emeritus of mathematics and education, Pennsylvania State University. His research interests focus on cultural and societal impact on mathematics learning and teaching. Among his recent books are *Legacy of the Luoshu: The 4000 Year Search for the Meaning of the Magic Square of Order Three* (2002) and *Teaching Mathematics to Children* (2003).

John Thorburn, Ph.D., is associate professor of classics at Baylor University, where he teaches a variety of subjects dealing with the classical world. He has published on Greek tragedy, Greek comedy, Greek and Roman history, and a variety of ancient subjects. He is the author of *The Alcestis of Euripides* (2002) and the *Facts on File Companion to Classical Drama* (2005).

Alain Touwaide, Ph.D., is a historian of sciences in the Department of Botany of the National Museum of Natural History at the Smithsonian Institution (Washington, D.C.). He has extensively published on the history of medicine in the Mediterranean world from antiquity to the Renaissance. Recently, he coedited the volume *Visualizing Medieval Medicine and Natural History, 1200–1550* (2006).

Francesca C. Tronchin, Ph.D., teaches Greek and Roman art and archaeology at Ohio State University. Her primary area of research is Roman domestic decor and issues of eclecticism in ancient sculptural displays.

David K. Underwood, Ph.D., teaches Western humanities, art history, philosophy, and Latin American studies at the University of South Florida in Tampa and at Saint Petersburg College in Clearwater, Florida. He is the author of two books and several articles and essays on Iberian and Latin American art and architecture.

David Vallilee is an independent scholar.

Frans van Koppen, M.A., teaches Akkadian at the School of Oriental and African Studies, London. He contributed to *The*

Ancient Near East: Historical Sources in Translation (2006) and *The Babylonian World* (forthcoming).

Lawrence Waldron, M.F.A., is an associate professor and doctoral candidate at the City University of New York, specializing in non-Western fields of art history and culture. He has presented and published various articles on the art and culture of the pre-Columbian Caribbean and Southeast Asia.

Ezekiel A. Walker, Ph.D., teaches African and world history at the University of Central Florida. His forthcoming book is entitled *Growth, Crisis and Transformation in the Cocoa-Farming Economy of Southwestern Nigeria* (2007).

Peter S. Wells is professor of anthropology at the University of Minnesota. His publications include *The Barbarians Speak: How the Conquered Peoples Shaped Roman Europe* (1999), *Beyond Celts, Germans and Scythians: Archaeology and Identity in Iron Age Europe* (2001), and *The Battle That Stopped Rome: Emperor Augustus, Arminius, and the Slaughter of the Legions in the Teutoburg Forest* (2003).

Jacqui Wood is an archaeologist and authority on prehistoric cooking and the lifestyles of prehistoric Europeans. She runs her own excavation in Cornwall, England.

Ronald Young, Ph.D., teaches in the Social Sciences Department at Canterbury School in Fort Myers, Florida. His teaching and research interests are in the area of Latin American Studies. In addition to numerous reference articles, he is presently working on a general history of Colombia to be published by Greenwood Press.

Katharina Zinn, M.A., is writing her Ph.D. dissertation on ancient Egyptian libraries and archives at the University of Leipzig, Germany. She works in a project on scarabs in the Fitzwilliam Museum, Cambridge (United Kingdom) and a project on Middle Kingdom Reliefs from Lisht in the Princeton University Art Museum. She has published articles on the organization of collective wisdom as well as multilingualism in ancient Egypt.

List of Illustrations

VOLUME I

Glass kohl tube in the form of a palm column, from Egypt	5	Marble statue of the Greek goddess of fertility, Demeter	37
Gold lion, used as a fabric ornament and found at Persepolis, Persia (modern-day Iran)	7	Section of the facade of a Roman aisled, barnlike building on a villa estate in the parish of Meonstoke, Hampshire, England	44

Toiletry implements from Roman Britain	10	The ruins of Persepolis (in modern-day Iran), the seat of the Achaemenian Empire of Darius I	63
Greek marble head, showing headdress of snail-shell curls	11	Panoramic view of West Lake in Lin'an (modern Hangzhou), China	66
Gold coin of the Roman emperor Marcus Aurelius, set in a gold ring	12	The theater at Epidaurus, Greece	76
Jade pectoral of the Olmec culture (Mexico), showing large holes in the earlobes, where earplugs would be placed	13	Engraving of the Roman Colosseum by Antoine Lafréry	80
View of rice fields in the Malagasy Republic of southern Africa	17	Petroglyph of animals and people at Tassili, Algeria, in North Africa	90
Wooden model of a man plowing with oxen, from Egypt	21	Banquet scene, fragment of wall painting from the tomb of Nebamun, Thebes, Egypt	95
Cuneiform tablet recording barley rations given to workers and their families at the temple of the goddess Bau, from Tello (ancient Girsu), southern Iraq	25	Human-headed winged bull from the palace of King Sargon II at the Assyrian capital Dur-Sharrukin (modern-day Khorsabad, Iraq)	99
Ritual spear blade from Japan	31	Schist head of the fasting Buddha, from Rawalpindi District, Gandhara, Pakistan	101
Iron Age farming tools, from Stantonbury Hill, Somerset, England	35		

Bird bone engraved with animal heads from the cave of Courbet, Penne-Tarn, France	106	Terra-cotta statuette of a lady in a swing, from Agia Triada, Herakleion	182
Hermes with the Infant Dionysus, by the Greek sculptor Praxiteles	111	Amphora from Pompeii, Italy	184
Roman terra-cotta relief showing an Egyptian scene set on the Nile	117	Feline-head ceramic bottle from Peru	185
Inner coffin of the priest Hornedjitef, Thebes, Egypt	125	Boys kept in seclusion in an initiation camp in Angola, southern Africa	188
Cuneiform tablet with observations of Venus, Nineveh, northern Iraq	126	Game of Senet from Egypt	190
Chinese covered jar	128	Terra-cotta figurine of a woman with a child, Cyprus	191
The Semna dispatches, administrative documents from an Egyptian outpost, from Thebes, Egypt	141	Profile of a Greek boy	195
Babylonian boundary marker, Sippar, southern Iraq	143	Roman rag doll made of linen, rags, and papyrus	196
Dedication by Alexander the Great to Athena Polias, from Priene, Asia Minor	146	Olmec figure of a baby (ceramic, cinnabar, and red ochre), Mexico	197
Wattle framework being filled with red mud, a construction technique used in ancient times, from Zambia	151	Ancient Egyptian city of Sesebi	206
Clay foundation peg from Bad-tibira, southern Iraq	154	Panels with striding lions, Neo-Babylonian, during the reign of Nebuchadnezzar II	211
Dolphin fresco in the queen's megaron (reception hall) at Knossos, the capital of Minoan Crete	159	Jade ritual reaping knife, from Henan, northern China	215
Iron window grill, Roman Britain	160	Roman silver coins depicting the founding twins of the city of Rome, Romulus and Remus	227
View of the royal tombs at Meroë, ancient city of northeastern Africa in present-day Sudan	164	Pottery vessel of the storm god, Teotihuacán, Mexico	232
Fragment of a basalt water clock, from Tell el-Yahudiya, Egypt	166	Grass, sand, and volcanic formation in the Sahara, southern Algeria	236
Kerma ware pottery beaker, from Kerma, Sudan	175	The Great Temple at Abu Simbel on the banks of the Nile	243
Painted pottery group of cattle, from el-Amra, Egypt	177	Ax made from reindeer antler found at Earls Barton, Northamptonshire, England	254
Ceramic bowl with abstract decoration, from Tall-i-Bakun in modern-day Iran	178	Petroglyph of a human figure wearing a loincloth, from the Sahara Desert at Tassili, Algeria, North Africa	273
Pottery jar with dragon handles, from China	180	Pair of child's leather sandals from Thebes, Egypt	275
Buccero ware water jug, from Chiusi, Tuscany, Italy	181	Two Assyrian court officials from the reign of Sargon II	276
		Caryatids from the Porch of the Maidens at Erechtheion, a temple on the north side of the Acropolis at Athens	280

Pottery figures of a drummer and a woman and child, Tala-Tonalá style, Jalisco, Mexico	283	Roman gold bars with assayers' stamps	368
Group of bronze tools for woodworking from Thebes, Egypt	287	Granite statue of Senmut holding Princess Neferure, the temple of Amun, Karnak, Thebes, Egypt	378
Stone bowl from Khafajeh, Iraq	288	Cuneiform tablet with schoolwork, probably from southern Iraq	379
Bird head made of stone, Papua, New Guinea	290	Yue ware water dropper in the shape of a frog drinking from a cup, from Zhejiang, southern China	381
Steatite vase from Greece	293	Fragments of painted plaster, Roman Britain, from Otford, Kent, England	385
Papyrus with part of the "Tale of the Eloquent Peasant" from Egypt	298	Colossi of Egyptian pharaoh Ramses II and his wife at entrance to Karnak Temple	395
Drawing by Michelangelo of the Crucifixion of Christ and two thieves	304	Portion of a relief in the tomb of Darius I, king of Persia, showing his throne bearers	400
VOLUME II			
Pyramid of a king, thought to be Adikhalamani Tabirqa, in Meroë, Sudan	312	Cowrie shells, the earliest form of money in China	429
A reconstructed Egyptian grave pit	314	Roman marble relief of Jason, the physician and patient	433
Jade eye plaques from China	316	Stucco head of a monk, said to be from Hadda, Gandhara	440
Iron Age pottery cinerary urn shaped like a hut, from Italy	318	<i>The Dream of Scipio</i> , by Raphael	444
Stele of Aristion, a philosopher of Athens	319	Papyrus marriage contract between the priest Pagosh and Teteimhotep, from Assiut, Egypt	449
Gold diadem, found in the Camaná valley, Peru	321	Scarab stamp seal and impressions, in lapis lazuli, depicting Ishtar, the Assyrian and Babylonian goddess of love, fertility, marriage, and childbirth	451
Bronze figure of Isis and Horus, from North Saqqara, Egypt	329	Fragment of an archaic Greek stele, with the heads of a mother and child	455
Babylonian lapis lazuli cylinder seal of Sin-ishmeanni	331	Ethiopian Orthodox priests at festival of Timkat	463
A 19th-century Indian painting depicting the climax of the epic the Ramayana	332	Roman hand of Sabazius, found at Tournai, Belgium	469
The figure of Silenus, the mentor of Dionysus, Greek god of plays	334	Pottery dog, from Colima, Mexico	471
Marble relief with two Roman theater masks	337	Fineware cup decorated with frogs and lotus flowers painted in black, from Faras, Sudan	473
The Great Harris Papyrus, from Thebes, probably Deir el-Medina, Egypt	347		
Mesopotamian stone vase depicting animals of the first city dwellers of Mesopotamia	351		
Indian bronze cast coin	355		
Mesolithic perforated part skull and antlers of red deer, from Star Carr, Vale of Pickering, North Yorkshire, England	359		

“Empress” pepper pot, from the Hoxne hoard in Suffolk, Roman Britain	478	Stone weight carved in the form of the head of an aquatic bird and thought to have been used in fishing, from Orange County, Florida	582
Terra-cotta utensil with six receptacles, thought to be an egg dish or cup holder	480	A bronze lamp found at the palace of Persepolis, Persia	586
Detail of an Ethiopian tribute bearer, from a relief in stairway of the palace at Persepolis, Persia (modern-day Iran)	486	Broken limestone lamp from the cave of Courbet, Penne-Tarn, France	589
Greek terra-cotta statuettes: woman holding pancake and woman kneading dough	500	Roman lamp showing a chariot race	591
Spout and bridge vessel in the shape of a woman, holding what is thought to be a spindle wrapped in cloth, from the Nasca culture of Peru	503	Paleolithic stone hand ax from Olduvai Gorge, Tanzania	593
Olmec jade perforator, from Mexico	536	Papyrus from the Book of the Dead of Nakht with agricultural scenes, from Thebes, Egypt	595
Coffin with skeleton of a child, from Speos Artemidos, Egypt	547	An administrative text in cuneiform (the world’s earliest form of writing), recording food supplies, probably from southern Iraq	597
Terra-cotta votive womb, Italy	551	Pair of fragments of silk, from Cave 17, Mogao, near Dunhuang, China	599
Hellenistic ivory figure of a hunchback thought to show signs of Pott’s disease	553	Roman aqueduct in Tunis	602
Altar from Roman Britain dedicated to the goddess Fortuna, the healing god Aesculapius, and Salus, goddess of health	554	VOLUME III	
Paleolithic stone chopping tools from Olduvai Gorge, Tanzania	562	Sandstone offering table with Meroitic cursive inscription around the edges, from Faras, Sudan	610
A folding wooden headrest, from Akhmin, Egypt	563	Clay tablet with Elamite inscription found in the treasury of the palace at Persepolis, Persia (modern-day Iran)	613
Stone bowl and pitcher from Greece	567	Jade disc inscribed with a poem by the Qianlong emperor, from China	614
Roman jug, two-handled cup (the handles now missing), strainer, ladle, and stirrer, from Arcisate, near Como, northern Italy	569	Linear A tablets, from Agia Triada, Heraklion	617
Archery case painted with a hunting scene, from Thebes, Egypt	574	The Rosetta Stone, from Fort St. Julien, el-Rashid (Rosetta), Egypt	623
Impressions of cylinder seals on clay, depicting hunting scenes and found in the treasury of the palace at Persepolis	575	Jade cicada, China	626
Harpoon tips made of antler from the cave of Courbet, Penne-Tarn, France	578	Page from the Book of the Dead of Hunefer, Thebes, Egypt	644
Fragments of a fresco from Tiryns, Greece, showing hunter and dog	579	Sculpted panel depicting Vishnu Trivikrama, eastern India	650
		Frieze of three Greek muses	657

Copper vessel with silver wire, from Ur, southern Iraq	680	Whistling vessel in the form of a macaw, Peru, Moche culture	773
Gold cup of the Bronze Age, beaten out of a single lump of gold and found in Rillaton, Cornwall, England	683	Rock inscription at Seheil, Egypt, recording a seven-year famine	777
Gold mask from Mycenae	684	Roman wall painting showing a coastal landscape, from Boscoreale, Campania, Italy	782
Hammered gold standing figure, Colombia or Ecuador	687	Petroglyph showing herders and cows, from Sahara Desert at Tassili, Algeria, North Africa	787
Granite statue of Senwosret III, from Deir el-Bahari, Thebes, Egypt	694	The Rhind Mathematical Papyrus, showing mathematical problems and solutions, from Thebes, Egypt	799
Albert Bierstadt, The Rocky Mountains, Lander's Peak	719	Painted Greek stele with metrical inscription	804
Detail of a Persian soldier from the stairway of the palace of Darius, king of Persia, at Persepolis (modern-day Iran)	728	Granite statue of Ankhwa, the shipbuilder, possibly from Saqqara, Egypt	810
The fortifications of Eleutherae, a city in the northern part of Attica, bordering the country of Boeotia	733	Spinning and weaving tools from Iron Age England	814
Roman marble statue of a youth on horseback and wearing a military cloak	735	Frieze of <i>hydriaphoroi</i> (water carriers) from the Greek Parthenon	815
Linen bag of salt for mummification, from Deir el-Bahari, Egypt, New Kingdom	743	Traditional healer in anti-smallpox costume, Nigeria, West Africa	820
Stone panel from the palace of Sennacherib, Nineveh, northern Iraq	744	Mesopotamian terra-cotta figure of an animal thought to be a dog	822
Lead pig (ingot), Roman Britain, from Hints Common, Staffordshire	749	Greek marble block from the frieze of the Temple of Apollo Epikourio (Apollo, the Helper), Bassae, Arcadia	826
The el-Amarna Hoard, from el-Amarna, Egypt	754	Limestone stela with images of the goddess Tanit, from Carthage (modern-day Tunisia)	834
Silver coins of various cultures found at Persepolis, Persia (modern-day Iran)	756	Limestone relief panel depicting the departure of Prince Siddhartha from his palace, to start on the spiritual journey that brings him to Buddhahood	846
Fragments of a stone mould and bronze knife money, from northeastern China	757	Iron Age horned helmet, from the River Thames at Waterloo Bridge, London, England	851
Cast ingots of bronze used as money in Rome before the invention of silver coinage	761	Frieze of the gods Greek gods Poseidon and Apollo and the goddess Artemis from the Parthenon	854
Babylonian relief plaque of harpist	766		
Red sandstone railing pillar in the form of a flute player, Mathura, northern India	767		
The Greek god Apollo with kithara, a stringed instrument similar to a lyre	770		

Jade votive ax of a figure combining human and animal traits and thought to represent a supernatural being, Olmec, from Mexico	863	Painted wooden model of a boat, from Meir, Egypt	977
Head of the Greek philosopher Socrates	878	Terra-cotta model of a merchant ship, Amathus, Cyprus	978
Ivory panel commemorating Quintus Aurelius Symmachus, an orator and figure in Roman government and a prominent pagan	881	Wall painting of Ulysses and the Sirens, Roman, from Pompeii	983
Section of the Neolithic Sweet Track, the oldest prehistoric timber trackway in Britain, from Somerset, England	888	A Scythian slave and the satyr Marsyas	992
Iron hipposandal, Roman Britain, found in London	891	Image of Psyche on a lead coffin lid, Roman, made in Lebanon	994
VOLUME IV			
Deep gorge in the Atlas Mountains of Africa	898	Sarcophagus of Nectanebo II, the last native ruler of Egypt, from Alexandria	1001
Limestone stela of Heqaib, from Abydos, Egypt	900	Basalt relief of a gazelle, Neo-Hittite, from Carchemish, southeastern Anatolia (modern Turkey)	1002
Iron Age Lindow Man, found in Lindow Moss, Cheshire, England	903	A Neolithic burial jade carved with faces, from southern China, Liangzhu culture	1004
View of Mount Olympus, in Attica	905	Coins from the Hoxne hoard, Roman Britain, found in Hoxne, Suffolk	1007
Gold ring bought by a pilgrim and showing the Roman Temple of Aphrodite at Palaepaphos	906	Servants carrying food for the king's tables, palace of Xerxes, Persepolis, Persia (modern-day Iran)	1019
Neo-Assyrian stone panel from the palace of Sennacherib, Nineveh, northern Iraq	912	Pottery, Japan	1026
Base-silver radiate of Carausius, with the emperors Diocletian and Maximian, Roman Britain	914	Double spout and bridge vessel with pelican and fish, Nasca culture of Peru	1041
Unwrapped mummy of a woman, perhaps from Thebes, Egypt, Late Period	926	Game of 58 Holes, made of ivory inlaid with gold and blue paste, from Megiddo, Palestine	1050
Bust of Pseudo-Seneca by Peter Paul Rubens	942	Ceramic Liubo players, from China	1052
Altar to the sea god Neptune, an offering from the Roman admiral of the British fleet, from Lympne, Kent, England	959	Bronze group of a bull and acrobat, Minoan, from Crete	1053
Aerial view of the Niger River and surrounding savanna during the rainy season	963	Hockey game, found in the Themistoclean wall, Athens	1054
Relief fragment showing Assyrian soldiers towing a boat through shallow water	967	Roman terra-cotta sculpture of two gladiators fighting	1056
		Stone <i>hacha</i> (ax), Veracruz, Mexico	1057
		Painted wooden model of a granary, from Aswan, Egypt	1063
		Amphora, a ceramic vessel used for storing and carrying oil and wine and other commodities, from Athens	1068
		Ugandan woman wearing a bark cloth dress	1074

Tapestry made of multicolored wool on linen showing Artemis and Actaeon, Egypt	1076	Bust of a Greek warrior known as Leonidas	1145
Wool textile fragment from Persepolis, Persia (modern-day Iran)	1078	Bronze statuette of the Mars, Roman god of war, Earith, Cambridgeshire, England	1151
Bone needles from the cave of Courbet, Penne-Tarn, France	1081	Stone ball found in Olduvai Gorge, Tanzania	1162
Greek utensil used for unwinding balls of wool, called Ariadne's clew box	1081	Short sword of steel, bronze, and gold from eastern Central Asia	1165
Mantle border fragment made of cotton and camelid hair, Peru	1084	Spear thrower carved in the shape of a mammoth, from the rock shelter of Montastruc, Tarn-et-Garonne, France	1167
Site of ancient walled town, Cameroon, Central Africa	1087	Vase from Mycenae portraying warriors in battle gear	1168
Gold bracelet or diadem, from the Phoenician trading center of Tharros, Sardinia	1099	Sixteenth-century shield depicting Roman battle scene	1170
Steatite seals from the Indus Valley	1100	Bronze duck weight, found in the treasury at Persepolis, Persia (modern-day Iran)	1175
Iron Age luxury imports from Italy, Rome, and the Near East, found at Hertfordshire, England	1102	Bronze steelyard with lead weights from Roman Britain	1178
The Crawford Cup, Roman, found on the border between Syria and Turkey	1105	Red porphyry one talent weight, from Knossos	1179
Petroglyph of camel and horse, from the Sahara Desert at Tassili, Algeria, North Africa	1111	Roman cup or bowl depicting a man carving the number 7 on a nilometer, a device used to measure the water level of the Nile's annual flood	1181
Achaemenid Persian gold model chariot from the region of Takht-i Kuwad, Tadjikistan	1114	Abu Simbel—hymn in praise of the Egyptian pharaoh Ramses II	1185
Horse harness fittings from Iron Age Britain	1116	Clay tablet with Babylonian inscription, found in the treasury of Persepolis, Persia (modern-day Iran)	1186
Chariot with horse and rider, from a sarcophagus at Heraklion	1119	Pillar edict of the emperor Asoka from Uttar Pradesh, India	1188
Frieze in the temple of the Egyptian pharaoh Ramses II, showing a listing of captured cities in Nubia	1127	Painted pebbles from cave of Mas d'Azil, Ariège, France	1188
Clay prism of King Sennacherib	1132	Bilingual milestone marker	1190
Stone figure of the war god Skanda, from eastern India	1139	Pottery inkwell from Roman Britain, inscribed with its owner's name, Iucundus	1191

Preface

Welcome to the *Encyclopedia of Society and Culture in the Ancient World*, a four-volume set that provides comprehensive coverage of the ancient world from prehistory through the fall of Rome in 476 C.E. For coverage after that point, readers are urged to consult our companion set, the *Encyclopedia of Society and Culture in the Medieval World*, which covers the period from the fall of Rome to the start of the Renaissance.

SCOPE AND ARRANGEMENT OF THE SET

The *Encyclopedia of Society and Culture in the Ancient World* contains 69 separate entries, each devoted to a specific cultural or societal topic. Of these 69 entries, 14 comprise “major” topics with longer, more in-depth coverage than the standard entries. The entries are arranged in alphabetical order by topic; readers may consult the Contents page for a listing of these topics.

Each entry includes a discussion of the topic from the perspective of the following centers of civilization:

- Africa
- Egypt
- The Middle East
- Asia and the Pacific
- Europe
- Greece
- Rome
- The Americas

Readers will note that there is some overlap in this list: Egypt is part of Africa, of course, just as Greece and Rome are part of Europe. However, because the civilizations of ancient Egypt, Rome, and Greece are so often studied separately, we decided to treat them as such in this encyclopedia. Entries devoted to Europe will thus not discuss Rome and Greece, while those devoted to Africa will not discuss Egypt.

In addition, we understand that the term *Middle East* has not traditionally been used to refer to the ancient regions of the Levant (Israel, Jordan, parts of Syria, the Palestinian Authority, and Lebanon), Anatolia (Turkey), Armenia, Persia (Iran), and Mesopotamia (Iraq and parts of Syria). However, some educators and scholars, especially those involved in comparative history, are beginning to adopt the term when discussing this region. We decided to use the term *Middle East* for this encyclopedia in light of that increasing usage.

ENTRY DETAILS

Each entry begins with an introductory essay that outlines the major developments on a given topic in the ancient world. Following that introduction are separate essays on the topic from the perspective of the named centers of civilization. At the end of the main text of each entry is a list of “see also” references to related entries, followed by a further reading list of books, articles, and Web sites on the topic.

OTHER ELEMENTS

In addition to the main text, the encyclopedia incorporates sidebars on topics that do not fit neatly into the central discussion as well key primary source excerpts scattered throughout the set. These primary source documents appear at the end of many entries. Our goal in identifying and including these primary sources is to facilitate additional comparative study between cultures on a given topic. Readers may consult the List of Primary Source Documents in the front matter for a guide to the individual sources found in the encyclopedia. The set also features more than 250 maps and illustrations. The front matter lists these maps and illustrations.

Aside from detailing the maps, illustrations, and primary source documents, the front matter includes a section about the set’s advisers and contributors and a general introduction

to the ancient world by Dr. Peter Bogucki of Princeton University, who served as the editor in chief of the encyclopedia. At the back of the set, readers will find a glossary of key terms, a general bibliography, a chronology by region, and a general subject index.

ACKNOWLEDGMENTS

In addition to Dr. Peter Bogucki and the members of the advisory board, we wish to thank the more than 100 scholars,

journalists, and writers who contributed to this work. At Facts On File, Claudia Schaab provided essential guidance throughout the project. A special note of thanks is due to Paul Halsall, who operates the Internet History Sourcebooks. This Web site supplied many of the primary source documents included in the encyclopedia.

—NEIL SCHLAGER AND
MARCIA MERRYMAN MEANS,
PROJECT MANAGERS

Introduction

The story of the ancient world spans the globe and covers vast amounts of time. It is the largely overlooked story of the tremendous diversity in human experience, ranging from the ice age societies whose way of life is so remote from ours to the citizens of Greece and Rome whom we easily recognize from history books. During the 2 million years since we became human, members of our species have settled every corner of the earth and organized their lives in countless different ways. The articles in this encyclopedia will provide you with an overview of the various ways in which people lived in the past and point to sources where you can find more information about the topics that interest you.

To learn about the modern world, all we have to do is look around, travel, read, or watch a video about what we cannot see. But we cannot travel back in time to see what life was like several thousand or several hundred thousand years ago. We cannot hear an ancient Roman speak, nor can we meet a Stone Age hunter in Siberia. We have to rely on researchers to piece together many different bits of evidence to come up with a picture of past life. A lot of the pieces are missing. Many people say that it is like putting together a jigsaw puzzle, but it is a puzzle in which most of the pieces are missing and, worse, there is no picture on the box.

The people who study the humans of the past call themselves various names. *Archaeologists* excavate and study the physical traces of past societies, called sites and artifacts, while *physical anthropologists* study the remains of ancient humans to learn about their evolution, health, and genetics. Researchers who study both the archaeology and the physical anthropology of the earliest humans are called *paleoanthropologists*. *Historians* and *epigraphers* study the texts and monuments of ancient civilizations, while *historical geographers* examine the ways in which past societies interacted through exploration and trade. *Paleobotanists* and *archaeozoologists* study the remains of the plants and animals that were used by ancient people, while *geologists* study events in the earth's history that may have affected the lives of nearby

people. Many other fields of research also contribute to our understanding of how people lived in the past.

SOURCES OF INFORMATION ABOUT THE ANCIENT WORLD

Scholars who study the ancient world have many sources of information to reconstruct life in the past. The most important categories are ancient sites, ancient artifacts, and ancient texts, supplemented by information on the ancient environment and climate. These are the pieces in the jigsaw puzzle that researchers must fit together.

SITES

Ancient sites are the locations where human activity took place in the past. Since there are many different types of human activities, there are diverse types of sites. The most important are settlements, burials, and ceremonial sites, but any location where ancient people performed some activity and left traces behind can be considered an archaeological site.

Settlement sites are probably the most common form of ancient site, for they are the locations where people lived. These can range from Stone Age caves to the residential parts of cities such as Athens and Rome. All settlement sites have characteristics in common that are of special interest to archaeologists. The first special characteristic of most settlement sites is that people built structures of various types. In the Stone Age cave they might have built a hearth by digging a pit and lining it with stones, while in larger settlements they built houses and other domestic buildings, along with storage pits, barns, and other necessary structures. The other important feature of settlement sites is that people create a tremendous amount of rubbish, and this rubbish contains a lot of information for archaeologists. In addition to the broken tools, pots, and other equipment of daily life, it also contains animal bones and charred seeds that provide information on the ancient diet.

Burials and cemeteries are another important category of ancient site. The skeletons of ancient people impart information about their diet and health, and the ways in which they were buried can tell a lot about how the society was organized. Sometimes burials are found within settlements, while at other times they are located in separate cemeteries. The corpses may have been buried intact, or they may have been cremated. Some burials are in simple pits, while others are in elaborate tombs. In many societies it was traditional to bury objects with the corpse that reflected the individual's status in life, while in other societies little or nothing is found in the tomb other than bones.

Another important type of site is the ritual or ceremonial site, sometimes called a "monument." Stonehenge in England is perhaps the most famous, but other examples include the mounds in Ohio that are shaped like animals when viewed from the air, the Nazca Lines in Peru, and the Sphinx in Egypt. While we do not know the exact purpose such monuments served, it is clear that they were not primarily the locations of settlements or cemeteries, though these sites may have been located nearby.

Finally, any location of ancient human activity qualifies as an archaeological site. These might include roads, boat landings, or even the boats themselves, buried in the mud. In Boston subway construction found the remains of an ancient fence that was used for catching fish by Native Americans around 2000 B.C.E. At high tide water and fish would pass over it, while at low tide the water would flow out and leave the fish stranded. This is an unusual and important type of site. Ancient sites are everywhere, and many more await discovery under our feet.

How Sites are Found and Studied Archaeologists are often asked how they find ancient sites. With the exception of well-known sites that are visible above the ground, like Stonehenge or the Mayan pyramids, the most common way that sites are discovered is by accident. A farmer plows up a stone ax, people digging a foundation find an ancient burial, a road construction crew discovers a prehistoric settlement—many sites have been uncovered by ordinary people who have the good judgment to alert scholars who can properly study the site. Sometimes, researchers search for sites using aerial photography or other scientific methods of detecting buried structures, and these techniques have also been very successful in discovering undisturbed sites.

When a site is found, it normally has to be excavated, which means digging away the soil to expose the structures, burials, and other finds and then measuring their exact location and documenting the discovery with drawings, photographs, and videos. This is the activity that most people associate with archaeologists, though it is only part of their job. It has to be done very carefully, because the act of digging up a site destroys it, even if the finds are removed or restored for display. For that reason, archaeological excavation must be done by trained and experienced investigators who know the proper techniques. Sites that are above the ground

still need to be measured and mapped as a way to understand their original size and their position in the landscape.

Archaeologists use many different techniques to determine the age of the remains that they find on sites. The most important scientific technique is carbon-14, or radiocarbon, dating, which is based on the decay of a radioactive isotope of carbon that is absorbed by living plants and animals and its measurement in charcoal, bones, and other organic remains. Carbon-14 dating is effective for artifacts between about 1,000 and 60,000 years old. For artifacts dating to before that time other methods are employed, depending on the circumstances. A very precise method of dating involves the counting of tree rings on sites where wood is preserved, and tree-ring chronologies that cover the last several thousand years have been established in many parts of the world. Archaeologists and ancient historians also can use artifact styles to date sites, especially when these styles can be correlated with historical events for which dates are known.

ARTIFACTS

Archaeological sites generally contain the objects made by ancient people and left behind as rubbish or as deliberate deposits in burials or simply lost. Researchers call these objects "artifacts," which refers to any portable object made by humans. If you look around you, you can see many types of artifacts. Those that are made from plastic, metal, and glass will probably still be around, if only in a landfill, in a thousand years, but those made from paper, leather, cotton, or wool probably will have decayed. On ancient archaeological sites, investigators usually find artifacts that might be made from stone, pottery, bone, or metals like bronze and iron if those were used by the ancient society. They might have served as tools, containers, ornaments, or symbols of rank. In very wet or very dry conditions wood, cloth, and netting might also be preserved.

Artifacts are studied closely by archaeologists and historians of the ancient world. First they are classified by material, form, and decoration. Then they are compared with other artifacts from other sites to see whether they are unusual or fit into a broader pattern of style shared throughout the region. Scientists also study the physical composition of artifacts to find trace elements that might point toward the source of the raw materials or which might show that the artifact was used for a specific purpose. For example, one of the most important recent breakthroughs in prehistoric Europe was the discovery of traces of fats associated with dairy products on pottery fragments, showing that animals were used for their milk as early as 5000 B.C.E.

DOCUMENTS

Toward the end of antiquity in many parts of the world people began to express themselves using systems of symbols to represent sounds, things, people, or ideas. Some systems of writing are tied to spoken language, such as the scripts used in the ancient Near East and the Mediterranean world; others,

such as the hieroglyphs of Egypt and Mesoamerica, represent people, places, and objects and the relationships among them. Some writing systems are not understood, such as the script used in the ancient civilization of the Indus Valley.

While documents may seem to provide very clear descriptions of ancient life, they need to be regarded with some caution. The ability to write was usually limited to a tiny fraction of the population in any ancient society, so the writing tells their story from their viewpoint, which naturally can be expected to be biased. The majority of the population had no representation among the literate, and thus they are known to us only through their sites and artifacts. Documents also may describe only a limited range of activities, such as royal histories or mercantile transactions, and usually they do not include discussions of everyday life.

ENVIRONMENTAL DATA AND GEOGRAPHY

Finally, scholars study information about the ancient environment, which would include pollen and seeds that reflect ancient vegetation and climate; animal bones to see what animals people hunted and herded; geological cores to study events such as volcanic eruptions; and lines scraped into rocks that show the advances and retreats of glaciers, which show when the climate warmed and cooled. Small creatures such as snails are very sensitive to changes in climate, and thus researchers study how the numbers of different species changed over time to track changes in the environment around a site.

Understanding the environment and climate in which ancient people lived enables researchers to comprehend why settlements are located in particular places, how agriculture and stock herding developed, what major events in the earth's history had an effect on human activity, and many other important aspects of ancient life. Although people could respond to changes in the environment and climate in many different ways, knowing the earth's history during the past two million years is important for grasping the variation in ancient ways of life.

AN OUTLINE OF WORLD PREHISTORY AND ANCIENT HISTORY

Although the scholars who study the ancient world focus on many different questions to guide their research, these questions can be grouped into several big areas. The following sections represent an attempt to delineate the matters that concern many researchers and at the same time to give a very broad summary of the story of the ancient world. The entries in this encyclopedia illuminate many aspects of these topics.

EARLY HUMANS AND ICE AGE SOCIETY

After archaic humans developed from their hominin ancestors two or more million years ago in Africa, they spread to Asia and Europe. On all three continents they lived in mobile foraging bands. Palaeoanthropologists debate whether they

actually hunted or rather scavenged the carcasses of dead animals, using stone hand axes and flakes. In Eurasia the ice age climate had a profound impact on their distribution and settlement. They developed the ability to make fire, probably between one million and 500,000 years ago, as shown by hearths at sites like Gesher Benot Ya'acov in Israel that are about 780,000 years old. Early humans also learned to organize sounds into language. Between 200,000 and 100,000 years ago, anatomically modern humans emerged in Africa and spread to Europe and Asia.

HUMAN DISPERSALS

Modern humans at the end of the last ice age made more elaborate stone tools and also had a capacity for symbolic expression, most vividly presented in the cave paintings in France and Spain between 30,000 and 15,000 years ago. They also colonized Australia, probably around 60,000 years ago, and the Americas, at least by about 15,000 years ago. Thus by about 10,000 years ago every continent except Antarctica was settled. The mammoths and other large animals that were found in ice age environments disappeared, replaced by the wild animals that we know today.

ADAPTATION TO MODERN CLIMATE

The end of the last ice age and the appearance of "modern" environmental conditions across the Northern Hemisphere and Southern Hemisphere led to many changes to human society. Rising sea levels cut off the Americas from Asia, so there was no further known contact between the Old World and the New World until the time of the Vikings and Christopher Columbus. The replacement of migratory herd animals such as reindeer by territorial forest animals like deer at temperate latitudes meant that people began to settle down and stay longer in one spot. They began to build substantial houses and to cross water bodies in dugout canoes.

SPREAD AND ADOPTION OF AGRICULTURE

One of the major consequences of settling down was the use of certain very productive wild plants such as wheat, barley, rice, and maize. Repeated human harvesting had the effect of domesticating these plants, enabling people to cultivate them to produce large quantities of edible food. Domestication took place at different times in different places: around 11,000 years ago in the Near East, about 9,000 years ago in China, and between 10,000 and 6,000 years ago in Central America, for example. In parts of the Near East and Asia people changed their relationships with animals, particularly cattle, sheep, goat, and pigs, from one of hunting to one of herding. Animals became livestock, which provided a continuous source of meat and also eventually milk, wool, and power for pulling carts and plows. From its core areas agriculture eventually spread to become the primary way that people in most parts of the world obtain their food.

DIFFERENTIATION IN STATUS, POWER, WEALTH

With agricultural surpluses and settlement in villages came opportunities for individuals and households to acquire more social status, political power, and wealth than their neighbors. Such social differentiation into elites and commoners, or patrons and clients, characterizes the later millennia of prehistory in many parts of the world (but not everywhere). At first, the differences were temporary and were not passed along from one generation to the next. Later, we often find that the children of elites inherited their parents' social status. Anthropologists often refer to small societies with hereditary social ranking as "chiefdoms." While chiefdoms did not occur everywhere, it does seem that they emerged in many parts of the world toward the end of prehistoric times.

RITUAL LANDSCAPES

Along with differences in status and power came the development of monuments and ceremonies meant to demonstrate and reinforce social relationships. Sometimes these monuments and ceremonies are connected with tombs that commemorate ancestral ties, while elsewhere they are connected with cosmology and religion. Many sites are mysterious and defy attempts to explain them. It is clear that their significance extends beyond the individual sites to their surrounding landscapes, where there are additional monuments and ritual structures. Thus archaeologists speak of "ritual landscapes" that held tremendous significance for ancient people.

THE RISE OF CIVILIZATION

In many parts of the world, civilizations led by kings and royal dynasties developed. Many early civilizations were based

in cities with large populations, such as those in Mesopotamia, while in others, such as Egypt and Central America, the rulers lived in royal precincts with their retainers, and most of the population lived as farmers in the countryside. Tribute flowed from the commoners to the elites. Many early civilizations developed the formal administrative structures and bureaucracy that are characteristic of states. Some, like the Romans and Assyrians, sought to expand their territory by conquest, thus becoming empires.

INTERACTION BETWEEN CIVILIZATIONS AND THEIR NEIGHBORS

Scholars are not interested only in states and empires by themselves but also in how they interacted with their neighbors, who may not have had such complex forms of organization. The classic example is the relationship between the Greeks and Romans and the people living outside their civilizations, which they called "barbarians," yet every civilization has to contend with the people outside their borders. The relationship may be complex. The outsiders might willingly provide important goods and even services, but they may also pose a threat to the civilization if they are belligerent. The rise and fall of civilizations in the ancient world is very much the story of their relations with the peoples beyond their frontiers.

With this background about the ancient world, you are now welcome to explore the articles in this encyclopedia.

Entries A to C

► **adornment**

INTRODUCTION

In modern life people in developed countries spend billions of dollars on personal adornments, including clothing, jewelry, makeup, hair-care products, and perfumes. It is tempting to believe that people who lived in ancient, simpler times, when mere day-to-day survival was their paramount concern, did not give in to the temptations of vanity. This belief would be incorrect. Throughout the world the archaeological record shows that people who lived thousands of years ago devoted considerable attention to their personal appearance and found numerous ways to adorn themselves. Of course, the extent and variety of this personal adornment varied with rank and social class in much the same way it does in modern life. Royalty and people of high social rank probably adorned themselves in much more luxurious ways than did the poor or members of lower classes. Not only could they afford the materials they needed for personal adornment; they also used such adornments as markers of their social class. Sometimes the adornments had religious significance as well.

Often, too, items of adornment had a more practical significance. In ancient times the world's population tended to cluster close to the equator, where climates were mild and people did not have to protect themselves from the bitter cold of more northerly regions. The trade-off, however, was that many ancient peoples were often exposed to extremely dry air and to intense sunlight. As a result, they took steps to protect and moisturize their skin using makeup made of a variety of substances, all with a view to restoring the skin's

moisture. Typically, as civilization developed, men were outdoors more than women, so they tended to have deep tans that protected them from the sun; women, on the other hand, spent more time indoors, so they needed more skin protection from both cosmetics and clothing when they ventured out.

The evidence that suggests a concern with personal adornment is found principally in tombs and artwork, though in some cases, such as ancient Greece, there is a written record of efforts people made to adorn themselves. Archaeologists, though, have discovered numerous artifacts in tombs that existed entirely for purposes of personal adornment, and surviving artwork shows people who used makeup, jewelry, clothing, and other items to enhance their personal appearance.

Most of these items were made from materials that were at hand, though as trade developed, the wealthy came to value imported materials as a symbol of status. Common materials used to create items of personal adornment included bone, shells, wood, precious metals such as gold and silver, other metals such as copper, and semiprecious stones, including, for example, jade. These materials were made into beads, necklaces, hair clips, rings, bracelets, necklaces, ankle bracelets, and similar items. Cosmetics were made primarily from plant materials, and spices were used for perfumes and lotions and for bathing. Henna, a dye still used in the 21st century, was often used as a hair dye. Throughout the world it was also common for people to use natural dyes to tattoo themselves. Among archaeological remains are also found such items as mirrors, tweezers, and similar cosmetic tools that would have been used particularly by women.

AFRICA

BY SUSAN COOKSEY

Most of what we know about African adornment in the ancient period is from archaeological evidence. Although a few objects such as beads have been found, the major sources of information are depictions of figures wearing various types of decoration. Even though few actual objects have been unearthed and many of the early representations of adornment items are difficult to decipher, we can hypothesize that most were made of natural materials. These probably included plant fibers, grasses, bark, wood, seeds, seed pods, roots, and leaves and animal hides, fur, feathers, bone, sinew, claws, horns, eggs, shells, and teeth. The earliest known forms of personal adornment—drilled ostrich shells—were found at the Kenyan site of Enkapune Ya Muto and date to 40,000 years ago. Shell beads have been used throughout many regions of Africa for both decoration and exchange.

Petroglyphs on cave walls in north-central Africa include images of male and female figures wearing various items of adornment. A cave painting in the region of Tassili n'Ajjer, done with white, red, and black pigments, depicts a large female figure with horns who appears to be running or dancing. In this painting that dates to 8000–6000 B.C.E., the figure has rows of dots on the torso and legs that may represent body painting, scarification, or tattooing. The horned figure also is wearing armbands and a rear apron made of long strands that appear to be fiber or hair. She has cuffs at her ankles, knees, elbows, and wrists with small random dots that may be multiple strands of beads, knotted fibers, or painted designs. Other figures in the painting have helmets and belts that seem to be made of shells.

In the Tsaisab Gorge in the Brandberg Mountains of Namibia in southern Africa, archaeologists have found rock paintings showing figures with body adornment. In one of these paintings, all of which date from 2000 to 1000 B.C.E., figures are depicted in a long procession. Rows of dots are painted on their heads, ankles, and knees that may represent beaded jewelry made of ostrich shell. Ostrich-shell beads are made from small sections of shell that are rounded to form flat white beads through which a hole is drilled so they can be sewn to a leather strip or strung on a thread.

Approximately 600 terra-cotta sculptures, many of which are adorned figures, have been found at Asinda Sika near Niamey, Niger. Dating from 200 to 1000 C.E., they include an elaborately ornamented male equestrian figure who has marks on his cheeks and forehead that may be scarification marks. Such facial marks may have signified his status or his ethnic identity. Large spiked bangles on his forearm are similar to armbands made of iron found on skeletons in Asinda Sika tombs. The equestrian figure also has crossed bangles on his chest and several choker necklaces. The pattern on these adornments suggests that they were made of either beads or braided fibers.

A great number of terra-cotta figures with various kinds of adornments were found in north-central Nigeria in the Jos Plateau region. They are a product of the Nok culture, named for the Nok Valley where many of the sculptures were found, an area between the Niger and Benue rivers. Through thermoluminescence testing, these figures have been dated to 500 B.C.E. to 500 C.E. Nok figures vary in style according to where they were found, but they all have elaborate head-dresses, hairdos, jewelry, and garments. Male figures have various types of hairdos and hats as well as distinctive and diverse forms of facial hair, including beards and mustaches. Among the hairstyles are long strands of hair hanging down their cheeks, upswept hairdos bound by bands, lobed hairdos with holes that may have been adorned with feathers, various types of buns, and ringlets.

Nok figures are also depicted wearing necklaces, collars, girdles, armbands, and anklets that may be multiple strands of beads. One small Nok figure of a kneeling man wearing many beaded strands is perforated with holes on the head and waist and may have been a pendant. A terra-cotta head has a trilobed hairdo with a band on the forehead that may represent a beaded headband, braided fiber, or iron chain. The beads depicted on the terra-cotta sculptures were probably made of quartz, as hundreds of quartz beads were found at Nok sites. The beads were made by placing the quartz pieces in a stone groove and grinding them into cylinders. Holes were then drilled in the cylinders with an iron tool.

Beginning in the first millennium B.C.E. and up to 300 B.C.E. there were thriving communities in the region of Asmara in Eritrea. These communities are referred to as Ona, after the site Ona Gudo. Archaeologists have excavated numerous artifacts of glass, stone, and ceramic, including beads, earlobe plugs, and lip plugs. The stone beads, made from chlorite, come in a variety of shapes. The lip plugs and earlobe plugs are ceramic and stone. One type of plug was made from soft black stone and has an incised surface. One lip plug resembles a type found in the eastern Sudan in the Atabi region, dating to the fourth millennium B.C.E. Similarly shaped glass ear and lip plugs were found in excavations of Axum, a powerful kingdom in nearby Ethiopia that arose in the latter part of the first millennium B.C.E.

EGYPT

BY EMILY JANE O'DELL

The ancient Egyptians adorned their bodies with jewels, perfumes, lotions, makeup, and a variety of hairstyles for aesthetic, health, and symbolic reasons both in life and in preparation for the afterlife. Both men and women in ancient Egypt took great care to moisturize and perfume their bodies, and they had various tools and palettes to help them create certain hairstyles and apply makeup.

There is no one hairstyle particular to ancient Egypt. Hairstyles changed with time, and different people in the same period were known to wear different hairstyles, based

on personal taste, fashion, sex, age, and social standing. Priests were required to shave their heads and whole bodies for ritual purification. However, other ancient Egyptians cropped their hair short or shaved it to fit their heads in wigs, to keep them cool in the heat, and to keep lice at bay. Small children had their heads shaved except for the so-called side-lock of youth, a long, side ponytail. Hairdressing tools were carved from bone or ivory and were used as metal hairpins and combs and to help curl, braid, and attach tresses of hair as extensions with the aid of beeswax and resin.

The upper class and royal family wore wigs of human hair reinforced with vegetable fibers. The hair of mummies, including those in the Royal Mummy Room in the Cairo Museum, has helped scholars piece together the various hairstyles, wigs, and hair colors of the ancient Egyptians. Gray hair was rare, for hair could be dyed with juniper berries and other plants. Hair loss and wrinkles could be combated with advice from medical texts.

One decorative element that continues to confound Egyptologists is the cone-shaped objects or headdresses that banqueters wear in reliefs from the Eighteenth Dynasty onward (after ca. 1550 B.C.E.). Although the symbolic meaning and practical use of these cones remains contested, it is generally assumed that they contained beeswax or perfume of myrrh along with wax, animal fat, or tallow. While they may have been used to combat the dryness of natural hair and wigs, their presence seems to be confined to party celebrations, suggesting that they may have been intended to be purely cosmetic and aromatic.

The ancient Egyptians took great care to clean, moisturize, and perfume their skin. Some of the body scrubs they concocted contained natron (a sodium carbonate-based cleansing agent), salt, honey, and animal fat and vegetable oils. Ancient Egyptian perfume did not utilize alcohol as a base; instead, Egyptians used a base of oils and fats that they infused with the scents of a multitude of plants, as displayed in tomb reliefs and Greco-Roman texts. Plants that may have been used for perfumes include the henna plant, the lotus, and the Madonna lily. In addition, it appears that ancient Egyptians used cinnamon, herbs, spices, carob, juniper, cedar, and resins that contained myrrh, frankincense, laudanum, and galbanum.

The ancient Egyptians are known for their use of kohl, a darkening cosmetic applied in the way we apply eyeliner today. It was not restricted to the living; it was also placed on statues of the gods and goddesses and on the deceased. Kohl was aesthetically pleasing but also may have helped reflect the rays of the sun and alleviate inflammation around the eyes by repelling insects that carry disease and cause infections. Kohl came in a variety of colors, such as black, taken from the bluish-gray lead ore galena, and green, which was derived from malachite. Kohl was placed on the eyes with a small stick of ivory, bronze, stone, glass, or wood both below the eye and above, on the eyelid. The ancient Egyptians also decorated their lips and cheeks with lip color and rouge

Glass kohl tube in the form of a palm column, from the Eighteenth Dynasty in Egypt (© The Trustees of the British Museum)

made from red ocher or henna combined with animal fat, which was applied to fingernails and toenails as well. Cosmetic containers and spoons were made of faience, glass, stone, clay, and wood in whimsical shapes and varying sizes. One popular form for the spoons had the body of a slender young woman as the handle. Cosmetics were mixed and ground on palettes that were frequently decorated in playful animal shapes.

Ancient Egypt is renowned for the colorful and finely crafted jewelry that was placed on images of deities and worn by royalty; men, women, and children all wore jewelry. Jewelry came in a variety of forms, such as rings, bangles, hairpins, arm cuffs, earrings, amulets, and beads. The high quality of the semiprecious stones and craftsmanship signaled the social class and wealth of its wearer. Jewelry was also traded and given for diplomatic reasons and to appease and influence the public, such as when the rulers Akhenaten (or Ikhnaton) and Nefertiti of the Eighteenth Dynasty (1550–1307 B.C.E.) threw jewelry down from the Window of Appearances, the central palace window from which the pharaoh would greet his court and foreign visitors. Jewelry was present in predynastic and early dynastic times, as evidenced, for example, by the bracelets from King Djer's (r. third century B.C.E.) tomb at Abydos as well as a type of pendant that was worn mostly by officials in the Old Kingdom (ca. 2575–2134 B.C.E.).

It is no secret that the ancient Egyptians favored gold. For those who could not afford gold, craftsmen used the process of gilding to make objects like faience, wood, and statite look like gold. Silver was not found in such abundance and had to be imported from the Near East and Aegean. The semiprecious stones used included turquoise, lapis lazuli, carnelian, amazonite, amethyst, malachite, calcite, obsidian, hematite, red and green jasper, and serpentine. These stones were used to fashion beads, amulets, pendants, and inlay pectorals. Glass, however, was not manufactured until the New Kingdom (after ca. 1550 B.C.E.). Faience was very popular for its malleability, color variation, and glazed appearance. Jewelry also featured flowers, shells, seeds, and ivory. A standard combination of red, green, and blue had arisen for royal jewelry in the Old Kingdom, but other members of society experimented throughout the rest of the pharaonic period (ca. 332 B.C.E.) with different colors and styles. A set of standard visual archetypes and designs crystallized in the Old Kingdom, such as the bee and falcon, lotus and papyrus, and text that would usually be a name of a king or deity accompanied by hieroglyphic signs.

Jewelry fulfilled more than an aesthetic function, as amulets were thought to provide good health, good luck, and stability in this life and the next. Most jewelry was believed to magically protect parts of the body. Perhaps the most phenomenal examples of jewelry from ancient Egypt come from the Middle Kingdom (ca. 2040–1640 B.C.E.) burials of the princesses Sithathoriunet (at Illahun) and Sithathor and Mereret (at Dahshur), which showcase a variety of bracelets and collars along with an exquisite gold diadem.

THE MIDDLE EAST

BY TOM STREISSGUTH

In prehistoric times the Mesopotamians were farmers and herders living in the fertile plains between the Tigris and Euphrates rivers. Their attire was simple and unadorned by jewelry and other personal effects. As the first cities were raised in Sumer (ca. 3000 B.C.E.), in southern Mesopotamia, trade with outsiders along the rivers and seacoasts allowed the import of stone and metal, resources not found in the region, and the gathering of wealth and possessions that marked high status. Social divisions emerged, while a centralized government gave rise to an aristocracy surrounding the kings and the priesthood. High status was shown by wearing more elaborate, ceremonial clothing decorated with embroidery and fringe and tassels at the neck and bottom hem and dyed with bright colors mixed from minerals and oil. Precious stones sometimes were woven into the clothing; in ceremony men of high status also carried swords, seals, and staffs, symbols of their authority.

Throughout Mesopotamia a great variety of personal adornments has been found in excavated cities, settlements, and graves. The most common item is a small bead, of clay, shell, or stone, which was strung onto leather and used in adornments of the head and neck, or sewn directly into clothing or footwear. Mesopotamian artisans developed great skill in drilling and stringing beads, even in the hardest stones and densest metals. Bead strings were the earliest mark of status and are commonly found in the most ancient gravesites and settlements of the Middle East. They often were used as a medium of exchange; in this time before the minting of coins, beads could be collected on their strings and easily unstrung or attached as people bought and sold their food and household goods.

The Mesopotamians also used pins and brooches to fasten clothing about the shoulders. (The most common item of clothing was a long mantle that hung from the neck and shoulders and was fastened on the left side of the body, leaving the right arm free.) Artisans worked these pins into long cylinders with one end shaped into a spherical head. Hairpins made of flattened and rolled metal were used to decorate the hair and hold plaits and braids on top of the head, a favored style. Small rings of metal were suspended from the hair locks and plaits. Headbands made of thin metal, some of simple design and some very elaborate, were worn around the forehead and tied in the back with a thin cord of string or leather. Royalty wore crowns worked in silver and gold, which covered the sides and back of the head like a finely woven metal helmet. Unadorned and undressed hair was a mark of the lower classes and slaves.

Men and women of the upper classes wore a great number of personal adornments, including amulets, ankle bracelets, necklaces, earrings, and seals. Artisans decorated these pieces with precious stones, including obsidian, turquoise, shell, serpentine, agate, jasper, and carnelian, a stone im-

ported from India. A favorite blue stone, lapis lazuli, was imported from the mountains of modern-day Afghanistan and worked into rings and necklaces. Gold was pounded into thin leaf and used as a setting, often shaped into leaves, cones, and abstract geometrical forms.

Some larger items of adornment allowed artists the space to depict the gods and spirits, or favorite scenes from myth. Pectorals were small plates sewn together, suspended from the neck and worn on the chest or over the abdomen. Pectorals (also used as body armor) and belts most commonly were worn by men, while both sexes wore armbands around the upper arm and bracelets on the forearm near the wrist. The Mesopotamians also wore knee rings, ankle rings, toe rings, and finger rings. The cylinder seal, which was originally meant to mark documents and possessions, later developed into a personal accessory. The seals were made of clay, ivory, bone, or stone and engraved with a geometric pattern, a symbol of high office, or a scene from mythology. They were

ANCIENT KOHL

The traditional black eye cosmetic known as kohl has several millennia of history, stretching back into the ancient kingdoms of the Near East and Egypt. Men as well as women used many different forms of eye makeup in Mesopotamia. It was a status symbol, indicating wealth and enough leisure time to care for and decorate the face. Makeup of different colors lengthened the eyebrows, accented the eyelashes, and rimmed the upper and lower eyelids to give a striking appearance.

In all times, painting the eyes with protective minerals also had a practical use: It warded off diseases of the eye that are still common in the dry desert climate of the Near East. Galena, a common ingredient of kohl, served as a disinfectant; it deterred flies and also provided some protection from the sun. Eye makeup also was believed to provide the wearer with psychic protection, warding off bad spirits and imparting good fortune.

Small glass tubes used to hold eye cosmetics are among the first glass objects of any kind. The tubes were made of silica, mined from quartz sand, and sodium carbonate, a substance made from the ashes of plants, which lowers the melting point of quartz. These tubes held galena or green malachite, which could be applied separately on the upper and lower eyelids. Later ingredients were antimony, lead, ocher, ash, malachite, and burnt almonds, mixed in various portions. The Akkadian word for galena, *guh*, was the original source of the word *kohl*.

hung about the neck and provided the wearer with protection and good fortune.

Men wore their hair long, with some going bearded, some clean shaven, and others shaving only the upper lip. Women braided their hair, wrapping a single braid around the head, fastening it with a pin, and adorning it with a head-dress on special occasions. They also made use of wigs and extensions to achieve the desired long and thick appearance. Both men and women wore headgear, most often in wool felt or linen. There were rounded, square, and conical caps worn by courtiers, soldiers, officials, and common citizens. In Persia of the Achaemenid dynasty (sixth century B.C.E.), prominent headgear indicated social position. Only Persian kings, for example, had the right to wear high turbans. Distinctive ribbons were worn by the king and the princes; royal officials and courtiers also had turbans and hats that showed their rank.

With bathing a relatively rare event, the Mesopotamians used a variety of oils and ointments to keep the body fresh and sweet smelling and to protect their faces from damaging sun and dry winds. On the occasion of a solemn religious ceremony, powdered minerals were applied to the face and around the eyes. Plant gums and resins, including cedar, myrrh, frankincense, lavender, thyme, rose, aloe, and cypress, were burned and mixed with vegetable oil (often sesame, olive, or almond) or rendered animal fat, to use as ointments and perfumes. Mesopotamian women distilled henna from a plant and used it to color their hair, hands, and nails.

Women also used mascara, lipstick, and face powder, applied with the tip of a reed; red or yellow ocher were the most common ingredients. By an Assyrian law passed in about 1200 B.C.E., women of the upper classes were permitted to go about veiled, but the veil was prohibited to slaves and prostitutes. Originally a sign of high status, this custom spread to the rest of society and throughout the Middle East in the millennia to come.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

In ancient China jewelry indicated a person's social status; the more expensive and elaborate the jewelry, the richer the wearer was considered to be. Most people wore earrings and amulets, charms used to ward off evil; they could be made of gold, silver, and stones such as jade, bone, or clay. Women wore headdresses made of gold or silver. Men fastened gold or silver pins on their hats. Most graves of the ancient Chinese contain pieces of jewelry owned by the dead person.

Because women dressed in long robes that hid the shapes of their bodies, they concentrated on decorating their faces, hands, and feet. Women spent a great deal of time on their makeup. They used powder to whiten their faces, rubbed red pigment on their cheeks and lips and gold makeup on their foreheads, and drew dots on their cheeks. Chinese people were very interested in eyebrows. They believed that only men should have natural eyebrows. Women shaved off or plucked out their eyebrows and drew them back in a more flattering shape. They used a black pigment made from a metal ore, charcoal, or ink. They might then paste designs between their eyebrows; plum blossoms were popular. They worked their hair into elaborate designs, the taller and more unique the better, and decorated their heads with combs and kerchiefs.

Jade was a common jewelry material; people started carving it as early as 12,000 years ago. By the time of the Zhou (1122–256 B.C.E.) and Han (206 B.C.E.–220 C.E.) dynasties jade carving was a highly developed art. Craftsmen made jade into bracelets, rings, pendants, and other objects—some of them elaborately carved. They fashioned jade into charms that had symbolic meanings and were meant to bring luck to the wearer; for example, a dragon charm was said to impart status and power to the wearer, and a butterfly could bring longevity.

Fans were the quintessential Chinese accessory. No upscale ensemble was complete without one. Dancers at the emperor's court raised fan manipulation to a high art form.

Fans could be made with bird feathers, paper, wood, or silk and were delicately perfumed. Silk was the first luxury fabric. Chinese people were wearing silk at least 3,000 years ago; at first only royalty could wear it, but soon it spread to the nobility and others concerned with showing their status. Silk provided the background for the elaborate embroidery that still decorates Chinese items today. The first known Chinese embroidery dates to about 1600 B.C.E. By the time of the Han Dynasty embroidery covered nearly every piece of cloth in the homes and on the bodies of the nobility. Women embroidered cloth with a vast range of images, including landscapes, wild animals, and geometric designs.

The ancient Chinese used scented gums and resins as incense and to anoint dead bodies, though in the earliest days they did not perfume themselves. They scented rooms to induce particular moods, choosing their incense based on the effect they wanted to achieve. In the early centuries of the Common Era, they made ample use of perfumes, scenting their bodies, clothing, ink, paper, and cosmetics. Scents could be made from Chinese camphor, Indian cinnamon, and sandalwood and from gum resins, ginger, nutmeg, and other spices from all over Asia.

People in the Indus Valley started making jewelry about 5,000 years ago. The habit of making and wearing jewelry quickly spread throughout India. At first Indian people made necklaces and bracelets out of beads of polished stone, clay, or shells. Around 1500 B.C.E. they began working with gold, making earrings, necklaces, bracelets, and other adornments. Women wore the majority of jewelry, often wearing several bracelets and necklaces at once to indicate their wealth and status. They also might wear rings, pins, and headbands of gold. Around 300 B.C.E. people in India began mining diamonds and other gems and incorporating them into jewelry. Indian people did not bury jewelry with their dead but instead passed it down to surviving family members.

Indian women used many cosmetics. The *Kama Sutra*, a manual written between 100 and 600 C.E. and describing

Jade ornament of four discs carved from a single jade pebble, from China, Eastern Zhou Dynasty, fifth century B.C.E. (© The Trustees of the British Museum)

methods for attracting lovers, suggests that women tattoo themselves and use makeup on their faces, nails, and bodies. They colored their eyelids with a dye made with antimony, a poisonous heavy metal. They colored their faces and arms with yellow saffron powder.

Henna, a paste that leaves red stains on the skin, was a popular cosmetic substance in ancient India and in other parts of Asia. Some historians believe that henna originated in ancient India about 5,000 years ago, though others think that it was brought to India from Egypt. Henna decorations appear in cave paintings in the Deccan in western India and in Sri Lanka, dating to the fourth or fifth century C.E. Indian people mixed henna with other plant substances, such as tea, coffee, or lemon, to make a paste and applied it to their hair to redden it. They also used it to draw elaborate designs on their bodies, especially for such special occasions as weddings. Henna stains can last for several weeks, until the upper layer of the skin wears off. The hands and feet were the most popular places to draw henna designs, partly because the stains last the longest on those areas of the body.

The art of making gold jewelry traveled with Hindu traders from India to Southeast Asia about 2,000 years ago. They landed in western Thailand, where the Mon people of the area learned the techniques and became expert goldsmiths in their own right. Early Mon jewelry looks very much like Indian jewelry of the time. Goldsmithing spread to the Khmer and Tai people to the east; they also made necklaces, earrings, and bracelets in the Hindu style. Pacific Islanders had limited materials with which to make jewelry. They made their adornments out of locally available materials, such as shell, feathers, bone, and wood.

Japanese adornment in ancient times was not nearly as elaborate as it became in later periods, and it usually had a practical purpose. Before 300 C.E. men and women wore clothing made of hemp, with loose belts that they tied in an attractive fashion. Between 300 and 500 C.E. the Japanese people began wearing robes made of silk, likewise fastened with decorative belts. These belts gradually evolved into the obi, a long, elaborately embroidered strip of cloth used to tie robes around the waist. The only jewelry Japanese people wore in ancient times were small pieces of jade carved into a comma shape and worn on a necklace. They buried these pendants with their dead. The Japanese did not begin working with incense until the fourth century C.E. They quickly developed incense into an art form, using it to set moods in rooms or to prepare the ambiance for ceremonies, but they did not regularly use perfume on their bodies until the eighth century.

EUROPE

BY CARYN E. NEUMANN

It is difficult to determine the types of adornment used in ancient Europe because much of the evidence did not survive the passage of time. Adornment included belts, brooches, crowns, hairstyles, and tattoos as well as perfumes and of-

ten served both ornamental and practical purposes. It also typically reflected class divisions. Many adornments, such as jewels and perfume, were available in only small quantities, and this rarity limited their use to the nobility.

Hairstyles are perhaps the simplest form of adornment. The Frankish kings in the second century wore their hair long, whereas the rest of the men in the royal court and other male subjects had short hair. Among the Celts, both sexes preferred long hair, which women wore in braided pigtails. Men apparently shaved all facial hair, preserving only mustaches. Among other groups, evidence of styles is lacking, though long hair appears to have been common for both men and women. On the other hand, perfume is one of the most complex forms of adornments, since the scent needs to be long lasting. Perfumes based on floral scents have been popular since ancient times.

Tattooing has been a European practice since Neolithic times (7000–2000 B.C.E.) but the purpose of tattoos at that period in history is not always clear today. Pict (from the Latin *pingere* for “painted folk”) warriors, active in present-day Scotland and noted in Roman literature in the third century C.E. colored their bodies with woad, a type of blue dye, before going into battle; this habit made them look terrifying to the Romans. The Picts may have turned themselves blue to intimidate their foes, to secure the protection of the gods, or to obtain some other advantage. Tattoos among Europeans often were animal designs, perhaps to give the wearers the attributes of the animals. The Picts were famously tattooed (or scarified, that is, cut or scratched) with elaborate dark blue woad designs. Germanic, Celtic, and other central and northern European tribes were also heavily tattooed, according to surviving accounts.

Belts were found at every level of ancient society because they had both ornamental and practical purposes. Distinctive belts served as insignia of high civil or military status. Beginning in the fourth century C.E. in Gaul and Germany, belts were buried in graves with their owners, since they expressed ideal status and were thought to protect their wearers. The wide belts of women found in Celtic graves have one or more leaves of beaten bronze, with geometric ornaments. In other parts of Europe gem-bedecked gold belts were offered along with swords as precious gifts and tribute. In Ireland belts sometime had hollowed spaces for holding relics or amulets.

Brooches in antiquity were also not simply ornamental items but frequently were employed to join pieces of clothing. However, most examples show some form of decorative elaboration, either through being made of showy metals like copper or gold or by being engraved or decoratively enlarged and used as a setting for gems. The Celts adorned themselves with copper and bronze bracelets and brooches of a style that has remained popular even in modern times.

Celtic jewelry is especially distinctive and has been well preserved through the ages. Highly imaginative representations of the human form, including both the head and full body, are found on Celtic jewelry. Geometric designs known as Celtic knots and representations of flora and fauna were also popular. Celtic knots are complete loops with no end or

beginning, possibly to ward off evil spirits. These intricately patterned knot designs undoubtedly had some significance, but those meanings changed from tribe to tribe and location to location. Celtic jewelry with animal patterns is similar in construction to Celtic knots, but the cords terminate in feet, heads, tails, and other animal elements. The animal designs reflect Saxon and Pict traditions of abstract beast forms. Much of Celtic jewelry was made of bronze, the preferred metal of this culture.

Crowns in ancient times were more exclusive. They served as symbols of rulership, as rewards, and as offerings in public and private ceremonies. Crowns ranged from ephemeral circlets of grass, leaves, and flowers to permanent insignia made of gold and gems. Their shapes also varied, from wide bands to diadems, tiaras, and ribbons. The type of crown used depended upon the ritual context and the wearers.

Various types of jewelry could be found throughout Europe. The Gauls had enameled torques, anklets, and rings,

which men wore on their left hands and women pushed only halfway onto their fingers. They also wore fibula, or clasps something like safety pins, with metal disks or openwork decorations. The fibula increased in size over time and was sometimes decorated with emblems. Much European jewelry was enhanced by gems. Amber, a stonelike substance composed of fossilized tree resin from the Baltic Sea coastline, may have been among the first substances used solely for decorative purposes. It was used extensively in ornaments in Europe from Paleolithic times (dating to as recently as 8000 B.C.E. but stretching back much longer). Nordic, Germanic, Celtic, and Slavic tribes all incorporated amber into their culture, with craftsmen fashioning the amber from its shapeless natural state into such personal adornments as beads and disks for the elite classes.

Other ornaments were made of tortoiseshell. The removable outside layer of a seagoing turtle's shell, tortoiseshell was used by cultures with access to sea turtles. The shell of the

Toiletry implements (including toothpicks, scoops to clean the ears, and instruments to handle cosmetics and creams) from Roman Britain, buried in the fifth century C.E. (© The Trustees of the British Museum)

green turtle was used in the Mediterranean, while loggerhead turtle shell had a northerly distribution. The high cost of the small tortoiseshell ornaments made them a luxury item limited in use to only the wealthy members of society. The Gauls were known to favor bold colors and used garnets in jewelry and other adornment. Gauls also preferred coral and enamels as decorative stones. Coral was often associated with lucky amulets, and workers even tried to imitate its color in enamel, a completely Celtic industry. Gaul craftsmen also made rings and bracelets from jet and ignite.

The use of adornment sharply diminished after the fourth century of the Common Era. The art of cutting gems declined rapidly, as did the use of amber. By the fifth century the only continuous jewelry-making practice within Europe was the cutting of garnets for cloisonné, or raised enamel work set into a metal background.

GREECE

BY SPYROS SIROPOULOS

It has been said that the fifth century B.C.E. was the age of vanity. This is what the thousands of beautiful statues, painted with lifelike colors, spread all around Athens signify. Greeks liked to see beauty around them. They certainly appreciated beauty and thought naught of enhancing it. In mythology the goddess of love, Aphrodite, was adorned by the Horae (female goddesses of the seasons) as soon as she was born. Then when Hera, the first lady of Olympus, needed to seduce Zeus to avert his attention from the battlefield of Troy, she called Aphrodite to make her up and help her with a beautifully adorned garment.

Adornment was popular among the Athenians of the Classical Period (480–323 B.C.E.), especially women. Archaeological excavations have unearthed a great number of artifacts used by the women of classical Athens, which are very similar to items used by women today. Among these are tweezers, pliers, mirrors, jewelry, and other means of enhancing one's natural beauty.

The Greeks knew nothing of soap. In order to clean themselves they used lead carbonate made of pure soda (ore); a solution of potash, made of wood ash (useful also for washing clothes); or a special clay, consisting of silica with chalk (*kimolia* in Greek). Even today the island of Kímolos in the heart of the Aegean Sea is famous for producing a light stone, rich in soda, called *kimolia*. For washing their hands, the ancient Greeks also used a kind of paste.

Women powdered their faces with a fine white powder called *psimythion*. In the fifth century B.C.E. Athenians thought much of women who stayed indoors and gave no reason for talk of them in public. Of course, only aristocratic women had no reason to go out to work in the sunshine, and thus a white complexion was associated with women of aristocracy, a detail often depicted in vase paintings from the same period. Women also liked to use red rouge for their cheeks and wore high shoes, to appear taller. The courtesans known as *hetaerae*

Greek marble head, from about 350 B.C.E., showing headdress of snail-shell curls (© The Trustees of the British Museum)

used the white color of carbonic lead and the red powder of a plant's roots, as well as dyeing their eyebrows.

The use of makeup was sometimes frowned upon, however. The philosopher Plato (ca. 428–347 B.C.E.) complained that using makeup was “harmful and deceptive” (*Gorgias*). Even the fifth-century B.C.E. playwright Euripides, in his tragedy *Medea*, seems to associate adornment and vanity with destruction. Planning to take revenge on her adulterous husband, Jason, Medea offers to his future bride, the princess of Corinth, fine veils and a golden headband, anointed with some kind of poison. Death finds the ignorant princess while she admires herself in front of the mirror.

Perfumes were bought from a *myropoleion* (“perfumery”), and they were of animal or plant origin, usually imported. A woman selling perfumes to a slave girl is depicted on one side of a *pelike* (a ceramic container for storing liquids) dating to about 460 B.C.E.; on the other side we see the girl carrying the small perfume jar home to her mistress. Perfumes were used by men, too, especially at symposia and wrestling halls, but it was considered disreputable for a man to sell perfumes.

However, there are cases when loans for establishing perfumeries by men are discussed by orators in court.

The length of hair varied from area to area. Spartan men wore their hair short, while Athenian men wore their hair long when they were young. Written and pictorial evidence attests to a tendency to curl hair—men did it too. Athenian women parted their hair in the middle and drew it back into a chignon. They never let it loose, except on the occasion of special celebrations and festivals. They cut their hair only when they were mourning, but slave women and hetaera wore their hair short.

Curling was so popular for men that they frequented professional hairdressers. One terra-cotta statuette from Boeotia from around 550 B.C.E. shows a man sitting on a hairdresser's chair, covered in a long towel that protects his clothes from falling hairs, while the hairdresser stands behind him holding scissors over his head. Not only women but men also used to lift and hold their hair in a kind of pug held by golden hair-pins that either looked like cicadas or sounded like cicadas as they walked. Dyeing of hair was not unknown. Facial hair was common for grown men in Athens, though they preferred to be clean shaven, especially in the years after Alexander the Great (356–323 B.C.E.), who was famously clean shaven. His successors continued the fashion.

Women cared much about smooth skin. Depilation with the aid of a blade and special creams or the burning of hairs with the aid of a lamp was very common. Women of the upper classes often wore a kind of hairnet or tight scarf called *kekryfalos*. From vase paintings we infer that this scarf pulled the hair from the forehead to the back of the neck and then pushed it forward. An ornament called a *diadema* added height to the forehead.

Golden and silver earrings, necklaces, rings, and bracelets have been made since the beginning of civilization. Many such findings come from the Minoan Period (2600–1450 B.C.E.) and the Archaic Period (680–480 B.C.E.). Stone inlay was rare, but men wore stone rings to be used as seals. Women often wore jewelry around their calves too. Heavy chains and pendants, popular in the Archaic Period, gave their place to thin coils and chains of linked wire and thin foil formed into petals and rosettes in the Classical Period. Bracelets were worn not only around the wrist but also between the elbow and shoulder, when that part of the arm was bare. Women pierced their ears for earrings, which were heavy and complex in the Mycenaean Period (1600–1100 B.C.E.) and took the form of light metal disks with a hole in the middle in the Classical Period.

ROME

BY ALAIN TOUWAIDE

Perfumes and cosmetics, which were much used in Greece, were not so common in the early Roman world. As time passed, their use spread, such that as early as 189 B.C.E., according to the Roman writer Pliny, a law banned so-called

Gold coin of the Roman emperor Marcus Aurelius, set in a gold ring, dating to 167 C.E. © The Trustees of the British Museum

unguenta exotica (“luxury unguents”), as they were seen as a corrupting influence causing Roman citizens to deviate from the traditional “*mos romanum*” (“Roman way”) of a more austere character. Nevertheless, the use of cosmetics and perfumes became more common with the transfer of Greek culture to Rome, particularly after the defeat of Greek troops in Pydna in 168 B.C.E., the presence of Greek hostages in the capital, and the arrival in a constantly increasing number of Greek physicians, technicians and others.

Perfumes in the Roman world reached their zenith under the empire (from 27 B.C.E. onward) with an extensive body of specialized literature on medicine and hygiene in general and also specifically on cosmetics. Among the writings focusing on cosmetics is a small booklet, *Medicamina faciei feminae* (Women’s Facial Cosmetics) by Ovid (43 B.C.E.–17 C.E.). The most famous and most specialized work on the topic was a volume by a disciple of Socrates, Criton (ca. 100 C.E.), now lost but which supposedly contained four books; it is known to the modern world only in fragments.

Perfumes were made of rare vegetal essences from the Near East, such as balsam, cardamom, and canella, as well as strongly odoriferous Mediterranean species, such as iris, saffron, and violet, together with gums and resins and, in some cases, such animal substances as musk and beaver glands. All such substances were soaked in olive oil, which had been treated to condense and separate out the fat component. They also included a fixative (moss, for example) and, for some, such colorants as saffron or ochre. The process of their production is described in *De odoribus* (On Perfume) by Theophrast (ca. 372–ca. 286 B.C.E.). One of the most famous perfumes was the so-called *koufi*, from Egypt, made of a wide range of substances. Because of the rarity of the ingredients, these perfumes were extremely costly and very much sought after. They were contained in small glass vials in the shape of fruits.

Cosmetics were aimed primarily at bodily hygiene. They were made mainly of perfumed lotions to be applied to the entire body several times a day. They also included a wide range of makeup products for women. On skin previously cleaned with a lotion, women applied mineral powders of different colors: white lead (which, in fact, was extremely harmful to the skin), chalk, and “Melian earth” (that is, earth from the island of Melos) for a pale color; *rubrica* and *purpurissum* for a touch of red; *stibium* (in fact, a derivative of lead) to make eyelashes and brows black. Various works on drugs and medicine, particularly *De materia medica* (The Materials of Medicine) by Dioscorides (ca. 40–ca. 90 C.E.), include an infinite range of recipes for the aesthetic treatment of wounds, scars, and other imperfections of the skin—not only to treat them but also to erase their possible traces. They were often made of caustic vegetal substances that eliminated the first layer of the skin, not without provoking problems due to excessive abrasion. Ancient Latin texts also describe cold creams for the skin, which were used to alleviate wrinkles and to make the skin soft.

Mouth hygiene was particularly important to ancient Romans. The *Compositiones* (Prescriptions) of the physician Scribonius Largus (fl. first century C.E.) describes toothpastes made of a pasty base, to which were added abrasive substances of a mineral nature (to clean the teeth) together with tasty vegetal products to refresh the mouth. Hair care was also important. Baldness was a major complaint, and medical texts list numerous vegetal and animal substances supposedly capable of regenerating hair. (In fact, they provoke a higher influx of blood to the scalp.) From the third century C.E. on, when recipes were listed in medical texts in detail, formulas against baldness always appeared first. All kinds of perfumed substances were applied to the hair, and it was colored either black or blond with vegetal and mineral products. Men’s hair, which was rather long, was dressed in early Roman times in a way very similar to the Greek style. The fashion trended toward shorter hair starting in the first century C.E. Women wore a rather simple hairstyle during the time of the Roman Republic, from the fifth century B.C.E. until the first century C.E. During the period of the Roman Empire that followed, however, they adopted extravagant styles dominated by the court. Later, from the second century C.E. on, simplicity made a comeback.

Personal adornment was completed with jewelry, even though extravagant jewels had been prohibited as early as the Twelve Table Law (the foundation of Roman Republic law, drawn up in about 451–450 B.C.E.). A short-lived prohibition against a woman’s right to own gold or wear elaborate clothing was instituted in 215 B.C.E. in the Lex Oppia (abolished in 195 B.C.E.). Nevertheless, the wearing of jewelry had a long tradition in the Mediterranean (dating back at least to the third millennium B.C.E.) and was widely diffused in Roman society, as the vestiges excavated at Pompeii, for example, testify. Women usually wore bands in their hair, earrings, neck chains, bracelets and arm rings, and rings on the index finger.

A particular case was gem rings, used as seals. The luxury of Roman adornment was sharply criticized by the first Christian apologists, who saw in it a sign of decadence that was rightly to be punished by God.

THE AMERICAS

BY JULIA MARTA CLAPP

Our knowledge of the objects that peoples from ancient American civilizations used to adorn themselves is largely dependent on findings at burial sites as well as on information deduced from paintings and sculptures. Many ancient American peoples were skilled metalworkers, and silver, gold, and copper were used frequently to great effect in addition to bone, jade, wood, and shell. The purposes of ancient adornment were often as an indicator of social rank and as part of religious rituals. Excavations from other ancient cultures, such as the ancient Egyptians, have yielded evidence of the use of cosmetics, both by depictions of made-up faces and the remains of cosmetics vessels. Unfortunately, in the ancient Americas no such evidence exists, owing partly to the relative lack of painted documents or sculpture. Any claims about the use of cosmetics at this point would be speculative and without significant material evidence.

Certain features are nearly omnipresent in Mesoamerican culture as early as the Olmec (1500 B.C.E.–400 B.C.E.). Stela 3, from the Olmec site La Venta (1200 B.C.E.–400 B.C.E.) in what is now Mexico, shows a ruler wearing a headdress so elaborate and tall that it nearly doubles the wearer’s height. Also notable from this era is the documentation of facial hair:

Jade pectoral of the Olmec culture (Mexico), showing large holes in the earlobes, where earplugs would be placed (© The Trustees of the British Museum)

Stela 3 has been dubbed “Uncle Sam” for its pointy beard. The early to middle preclassic Olmec Wrestler from Veracruz also has a beard and moustache, as does one of Los Danzantes (The Dancers) from Monte Albán, Mexico.

Other figural sculptures (sculptures that represent human beings) reveal still other kinds of bodily ornamentation that must have been practiced during this period. First and foremost are the holes left for earpools and lip plugs, which are larger than traditional pierced jewelry and require stretching of the skin. For example, a preserved wooden mask from the Olmec culture has stylized, rectangular ears with large holes in the lobes, indicating the use of earplugs during this period. One figure of a man from the Nayarit region of western Mexico (400 B.C.E.–150 C.E.) has bands around the upper arms and large rings in the nose and ears and a relatively elaborate hairstyle.

Of particular interest during this time in Central America was the harvesting and sculpting of jade in Costa Rica, particularly during the period 300 B.C.E. to 700 C.E. Ornamental objects in general—and jade, in particular—delineated social rank at a time when such distinctions were gaining importance in Central America. Personal adornment carried with it not only socioeconomic significance but religious importance as well. The first group in Mesoamerica to work jade was the Olmec, in the first or second millennium B.C.E. It is unclear whether jade working began indigenously in Costa Rica (ca. 500 B.C.E.) or as a result of intercultural contact (or some combination of the two). During the initial period (500 B.C.E.–300 C.E.), Costa Ricans carved pendants of jade, which may have been strung with beads. At the site of La Regla on the Gulf of Nicoya, archaeologists found a jade pendant and wooden beads that were likely strung together (ca. 500 B.C.E.).

The use of jade in Olmec cultures yielded some particularly interesting and beautiful objects. One jade pendant is in the form of a winged figure, though the wings are schematic and difficult to associate with a particular bird or beast. The pendant has holes, which would have allowed it to be attached to a ruler’s headband.

Burial sites of the Chavín culture (900 B.C.E.–200 B.C.E.) in what is now Peru offer insight into the adornment practices of ancient Andean peoples. At these sites archaeologists have found bone hairpins used to fix hairstyles and mantles (some with beads affixed to them), stone beads, earplugs made of wood (some with white shell attached to them), beaded necklaces of stone and shell, and a necklace with gold discs embossed with a serpentine design.

In the middle to later part of the Chavín civilization, as in other ancient American civilizations, these ornaments served to indicate the wearer’s social status. As they are today, items crafted with precious material and fine technology were prized. At a burial in Chongoyape, Peru, archaeologists found gold ornamental items, such as headbands, beads entirely in gold, pottery beads encased in gold, headdresses, rings, and pins. Metalworking was common in the Americas, especially using gold and silver in South and Central America.

At the Hacienda Almendral near Chongoyape, archaeologists discovered decorated gold crowns and earpools. Crowns were formed into a cylinder shape similar to an upside-down bucket. The gold was either molded or pressed into both abstract patterns and faces of people or animals. The ear flares had decorations similar to elaborate sun rays extending outward from the circular base. Another clue to the practices of hair grooming during this period is linked to the presence in the burial of tweezers, which may have been used by men to remove facial hair.

Burial items were deeply symbolic and significant, and the placement of the objects as well as their quantity and material were meaningful. One burial included a body with a quartz crystal in its mouth, which was of importance in terms of its placement and the value this civilization placed on quartz. Archaeologists also have found fascinating artifacts in the burial sites of rulers in Paracas, Peru (750 B.C.E.–100 C.E.). In addition to clothing and headbands, the sites also contained wigs made of human hair.

Some of the most spectacular examples of ancient Andean ornamental craftsmanship came from the site of Sipán, Peru (early Moche culture, 100 C.E.–700 C.E.). Sipán had three tombs filled with extraordinary examples of Andean gold work. In Tomb 3 (known as the Tomb of the Old Lord), archaeologists discovered a necklace made of 10 gold “spider” beads. The back of each bead was formed by a concave disc and the front of a human head with a spider body, with thin strands of gold forming the legs and web.

The Hopewell Indians of North America (ca. 200 B.C.E.–400 C.E.) left burial sites that also provide modern-day archaeologists and anthropologists with indications of what ancient American adornment looked like. In Hopewell burials archaeologists have discovered earpools, which often were made of copper, a costly material commonly used in jewelry. Earpools also were made of silver, sometimes in conjunction with copper, providing a contrast in color. Because ancient American cultures were deeply steeped in symbolism, the circular shape of the earpool probably was meaningful. The presence in a burial of more earpools than the deceased was capable of wearing indicates that their mere inclusion was significant. They would have testified to the social status of their owner.

Other copper items found at burial sites were bracelets and beaded necklaces. Copper was combined with leather to create what is known as a headdress but which more closely resembles a contemporary skullcap or ski cap. The leather was fashioned to fit over the skull to the ears, and a curved copper plate decorates the front middle portion of the headdress. In addition to copper beads, the Hopewell made necklaces of marine conch shells and beads in the shape of animals and birds.

► agriculture

INTRODUCTION

For most of human history people survived as hunter-gatherers. Hunter-gatherers fed themselves by hunting game, including fish, seafood, and birds (as well as birds' eggs) and by foraging for plant foods that grow wild, including fruits, berries, roots, leafy vegetables, rice, grains, and the like. Hunter-gatherers lived in small nomadic bands, meaning that they moved from place to place in search of food, especially as the seasons and weather conditions changed.

Because the ancient world was sparsely populated, hunting and gathering were successful ways of finding food much of the time. Populations did not have to compete with one another for territory and the foodstuffs it might contain. Further, the food supplies of a territory usually did not run out because of too much consumption; if they did, the band of people could simply move on to another territory.

As the world became more populated, however, it became less and less practical for roving bands of hunter-gatherers to move about at will. One band of hunter-gatherers often found itself in competition with another for food, leading to conflict. Growing numbers of people meant that food supplies in a territory could quickly become used up. Furthermore, hunting and gathering were extremely uncertain ways to obtain food. Early peoples were dependent on what they could find when they could find it, but such factors as drought, monsoon rains, and temperature extremes made the availability of food supplies inconsistent over time. Furthermore, early hunter-gatherers had no way of storing and preserving food. The result was often famine and starvation.

A major development in the history of humankind was the advent of agriculture—not just as a way of providing food but as a way of life. In roughly 7000 to 6000 B.C.E. humans began to trade their lives as hunters and gatherers for the more settled life of agriculturalists, though hunting and gathering did not disappear. By learning to plant, cultivate, harvest, and store crops, particularly important crops such as wheat, barley, and legumes (beans), people could provide themselves with a greater variety of food. They were no longer dependent entirely on what was locally available at a given time but could supplement their diets with other plant foods as well as with animal foods, such as goats, sheep, cattle, chickens, and, in some parts of the world, dogs.

Additionally, they could make use of by-products from agriculture for other purposes. The straw left over in the fields after a grain crop was harvested was used to give strength to mud bricks used in the construction of homes. Hides could be used for their leather, and such animals as sheep could be sheared to provide clothing, fabrics, and similar goods. Domesticated animals provided manure used to fertilize fields; in the case of sheep, goats, and cattle they also supplied milk. In turn, milk could be used to make cheese and butter. Chickens and other fowl provided meat and eggs as well as feathers that could be used in such items as bedding. Little went to waste on an ancient farm.

Agriculture enabled people to store and preserve food for the lean times. In such places as ancient Egypt, for example, farmers were able to grow a year's worth of grain, perhaps more, which then could be stored throughout the year and distributed to people as it was needed. This ability to store and preserve food evened out many of the ups and downs of food availability, reducing the threat of famine and starvation. The result was longer life expectancies, improved health, and the growth of populations. Adding to population growth was the fact that women, no longer having to move about in search of food, could bear and raise more children, who then were able to provide labor in the fields.

Perhaps most important, agriculture resulted in a more sedentary way of life. In modern times, the word *sedentary* has a negative connotation. It implies lack of physical activity, perhaps to the point of laziness. Historians, though, use the word to refer to settled cultures that did not move about as

nomads. Once people began to settle in villages and hamlets that were surrounded by their farming plots, cities began to grow. The growth of cities, in turn, gave rise to governments, institutionalized churches, art and architecture, trade and manufacture, and all the other characteristics of more modern civilizations.

Moreover, because farmers in outlying regions could produce a surplus of food, not everyone in the community had to be involved in agriculture. Surplus food meant that the community could support a class of civil servants, architects, engineers, soldiers, priests, artists, poets, and crafts workers, all of whom provided goods and services that enhanced the quality of life for their neighbors. As people gathered in larger towns and cities, they developed a sense of community and were able to bring individual points of view to public discussion, leading to more formalized belief systems, systems of government, economic and trade networks, public works, and the like. None of this would have been possible without the development of agriculture.

Agriculture, though, was not just a matter of sticking seeds into the ground and waiting for food to appear on the table. As agricultural systems became more complex and as the number of mouths to feed grew, people looked for ways to control their environment in order to maximize their food output. In many parts of the world, for example, rainy seasons were followed by drought, and the annual flooding of rivers was followed by a period of receding waters. In some parts of the world, particularly around the equator, the climate was desertlike.

As a result, humans put their ingenuity to work to develop dams, canals, sluices, waterwheels, and other engineering feats that enabled them to control and store water for use during the dry season. In turn, the ability to control water gave rise to systems for supplying drinking water and sewage systems for cities. Some people turned their attention to experimenting with different types of seeds to increase the variety and yield of their crops, in effect becoming the world's first experimental scientists. Still others focused their attention on developing tools that made agriculture more efficient. Early tools consisted of such items as simple wooden blades for cutting and stones for grinding grain. In time, agriculturalists developed more sophisticated cutting and grinding tools that enabled them to increase their output. Development of these tools provided the technology for tools used in other endeavors, such as the construction of palaces, temples, and other public buildings.

AFRICA

BY AMY HACKNEY BLACKWELL

Agriculture arose independently in many locations throughout the world, and each time it was the result of people's manipulating plants and animals that already lived around them. In Africa this process happened numerous times in different locations. Africa's geography prevented the smooth transmission

of crops and livestock from place to place. As a result, people on the continent never had the chance to develop large agricultural civilizations such as those in Mesopotamia.

Egypt was the first place agriculture appeared in Africa, arising about 6000 B.C.E. as traders from the Near East ventured into the Nile River valley, bringing crops with them. Near Eastern agriculture traveled as far as the Ethiopian highlands but could not move farther into the continent, owing to geographical and climatic barriers. Hunter-gatherers in the area just south of the Sahara domesticated livestock starting about 3000 B.C.E. but did not begin growing crops for another thousand years or so. Between 2000 B.C.E. and 1 C.E. people living south of the Sahara developed several different kinds of crops, depending on climatic conditions; people in West Africa grew rice and yams, while people in the Sahel grew drought-resistant grains.

Farming and herding did not travel south of the Serengeti until about 1 C.E.; eastern Africa around Kenya and Tanzania was home to the tsetse fly, which caused sleeping sickness, deadly to both humans and cattle. As cattle evolved resistance to the disease, farmers and herders began moving south into southeastern Africa, bringing African crops with them. People in this area gradually adopted some Asian crops as well, importing them from Indian traders. The southward progress of agriculture continued to be very slow; domesticated crops did not arrive in South Africa until the 17th century, and they came with European sailors, not overland.

AFRICAN GEOGRAPHY: AN OBSTACLE TO AGRICULTURE

Africa's geography presented a major obstacle to the spread of agriculture. Africa is a large continent with a wide range of climatic conditions. Its longest axis runs from north to south and crosses the equator, which means the various parts of Africa are very different from one another. The length of days varies depending on distance from the equator; this is important, because many plants grow well only in days of a particular length. For example, at the equator days are about the same length year-round. Far south of the equator, in South Africa, days are long in summer and short in winter. Plants that thrive at the equator may not succeed in South Africa. Seasons are different in different places as well; summer in North Africa is winter in South Africa. Tropical eastern Africa experiences the monsoons of the Indian Ocean. Rwanda is mountainous and has its own climate. By contrast, agriculture spread quickly through the Middle East and Asia because the Eurasian continent stretches from east to west on roughly the same latitude. Plants that grow in southeastern Turkey will also grow in Spain or Iran. Rice that grows in western China will also grow in Japan and India.

The Near East is close to Africa, so it would seem that agriculture would have quickly moved from there to Egypt, but in fact agriculture entered Africa a good 1,000 years after it traveled to Europe around 6000 B.C.E. The Sinai desert was

View of rice fields in the Malagasy Republic of southern Africa (© Board of Regents of the University of Wisconsin System)

the first obstacle; most people did not want to venture into it. The Sahara was another enormous impediment. Central Africa is full of dense rain forest and mountain ranges, both of which present difficulties to travelers. Middle Eastern crops grew well in the Nile River valley, with its stable climate and regular flooding. They also grew well in other locations with climates similar to that of the Near East, such as the Ethiopian highlands. They did not, however, grow well in Sudan, which has periodic monsoons. The Sahara likewise did not provide a suitable climate for Near Eastern grains. South Africa has a climate suited to Near Eastern grains, but it was so far away that no one could get there from North Africa.

As a result of these geographical limitations, agriculture did not spread readily through Africa, as it did through Europe and Asia. People domesticated plants and animals, but they did so in isolated pockets and independently of one another. This domestication also happened much later in Africa than it did in Eurasia; scholars believe that Africans did not domesticate their own grains until 2000 to 1000 B.C.E.

NILE RIVER VALLEY

The Nile River valley was the first place agriculture appeared in Africa. The Nile is a very long river, flowing more than 4,000 total miles through eastern Africa. The White Nile begins in Rwanda and flows north through Tanzania, Lake Victoria, Uganda, and Sudan. The Blue Nile starts in Ethiopia and flows through Sudan as well. The two tributaries meet in Sudan and flow north through the desert into

Egypt. People lived all along the length of the river. Thousands of years ago they lived as hunter-gatherers, hunting wild animals, fishing in the river, and gathering the many wild plants that grew in the river valley. The Nile River valley has a very regular annual flood schedule. The Nile overflows its banks every summer, and the flooding reaches southern Egypt by the middle of August and the Mediterranean about a month later. This flooding wets the soil along the length of the river for about two months, creating a moist environment for plants.

Agriculture traveled south down the Nile River valley between 6500 and 5500 B.C.E. People living in the Near East had started growing plants for food about 8000 B.C.E. Travelers venturing southwest into Egypt brought agricultural techniques with them, and these practices gradually made their way south into Africa. By 5000 B.C.E. the Nile River valley was populated by people living off domestic crops and livestock. They also made pottery similar to that of the Near East. Near Eastern agriculture traveled as far as the highlands of Ethiopia, where the climate was similar to the climate where the plants and animals had first been domesticated.

SUB-SAHARAN AFRICA

The Sahara is now a desert that grows bigger every year. Few people venture into it, and no one farms it. In prehistoric times, however, the Sahara was very different; it was fertile enough to be one of the places where humans developed agriculture. Scholars are not sure whether people living in Africa

invented agriculture or learned of agriculture from foreigners; archaeologists have not studied African history nearly to the extent that they have in other parts of the world. Nevertheless, it seems entirely possible that humans could have independently domesticated crops in the Sahara and Sahel.

Between 5000 and 2000 B.C.E., the Sahara had greater rainfall than it does now. Parts of it had so much rainfall that the areas were among the most fertile environments in Africa. The Sahel, the grassy area south of the Sahara, extended farther north and covered the areas that are now the southern and central parts of the Sahara desert. During the rainy season these grasslands became marshy in places, and seasonal lakes appeared. Hunter-gatherers lived on the shores of these lakes, gathering wild plants, fishing, and hunting the animals that came there to drink.

Africans domesticated cattle before they domesticated plants. Starting around 3000 B.C.E., people in the southwestern Sahara began to herd cattle. Most scholars believe that these cattle had come from domesticated cattle in the Near East that had traveled into Africa with herders in search of pastures. Other historians think that Africans caught and domesticated wild cattle living in the area. In any case, by 2000 B.C.E. numerous people in East Africa lived off their cattle herds, consuming meat and milk. The climate in the Sahara was starting to get drier around that time, and it was impossible to cultivate grain. Cattle became central to the economy there. People also herded goats, but cattle were much more important to them. They lived in villages with several houses made of mud and sticks, and they made pottery and traded with neighboring villages.

Around 2000 B.C.E. the Kintampo people of present-day Ivory Coast and Ghana began herding and trading sheep and goats in addition to cattle. They started growing pearl millet and extracting oil from oil palms around 1,500 B.C.E. At about this time agriculture began spreading slowly throughout central and southern Africa. People in the area had lived as hunter-gatherers, but they gradually began settling down and farming instead. These people were of the group called the Bantu. Bantu people started growing crops in the Lake Victoria region between 500 and 250 B.C.E.

In the first century of the Common Era people in modern-day Kenya, Malawi, Zambia, and Mozambique started cultivating African crops, including pearl millet, finger millet, and sorghum, and raising cattle, sheep, chickens, and goats. During the first five centuries C.E. people living on the Kenyan coast began trading with people sailing from India and Southeast Asia. They adopted Southeast Asian crops, such as bananas, yams, and taro, which grew equally well in the East African climate. During this period people living in wet coastal areas began settling in villages, feeding themselves with their crops. People in the drier inland regions continued to live as herders.

Agriculture and domestic animals did not reach the northern parts of South Africa until the late fifth century C.E. Farmers and herders could not settle farther south, across

South Africa's Fish River, because their crops could not grow in South Africa's Mediterranean-like climate. Agriculture did not reach South Africa until Europeans arrived in ships in 1652, carrying with them European crops that could thrive in the local climate. Agriculture's progress southward through the continent was quite slow, mainly because Africa itself presented so many geographical difficulties. In addition to the problems of terrain and adapting plants to new climates, pests such as the tsetse fly devastated populations of cattle and herders. Herders stayed north of the Serengeti Plain from 2000 B.C.E. until 1 C.E., by which time new breeds of livestock had evolved that could cope with the southern conditions. Humans had to adapt their trading economies as well; because travel was so difficult, different tribes rarely met and had to learn how to communicate with one another.

The people who adopted agriculture began raising several types of crops and animals at once. They grew sorghum, pearl millet, and finger millet, and they raised cattle, sheep, goats, and chickens. They began to work with iron as well, as the technology spread through the continent. As agriculturists took over the landscape, groups of hunter-gatherers were pushed to the margins. The Khoisan Bushmen were forced into the Kalahari Desert and South Africa, where they took up sheep herding. The jungle peoples of the Congo region continued to hunt and gather wild plants deep in the forests. The Bantu people themselves never formed the large civilizations that appeared in other parts of the world. They had villages and trading networks and cultural traditions, but they did not build cities or develop advanced technologies.

NORTH AFRICA

North Africa's climate and geography are very different from those of sub-Saharan Africa. Although the desert begins within a few miles of the sea, the area along the Mediterranean coast is fertile and flat. Phoenicians traveling from Lebanon colonized North Africa from Libya to Morocco between 1000 and 600 B.C.E. People living in the area farmed Near Eastern crops, such as wheat, for export to other areas. Carthage became the center of the North African trading empire in the fifth century B.C.E. Rome took over much of Carthage's territory after the Punic Wars, fought with Rome, forming a new province in northern Tunisia in 146 B.C.E. This province encompassed some 5,000 square miles of the most fertile part of North Africa. The land there became Roman public land, and the government leased it out to grain farmers, who grew wheat for export to Rome. North African estates were vast. Most of the land was in the hands of a few absentee landowners, although there were also more modest estates owned by locals. Scholars believe that about half a million tons of wheat left Carthage annually. Carthage became the second-largest city in the Mediterranean on the basis of its agricultural exports. By the second century B.C.E. North Africa was also exporting olive oil, figs, grapes, and beans. North Africa continued to supply grain to Rome until the end of the Roman Empire.

The main agricultural challenge in the region was lack of water. All African farmers had to irrigate their crops, and they invented elaborate systems to transport water to their fields. In areas with narrow rivers and flat lands, farmers dug canals and built dikes to channel and contain water. Every year large numbers of people worked together to clear canals of debris and repair damage to structures. In the areas closest to the sea farmers had to ensure that saltwater did not enter into their irrigation structures and kill their crops.

In areas where fields lay above the level of floods, farmers had to use mechanical systems of irrigation. One irrigation device was the *shaduf*, or *shadoof*, a device that lifted water in a container. It consisted of a wooden or stone frame with a long horizontal pole affixed to a hinge at its top. A farmer would tie a bucket or skin bag to one end of the pole and attach a stone or clay weight to the other end. If the device was balanced correctly, it was very easy for the farmer to lift the bucket or bag of water from a body of water and swing it over to an irrigation ditch that flowed into a field. Although irrigating a field with a *shaduf* was less work than carrying water by hand, it was still slow and laborious; one *shaduf* could irrigate about an acre a day.

During the Hellenistic Period two more advanced irrigation devices appeared. One was the Persian water wheel known as a *saqiya*. This device was a large wheel with buckets attached to its perimeter. An ox or donkey turned it to raise water from a river or pond and transfer it to an irrigation ditch. The Archimedean screw, or Egyptian screw, was a device that raised water by means of a large screw inside a pipe attached to an inclined plane. The lower end of the screw was placed in a body of water, and laborers turned the screw by hand. As it turned, it collected and raised water and then dumped it out at the top. Both the *saqiyah* and the Archimedean screw were large and expensive devices, out of the reach of most small farmers. Only large landowners could afford to use them.

AFRICAN CROPS

Africans south of the Sahara domesticated several crops that are not widely grown in other continents. All the African grains are annuals, plants that complete their life cycles in one year. Unlike the grains domesticated in the Near East, however, African grains all show a strong tendency to cross-pollinate. Near Eastern grains will pollinate themselves, which results in seeds that produce offspring just like their parents, a desirable trait for a crop. African grains will cross-pollinate with wild grains and produce plants that are very little like their parents. This probably made it much more difficult for African farmers to domesticate crops than it was for people in the Near East and Mesopotamia. They would have had to grow their crops far away from patches of wild grains that might contaminate the fields.

The main African grains were sorghum, pearl millet, and African rice. Africans also domesticated yams, oil palms, cowpeas, and groundnuts. Sorghum and pearl millet were

domesticated in the dry areas of the Sahel. Rice and yams grew better in the wet regions of the forest-savanna border in West Africa. In Ethiopia people domesticated two unique grains, finger millet and tef. Sorghum is a grass grown for its grain. People made it into couscous (a grainlike type of pasta) and porridge, which they ate with vegetables and sauces. Sorghum straw was used as a building material, mixed with mud to form bricks for walls. Sorghum is highly resistant to drought, an advantage in the dry climate of the sub-Saharan region. People were gathering wild sorghum for food about 6000 B.C.E. It was domesticated in the Ethiopian highlands of Africa around 1000 to 500 B.C.E.

Pearl millet is another drought-resistant grain. It grows wild in the region, and people evidently started gathering it more than 8000 B.C.E. It produces small seeds and is currently grown worldwide both as food for humans and as fodder for animals. Millet contains about 11 percent protein, about the same as wheat. It does not rise like wheat, so it cannot be used to make leavened bread. People generally grind it into flour to make into flat bread or boil it into porridge. Pearl millet probably was first domesticated in the southwestern Sahara, in what is now Mauritania and northern Ghana, around 1000 B.C.E. In addition to making pearl millet into porridge, couscous, or unleavened bread, people also used the stalks of the plants for building. Pearl millet traveled from Africa to India around 1500 B.C.E., and it became a staple crop there as well.

African rice is very similar to Asian rice. The ancestor of African rice resembles the wild rice of Asia and is closely related to it. Ancient wild African rice grew in holes in the ground that filled with water during the rainy season and dried out in the dry season, a similar environment to that in which Asian rice evolved. African rice became the staple crop in West Africa, where people boiled it and ate it with vegetables and meats. African rice was domesticated in West Africa near the Niger River around 200 C.E.

Yams are tubers or roots that grow underground. People prepare them like potatoes, boiling or roasting the flesh; certain substances in yams can cause illness if the yams are not cooked before they are consumed. A single yam can grow up to seven feet long and weigh 150 pounds. They have thick skins and brown or pink interiors. They can be stored for several months without spoiling, which made them an attractive crop for tropical climates, where the heat and dampness of the wet season quickly spoiled grains. They were especially common in West Africa.

Oil palms grow in West Africa. People domesticated them to harvest their fruit, which grows in clusters; each fruit consists of an oily seed surrounded by oily flesh. They pressed the fruit to extract the oil. Palm oil is high in calories and vitamin K, which made it a valuable addition to African diets. Animals can eat the meal left over from extracting the oil.

The cowpea is a type of bean. There are several varieties of cowpeas today; the best known are black-eyed peas and crowder peas. The cowpea plant can tolerate drier weather

than other beans, such as those domesticated in the Americas. It grows well in poor soils, can thrive in some shade, and is good for improving soils by adding nitrogen to it. Africans used the cowpea to correct the soil in their fields in between crops of millet or sorghum. Cowpeas appear to have been domesticated in West Africa between 2500 and 600 B.C.E.

Groundnuts are legumes related to peanuts with pods that ripen underground. They originated in West Africa, where they added protein to people's diets. The most common means of preparation was boiling. Like cowpeas, groundnuts were domesticated in West Africa sometime between 2500 and 600 B.C.E.; historians do not know more precisely when this happened.

Ethiopia, in eastern central Africa, developed its own unique agricultural products. Tef is a grain that is similar to millet, though tef contains more amino acids and minerals and therefore is a more complete food than millet. It grows well in the dry climate of the region, though it also grows well in waterlogged soil. Insects do not eat it, so they are not a problem during growing or storage. Cooks ground tef into flour to make flatbread or boiled it to make porridge. Ancient farmers also fed tef grain and stalks to their cattle and used the stalks to reinforce their mud bricks. Tef was domesticated some time before 1 C.E., most likely in western Ethiopia. It was probably more difficult to domesticate than wheat. Tef seeds are small, which makes it difficult to sow them evenly and to find them on the ground once they are sown. Because tef fields grow unevenly, farmers have always had to weed them by hand.

EGYPT

BY MICHAEL J. O'NEAL

Thousands of years ago, before the existence of Egyptian civilization, the regions of North Africa that surround the Nile River were fertile grasslands and woodlands, providing farmland and grazing land for communities of people. Historians estimate that around 3500 B.C.E., however, the environment in these grasslands began to change dramatically, perhaps because of overgrazing of the land, and eventually the region turned into desert, primarily the Sahara. Looking for a place where they could grow crops and keep herds of farm animals, people migrated into the area around the Nile River, forming small settlements beginning in about 3000 B.C.E. Because Egypt then and now has almost no rainfall, the Nile, which flows northward from Lake Victoria in Uganda, became the central feature of Egyptian agriculture, as well as of the Egyptians' cultural and religious life.

The region's very earliest settlers relied primarily on hunting, fishing, and foraging. They produced food, including limited crops, only for personal consumption. They were unable to store food, so food production was limited by the seasons. The development of more organized agriculture in many senses led to the rise of Egypt as a nation, for it was only through the agricultural surpluses that farmers produced

that Egypt was able to take part in trade and support a class of rulers, soldiers, scholars, civil servants, and others who made the existence of the state possible. Further, by growing crops that could be stored, the Egyptians could maintain a steady supply of food throughout the year. This enabled the population of ancient Egypt to expand dramatically, because famine became far less common. Without the Nile River, the world's longest river at 4,037 miles, ancient Egypt could not have existed as a nation.

THE FLOODPLAIN

The Nile River was surrounded by a fertile strip of land that provided the ancient Egyptians with most of their material needs. Immediately adjacent to the banks of the river was the floodplain. Each year, this land flooded with rising waters from the Nile, which was fed by water from monsoon rains in Ethiopia, far to the south. In an average year, the water would rise about 27 feet during a period called *akhet*, or the inundation, which ran roughly from July to December, with the flooding reaching its peak in late September and then beginning to recede in October. During this period, the land was flooded, and farm animals were moved to higher ground. The flood waters provided not only moisture for growing crops but also large amounts of fertile silt—that is, tiny particles of soil that were carried and left behind by the water when it receded. This silt was rich in nutrients, and it was in the waterlogged silt that the Egyptians planted their crops. The soil was so rich that it was black, causing the area often to be referred to as the Black Land.

In addition to the floodplain were higher elevations around the river. These areas of low desert did not become flooded, so they were not used extensively for crops. They were used primarily for hunting and burial of the dead. At still higher elevations away from the river were sparsely inhabited desert regions. In these areas, dates and grapes were cultivated. Traveling caravans passed through the desert, and the dates and grapes were often picked up and used to trade with other regions in North Africa and beyond. Water for these crops had to be laboriously transported from the river.

WATER MANAGEMENT

Growing crops in the floodplain was not simply a matter of allowing the water to recede and then sowing seed. The ancient Egyptians relied on a complex system of locks and dams to control, contain, store, and distribute the water. They built dams at right angles to the water's flow, forcing the water into large basins that covered some 1,000 to 4,200 acres of ground. These basins were lined with clay to prevent the water from seeping into the ground. The water in the basins was then diverted by a system of dikes into canals, where it flowed where it was needed. Keeping this system of dikes and canals in working order was an ongoing task. Each year every Egyptian (and most took part in agriculture) had to move on average about 23 cubic yards of soil to keep the canals and dikes working properly.

Wooden model of a man plowing with oxen, from the Middle Kingdom of Egypt (© The Trustees of the British Museum)

Overall, about 5 million to 8.4 million acres were flooded in this way. Construction of these dams, dikes, and basins occurred over a thousand years, so that by about 2000 B.C.E., the entire region bordering both sides of the Nile each year became a checkerboard of flooded basins during the high-water season and beyond. Water was regarded as property held in common, so the basins were also connected by sluices (canals with gates) so that it could be drawn for use upstream whenever there was not enough water downstream.

On average, the river rose 27 feet during the flood season. In some years, though, the river's rise would be less, sharply reducing the amount of water and silt and therefore the area available for crop cultivation. In these years, famine could result. On the other hand, in some years the water rose higher than 27 feet. The result was chaos, as people and farm animals could lose their lives as they scrambled to find higher ground. In modern times, the floodwaters of the Nile are controlled by the Aswān Dam. Construction of the dam was begun in 1902 and completed in 1988.

PLANTING

Planting usually began in December, after the waters had receded enough for work to begin. This period of receding waters was called *proyet* or *peret*, meaning “the emergence,” when the ground emerged from the water. The period December through March was the coolest season of the year. It was during this time that crops germinated and grew (unlike many other regions of the world, where crops are grown during the warmest months).

Unlike the soil in such places as the American Midwest, which has to be turned over with heavy plows, the light alluvial silt in which the ancient Egyptians planted their crops had only to be broken up on the surface. (*Alluvial* describes deposits of soil on a floodplain or anywhere it collects next to a body of water.) For this purpose the Egyptians used

plows that were light in weight and connected to the horns of oxen or even cattle. These draft animals were driven by a person, often children, with a stick. The plows were generally made of wood, although some had bronze blades. Sometimes draft animals were not available, so people pulled the plows or used short-handled wooden hoes to break up the surface of the soil; these hoes were so short that the work was backbreaking.

One important tool was the *shaduf* (also spelled *shadouf* or *shadoof*). This was a tool for irrigation that was originally developed by the ancient Sumerians. It was made of a long branch or pole on an upright frame. At the long end of the pole hung a skin bag, a bucket, or even a reed basket coated so that it would hold water. At the short end of the pole was a weight, typically a stone. This weight served as a counterweight to the bucket when it was filled with water. The operator lowered the bucket into the water and then easily raised it out with the help of the counterweight. He then swung the pole to carry the water to where it was needed, often an irrigation canal. Thus, the floodwaters continued to irrigate crops even after the river receded. Estimates are that a farmer could move about 660 gallons of water each day with the *shaduf*.

The planting of crops at this point was relatively easy. The farmer simply walked over the ground with a bag of seed, sowing the seed as he walked. Frequently, the farmer would then drive a herd of goats, cattle, or sheep over the ground. In this way the seed was pressed into the soil so that birds were not able to eat it. The ancient Egyptians grew a variety of crops in this way. The most common crops were grains. (In many older texts, readers are likely to find the word *corn* used to refer to these grain crops. To Americans, *corn* refers to the yellow vegetable found on cobs, but in earlier eras it was a general word for *grain*.) One was emmer wheat, though the Egyptians stopped growing this crop after the Romans took over the area. Other varieties of wheat were grown as well. Barley was grown for use in beer and in baking, though this crop became less important after the Romans invaded and replaced beer with wine as the favored beverage.

Other crops included flax, used to make ropes and cloth; papyrus reed, used to make such products as boats, paper, rope, sandals, and various household goods such as mats; and the castor oil plant, from which oil was pressed. Also grown were vegetables, though typically in smaller plots for consumption by the farmer and his family. Fruits included melons, pomegranates, dates, figs, and grapes. An enormous number of bees provided honey used in desserts.

In addition to crops, the ancient Egyptians relied on livestock for food. Some of this livestock, including oxen and donkeys, was used to help with the work of plowing and harvesting. Later, around 1600 B.C.E., camels and horses were imported from Asia for similar purposes; camels were unknown in Egypt during the time of the pharaohs. Otherwise, the Egyptians also kept sheep, pigs, goats, ducks, and cattle for consumption as well as for hides and milk. Dried animal dung was put to use in cooking fires.

HARVESTING

The dry season began in March and continued to July. This period was called *shemu* (also *shomu*), meaning “the drought.” Harvesting usually occurred in May or June and sometimes in April, before the next flood began. Grains were harvested using sickles made of wood that was cut and glazed to form a sharp edge; by Roman times sickles made of iron were becoming more common.

Large estates made use of traveling harvest teams, who began their work early in the season and followed the maturing of crops downriver as the season progressed. (The Nile flows north into the Mediterranean Sea, so *downriver* means in a northerly direction and *upriver* refers to a southerly direction.) Because harvesting involved a great deal of work in a relatively short period of time, nearly everyone participated. Livestock was then allowed to graze in the fields to eat the stalks left behind. Also, poor people often followed harvesters, hoping they could scavenge some bits of grain for themselves.

After the grain was cut with sickles, it had to be bundled. Sometimes the bundles were loaded onto the backs of donkeys, but often they were carried in sacks suspended from poles, each pole carried by two men. The grain was then taken to a dry place to undergo a process called *parching*, or drying out the grain so that it did not later get moldy or rot. There, the threshing process would begin. Workers spread the grain, still on its grassy stems, in a fenced or otherwise contained place where the ground was packed hard and first carefully cleaned. Donkeys then trampled it. In some places cows performed this job. This trampling helped separate the grain from the chaff, or the seed coverings and other debris that is not eaten.

During the next step in the harvesting process, called winnowing, workers used large forks, like pitchforks, to scoop up the straw, leaving behind mostly grain. The straw was kept for use in the production of mud bricks, which were strengthened by the inclusion of the straw. Using sieves made of palm leaves and reeds, workers—usually women at this stage—sifted the materials to further separate the grains from the remaining smaller bits of chaff. Finally, the grain was ready to be stored in granaries for later consumption.

The fields of ancient Egypt were highly productive, particularly considering that crops were grown without benefit of modern tools or fertilizers. Records show that at that time an acre of land could yield nearly 4,200 pounds. Total production could range as high as 2.8 million tons, though 2.5 million tons was the production for a typical good year. This amount of grain fed a population during the New Kingdom (1550–1070 B.C.E.) that has been variously estimated from as few as 2 million to as many as 5 million people. During bad harvest years, production fell to as low as about 1.5 million tons.

One period of dryness demonstrates the vital importance of the Nile and its annual flooding in the life of the ancient Egyptians. Late in the third millennium B.C.E., Egypt suffered a period of great political instability. The

royal families were feuding, and questions arose about the proper succession of kings. Then, around 2134 B.C.E., the Eighth Dynasty fell. In the resulting power vacuum, local nobles seized control of the land in their areas and gained command of portions of the king’s army. Although in theory

HYMN TO HATHOR: THE EGYPTIAN AGRICULTURAL CYCLE

About two miles southeast of the town of Dendera, Egypt, is the Dendera Temple complex, which features one of the best-preserved temples in all of Egypt. Covering about 430,000 square feet, or nearly 10 acres, it has become a major tourist attraction. The main temple in the complex is the Hathor Temple, dedicated to the goddess Hathor, whom the Egyptians regarded as the mother-goddess of the world and the patron of, among other things, the sky, the sun, music, dance, and the arts. The dates of construction provided in the texts inscribed on the temple range from 54 B.C.E. to 64 C.E.; it was built on the site of an earlier temple from the Middle Kingdom (ca. 2140–1640 B.C.E.).

Hathor’s name means “house of Horus,” referring to the night sky and therefore the god of the sky, Horus, who was the son of Osiris. As a mother-goddess, Hathor had been considered in earlier centuries as symbolic of the Milky Way, which the ancient Egyptians believed was the milk that flowed from a celestial cow. Thus, as far back as 2700 B.C.E., Egyptians worshipped her as a cow deity. She was also known by the name Mehturt (also spelled Mehurt, Mehet-uret, and Mehet-Weret), a name that means “great flood,” again in reference to the Milky Way. However, because the Egyptians saw the Milky Way as a waterway on which the gods could travel, they came to associate it with the Nile River. Hathor, then, was believed to be responsible for the yearly flooding of the Nile. In this way, she also became associated with motherhood, for the breaking of the amniotic sac as a signal that a woman is about to give birth was thought of as analogous to the flooding of the Nile, with the “birth” of the crops that would grow after it receded.

Archaeologists discovered a hymn to Hathor when they refurbished the Dendera Temple complex. This hymn, inscribed on the Hathor Temple, makes clear her connection with Egyptian agriculture. Hathor is said to “cause the flood flowing downriver in its season.” To farmers, Hathor caused “the watered earth to close over the seed when its right time has come,” making men to “work it in joy.”

Egypt retained a ruling monarch, in practice these nobles ruled Egypt, often causing suffering among their people. Much of this instability came about because of a long period of dryness. The people were starving, and in response many became violent. Peasants revolted and seized property from landowners, turning them into servants. Order was restored to the country beginning in about 1900 B.C.E., when Amenemhet I took power and began a new dynasty. It is likely that much of this instability would not have occurred had it not been for the famine caused by low flooding of the Nile.

Amenemhet and his followers believed that Egypt had suffered famine and instability because it had been abandoned by the gods. This abandonment was the result of the injustice and cruelty of previous dynasties. Amenemhet resolved to rule more justly. In particular, he acknowledged that common people and not just nobles could enjoy an afterlife and meet the god Osiris after they died.

OSIRIS

The ancient Egyptians did not see agriculture as merely a physical process. For them, agriculture was an expression of the will of the gods in their daily lives. One of these gods was Osiris, who represented a number of elements of Egyptian life, including the Underworld. Beyond that, Osiris was the god of vegetation and the earth. The year's dry period represented the death of Osiris, who was reborn when the Nile flooded and crops grew.

According to legend, Osiris was the son of Nut and Geb, Egypt's original king, and he took the throne when Geb gave it up. His brother was Seth, and his sister was Isis, to whom he was married. At the time he took the throne, Osiris saw that the land of Egypt was backward and primitive, inhabited by barbarous cannibals. In an effort to bring civilization to the Egyptians, he traveled among them, teaching them about agriculture.

A major myth surrounds Osiris. According to ancient texts, Osiris traveled to other lands to bring them the benefits of civilization. While he was gone, his brother Seth plotted to take over the throne. He and a band of conspirators later murdered Osiris, placed his body in a coffin, and cast the coffin into the Nile. After much searching, Isis found the body, but Seth then tore the body into pieces. He scattered the pieces throughout Egypt, but Isis found them. After she reassembled them, Osiris was magically reborn and lived long enough to father a new king. After his death, he was king of the afterlife, where he admitted people to a fertile, green land.

In time, the life, death, and rebirth of Osiris became symbolic of the cycle of the seasons in Egypt. His death represented the receding of the Nile and the dry season; his rebirth represented the flooding and the growth of crops. This cycle of death and rebirth was also seen as symbolic of the sun, which daily "dies" and then is "reborn" the following day. Further, Osiris's battle with Seth came to be seen as symbolic of the eternal struggle between the green, fertile area around the Nile and the surrounding harsh deserts.

To celebrate Osiris, the Egyptians held annual festivals. A festival called the Fall of the Nile was a period of mourning; during this festival the Egyptians brought gifts to the banks of the Nile and expressed their grief. When the river flooded again, another festival to Osiris celebrated the event, commemorating Isis's location of his body. Shrines to Osiris were thrown into the river, and priests officiated at celebrations signifying that Osiris's body had been located again. The Egyptians also believed that Osiris entered a person's body when he or she ate the vegetables of his creation. Isis became a model of womanhood, who taught women to weave cloth and grind grain.

ADMINISTRATION

Agriculture in ancient Egypt was a highly organized activity. Most people were involved in agriculture in some way. Nobles and wealthy people often owned the land that was farmed and supervised the activities of farmers, who worked the land in exchange for shelter and food. Because land was owned privately (though, in theory, it was owned by the gods and therefore by the pharaoh as the gods' representative), some landowners became wealthier than others, and class divisions inevitably came about, sometimes leading to conflicts such as boundary disputes that had to be resolved. In other cases, people rented land from wealthy landowners, paying them with a percentage of their crops. The Egyptian government also enlisted people to work on the dikes, canals, and other components of the irrigation system. This work was in effect a type of tax called *corvée*, or unpaid labor exacted in place of taxes by a governmental authority, usually for public works.

The economic system of ancient Egypt was a command economy, that is, an economy controlled and directed by the state. The state employed a large class of scribes, surveyors, inspectors, and supervisors to manage agricultural activity. For example, keeping track of land boundaries was difficult, because the Nile River valley flooded each year, changing the contours of the land, so surveyors had to be employed each year to remeasure and mark out fields with stones. An oath had to be taken that the boundary was correct: "I swear by the great god that is in heaven that the right boundary stone has been set up."

Establishing boundaries was important, because the output of each field determined how much tax, in the form of a percentage of the crops, the landowner or farmer had to pay to the government. The amount of this tax varied, with higher taxes assessed on the most fertile land, a smaller amount on higher and less productive land, and a still smaller amount on the highest and least productive land. Generally, it is estimated that the tax amounted to about 10 percent of output, usually assessed as a number of bags per unit of land. The bureaucrats who measured and surveyed the fields also assessed the tax and were responsible for collecting the grain, storing it in local and regional granaries, and distributing it as needed throughout the year.

Ancient Egypt experienced dry periods, when the Nile did not rise as much as it did in other years and agricultural

output was reduced. In general, though, the Nile Valley produced an abundance of food. This surplus enabled the state to support traders, merchants, craftsmen, civil servants, priests, an army, scribes, and others who contributed to the rise of Egyptian civilization. Without this surplus, people would have been limited to subsistence agriculture, or agriculture that provided just enough food for a family to stay alive. Further, the abundance of grain enabled ancient Egypt to engage in trade with neighboring regions. By trading its surplus of grain, the nation was able to acquire many commodities, including lumber, metals, precious and semiprecious stones, minerals, and the like.

HORTICULTURE

The word *agriculture* refers to the cultivation of major crops such as grains, usually grown in large fields and harvested a single time at the end of a growing season. In contrast, the word *horticulture* is used to refer to the cultivation of flowers, fruits, vegetables, and ornamental plants, usually in smaller family plots of ground. Because these plots were not irrigated in the same way as the fields were in ancient Egypt, water typically had to be carried in by hand. Also, because the soil was poor without the silt carried by the flooding Nile, it had to be fertilized. Some families kept pigeons in cages and used the birds' droppings to fertilize their gardens.

The ancient Egyptians devoted considerable energy to horticulture. The earliest record of a private garden dates to 2200 B.C.E. The ground surrounding nearly every home had trees that were thought to be the dwelling places of spirits and gods. Additionally, the Egyptians cultivated flowerbeds; if space was limited, they grew flowers in pots or troughs. Flowers included poppies, cornflowers, irises, jasmine, chrysanthemums, ivy, mandrakes, mallows, lotus lilies, and larkspurs. Families grew fruit such as dates, as well as oil-bearing trees such as the baq, or horseradish tree. Grapes were a popular crop, used in making wine. Vegetables and herbs such as lettuce, cabbage, cucumbers, radishes, beans, leeks, garlic, dill, chickpeas, and lentils were routinely grown for family consumption. The flower gardens attracted bees, so honey was a staple in the ancient Egyptians' diet. Many gardens had ornamental ponds with fish.

The ancient Egyptians also made use of trees, shrubs, and other plants that grew wild. These plants were used to produce dyes as well as wickerwork, including sandals, mats, baskets, and similar items. In marshlands the Egyptians found papyrus used to make not only paper but also amulets thought to have magical powers. Bouquets of papyrus symbolized joy and victory.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Agriculture first appeared in the Near East. The world's first agricultural societies appeared between 8000 and 6000 B.C.E. in an area called the Fertile Crescent, which stretches

over 1,200 miles from the Mediterranean coast of Israel and Lebanon to the Zagros Mountains in Iraq and Iran. Climate change made agriculture possible. At the end of the last ice age in about 11,000 B.C.E. the climate in the Fertile Crescent grew warmer and wetter. This improved growing conditions for many local grains and other plants. Grasslands and forests expanded, increasing the available habitats for both animals and humans. The local grazing animals became more plentiful along the edges of woodlands; the most common game animals were wild sheep and goats, two species of gazelles, onagers (wild donkeys), aurochs (wild cattle), and several kinds of deer. Small mammals and waterfowl also thrived in the improved climate. Wild grasses such as einkorn wheat, wild emmer, and wild barley grew more abundant. These local plants and animals served as the raw materials that humans domesticated.

Humans had been in the area for thousands of years. They lived as hunter-gatherers, feeding themselves by gathering wild plant foods and killing wild animals. The increased availability of wild cereals and wild animals for meat allowed them to expand their populations throughout the Fertile Crescent. Groups of humans tailored their lifestyles to local conditions. In the eastern part of the region, hunter-gatherers moved up and down the mountains, depending on the season. In the spring they pursued herds of wild sheep and goats up to higher elevations, harvesting wild grasses along the way. In the winter they moved to lower elevations along with their game animals. In the more temperate zone of the western Mediterranean, groups of hunter-gatherers lived in permanent settlements, harvesting the more than 40 species of wild plants that grew around them and hunting and trapping local animals. These settlements were the precursors to the permanent agricultural settlements established in the next two to four millennia. Humans did not switch from hunting and gathering to settled agriculture instantly. The transition took centuries and occurred at different times in different places throughout the region.

FERTILE CRESCENT CROPS

The Fertile Crescent was an ideal location for developing agriculture. Its climate was characterized by long, hot, dry summers and wet winters that rarely got too cold. The seed-bearing plants that grew there just after the last ice age were perfect for cultivation. They were annuals, which meant they completed their life cycles in one year; because the plants' lives were so short, they put all their energy into making many big seeds and little into making stalks or leaves. They were productive enough even in their undomesticated state to allow hunter-gatherers to live in permanent settlements largely supported by wild plants. They were easy to cultivate because they did not have complicated fertilization requirements.

The Fertile Crescent had a large number of wild grains suitable for human consumption, all of them nutritious and high in calories. Eight separate crops launched human agriculture in this area. Historians call them the eight founder

crops. They included three grains: emmer wheat, einkorn wheat, and barley; four legumes: lentils, peas, chickpeas, and bitter vetch; and flax, a fibrous plant that furnishes the raw material for linen. Historians know little about the domestication of the legumes and flax but have found a great deal of information on the domestication of the grains.

The grains were the first cultivated plants. Emmer wheat, einkorn wheat, and barley are all grasses that are so-called edge species in the wild, growing naturally on fine-grained soil at the edges of woodlands at high elevations. All three of them appear to have been domesticated in a relatively short period of time, between 8000 and 7800 B.C.E. Emmer was first cultivated around Jericho in the Jordan River valley and near Damascus in present-day Syria around 7800 B.C.E. Einkorn wheat grew throughout the Anatolian Peninsula, and hunter-gatherers are known to have harvested it between 9000 and 8000 B.C.E. Farmers were cultivating it near Damascus and Jericho around the same time as they were domesticating emmer.

Barley grew wild throughout the entire Fertile Crescent. Archaeologists have found evidence of domesticated barley near Damascus and Jericho between 7800 and 7600 B.C.E., and it is clear that farmers of the time were gradually selecting barley types to maximize yields. Wild barley has two rows of grains on its heads. The earliest farmers grew this type of barley, but by 7500 B.C.E. they were also growing a denser type of barley with six rows of grain per head. Farmers in other areas did not manage to produce the denser six-rowed barley and continued to grow the two-rowed type along with emmer and einkorn.

Grains soon became the staple of Fertile Crescent diets, furnishing the majority of calories for agricultural peoples in the region. In addition, grains kept well in the dry climate of the region, providing a steady supply of food year-round. People ate wheat by grinding it into meal and cooking it as bread or porridge. Legumes were also an important food source. Lentils and peas were domesticated around the same time as grains. Both grew wild in the Fertile Crescent, and hunter-gatherers had been gathering them long before they were domesticated. Wild peas and lentils grow in pods that usually explode to spray the seeds outward, but some mutant pods do not. Humans selected these nonpopping pods as the most desirable because they kept the peas and lentils conveniently packaged until they could be picked. Peas and lentils are high in protein, keep for a long time when dried, and can be cooked quickly by boiling.

THE FIRST AGRICULTURAL SETTLEMENTS

The first places in the world where humans deliberately planted seeds in order to harvest their crops in the future were isolated to a small area called the Levantine Corridor, a six- to twenty-five-mile-wide corridor along the Jordan River extending from the Damascus basin to Jericho and neighboring sites. Each of these sites had a high water table and high water supply. Early farmers had no irrigation systems

Cuneiform tablet recording barley rations given to workers and their families at the temple of the goddess Bau, about 2350–2200 B.C.E., from Tello (ancient Girsu), southern Iraq (© The Trustees of the British Museum)

and so conditions had to be optimal for them to succeed. As of 8000 B.C.E. people were clearly collecting wild grasses to eat their seeds. They already had the equipment used to process grains: flint sickles for harvesting, flat grinding stones, and bowls.

At the site called Netiv Hagdud in Israel, archaeologists have found evidence of the first steps toward genuine agriculture. Some 9,800 years ago a single type of domesticated two-rowed barley appeared along with the wild grains people continued to harvest. This is the earliest known example of people deliberately transitioning from gathering to cultivation. Archaeologists are not sure exactly why people began settling down and cultivating crops, but they believe it was tied to a growing population that made it harder for people to wander from place to place without running into competitors. As for what inspired people to begin experimenting with putting seeds in the ground, that, too, is unknown. Once people settled in one place and built structures, they naturally developed rules for running their new social structure. They had time to make tools to facilitate gathering of plant foods and were not constrained by the need to move them.

The earliest farmers were Stone Age people; they did not know how to work metal into tools so they made tools out of stone, bone, wood, and clay. Ancient farmers at first dug the soil with pointed wooden sticks called digging sticks. These were soon replaced by hoes with stone blades and wooden handles. As farms grew larger, farmers began using wooden

plows to churn up the soil; plows could dig much deeper than hand tools. The first plows were pulled by humans; after about 6000 B.C.E. people began using oxen to pull plows. Farmers harvested their crops with sickles made of stone. They stored seeds and dried beans in containers made of baked clay. In order to eat grain, people had to grind it into meal or flour, which could be made into flat bread. Grinding wheat was extremely laborious work, done entirely by women. They used a device called a quern, a primitive mill made of a flat piece of stone. They would place a handful of wheat on the quern and crush it with another stone.

DOMESTICATING ANIMALS

Long before they began domesticating animals, humans had contact with wild animals that they hunted and trapped for meat and leather. Sheep and goats in particular were abundant in the region, and both of them are known to have been domesticated in the Fertile Crescent by around 8000 B.C.E. Pigs and cattle followed suit about 2,000 years later, around 6000 B.C.E. In choosing animals to domesticate, people observed the habits of the mammals that shared their environment. They noticed which animals were incurably dangerous or bad-tempered. They also noticed which animals had a dominance structure that could be manipulated. Dogs, horses, pigs, and sheep all follow leaders and care about their rank within their group. Humans substituted themselves for animal leaders and, after several generations of selective breeding, soon had domesticated animals.

Sheep and goats became the first domestic animals, because they share several characteristics not held by other local large mammals that were equally populous, such as gazelles or onagers. Sheep and goats are fast growing and easily fed on local vegetation. They are herd animals that imprint on leaders, meaning that an entire group of animals will imitate the actions of the animal they accept as their leader. In this way they could be trained to follow humans. They do not mind living in crowded conditions with limited mobility. They are relatively easy to tame. Humans began taking over herds as their own, persuading the animals that they were their leaders, herding them to and from pastures, and manipulating the populations to maximize human interests. They had already been following herds for millennia, going up and down mountains with goats and sheep, so they knew a great deal about herd behavior. Once they had taken possession of the herds, people furthered their advantage with selective techniques. They killed off aggressive animals or poor milkers and allowed the animals with more desirable traits to live and breed.

Archaeologists know that animals were domesticated between 8000 and 6000 B.C.E. The numbers of sheep and goat bones have been found to increase dramatically in more recent layers at archaeological digs. Domesticated animals of this period are smaller than their wild counterparts, partly because people eliminated the larger and more aggressive males and partly because the beasts did not eat as much as

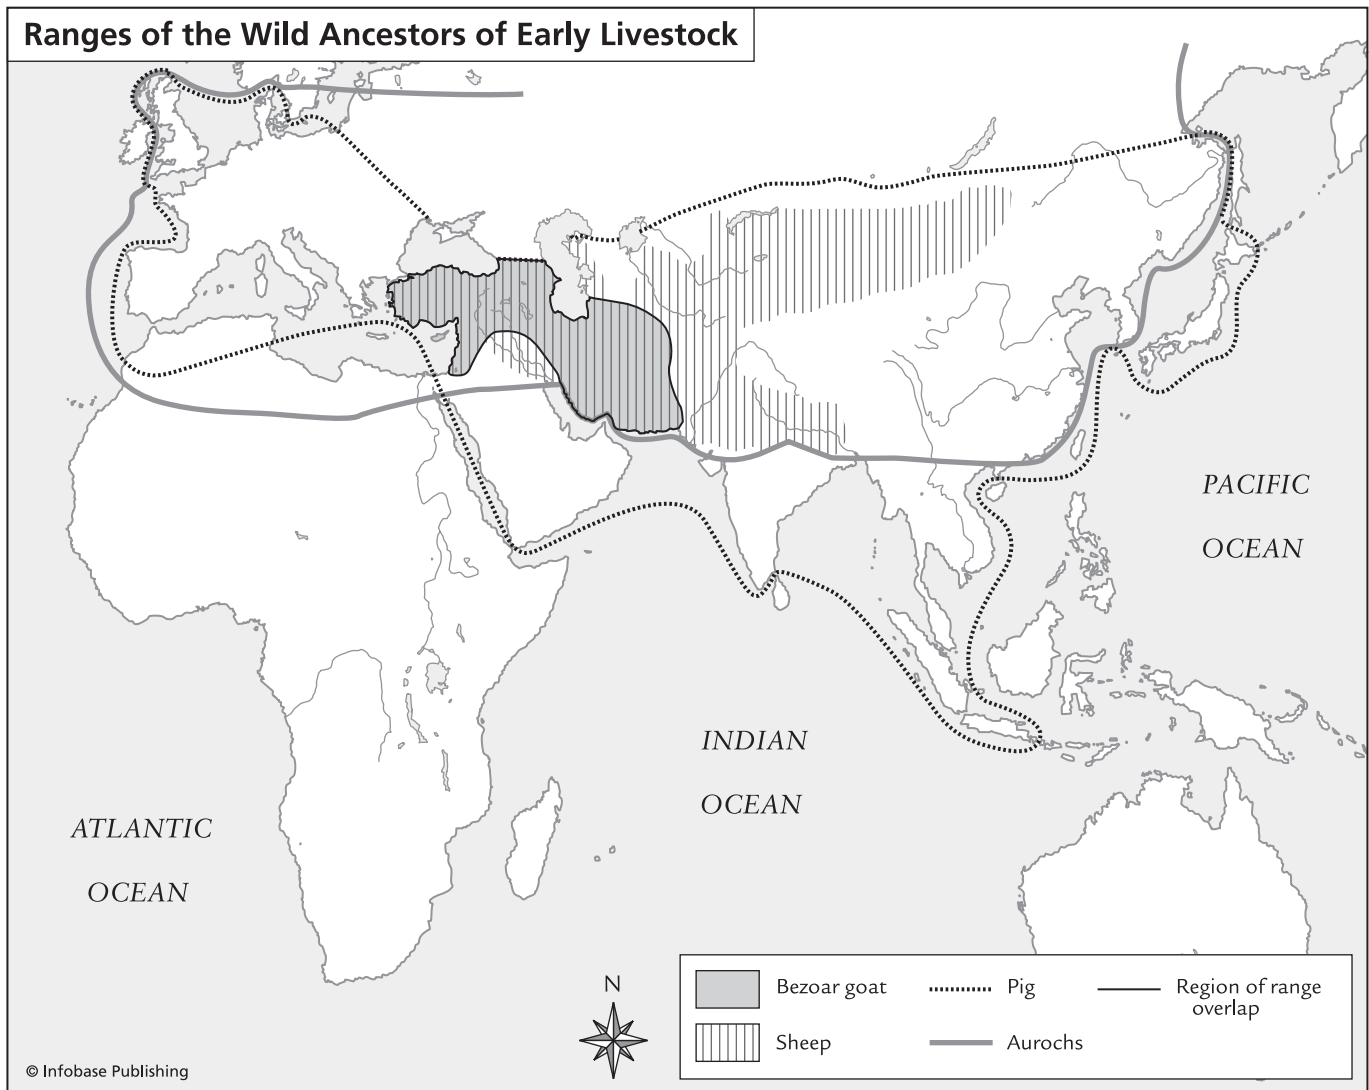

they did in the wild. Another reason for the smaller size of bones is that domestic herds contain many more females than males; herders wanted animals that could produce milk and young and that were less likely to attack them, so they kept females and slaughtered young males. Sheep were domesticated primarily in the area that is now Lebanon, southeastern Turkey, northwestern Syria, and southwestern Iran. Sheep needed good pastures and hilly grasslands to survive, so they did not thrive in other parts of the Fertile Crescent. Goats, on the other hand, are not as particular, and were domesticated throughout the Near East.

Another domestic animal that soon became common was the pig. Wild pigs ranged throughout the region. Although pigs do not live in herds, they have a dominance structure that allows humans to take control of them. They eat anything, grow quickly, and produce large litters frequently. Pig bones from about 8,000 years ago show the same decrease in size seen with sheep and goats, indicating that they were under human management. It appears that pigs were domesticated in the central part of the Fertile Crescent, modern Lebanon, Syria, and eastern Turkey and spread to other parts of the region already domesticated. They never became as common as sheep or goats. Cattle also appear in the archaeological record. These cattle were bred from the large and dangerous aurochs, wild cattle that roamed the region and had been hunted for thousands of years. Smaller cattle bones appear in the Fertile Crescent about 6000 to 5000 B.C.E.

SOCIETAL CHANGES FOLLOWING THE INTRODUCTION OF AGRICULTURE

Once humans had learned the basics of agriculture and animal husbandry, their lives changed dramatically. Domesticating plants and animals allowed humans to feed more people with available resources. Farmers could feed between ten and 100 times more people than hunter-gatherers could do with the same amount of land. This was because they had concentrated edible plants in the available space, removing all competing plants that would decrease the available food. Livestock could make land more productive by adding manure to the soil to function as a natural fertilizer. Domestic animals also supplied people with milk and eggs and meat, and they helped humans cultivate larger plots of land by pulling plows. When animals were no longer useful for labor or the production of milk and eggs, people used their bodies, eating all the edible portions and using everything else for nonfood items, such as leather and bone tools. Agriculture and livestock furnished the raw material for cloth as well.

Growing crops forced people to stay in one place. Hunter-gatherers typically moved around frequently, and they had to be able to carry all their possessions with them every time they moved. In particular, mothers had to carry their young children. As a result, hunter-gatherer mothers could have only one baby every four years or so, spacing their births so that they never had to carry more than one child at a time.

People in the ancient Middle East began domesticating wild sheep and goats around 8000 B.C.E. and wild cattle and pigs around 6000 B.C.E.

Farmers, on the other hand, could live in the same place year after year and did not have to worry about transporting young children long distances. Societies that settled down in one place were able to shorten their birth intervals from four years to about two. This meant that each woman could have more children than her hunter-gatherer counterpart, which in turn resulted in rapid population growth among farming communities. An increased population was actually an advantage to agricultural societies, because farming required large amounts of human labor.

Between 8000 and 4000 B.C.E. most settlements of the region resembled one another. They were all located near a source of water. They contained a number of houses built of mud bricks. The settlement was surrounded by wheat or barley fields and animals were pastured beyond them. Most people could not read and spent their days handling their basic needs: farming, hunting, cooking, hauling water, and

tending children. Life in farming communities was guided by the agricultural calendar, with festivals and other events tied to agricultural events such as the harvest. Agricultural equipment gradually improved. People had started farming by hand, using stone or metal tools to work the soil. The invention of the wooden plow around 4000 B.C.E. made this job easier, and employing animals to pull the plow helped farmers produce even more crops.

Not all societies perfected every agricultural technique at once. Some regions specialized in growing one or two kinds of wheat. Others concentrated on herding goats. Regardless of which agricultural methods they used, however, communities did not depend entirely on agriculture for their sustenance. People continued to gather wild foods such as wild legumes, oats, wild alfalfa, and canary grass. They caught and ate fish, shellfish, turtle, migratory waterfowl, and other waterbirds. They continued to hunt gazelle, wild pigs,

aurochs, and onagers. Agriculture supplemented their diets but did not necessarily dominate it. The cultivation of plants quickly spread from areas with a good water supply to regions that were watered only by sporadic rainfall, but these latter areas could not produce much in the way of crops. In areas that were marginal for agriculture, people kept up their gathering habits for thousands of years, and their populations did not increase as rapidly as those in more fertile regions.

In these fertile regions agriculture dramatically altered human society. Towns that could produce large amounts of food quickly grew larger. Farmers improved their techniques, experimenting with grains and developing more productive crops by selective breeding. They also applied selective breeding to livestock. In addition to growing wheat and legumes, they also kept orchards of fruit trees; dates were the most important product, but farmers also grew apples, cherries, figs, pears, plums, and pomegranates. They used techniques such as grafting (attaching a branch from the desired plant to a root from a stronger plant) to grow the strongest trees and employed date palms to give shade to lower-growing trees that disliked the excessive heat of the region.

Water was always a limiting factor. The entire region was fairly dry, but some portions were drier than others. The first settlements arose close to rivers, but as the population grew, people were forced into drier land farther from the river. Drought was always a danger. To ensure a steady water supply, farmers invented irrigation techniques and devices. The earliest farmers carried water to the fields by hand, using baked clay containers to scoop up water from ponds and rivers and transport it to crops. As farms grew larger, people began digging irrigation ditches to direct water from rivers to their fields. They also dammed rivers to prevent water from flowing downstream.

Farmers built several types of machines to help with the task of moving water from its natural sources to their fields. The *shaduf* (also spelled *shadoof*) was a counterweighted device that used leverage to lift water. It consisted of two upright posts made of wood and a wooden crosspiece with a weight on one end and a bucket on the other. The weight made it easy for farmers to lift water from ponds or wells and swing it up to their fields or irrigation ditches. Around 300 B.C.E. large farms began using more complicated devices such as the *saqiya* and the Archimedean screw (also called Archimedes' screw). The *saqiya* (also spelled *sakia* or *sakieh*) was a large wheel with buckets attached to its circumference and turned by oxen or donkeys. The buckets filled with water when they were submerged and then poured the water out into a pipe or other device that allowed it to flow where it was needed. The Archimedean screw consisted of a pipe placed on an inclined plane, with the lower end in the water. Inside the pipe a large screw turned, raising water as it moved; the water poured out of the top of the pipe into an irrigation ditch or channel.

Developments in irrigation increased agricultural productivity and heightened the need for food storage. Eventually farmers developed methods of storing grain. Agricultural

surplus has many advantages for those who can store it; it can stave off famine in lean years, and it means that not everyone must work at farming. A successful agricultural community can support people who do not produce foods, such as craftsmen, scholars, soldiers, priests, bureaucrats, and rulers. The rise of agriculture was thus accompanied by the growth of towns and eventually cities. In a city there was space to store grain, and the inhabitants gradually developed the means to control and distribute it; kings and scribes facilitated this process, kings by making decisions and scribes by keeping records of grain storage and distribution.

ANCIENT AGRICULTURAL SOCIETIES

Agriculture spread throughout the Middle East; by 7500 B.C.E. people were cultivating crops throughout Anatolia, the Levant, Mesopotamia, and Persia, and grain crops were beginning to make inroads in Pakistan and the Caucasus Mountains. One ancient Near Eastern agricultural community was Çatalhöyük, a large settlement in southern Anatolia, near modern Konya, Turkey. This town appears to have been first settled around 7500 B.C.E. and was continuously inhabited for thousands of years. Its population was between 8,000 and 10,000 when the town was at its largest. Its residents lived in mud-brick houses with holes in the ceiling that served as both a source of ventilation and a door; people climbed ladders to get in and out. Archaeologists have found storage bins used to hold wheat and barley, and the inhabitants also grew peas and harvested local pistachios, almonds, and fruits. In addition, they herded their own sheep. Archaeologists believe the residents may have worshipped a female deity who protected the harvest; some grain storage bins contained female figurines that may have depicted a mother or fertility goddess.

The Sumerians (5200–2000 B.C.E.), based in the city of Sumer in southern Mesopotamia, developed the first major agricultural society. Sumerian farmers were constantly plagued by lack of water. The region received only about five inches of rain per year, and, thus, farmers had to invent ways of getting water to their fields. They dug canals and reservoirs and built dams. The Tigris was prone to flooding, and the canals required constant maintenance to remove silt and repair banks. Once a year, however, the farmers deliberately flooded their fields by opening the canals; this was to wet the soil in preparation for sowing. After the water drained back out, they released cattle into the fields to stomp out weeds and fertilize the ground with their manure. They used oxen to pull plows to break up the earth and then raked it to smooth it out before sowing their grain. During the fall farmers reaped their grain with stone or bronze sickles and bound it into sheaves before threshing and winnowing it to separate the grain from the straw and chaff. In addition to wheat and barley, Sumerians grew other crops, including lentils, chickpeas, onions, leeks, as well as garlic and lettuce.

As their population grew, Sumerians became an urban people; by 3000 B.C.E. nearly 90 percent of Sumerians lived

in cities. Because of the limited water, settlement was concentrated on riverbanks. The population grew steadily but remained concentrated in the same areas because it was impossible to farm land more than a few miles from the river. Towns grew into cities, and the people of the cities developed governments that organized farming and food distribution. Most Sumerian people had to spend part of the year farming, but they did not own their own farms. They were working for their city, which oversaw all aspects of agriculture, from irrigation to sowing to harvest. The city also stored and distributed grain to its citizens. Sumer's communal agricultural form was successful enough to create an extensive empire based on its flourishing agriculture. The farmers produced such a surplus that the society could support a large army. The Sumerian Empire eventually encompassed some 21 known cities, each ruled by its own priest or king.

The farmers' practice of flooding the fields yearly gradually made the soil around Sumer get too salty for wheat. Toward the end of the Sumerian Empire they could grow only barley, which tolerates higher salinity. Eventually the region became too saline for successful agriculture, and the empire collapsed around 2000 B.C.E. By the Bronze Age (3500–1200 B.C.E.) agriculture supplied the majority of the food for residents of the ancient Near East. Some nomads depended largely on their herded sheep or goats, but most people lived in or near cities or towns and had to grow food to survive. During the Bronze Age people throughout the Middle East began using bronze to make farming implements. This was an improvement over the stone tools of the Neolithic Period. Bronze plows in particular were much more efficient than earlier wooden and stone plows.

The Bronze Age was characterized by the rise of city-states. Following the example of the Sumerians, societies organized themselves around cities and agriculture. The famous empires of the ancient Middle East—the Assyrians, Babylonians, Hittites, Hyksos, Persians, Parthians, and Israelites—were all founded on agriculture. They competed with one another for farm space and access to water, which are still points of contention in the region today. Governments in the region regulated irrigation very closely. The Iron Age began around 1200 B.C.E. People had already started working iron in Anatolia by the 14th century B.C.E., and iron became more prevalent than bronze throughout the region. Much iron was worked into weapons, but iron farming implements became common as well. Iron plows especially helped increase production. Farms grew smaller again as large cities disappeared during times of drought, such as the three-century-long drought that ended the Akkadian civilization around 2200 B.C.E.

The Persian Empire arose in Iran starting in 648 B.C.E. Persia, like most of the Middle East, was plagued by constant water shortages. Most years it received between four and eight inches of rain. In order to prevent this scant rainwater from evaporating, Persian engineers created a system of underground tunnels called *qanats* (also called *karez*) that

channeled water from water sources to the fields. The emperor Darius (r. 522–486 B.C.E.) encouraged research into irrigation and agriculture by rewarding skilled innovators. The government regulated irrigation systems and encouraged experimentation with new crops, introducing crops such as alfalfa, rice, pistachio, and sesame into various parts of the Persian Empire.

Agriculture continued to improve during the classical Greek and Roman periods. People had by now domesticated a larger variety of crops, including almonds, walnuts, grapes, and olives. Letting fields lie fallow from time to time improved the fertility of the soil. Under the Romans, wealthy landowners began creating large estates worked by slaves and running them as businesses. During the Roman Empire slaves from all over Europe and the Middle East went to Rome and then brought Roman agricultural techniques and crops back to their homelands. Many agricultural products were exported from the Middle East to Rome. These included wines, nuts, onions, and fruits such as the plums from Damascus and the dates from Jericho; nonfood exports included linen from Palestine and wool from Damascus.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Agriculture first appeared in China in about 6500 B.C.E. Although the Fertile Crescent of the Near East is generally credited with being the first place where agriculture arose, about 8000 B.C.E., China was not far behind. Just as wheat spread from the Middle East into Europe and brought with it cultural changes, rice spread through Asia. Although rice was not the only crop domesticated in Asia, it was by far the most important. Rice helped China grow into a well-organized, technologically advanced, and populous civilization while neighboring countries were still inhabited by hunter-gatherers using stone tools. People throughout the entire Asia Pacific region eventually acquired agriculture for themselves; however, the Chinese remained the dominant culture, thanks in part to their head start in growing rice.

ASIAN CROPS

Asians domesticated several staple crops and grew them throughout the Asia Pacific region. Rice, by far the most important staple, is a grassy plant with edible seeds. It comes in many varieties and can be grown almost anywhere, though most varieties thrive in water. To eat rice, people first remove the outer hull and possibly the bran as well, producing white rice. This milling process removes many of rice's nutrients, making it a source of calories and little else. People generally prepare rice by boiling it, though it can also be pounded into flour to make sticky dumplings. Rice originated in China and quickly spread throughout Asia, where it became the staple cereal of many people's diets. Today more than half the world's population eats rice as its main food. The people of

China, Japan, Southeast Asia, and India have all grown and consumed vast quantities of rice for thousands of years.

Millet, a grain that produces small seeds, is currently grown worldwide both as food for humans and as fodder for animals. Millet contains about 11 percent protein, about the same amount as wheat. It does not rise like wheat, so it cannot be used to make leavened bread. People generally grind it into flour to make flat bread or boil it into porridge. Millet was first domesticated in China around the same time as rice.

A leafy plant that grows from a tuber, taro is much like a potato. People grow taro mainly for its root, though they eat the leaves as well. Taro plants, also called elephant ears, look like caladiums, which are common garden plants. Taro was one of the first plants to be cultivated, and it is still grown throughout Southeast Asia and the Pacific islands. Its ancestors grow wild in much of tropical Asia, and tubers are easy to propagate by cutting them into pieces and burying them. Taro needs a steady supply of water, but most of the region has ample rainfall. Taro root is very starchy; people eat it mainly for calories. It also contains some fiber, vitamin B₆, and manganese. Taro must be cooked before eating, because the raw plant can damage the stomach and intestines. Generally, ancient people boiled it into a kind of porridge. Taro leaves are full of vitamins and supplied many necessary nutrients to peoples' diets.

Asian nations grow a huge variety of fruits and vegetables, many of which were domesticated thousands of years ago. In tropical areas people long ago cultivated bananas, oranges, coconuts, breadfruits, durians, mangoes, papayas, lemons, grapefruits, sago palms, cucumbers, and jackfruits, as well as many others. In China people grew mustard greens, daikons, numerous beans, snow peas, eggplants, cabbage plants such as bok choy, and melons. These vegetables and fruits added color and nutrients to an otherwise bland and nutrient-poor diet composed mainly of starches.

The soybean has been grown in Asia for many centuries. People first grew soybeans not for food but as a nitrogen-fixing crop; they grew the plants and then plowed them back into the fields to prepare the soil for other crops. Around the first century C.E. people discovered methods of fermentation and used those to form soy into a variety of food products, such as miso, soy sauce, and tofu. After that discovery, soy became an important source of protein for many people in China, Korea, and Japan. Asian people from ancient times to the present have obtained most of their calories and nutrients from vegetable foods. Animal protein in the ancient world came in large part from domestic pigs and chickens, which provided both eggs and meat. People also caught fish and hunted for wild birds and other game. In some areas people ate rodents and insects.

THE ORIGINS OF AGRICULTURE IN CHINA

Agriculture in China developed independently in two very different locations. Farmers domesticated rice along the Yangtze River in southern China between 6500 and 4500

B.C.E. During approximately the same time period, farmers in northern China concentrated on the cultivation of millet on the banks of the Yellow River.

The Yangtze River runs through the southern part of China and enters the Pacific Ocean near the site of the modern city Shanghai. The Yangtze basin is warm and wet and has a stable temperate to subtropical climate. Rain falls year-round, though about half of the annual rainfall occurs in the three months of summer. The lowlands around the river become inundated with shallow water every summer, and this water drains away by autumn. Major floods, droughts, cold snaps, and other extremes of weather are uncommon. Such a temperate climate made the Yangtze basin an ideal location for early experiments in agriculture.

The first farmers had to work with plants that already grew in the area. Wild rice existed throughout southern China and Southeast Asia before it was cultivated. Archaeologists and botanists have tried to identify the wild ancestor of modern rice, but they have had only limited success; rice has been so widely cultivated and moved so far across Asia that it is impossible to tell which ancient grain was its ancestor. There are still annual (living only one year) and perennial (living several years) varieties of rice growing in South Asia, and scientists have based their theories about the domestication of rice on these plants.

Modern wild rice varieties live in places that flood yearly. They start growing when the land is covered with shallow water, up to about 18 inches deep. When the rainy season ends, they release their seeds, which scatter on the drying ground and lie dormant until the floods arrive the next year. The earliest cultivated types of rice, then, were plants that grew in the border zone between land that was permanently dry and land that was always covered with water.

Ancient people lived as hunter-gatherers, hunting for wild game and fish and gathering wild plant foods. Wild rice was one of the foods they collected and ate. They would have noticed the life cycle of the rice plant, following the progress of its growth through the yearly floods. Farming probably resulted from attempts to increase the area on which wild rice grew. Historians believe that people built circular dams to trap floodwaters, flooding land that had previously stayed dry and allowing rice to grow there. They would break down the dams at the end of the wet season to let the ground dry and permit the rice seeds to germinate. They might have further increased the rice crop by scattering wild seeds they had collected elsewhere inside the artificially flooded area. The next step was the deliberate harvesting and sowing of the seeds that grew in these enclosures, sometimes called *rice paddies*.

The oldest-known site of rice cultivation was Pengtoushan on the Liying Plain; scientists believe its inhabitants were growing rice around 6400 B.C.E. Hangzhou Bay, just south of the mouth of the Yangtze, was the site of a large society that grew up around rice cultivation about 4500 B.C.E. People grew rice and other aquatic crops in the

lowlands. They lived in houses built of reeds and clay placed atop mounds to keep them out of the floods. They kept domestic dogs, pigs, and water buffaloes. They made agricultural tools out of wood and the bones of their animals; for example, they constructed shovels with wooden handles and blades made from water buffalo shoulder blades. Growing rice was very labor intensive, and most of the people in the settlement would have spent much of their time sowing rice, tending plants, and harvesting grains. Upriver a collection of lakes formed the center of the settlements of the Hubei Basin. These towns arose between 4000 and 3000 B.C.E. The people there used stone sickles to harvest rice, which was then stored in ceramic bowls.

While southern Chinese farmers were domesticating rice, their counterparts in northern China were conducting their own experiments with millet. The Yellow River is north of the Yangtze and is separated from it by the Qin Ling Mountains. The land surrounding the Yellow River is buffeted by the cold, dry winds blowing east from the Central Asian plains. The climate is harsh and unstable, prone to droughts and unexpected violent floods. Summer rains are unreliable, and winters can be severe. The plants native to this region were drought-resistant grains adapted to growing with little rainfall. Hunter-gatherers in the area knew these grains and had been collecting them as food for centuries. In addition to grains, they collected walnuts, hazelnuts, berries, acorns, and dates, and they caught fish and killed deer.

Two species of millet, broomcorn and foxtail, both of which need little water to survive, were chosen for cultivation in northern China. Archaeologists know that people were deliberately growing millet, because the settlements they have excavated are too large to be anything but agricultural communities and because they have found many millet grains on the sites. The earliest evidence of millet agriculture is that of the Peiligang culture in northern China. These people lived near the Yellow River starting about 7000 B.C.E. By around 4500 B.C.E. the Peiligang people were living in oval-shaped towns surrounded by protective ditches. Within this enclosed space families lived in circular houses with thatched roofs arranged around a central square. They stored their food in

pits and kept animals in enclosures in the main plaza. Dead people were buried outside the town. Society was organized according to kinship, and the year's work was planned according to the agricultural calendar. This pattern of social organization continued unaltered in rural China up until well into the 20th century. Millet was never as dominant a grain as rice, but it did spread to Japan by 4000 B.C.E. and Korea by about 3000 B.C.E.

ASIAN ANIMALS

Domesticated animals were important to the ancient people in both northern and southern China because they offered a reliable source of protein and could provide labor as well. The earliest evidence for the domestication of chickens comes from the Yellow River region about 5400 to 5200 B.C.E. Pigs appear at archaeological sites in the same area at about the same time. Some historians have suggested that domesticated pigs could have been brought to China from Mesopotamia, but others think it more likely that native pigs were domesticated independently in China by Chinese people. Water buffaloes seem to have been domesticated as draft animals in the Yellow River basin about 4500 B.C.E. Their use had spread to Southeast Asia by 1500 B.C.E.

CONSEQUENCES OF AGRICULTURE

Once humans had learned the basics of agriculture and animal husbandry, their lives changed dramatically. These changes in Chinese life had major implications for people throughout Asia over the next several millennia. Farming had several advantages over hunting and gathering. Domesticating plants and animals allowed humans to feed more people with available resources. Domestic animals supplied people with milk, eggs, meat, fertilizer in the form of manure, and labor, pulling plows so that humans could cultivate more land. Crops and livestock also provided humans with nonfood items such as leather, feathers, and fabrics. Growing crops allowed people to stay in one place, instead of forcing them to move about regularly in pursuit of food as hunter-gatherers did. Farming women had babies more often than hunter-gatherer women, which resulted in rapid population

Ritual spear blade from Japan, from the Yayoi Period (ca. 300 B.C.E.–300 C.E.), made for burial in a ceremony thought to have been connected with agriculture (© The Trustees of the British Museum)

growth. More people meant more labor to work on farms and, hence, larger harvests.

Larger harvests in turn made for greater security. Agricultural surplus could stave off famine in lean years, and it meant that not everyone had to work at farming. A successful agricultural community could support people who did not produce foods, such as craftsmen, scholars, soldiers, priests, bureaucrats, and rulers. The rise of agriculture was accompanied by the growth of towns and eventually cities, as well as the development of increasingly elaborate belief systems and organized religion.

The early invention of agriculture in China gave the Chinese many advantages over people in neighboring countries, which resulted in China's coming to influence or dominate much of the Asia Pacific region. Rice quickly became the main cultivated grain throughout southern Asia. Rice did not travel on its own; it was carried by Chinese people who moved into Southeast Asia around 4000 B.C.E. It arrived in Thailand between 3000 and 2000 B.C.E. People were growing rice in Mahagara, India, on the upper Ganges about 1500 B.C.E., while the earliest known rice cultivation in the Philippines dates to about 1400 B.C.E. In Japan and Korea people began growing rice in about 1000 B.C.E. Archaeologists have found rice in a cave in Celebes, Indonesia, that was probably grown during the first century C.E.

Chinese culture became the standard against which all other regional cultures compared themselves. Korea and Japan not only adopted rice farming from China but also borrowed its system of writing. The modern Japanese language contains a large portion of Chinese words and characters, a relic of China's cultural conquest. Modern people from Thailand, Burma, and Laos are descended from southern Chinese ancestors. The previous occupants of the region, hunter-gatherers of different ethnic groups, were almost entirely eradicated.

SOUTHEAST ASIA, INDIA, AND THE PACIFIC ISLANDS

Once humans had mastered agriculture, increasing populations led them to investigate other lands. Over the course of about 5,000 years, people managed to spread agriculture through the entire Asia Pacific region. Scientists are not sure that rice cultivation was the first form of farming to reach Southeast Asia. Southeast Asians have long grown a variety of roots and tubers, including taro, arrowroot, and yam, as well as fruits such as coconut, sago palm, citrus, banana, breadfruit, and jackfruit. No one knows exactly when these crops were domesticated. Some historians believe that agriculture arose independently in the region long before rice cultivation arrived around 3000 B.C.E. and that the first domesticated crops were replaced by rice farming. They theorize that roots and trees are plentiful in Southeast Asia and that they are easier to cultivate than rice and other grains, so it makes sense that people should have started farming them before rice arrived with the Chinese.

Scientists have found evidence of rice cultivation in Thailand that dates from 3000 to 2000 B.C.E. at the sites Ban Chiang and Non Nok Tha. The rice grains found at these sites are larger than the grains of wild rice, a common sign of domestication. The settlements themselves appear to have been permanent, and there are many ceramic and metal objects in graves, indicating a well-established society. Throughout Southeast Asia people modified the land to grow their crops. They terraced hills to make flat surfaces that would not erode. They dug drainage canals. They cut down trees and burned underbrush to make room for crops.

India received agriculture from both east and west. The earliest agricultural societies in India clustered around the major rivers, the Indus and the Ganges. The people of the Indus valley began cultivating Near Eastern grains such as emmer wheat and barley as early as 5000 B.C.E.; they also began growing cotton and lentils around the same time. Additionally they domesticated cattle, which became the main measure of wealth in their society. Along the Ganges, people began cultivating rice around 1500 B.C.E., and rice culture gradually traveled south through the subcontinent.

Most of the Indian subcontinent was subject to annual monsoons, which brought nearly all of the year's rainfall in a single season. Although in some areas the soil retained enough water from the monsoon to sustain crops year-round, in most of the region farmers had to use artificial irrigation, especially canals. Floods and droughts were perennial problems. Some years the monsoons did not bring much rainfall; in other years they brought far too much.

In New Guinea people began experimenting with agriculture around 7000 B.C.E. This makes New Guinea one of the few locations in the world where agriculture arose independently. Historians believe that humans invented agriculture in several places; the Fertile Crescent of the Middle East and the rivers of China are two of the most significant cradles of agriculture. Agriculture spread from these places as people moved around, bringing along with them seeds, tools, and expertise. In a few places, however, people invented farming by experimenting with wild seeds or roots and gradually domesticating them, creating plants that could grow only with human assistance. New Guinea is one of the places where this happened. Native New Guineans had no contact with the rest of Asia, so external agricultural techniques could not be brought in. The island was home to several wild plants that lent themselves to agricultural experimentation. Although most people on the island in the eighth millennium B.C.E. lived as hunter-gatherers, early farmers had begun growing bananas, nuts, grasses, and green vegetables. They also grew breadfruit, sugarcane, yam, taro, and other roots. Root vegetables that survived in the hot, wet climate predominated.

New Guinea has several natural limitations that prevented farmers from growing other major crops, notably grains. No grains like wheat or barley are native to the island, so farmers had no opportunity to domesticate them. New Guinea also lacked large mammals; thus the human

residents had nothing to domesticate. This meant that they had to depend on wild animals such as fish for protein. As the population of New Guinea grew, people came to subsist entirely on the food they grew. The local landscape could not support many hunter-gatherers. Taro made up the bulk of the local diet, but it contains almost no protein and few other nutrients. This locally grown diet was deficient in many ways and caused children to grow up malnourished. New Guineans ate small rodents, frogs, spiders, and insects in an effort to consume some protein; they even ate the bodies of their dead, but these measures could not make up for a general lack of nutrients.

Over the years humans traveled by boat to the far-flung islands of the Pacific. They started with the islands closest to the mainland, near southern China and Southeast Asia. Taiwan had human inhabitants by 3500 B.C.E. and Java by 2000 B.C.E. Borneo was inhabited by 1600 B.C.E. In 1200 B.C.E. people settled in Samoa. Pacific peoples made it to Hawaii and Easter Island by 500 C.E. Wherever humans settled, they adapted their agricultural practices to local conditions. The staple crops of most Pacific islands were those of New Guinea: taros, yams, bananas, coconuts, breadfruits, and other tropical fruits and vegetables. To augment their diet, many Polynesian islanders kept domestic dogs as a source of meat.

Australia was the only large landmass that humans failed to turn to agricultural production. It has an extremely dry climate, infertile soil, and unpredictable extremes of weather. No suitable wild plants grew there for humans to domesticate. None of Australia's large mammals were amenable to domestication; kangaroos are notoriously dangerous, and the other large marsupials that lived in Australia during the last ice age all became extinct soon afterward. Aboriginal Australians did modify their environment by burning it from time to time, which drove out game animals and made some edible grasses and ferns grow better, but they did not sow and harvest their own crops. These techniques were a way of maximizing the foods they could collect as hunter-gatherers, which remained the way of life for Aboriginal Australians into the 20th century.

EUROPE

BY AMY BOGAARD

Farmers across Europe face a wide range of climatic conditions. Mild winters and hot, dry summers characterize southern regions bordering the Mediterranean; harsh winters and hot summers are typical in central Europe; and the Atlantic coastline experiences moderate seasonal shifts. Climatic differences underlie broad regional contrasts in crops. Plants that cannot withstand frosty winters (such as chickpeas and olive trees) are confined to the Mediterranean region, while hardier crops (such as barley, rye, and oats) can be grown in the far north. The timing of farming tasks is also related to climate. The winter rainfall of the

Mediterranean encourages farmers to sow their crops in the autumn, while the long, cold winters of northern Scandinavia necessitate later sowing, in the spring.

Climatic conditions alone, however, do not dictate which crops to grow or when and how to sow them. Nor do they determine the amount of care taken to tend crops throughout the growing season, the area of land planted, and so on. Rather, a series of social factors, reflecting the particular nature of a society, come into play. One factor is the relationship between the producers and the consumers of crops: Do farmers grow crops for their own use or for others who do not farm? A related factor is land ownership: Is land held communally, divided up by family, or controlled by an elite few? Available labor, patterns of settlement, culinary tradition, and ideology are also important factors. Study of early agriculture in Europe is thus concerned not only with adaptation to diverse environments but also with changing social conditions. In some cases, new social formations emerged through constraints and opportunities introduced by the farming way of life.

THE EMERGENCE AND SPREAD OF AGRICULTURE IN EUROPE

The earliest agriculture in Europe appeared around 9,000 years ago (ca. 7000 B.C.E.) in the Aegean, on the eastern side of the Greek mainland and on the island of Crete. The early emergence of agriculture in the Aegean reflects its proximity and environmental similarity to the area of the Near East, where agriculture and herding began. This area is known as the Fertile Crescent: an arc of grassland and open oak-pistachio woodland curving round from the Mediterranean coast in the west (modern Israel, Jordan, Lebanon, Syria, and southeast Turkey) to the Zagros mountain range in the east (northern Iraq and Iran). By 8000 B.C.E. agriculture and herding were established in the Fertile Crescent and on the nearby island of Cyprus in the eastern Mediterranean.

Cultivation of a range of crops (cereals, such as wheat and barley; pulses, such as lentils and peas; and flax or linseed) and herding of animals (sheep, goats, pigs, and cattle) were linked practices that spread together from the Near East to Europe. The crops that formed part of this package complement one another in terms of nutrition (cereals and pulses together providing complete protein, for example) and ecology (allowing rotation of crops on the same land). Similarly, the grazing preferences of sheep, goats, and cattle target different components of vegetation, while pigs consume a variety of settlement waste. It appears unlikely, on current evidence, that any members of this original set of Neolithic crops and livestock were domesticated independently in Europe.

Agriculture and herding spread into Europe by two major routes: a land route that followed river valleys up the Balkan Peninsula and into central Europe and a maritime route along the northern Mediterranean coast. Farmers along these two routes emphasized different types of cereals: Those on the land route grew mainly the hulled wheats einkorn and

emmer, while those on the Mediterranean coastal route focused on naked wheat. By around 6000 B.C.E. these dispersals had reached the Great Hungarian Plain of central Europe and southern Italy in the western Mediterranean; 500 years later farming and herding had spread as far as southwestern Germany and the Iberian Peninsula. By around 5000 B.C.E. farming and herding were practiced all along the Mediterranean coast and across much of the European interior. After a pause of about 1,000 years, agriculture was eventually adopted in southern Scandinavia, the Atlantic fringe of western Europe, and the British Isles. This conspicuous halt in the spread of agriculture probably reflects the tenacity of local hunter-gatherer communities and their way of life in resource-rich coastal environments, though climatic factors may also have played a role. Farming did not reach some regions of northern Europe until the first millennium C.E.

Scholars are divided on the question of whether agriculture and herding spread as a consequence of the movement of people or as novel practices imparted from one group to another. A combination of the two processes is a strong possibility, but in either case the nature of agricultural and the nature of herding practices are equally important for understanding these early farming communities. These everyday routines subsequently shaped the development of later prehistoric communities.

As new practices that spread together into Europe, early farming and herding were closely associated from the outset. The most common domesticated animal of the early Neolithic in the Near East and in adjacent parts of southeast Europe (Greece and the Balkans) was the sheep. The zooarchaeologist Paul Halstead has pointed out that sheep are particularly suitable for integration with farming, since they provide manure for maintaining soil fertility and are used to graze fields of unripe cereals in order to regulate crop growth. Halstead developed a model of small-scale, labor-intensive farming for Neolithic Greece that incorporates manure from livestock and rotation between crops as well as careful tilling, weeding, and watering during the growing season. This model, which has relevance across Neolithic Europe, has largely replaced earlier theories based on the idea of shifting cultivation, or slash-and-burn (short-term cultivation on newly cleared forest soil, followed by a shift to new plots due to soil exhaustion). Current zooarchaeological and archaeobotanical evidence from various parts of Europe suggests that early farming was of a sustainable type, relying on high inputs of time and effort to create small but very productive cultivation areas, in some ways resembling gardens. Early European agriculture, therefore, was more akin to horticulture (small-scale cultivation of diverse garden crops) than to the large-scale cultivation of grain crops that is dominant in Europe today.

Viewed from above, the landscapes of Neolithic Europe would appear largely to have retained the extensive woodlands that developed after the end of the last ice age. Early farming communities were largely confined to areas with

fertile, easily tilled soils. The small scale of cultivation did not require extensive clearance, and nearby woodland was carefully managed to provide a renewable source of firewood and timber.

The crop and livestock package that initially spread to Europe was altered as it passed from the Mediterranean climate of mild, wet winters and hot, dry summers to the frosty, harsh winters of central Europe. These changes are visible as a reduction in the number of original Neolithic crops from the Near East, since certain crops (such as chickpeas) could not be grown successfully in colder climates, and as a general shift from sheep to cattle, which are better adapted to colder climatic conditions. New additions to the original crop spectrum also began to appear: The opium poppy, native to the western Mediterranean, was probably exploited for both its oil-rich seeds and its narcotic properties.

Although agriculture continued to play a major role in Neolithic communities of central and western Europe, there are archaeological indications that it was increasingly supplemented by more intensive use of livestock, in particular for dairy products. Zooarchaeological data on cattle-culling patterns (the ages at which male and female animals were slaughtered) and recent analysis of organic residues on pottery suggest that milking was practiced in various parts of central and northwestern Europe during the earlier Neolithic.

Milking is one example of the exploitation of secondary products from animals: resources that can be extracted repeatedly during the animal's lifetime, such as milk, wool or hair, and muscle (draft) power for pulling a sledge, plow, or cart. As early as the seventh millennium B.C.E. on Crete (at Neolithic Knossos) there is evidence for the use of cattle as draft animals, which leaves characteristic deformations and wear patterns on certain parts of the skeleton. Early cattle traction in Crete, and probably elsewhere in Europe, focused on cows—female animals kept into their advanced years for the purpose of reproduction and milking and not specifically raised and bred for the purpose of pulling a cart or a plow. These early draft cattle, therefore, were not the powerful ox teams of later times, and their impact on the nature of farming was limited, though they would have spared human labor to an appreciable degree.

A detailed snapshot of Neolithic farming life in central Europe is provided by Hornstaad-Hörnle, a village on the western shore of Lake Constance in southwest Germany and one of many prehistoric lakeshore villages in the Alpine Foreland (the foothills of the Alps). Ten years after the first houses were built (in 3915 B.C.E., according to tree-ring dating), the village burned down shortly after harvest time, preserving large amounts of stored crops in each house. These household crop stores, along with similar tool kits found in each dwelling, suggest that each family produced its own food. Farming tools recovered at the site included angled wooden digging sticks and the remains of a sieve for removing weed seeds and chaff from the threshed and winnowed crop. Weed seeds found as occasional contaminants

in the crop stores indicate effective and careful tillage and high fertility, as would be expected in small-scale intensive cultivation located near the settlement. It appears that cereals were harvested by cutting with a harvesting knife about a hand's breadth below the cereal ear and spread out in the roof space of each house for drying. After threshing outside the village, the crop would be processed for food preparation on a daily basis. Carbonized lumps of cereal-based food were found, including porridge-like food of ground wheat grains and bread of finely milled flour. Botanical remains in preserved human feces indicate that people ate a combination of cereals and wild plant foods.

The clear example at Hornstaad-Hörnle of what the anthropologist Marshall Sahlins called the domestic mode of production (production by the household for its own use) provides insights into the social consequences of early agriculture in Neolithic Europe. Households undoubtedly cooperated in certain activities, and similarity of house layout and size reflects relative equality between families. Nevertheless, imbalances in household production must have occurred, and there is evidence of differences between houses in access to rare goods, such as copper objects. The very insistence on house uniformity may have functioned to discourage emerging inequalities and tensions between families. Under certain conditions, such tensions led to new social formations in the Bronze and Iron Ages.

AGRICULTURE IN THE BRONZE AND IRON AGES

The European Bronze Age (ca. 2200–800 B.C.E.) and the Iron Age (ca. 800 B.C.E.–100 C.E.) occupy a shorter chronological span than the Neolithic Period, which stretched back some 5,000 years earlier. The quickening pace of economic and social change, however, makes these episodes crucial to an understanding of early agricultural development in Europe.

The most dramatic change occurred in that part of Europe where agriculture had the longest history: the Aegean. Halstead has charted the emergence of increasingly complex society from the early agricultural villages of the Greek Neolithic. Social advantages gained by the most successful farmers eventually led to the formation of an elite social stratum in the late Neolithic Period and Bronze Age. Furthermore, the growth of larger settlements encouraged more efficient means of cultivating larger and more distant fields. Harnessed to a simple plow, powerful teams of oxen are capable of tilling soil at a much faster rate than is possible by hand and hence can produce large-scale surplus—that is, far more food than is needed by those carrying out the farming tasks. In parallel with ox-drawn plow agriculture, large-scale herding of wool-bearing sheep developed to produce woolen textiles for exchange. Other surpluses included luxury products, such as wine and olive oil-based perfume. All of these developments are reflected in the earliest European written records to have been deciphered fully—the Linear B tablets of the Late Bronze Age Mycenaean palaces, mostly preserved in destruction layers of the 13th century B.C.E. These surplus-oriented systems

emerged under special conditions, however; elsewhere in the Aegean, beyond the sphere of the palaces, small-scale intensive agriculture of the Neolithic type continued.

Agricultural features generally associated with the Bronze Age in Europe include the use of animals for muscle power, transport, wool, and dairying; the diversification of the seed-crop spectrum with spelt wheat, millet, and broad bean; and the establishment of olive, vine, and fig cultivation in the Mediterranean. Horse bones are increasingly common on archaeological sites of this time period, and decorated bridle pieces suggest that horses played an important role in social display. Aspects of the radical social change seen in the Aegean Bronze Age developed elsewhere in Europe, visible most clearly in the emergence of elaborate elite burials. This trend toward increasingly complex society was based in part on the ability to produce and mobilize agricultural surpluses. The introduction of bronze and, later, iron tool making had a direct impact on agriculture. Metal sickles could be used to bring in the harvest more efficiently than previous methods of collection by hand or with stone sickles—an important development, making larger scale cultivation and harvesting more feasible.

A general phenomenon of Bronze Age Europe, visible in different ways from the Aegean to Britain, is expansion of the agricultural landscape to include increasingly marginal areas with thinner, poorer soils. This marginal colonization may have had diverse local causes, but its environmental consequences were often dramatic. In Britain, for example, upland clearance for cultivation and herding, evidenced by pollen records and clearance cairns (piles of stones cleared to make way for cultivation), accelerated the formation of heath and moorland areas that persist to this day. Many of these landscapes were eventually abandoned for agriculture owing to

Iron farming tools of the Iron Age, from the Stantonbury Hill hillfort, Somerset, England (© The Trustees of the British Museum)

deteriorating soil conditions, leaving behind preserved field systems, such as the Dartmoor Reaves in Devon, England.

Social change during the Iron Age is reflected in the construction of hill forts across much of Europe. Hill forts reflect the accumulation of wealth chiefly by elites through long-distance exchange in materials as well as the collection and storage of local agricultural surplus, indicated by storage pits containing substantial deposits of charred grain. The Iron Age elite were also interested in acquiring exotic food and drink. Archaeological evidence indicates that they obtained wine and drinking paraphernalia from the Mediterranean sphere as well as the domestic chicken, introduced from southern Asia via the Near East.

AGRICULTURE IN THE ROMAN PERIOD

The Roman period offers an abundance of ancient commentary on agricultural matters (especially Cato, Varro, Columella, and Pliny the Elder) and a wealth of archaeological evidence, extending from the agricultural hinterland of Rome itself to its eastern frontier provinces in the Balkans and its westernmost province of Britain. A number of agricultural innovations are associated with the Romans, including the introduction of a heavier plow, the asymmetrical plowshare (capable of turning the soil to one side), and the coulter (added to make a preliminary vertical cut in advance of the plow). All of these introductions made it easier to cultivate heavier soils. Expansion of arable farming to new ground also involved the introduction of water mills for irrigation or drainage.

With the disintegration of the Roman Empire, improved farming methods and government-led developments in agricultural organization largely disappeared, to reemerge in different forms under new political regimes in medieval times. Other Roman practices, such as the widespread grafting of fruit trees and use of new varieties, may have continued in some areas. Across much of the European countryside, however, older methods of farming using simple tools and traditional techniques reasserted themselves. These local farming traditions can be traced back to the Europe's earliest farmers of the Neolithic Period.

GREECE

BY DAVID B. HOLLANDER

Agriculture was essential for the ancient Greeks. Farming was both the fundamental basis of their economy and for much of Greek antiquity about the only profession befitting a respectable citizen. Greek farmers not only produced high-quality wine and olive oil, exported throughout the Mediterranean, but also formed the armies that defeated the mighty Persian Empire when it invaded Greece in 490 and 480 B.C.E.

SOURCES ON AGRICULTURE

Despite agriculture's importance, ancient written sources describing Greek farming practices are difficult to find. Col-

umella, a Roman agricultural writer of the first century C.E., knew of many Greek authors who wrote on the subject, but nearly all of their works are now lost. The ones we still have tend to be moral, poetic, or botanical writings, not technical manuals. Hesiod's *Works and Days*, written around 700 B.C.E., is one of the earliest and best sources still available. This poem provides valuable information about the working of an Archaic Greek farm and the times that various tasks had to be completed during the year. Xenophon's *Oeconomicus* (*The Estate-Manager*), written more than 300 years later, consists primarily of a conversation between Socrates and a wealthy Athenian named Ischomachus about the management of a farm household. Ischomachus describes his practices to Socrates, who concludes that farming is the best profession for an Athenian man to pursue, since farmers produce food and are the most willing and able to defend the city-state.

Theophrastus, a philosopher of the fourth century B.C.E., wrote two botanical treatises, *De causis plantarum* (*On the Causes of Plants*) and *Historia plantarum* (*History of Plants*), both of which contain much useful information about Greek agriculture. Theophrastus also produced an amusing, if stereotypical brief, character study of the Greek farmer, whom he describes as boorish and unsophisticated. Theocritus, a poet of the third century B.C.E. from Syracuse, invented the genre of bucolic poetry, in which life in the countryside is described in idealized form. A number of his *Idylls* survive, and they tend to feature herdsman relaxing and singing songs in pleasant rural surroundings. From Greek estates in Ptolemaic Egypt a different type of evidence has emerged: account books and other documents related to the management of large farms. These texts, though often fragmentary and difficult to read, provide valuable information concerning what was grown, who worked on the estates, and how much they were paid.

Archaeology has also begun to provide some information concerning Greek agriculture, despite a continued preference for urban over rural sites. With respect to the study of ancient farming, the most important archaeological tool is survey archaeology, in which a team of archaeologists walks over and examines large areas of land for surface traces of ancient activity. This process can reveal evidence of ancient farmhouses and villages, thus enabling the archaeologists to build up a picture of settlement and land use. Aerial photography and remote sensing technology, such as soil resistivity testing (using changes in the electrical resistance of the soil to detect the remains of structures hidden beneath the ground), can accomplish some of the same ends, though it is the fragments of pottery found in surface surveys that allow archaeologists to date newly discovered sites. The excavation of such rural sites as farmhouses has also yielded important information about Greek agriculture. One problem that archaeologists face in studying Greek farming is that many of the tools used in agriculture were made of wood and have not survived.

THE DEVELOPMENT OF GREEK AGRICULTURE

Agriculture arrived in Greece during the sixth millennium B.C.E., well before the earliest known Greeks, the Mycenaeans, built their great palaces in the middle of the second millennium. The Mycenaean kingdoms operated centralized economies in which the products of agriculture were gathered in by the palaces and then redistributed as needed to the subject population. This system collapsed along with Mycenaean civilization around 1200 B.C.E. In the unsettled conditions of the Dark Age that followed, the population of Greece declined dramatically, the economy deteriorated, and Greeks came to rely more heavily on livestock than on agriculture to supply them with food.

The eighth century B.C.E. saw a revival of Greek fortunes. The population increased, and land soon became scarce. The desire of many Greeks to have their own farms probably contributed to the boom in colonization that lasted down to the beginning of the fifth century. During this period an ideology linking landownership and agriculture to citizenship and virtue began to emerge. In the Classical Period (fifth and fourth centuries B.C.E.) and later some Greek philosophers argued that farmers were a city-state's best defenders and most prudent citizens. Agriculture continued to be highly regarded during the Hellenistic Period (323–31 B.C.E.). The new Greek kingdoms in Asia and Egypt encouraged the further development of agriculture through experimentation and scholarship. The Roman conquest of the eastern Mediterranean over the course of the last two centuries B.C.E. seems to have brought about no substantial changes in the practice of agriculture there.

GEOGRAPHY AND CLIMATE

Before a discussion of specific farming practices, it is necessary to consider briefly the geography and climate of Greece, since the nature of the land and the weather dictated where and how farming could be done. Greece is a very mountainous country, and much of it was not well suited to agriculture. Terracing—building walls along the sides of hills to create flatter farmland and prevent soil erosion—seems to have been a common practice among ancient Greek farmers. The best farmland, like that in Messenia in the southwestern Peloponnese, was extremely valuable. The Spartans conquered Messenia in the eighth century B.C.E. and used its rich lands to support their totalitarian military system. Unfortunately, much of the textual evidence for Greek farming comes from Athens, whose territory, Attica, had some of the poorest farmland in the region. What crops could be grown and when and how they should be cultivated, varied, sometimes considerably from place to place. Thus it is difficult to generalize about Greek agriculture.

The Greek climate is quite variable both from year to year and from region to region, especially with respect to rain. Although springs supplied some water for agriculture, there were few rivers or streams capable of supporting irriga-

Marble statue of Demeter (carved ca. 350 B.C.E.), Greek goddess of fertility who governed the cycle of the seasons and the growing of grain (© The Trustees of the British Museum)

tion, so most farms depended on rainfall. This made farming an unpredictable and risky proposition. It was better to have many widely scattered plots of land rather than one big one; with fields spread over a relatively large area, a farmer could be confident that at least some of his plots would yield a good crop in any particular year. If, on the other hand, a farmer had one large plot of land and there was insufficient rain to support the crops he was growing, he could face famine or bankruptcy. Summers in Greece tend to be warm and dry, while the winters are relatively mild and wet. Because irrigation was usually not an option, most crops were grown in the winter rather than the summer. Wheat was sown early in the fall and harvested in May and June of the following year. If, however, the winter crops failed, one could sow quick-growing plant varieties in the spring.

CROPS

The main Greek crops were the olive, the grape, and grain (barley and wheat). These three crops are often referred to as the “Mediterranean triad,” since they were staple foods of many people living in the Mediterranean basin. Nevertheless, the Greeks supplemented their diet with a variety of foods, such as figs, apples, pomegranates, peas, beans, lentils, turnips, cabbage, dates, and plums. As Greek traders and conquerors ventured farther afield, they imported new crops such as the peach, which was introduced to Greece in the second century B.C.E. The Greeks seem to have preferred eating wheat over barley, but wheat required much more water to grow; thus, many farmers had no choice but to grow barley. They cultivated several varieties of barley, which was harder than wheat and grew well in poor soils. The Greeks were aware of the importance of crop rotation; they also knew that some crops could reinvigorate the soil, as could periodically leaving fields fallow.

The olive was an important source of fat but was also grown to produce soap, perfume, and fuel for lamps. Olive trees require a considerable investment of time, money, and labor. They must be grown from cuttings rather than seeds so that the plant does not revert to its wild state, and they must be pruned annually. It could take many years for a new plantation to reach full production. The trees required weeding as well as hoeing around their bases to drive the roots down into the soil. This practice made the trees more resistant to drought. Apparently as a natural defense against drought, olive trees produce a good crop only every other year. These fluctuations in crop size are a regional phenomenon, since all the trees in a given area face roughly the same climatic conditions. Olives ripen in October and are harvested through the winter. They must be treated before becoming edible. Greek olive oil was traded throughout the Mediterranean, and the oil produced in certain regions such as Attica became especially popular. Jars of Athenian olive oil were given to the winners of some competitions at the greater Panathenaea (a quadrennial festival celebrated at Athens).

Wine was the staple drink of the ancient Greeks. Vineyards, like olive groves, required a lot of labor: weeding, pruning, and tilling the soil around the vines to drive down the roots (again, drought resistance was of critical importance). Stakes, trellises, and trees were used to support the growing vines. In Greece the grapes would be harvested in the early fall, and laborers would press the grapes and store the juice for fermentation. The wine of certain Aegean islands, such as Cos and Chios, was in particularly high demand. Even though they produced their own vintages, the Romans imported considerable quantities of Greek wine into Italy. Most Greeks would consume wine every day, though it was normally mixed with water. The symposium, a fundamental Greek institution, was a drinking party at which aristocratic men enjoyed wine while socializing, playing games, and listening to music and poetry.

PASTORAL AGRICULTURE

In addition to growing crops, the Greeks also practiced pastoral agriculture, keeping cows, sheep, goats, and pigs. Cows were a good source of labor in addition to meat. Cattle were expensive, and most people would have been unable to eat meat except when cattle were sacrificed at religious ceremonies. Cow’s milk was apparently not used, but their hides were an important product. Sheep provided wool (the primary fabric for Greek clothing) and meat, and their milk was used to make cheese. Goats also were a source of meat and milk for cheese. Herds often grazed on the marginal land unsuited for farming. Some shepherds would move their herds to mountain pastures in the summer, when the lowlands became dry and fodder was harder to come by. This practice is called transhumance. The summer pasturelands were sometimes in border areas, and competition for these regions could lead to war with neighboring city-states. Pigs were kept for meat and also sometimes sacrificed. Some Greeks raised poultry for eggs, meat, or sacrifice. Beekeeping was also important. Honey sweetened many dishes, preserved food, could be mixed with wine, and was an ingredient in some medicines. Throughout antiquity wild game was hunted, and wild herbs and nuts were gathered to supplement the Greek diet.

LABOR

Some animals were kept for their labor rather than as a source of food. Horses were not widely used in agriculture both because they were too expensive (considerable amounts of land would have been needed for cultivating their fodder) and because the proper type of harness had not yet been invented to exploit their labor in plowing fields. Oxen, donkeys, and mules performed the heavy work, since they required less food than horses and were physiologically better suited to the available harness technology. Donkeys and mules also live longer than horses and so were a better investment. Since mules are the product of a male donkey and a mare—and must be nursed by the mare—most farmers would have had to purchase them rather than raise their own.

On most farms people did the bulk of the labor. Poorer farmers worked the land themselves, while those who could afford to own slaves assigned them to perform various agricultural chores. In some Greek communities slaves formed a major part of the workforce. The Spartans, for example, had effectively enslaved both some of the population of Sparta as well as many of the neighboring Messenians. These slaves, known as helots, worked the land for their Spartan masters and were required to turn over to them a large quantity of produce. Other city-states, such as Syracuse, and some Cretan communities developed similar systems of exploitation. In some times and places estate owners would hire free laborers to work on their farms either on a regular basis or at times of peak demand such as during harvest times. Unfortunately, the upper-class Greek writers tended to look

down on all labor performed for wages as demeaning and servile. Hence there is little evidence of such practices. Tenancy was another option for those possessing large tracts of land. Landowners could lease parcels of land to tenants who would farm the land and pay them a rent, usually a portion of their harvest.

AGRICULTURAL TOOLS

Greek farmers used a variety of tools to cultivate their crops, but most of them, constructed of wood or iron, deteriorate considerably over time and so rarely appear in the archaeological record. Among the most important tools were plows that were fitted with bronze or iron plowshares and used to break up the earth prior to the sowing of seeds. Hoes helped those engaged in weeding, while sacks and baskets held seed grain for sowing the fields. Harvesters used iron sickles to cut down the stalks of grain, which they would then bind together in sheaves and transport to the threshing floor. Either livestock or a sledge could be used to remove the hulls from the grain. Then the grain would be tossed in the air to separate out the chaff, and mills would grind the grain into flour. Olive and vine cultivation also required specialized equipment, such as baskets to hold the grapes and olives, mills to crush olives, and presses to extract the oil or grape juice. Such equipment could be expensive, and operating a vineyard or olive grove constituted a major investment.

LANDHOLDING

There is little firm evidence for the size and distribution of landholdings. The study of Greek colonies and the remarks made by the philosopher Aristotle (384–322 B.C.E.) on the subject suggest that, ideally, land was to be divided into a relatively large number of small plots owned by individual citizens. Aristotle claimed that farmers of moderate means made the best citizens, since they had enough land to support themselves but were not rich enough to have much leisure time. Under such circumstances, Aristotle believed, farmers would not allow politics and excessive public meetings distract them from their work. Furthermore, great disparities in landholdings often led to civil war in Greek city-states. Such conflict was thought to be among the greatest evils that could afflict a community. Relative equality of wealth among citizens would ensure tranquility. Unfortunately, the Greek practice of bequeathing property equally among all sons and the inherently risky nature of agriculture meant that even if a community's land was at first evenly divided among its citizens, that situation was unlikely to last long.

Farmers who were unlucky and suffered a string of poor harvests would have to borrow money, going into debt to continue cultivating their land. Some might be able to pay off those debts eventually, but many were not. Such farmers were forced to sell part or all of their land to their more successful neighbors. For some, even the sale of their land was not

enough to pay off their debts, and they found themselves sold into slavery. The Athenian politician Solon faced just such conditions in 594 B.C.E. when, as archon, or magistrate, he was chosen to mediate a dispute between debtors and creditors. In this position of power he addressed the situation by canceling debts, freeing enslaved citizens, outlawing debt bondage, and reorganizing the city-state's constitution. In many cities and on many occasions throughout Greek antiquity, poor and indebted citizens demanded the cancellation of debts and the redistribution of land. Similar movements were successful, but others met with violent repression. On the other hand, farmers who were fortunate enough to have high yields were able to invest the profits, lending money or food to their neighbors. If those neighbors were unable to pay off their loans, their creditors could seize their property as collateral. Farmers with more land were less likely to suffer in times of drought, since they could store or sell the surplus food they had accumulated. Thus rich farmers tended to get richer as the poor got poorer.

At Sparta there seems to have been an increase in the size of individual landholdings during the fifth century B.C.E. At the same time, Spartan women came to own a larger portion of the land through inheritance. Since citizenship and military service were tied to landholding at Sparta, the size of the Spartan army and citizen body (both exclusively male preserves) began to decline at this point. In the fourth century the Spartans were unable to field the large, highly trained armies with which they had once fended off the might of the Persian Empire and dominated the neighboring Greek communities. In 369 B.C.E. the valuable lands of Messenia were wrested from Spartan control and became independent. In the third century B.C.E. the kings Agis IV and Cleomenes III attempted to revive Spartan power in part by canceling debts and redistributing land to create a larger and more equal pool of citizens. Their efforts ultimately failed.

From the fourth century B.C.E. onward much of Greece saw the same trend in landholding that Sparta had experienced. In general, fewer people came to own more land. Urbanization increased, as did the gap between rich and poor. These trends led to the development of new pools of manpower, which the Hellenistic monarchs of Egypt and Asia exploited to hire mercenaries and administrators. From the late fourth century onward the great kings of the Seleucid, Antigonid, and Ptolemaic dynasties lured poor Greeks to their kingdoms with grants of land confiscated from the indigenous populations. This practice drew off a substantial part of the free poor of mainland Greece, though many still remained behind to demand debt cancellation and the redistribution of land. Thus revolution became a persistent fear among the wealthy in the Hellenistic era. At the same time, as fewer people owned farmland and more and more people lived in cities, nostalgia for the countryside developed. The rural-themed works of poets such as Theocritus reflect this increased yearning for a now idealized rural life.

WARFARE AND AGRICULTURE

Farmland was a regular target in Greek warfare. Invading armies needed to travel light and so would ransack farms and storehouses in enemy territory for food. Often armies sought to damage their enemies by destroying the crops growing in the fields as well as olive groves, vineyards, and farmhouses. Olive trees and vines were difficult to destroy. The real toll on the countryside from warfare was financial, as it took money to rebuild structures and replace lost stores of seed grain, wine, and oil as well as damaged equipment. War forced farmers to spend their savings or borrow and thus pushed many into debt, enabling richer neighbors to acquire their land. During the Peloponnesian War between the Athenians and the Spartans (431–404 B.C.E.), Sparta and her allies invaded Attica repeatedly and did considerable damage to the Athenian countryside. Their attacks sought to do economic damage to the Athenians and also provoke them into leaving the protection of their walls and fight an infantry battle (in which the Spartans would have a considerable advantage). Such tactics were common throughout the ancient world.

RELIGION

The main Greek crops were all associated with particular gods. Dionysus was the god of wine, while Athena was credited with the olive tree. Demeter was the goddess of grain and agricultural fertility, and her sanctuary at Eleusis in Attica was an important cult center from the Archaic era down to the Roman Empire. People came from all over Greece and beyond to be initiated into the “Eleusinian mysteries” at the sanctuary of Demeter and her daughter Kore (also known as Persephone). There were religious festivals associated with all the main events in the agricultural cycle. Many farmers offered “first fruits,” or food from the harvest, to the gods each year. At Athens all farmers had to give a small portion of their barley and wheat crops to Demeter. Some temples even owned their own land and leased it out to generate income to pay their operating expenses.

ROME

BY AMY HACKNEY BLACKWELL

A vast and efficient system of agricultural production was essential to Rome’s success as an empire. The staple ingredients of Roman cooking were olive oil, wine, and wheat. Producing these basic foodstuffs occupied more than 30 percent of the total workforce. The Italian countryside, Sicily, Sardinia, North Africa, and Egypt were all cultivated to keep food on Roman tables. Romans brought home foods from foreign lands and in return left some of their favorite crops in far-flung provinces. A complex governmental bureaucracy managed the distribution of grain to citizens to avoid famine and riots. Over the centuries of Roman history, agricultural enterprises progressed from small farms to larger businesses worked by slaves to the precursor of the medieval tenant farmer system.

ROMAN WRITINGS ON FARM MANAGEMENT

Marcus Porcius Cato (Cato the Censor) (234–149 B.C.E.), wrote one of the best-known works on Roman agriculture, *De agri cultura* (ca. 160 B.C.E.). Cato was born to a peasant family in Tusculum, and although he had a lengthy career in the army and the Roman government, he devoted a great deal of his time and energy to the subject of farm maintenance and domestic economy.

Cato believed that a farm should be run as a business. In *De agri cultura* he provides directions on all aspects of farming. Cato assumed that the farmer reading his manual would be an absentee landlord who lived in Rome and made only occasional trips to his farm. The farm’s daily operations would be handled by a slave overseer and his wife, who would manage a large staff of slaves. Whenever the farmer arrived at the farm, Cato directs that he first greet his household gods and then go around the property. Having assessed the situation, he would then meet with the farm’s manager to discuss operations. The farmer should always seek the highest profit. He should hold his olive oil until the price was high and then sell it. He should sell livestock as soon as the animals became too old to work; likewise, old tools, carts, or slaves should be sold without sentiment. Cato was himself known for frugality; he disapproved of frivolity, and he believed that the farmer should always sell more than he bought.

De agri cultura contains detailed instructions for all types of farming jobs. Cato explains how to build a farmhouse and an olive press. He describes grape culture and wine production. He mentions other fruits that might be profitable for a farmer in Italy. He also includes a list of recipes for preserving food produced on the farm. These recipes were intended to help the farm be self-sufficient and produce surplus items for sale. Cato also provides recipes for cheesecakes, pastries, medicines, and special wines. Some of the wine recipes suggest ways, such as by adding seawater to make local wines taste like more fashionable vintages from Greece. Cato also describes the use of spices in making olive relish and other snacks.

Cato lived fairly early in the Roman period, but subsequent writers proved just as interested in matters of family farms. Wealthy Romans often owned property in the country, and they liked to farm it, both for profit and as a matter of fashion. Many people enjoyed serving their dinner guests with food that had come straight from their family farm. The poet Juvenal (ca. 55–ca. 127 C.E.) mocked fashionable Romans who bragged about the fresh meat and produce served in their homes.

GOVERNMENT POLICIES ON GRAIN

Feeding Rome’s people required a vast amount of grain. Wheat does not grow in cities. By ancient standards Rome and its environs covered a large area and housed a large urban population that could not grow food to feed itself. Rome therefore relied on imports of grain from North Africa,

Spain, Egypt, Sicily, and Sardinia. This grain needed to arrive on a regular basis and be available at a reasonable price—both uncertain propositions in the ancient world. The government therefore stepped in to help. A large portion of the governments of both the republic and the empire was dedicated to getting this bread to Roman tables.

In order to prevent famines and the peasant revolts that could accompany them, the Roman government created a system to provide wheat to all citizens. This began under Gaius Gracchus, who in 123 B.C.E. passed a *lex frumentaria*, or grain law, that provided each citizen grain at a subsidized price. In 58 B.C.E. Clodius Pulcher made grain free to all citizens. Administering this enterprise required a large bureaucracy of officials to keep track of distributions. An elected official monitored the grain imports that arrived in Rome's port, Ostia, and saw to the proper distribution of the supply. The free grain was immensely popular, and by the time of Julius Caesar (100–44 B.C.E.) some 25 percent of Rome's population was receiving it. For financial reasons, both Caesar and the emperor Augustus (63 B.C.E.–14 C.E.) had to reduce the number of people receiving the grain dole. Despite these difficulties, the free distribution of grain continued until the end of the empire.

Rome furthered its agricultural needs through the use of *ager publicus*, or public land. When a community or a foreign possession rebelled and was subdued, the government would claim a portion of its territory, usually a third, for public use. The best-known *ager publicus* was the rich land around the city of Capua in southern Italy, which Rome's government took after Capua rebelled several times. In 59 B.C.E. Caesar distributed this land to Pompey's veterans, the soldiers who had fought in Pompey's army during the civil war. There was *ager publicus* in every Roman province, both overseas and on the Italian peninsula. Some of this land was given to Roman colonists, and the state held other portions of it. The censors (magistrates) leased land to those who requested it, typically favoring those who wanted to run large estates. Generals would give away plots of public land to their soldiers after concluding military campaigns. Most recipients of plots of public land used them for agriculture, building small farms for their own families or running large estates if they held enough acreage. During the empire most of the *ager publicus* was eventually incorporated into the emperor's own estates.

ROMAN CROPS: WHEAT

Romans grew mainly wheat and barley. The barley was used chiefly as fodder for animals, while wheat was the primary energy source in the Roman diet. In the earliest days of Rome, the wheat was most commonly cooked into porridge, but by the time of the republic baked bread was more common and formed the bulk of most meals. This transition in culinary habits went along with a change in agricultural preferences; as people began to eat more bread, farmers replaced husked species of wheat (suitable only for boiling) with wheat that did not have a husk and could be baked. These new “naked” spe-

cies of wheat included durum wheat, now used to make pasta, as well as the types of wheat still used in modern bread.

ROMAN CROPS: OLIVES

Olives were tremendously important to ancient people. They ate cured olives as a vegetable, but the oil from the olives was more significant. Olive oil was the principal or even the only source of fat in many people's diets and a good source of nutrients, such as vitamin E. People also used olive oil as a skin moisturizer and a cleaner; instead of cleaning themselves with soap, they would rub themselves with olive oil and scrape it off. Olive oil could also be burned in lamps.

Olives grow wild in the Mediterranean region, so they were readily available to ancient farmers. The ancient Greeks improved the cultivation of olives, and the Romans took their techniques and varieties to Italy and throughout the Mediterranean. Olive farmers grew the trees in groves; olives could grow in areas where grain could not, allowing farmers to take advantage of more land. Olive trees thrive on drought and are not particular about soil quality. They can live for hundreds of years.

Romans knew of at least 27 different varieties of olive. They used grafting to combine hardy rootstocks with productive trees, grafting cultivated olive cuttings onto fig tree stocks or wild olive cuttings onto cultivated olive tree stocks. Once trees reached a productive size, they were kept small and fruitful by yearly pruning done by slaves. Slaves also did most of the olive harvesting, an operation that required a great deal of labor because every tree branch had to be beaten with sticks to loosen the olives.

Most farmers did not grow only olives; an olive grove was typically just one component of a larger establishment that might include several other crops. Olives typically bear a crop every other year, but harvests can be erratic, so it made sense for farmers to diversify their holdings. Cato's ideal olive grove, for example, included a shepherd, a swineherd, and a herd of 100 sheep; the pigs ate the material left over from making olive oil, and the sheep ate the grass under the trees so that slaves did not have to weed. To make oil, slaves crushed the olives in a large stone press. The oil flowed out through openings at the bottom of the press and could be collected in fired clay jars. To eat the olives themselves, people cured them by soaking in a salt solution for several weeks or by packing in salt. This treatment removed the olives' natural bitterness and preserved them.

In his handbook, Cato describes an ideal olive plantation; this farm was run by a slave overseer and his wife and was worked by five slaves, three ox drivers, one donkey driver, a swineherd, and a shepherd. It covered 160 acres of land and had its own oil press, so oil could be made on the premises. The size of this establishment and the time it took olive trees to mature (15 years) made olive cultivation difficult for small farmers. On the other hand, olive trees live up to 1,000 years, so an established olive grove could be very valuable. For a wealthy landowner olive farming could be

quite profitable. Cato writes that the average profit was 6 percent on invested capital.

ROMAN CROPS: GRAPES

Wild grapes grew throughout the ancient Mediterranean. Humans were cultivating grapes in the Middle East and in Minoan Greece long before the Romans arrived on the scene; the Greek authors Homer and Hesiod both mention wine in their writings. Before the start of Rome, Etruscans in northern Italy and Greek colonists in southern Italy grew grapes and made wine. By the second century B.C.E. Romans were maintaining and investing in vineyards throughout the Mediterranean, and grapes had become a more profitable crop than grain. The government was quick to notice that the wine industry was extremely profitable, and as early as the fourth century B.C.E. Rome had passed laws protecting local growers from foreign wine imports. By 150 B.C.E. Rome had begun exporting wine to the provinces; the wine sent to Gaul was traded for slaves who came to Italy to work the large vineyards.

The source for most Roman knowledge on viticulture came from a work that was written in Carthage and was translated into Latin in 146 B.C.E. Ancients knew of many different species of grape. Grape plantations could include other fruits and vegetables, but as time went on farmers specialized in vines exclusively. Cato describes an ideal vineyard: It required 66 acres of land and was managed by a slave overseer, his wife, sixteen slaves, two oxen, three donkeys, and a large amount of equipment.

Starting a new vineyard was a complicated and time-consuming process. Before planting the vines, the farmer ploughed the fields, did any necessary terracing, and created an irrigation system. He then planted the new vines and tied them to stakes or trees for support. After planting, he would dig the ground in the entire vineyard to loosen the soil and allow water to reach the roots and then cover the dirt with manure for fertilizer. As the vines grew, the farmer would remove the young sterile shoots to nurture the productive parts of the plant. Once the grape crop was ripe, the farmer tied up the vines and watered the whole field thoroughly before harvesting. Vines could live for many years but eventually would die and have to be replaced. Good vines were valuable, and farmers had to guard their fields against thieves. Farmers also surrounded fields with walls or fences for protection.

The grapes had to be picked by hand. Once grapes were harvested, slaves would crush them to extract their juice, either by using a wine press or by stomping on the grapes with their feet. Then the new wine was left to ferment. Ancient Roman winemakers used many of the techniques that are still employed by winemakers today. To create sweet wines, they would leave the grapes on the vine well into autumn to develop natural sugars. Weak wines were aged in large clay containers buried underground. Robust wines fermented in the open air, where the sun, rain, and other elements helped them develop flavor. Vintners added honey or spices to wines for flavoring and as preservatives. Once the wine was finished,

the vintner poured it into large clay jars called amphorae and either stored it to age it or sent it away for sale. It was much easier to transport wine by sea than by land, so most vineyards were located near the coast or on rivers.

OTHER CROPS

In addition to wheat, grapes, and olives, Romans grew a number of other plants. Beans, chickpeas, and lentils were the main sources of protein in most people's diets. Farmers grew numerous vegetables to eat fresh or to preserve. The most common vegetables included onions, garlic, radishes, celery, asparagus, carrots, beets, and zucchini. Typical fruits included figs, grapes, dates, apples, pears, mulberries, peaches, apricots, and cherries. Walnuts and almonds were popular nuts. Roman cooks loved to add herbs and spices to food, so farmers grew a range of them: oregano, cumin, coriander, fennel, lovage, rue, and silphium, or asafetida, the resin of a plant related to fennel. Roman farmers did not grow either tomatoes or potatoes, which are New World vegetables. Farmers also kept chickens and other fowl for their eggs and meat, and they raised some goats and sheep for their milk and wool. Italy's terrain is not good for growing large livestock, so few farmers would have kept herds of cattle.

Honey was the most common sweetener, so many farmers kept bees. The Greeks had already been keeping bees for centuries, and the Romans continued their work in selecting breeds of bees and maximizing honey production. A single beehive could produce between six and 18 pints of honey every season. Romans sought out honey from the best areas, which included Sicily (especially the area near Syracuse), Liguria, and the south of Spain. They also imported honey from Rhodes, Cyprus, several regions of Greece, and Syria. The Roman authors Virgil and Varro both wrote about the practical details of beekeeping.

TYPES OF FARMS

The most common type of farm was known as a villa. This traditional farm was located in a rural area and consisted of a house, stables, and workshops with a central courtyard. The author Varro describes villas in some detail in his writing. Villas were usually maintained by slaves for an urban owner, but small farms owned by their residents were also common and were built according to the same structure.

Life on a farm was fairly simple, with none of the glamour that went with living in Rome. A farmer and his wife who owned their own small farm had jobs to keep them busy from morning until night. They had to till fields, sow crops, weed, fetch water, and occasionally guard their plants from thieves. At harvest time they had to gather all the crops and process them, threshing the grain and drying or preserving any vegetables they could not eat fresh. Farm wives would spin their own thread and weave their own cloth to make clothing. During lengthy military campaigns the wives of soldiers would be forced to run the farms themselves for months or years while their husbands fought in distant wars.

During the early Roman Republic farmers began to specialize in particular crops and to run their farms as businesses. Agriculture became even more widespread and productive during the late republic and early empire. Large estates called *latifundia* began to appear in the early second century B.C.E. as wealthy Romans took over the *ager publicus*. Large villas, with their wealthy landlords and body of slave laborers, quickly became more prosperous than the smallholdings owned by local residents. Wealthy owners had the money to experiment with new crops and breeds of animals, and they had the economic weight to dictate prices. As a consequence, large numbers of small farmers lost their farms. The slaves who worked the *latifundia* were often prisoners taken in war. Conditions for these slaves were notoriously bad because slaves were cheap and plentiful, so landowners had no reason to treat them well.

The *latifundia* system was prominent until about 100 C.E., when slave labor became more expensive and landowners moved toward a system that used tenant farmers, a precursor of the medieval system of serfs tied to the land. Large farms ceased to be profitable. Gradually the landowners broke them down into smaller plots of land tilled by tenant farmers, peasants who were bound to the land. During the heyday of large estates, small farmers had made little technological progress and continued to use ancient cultivation techniques, but now landowners ensured that their tenants improved their techniques to keep the farms productive. German and Asian prisoners of war who worked Roman farms learned Roman techniques and took them back to their home countries. Agricultural practices of the late empire laid the foundation for the medieval system of tenant farming.

AGRICULTURAL PRACTICES

Almost all ancient agricultural work was performed manually, without even the use of oxen or mules. Farmers had to till their fallow fields constantly to prevent the incursion of weeds, and they did this work with hoes. Plots of arable land in Italy were small and rocky. Large, flat fields were quite rare, so plows were impractical, though they did exist and were occasionally used to break up rough soil.

Italy had a wide range of soil types, and Roman farmers created a variety of different tools to suit different conditions. They invented hoes with multiple tines to make the soil finer; footrest spades to help them till deeply; and several kinds of sickles, such as the balanced sickle and the “spitted” sickle, which helped the user collect harvested crops. Roman farmers also made great improvements in devices to lift water. During the empire farmers in Gaul began using a reaping machine called a *vallus*, which was pulled by an animal and used to cut off the heads of wheat stalks and drop them in a container. Many of these tools were made of iron instead of the bronze that was popular in earlier days, allowing Roman farmers to produce many more crops than their predecessors.

Most threshing was done by hand, the farmers hitting the grain with sticks to separate the grain from the straw.

Sometimes farmers had animals walk on the harvested stalks to thresh them. Wealthier farmers occasionally used a device called a *tribulum* to thresh grain; this device, also used by the Greeks, consisted of a heavy board with flints or small wheels on its underside and was dragged over the stalks to remove the wheat kernels.

The Greeks had pioneered many agricultural techniques, such as using manure for fertilizer, choosing crops based on soil type, and rotating crops. By rotating two or three different types of crops, they managed to keep fields in continuous cultivation without needing to let fields rest when they were depleted of nutrients. Roman farmers adopted these practices as well.

IMPORTS AND EXPORTS

Rome depended on its many provinces to supply it with grain and other crops. Sicily, Sardinia, North Africa, and Egypt all produced vast amounts of wheat for Rome at different times in Rome’s history. Sicily and Sardinia were important sources of grain throughout Roman history. Both islands are mountainous but fertile; Sicily’s warmer climate makes it especially suited to agriculture. Sicily was located near the center of the Mediterranean, making it a crossroads for all ancient traffic and a magnet for conquest. The Greeks colonized it in the eighth century B.C.E. and used it as a point of trade with Corinth, Rhodes, North Africa, and Italy. Carthage gradually claimed most of the island, but by 211 C.E. Rome had taken all of Sicily for itself. The Romans decided that Sicily would be best used for growing wheat. Much of Sicily’s land was divided into *latifundia* worked by slaves on behalf of owners back in Rome. Conditions were deplorable, and slaves revolted many times; some of the most serious revolts occurred in 135–132 B.C.E. and 104–100 B.C.E. Under the empire the *latifundia* system continued in Sicily even as it declined in the rest of Europe, and Sicily remained an important source of Roman grain.

Sardinia was wilder than Sicily. The Greeks seem never to have colonized it. Carthage took it in the sixth century B.C.E. but did not make any progress toward pacifying the natives. Rome took the island from Carthage in 238 B.C.E. and turned it into a colony together with nearby Corsica, which was less fertile. The Roman government and people never thought much of Sardinia or the Sardinians and looked on the island purely as a source of grain. It continued to supply grain to Rome until the end of the empire.

North Africa also supplied a vast amount of grain to Rome’s tables. Rome took over much of Carthage’s territory after the Punic Wars (a series of three wars fought between Rome and Carthage between 264 and 146 B.C.E.), forming a new province in northern Tunisia in 146 B.C.E. This province encompassed some 5,000 square miles of the most fertile part of North Africa. The land there became Roman public land, and the government leased it out to grain farmers, who grew wheat for export to Rome. North African estates were vast. Most of the land was in the hands of a few large absentee land-

Section of the facade of a Roman aisled barnlike building on a villa estate in the parish of Meonstoke, Hampshire, England, dating to the early fourth century C.E. (© The Trustees of the British Museum)

owners, though there were also more modest estates owned by locals. Scholars believe that about half a million tons of wheat left Carthage annually. The province of Carthage's capital city (also called Carthage) became the second-largest city in the Mediterranean on the basis of its agricultural exports. By the second century B.C.E. North Africa was also exporting olive oil, figs, grapes, and beans.

All African farmers had to irrigate their crops, and they invented some elaborate systems of getting water to their fields. The simplest forms of irrigation were ditches dug from rivers to fields and dams to hold the water in place, but African farmers also used machinery to move water mechanically. The *shaduf* was a seesaw-like device consisting of a bucket attached to a long counterweighted pole on top of a frame; the weight opposite the bucket allowed farmers to

lift water easily and swing it over to an irrigation ditch. The Archimedean screw was a large screw in a tube resting on an inclined plane. The bottom of the tube sat in water, and as the screw turned, it lifted the water up and out of the top of the tube. The *saqiya* was a type of water wheel turned by donkeys or oxen.

Rome took over Egypt in 30 B.C.E., after Augustus defeated Marc Antony and Cleopatra at the battle of Actium. Augustus annexed Egypt as a Roman province. This event caused Egypt's fortunes to plummet. Augustus considered Egypt his own personal estate and exploited it at the expense of its inhabitants. Most of the country's land was turned over to agriculture, and Egypt ended up growing a large portion of the grain eaten by Romans. Egypt also supplied Rome with papyrus, a reed used to make paper.

Over the next three centuries this agricultural exploitation resulted in the loss of farmland and declining fortunes for Egypt. Only after the Romans left did Egypt's farmers reorganize their properties.

Roman provinces had their own agricultural specialties that they exported to the capital. Crete was the best source for herbal medicines. Spain and Gaul made the best *garum*, a sauce that was made by fermenting fish in salt and that was used to flavor most Roman dishes. Romans also exported their own plants to other countries. Roman soldiers and colonists missed their wine, lentils, and olives, and so they attempted to plant their own favorite foods wherever they went. Grapes did so well in Gaul (France), Germany, and Spain that wines from those regions began to be popular with Romans during the imperial period. Even distant Britain, which the Romans occupied from 43 to 410 C.E., acquired Roman crops; celery, cilantro, fennel, carrots, pears, peaches, mulberries, and many other plants that now grow there were brought by the ancient Romans.

THE AMERICAS

BY AMY HACKNEY BLACKWELL

Historians do not know much about early agriculture in the Americas. The earliest farmers did not leave written records of their farming practices. To discover what crops were grown and when, scholars have to look for evidence of crops at archaeological sites, digging for fossilized seeds and attempting to date them through various scientific processes. There is currently a fair amount of disagreement among historians of agriculture as to when early Americans began farming, what they grew, and how crops spread through the Americas. Some scholars believe that the first American farmers grew corn in the highlands of Mexico around 4000 B.C.E. Others insist that agriculture began much earlier, perhaps as early as 8000 B.C.E., in the lowland forests of Central America and northern South America. At present there is not enough evidence available to answer any of these questions conclusively.

Despite the scholarly disputes, it is known that Americans did grow crops in ancient times and that they were certainly farming by 4000 B.C.E. Agriculture seems to have arisen independently in four separate areas: the Andes, Middle America from northern Panama to central Mexico, the Southwest of the United States, and the Eastern Woodlands of the United States. In the Andes, from central Ecuador south to Chile, people began farming between 3500 and 2000 B.C.E. People in Mexico are believed to have started farming corn about 4000 B.C.E. and soon added beans and squash to their crops. The cultivation of corn traveled north to the Southwest of the present-day United States by 2000 B.C.E. Farmers in the Eastern Woodlands started cultivating a few local crops around 2000 B.C.E. but did not engage in large-scale agriculture until corn appeared there in the first century C.E.

The Americas, like Africa, were a less-than-ideal environment for the development and spread of agriculture. Unlike the Middle East, Europe, and Asia, the Americas do not have many native wild grains suitable for domestication. Teosinte, the probable ancestor of corn, was not nearly as easy to domesticate as wheat in the Middle East or rice in Asia. The Americas also lie along a north-south axis, as opposed to an east-west axis like Eurasia. Plants tend to be adapted for particular latitudes; they can move from east to west fairly easily because climate and day length remain the same, but they cannot move as easily from north to south because climate and day length change too much. In addition, the mountain ranges that run north to south in the Americas separated the east coasts from the west, preventing easy east-west transmission of crops. As a result, agriculture in the Americas was slow to develop and travel through the continents, and American civilizations never reached the level of development achieved by those in Eurasia.

THE TRINITY: CORN, BEANS, AND SQUASH

Humans developed agriculture in the Americas long before Europeans arrived and long before the famous three New World civilizations of Maya, Aztec, and Inca arose. The staple crops of these societies were corn, beans, and squash. These three crops were so ubiquitous and so often found together that historians have christened them the "trinity." Combining the three ingredients made for a balanced diet; the corn supplied energy, the beans provided protein, and the squash furnished other nutrients.

The trinity is very old. Historians have found numerous caves in Mexico that were inhabited by about 4000 B.C.E. Within these caves are traces of corn, beans, and squash. The residents of these caves lived primarily as hunter-gatherers; in the caves, archaeologists have found many bones of wild animals, such as deer and rabbit, as well as traces of pine nuts, hackberries, and other wild plants. Wild ancestors of squash, beans, and corn grew in the area, and the cave dwellers certainly gathered and ate them, but scientists have analyzed the remains in the caves and determined that some of the corn, beans, and squash were definitely domesticated. Corn, or maize, was the foundation of the trinity. It provided the bulk of calories in the form of carbohydrates. Transforming corn from its wild ancestor into the cultivated version took a long time; it was much more difficult than the process of domesticating wheat in Mesopotamia, mainly because the wild ancestor of corn is so drastically different from the domesticated version.

Modern corn is probably descended from a plant called teosinte. No one knows exactly how this transformation occurred. Teosinte, in fact, looks almost nothing like corn. Corn grows as a single stalk with many ears on it; each ear has multiple rows of seeds. Teosinte, in contrast, is a grass with many stalks, each of which contains several spikes with single rows of seeds. Hunter-gatherers could have used these

seeds, but wild teosinte is not an impressive source of food. It grows throughout Mexico, Guatemala, and Nicaragua. There are five different species, some of which are annual (completing their life cycle in one year) and others perennial (living several years). Archaeologists believe that two of the annual species that grow in the Tehuacán valley in Mexico were probably the ancestors of corn. The first primitive cobs of what appears to be domestic corn grew between 2700 and 2600 B.C.E. near inhabited caves in the Tehuacán valley. The inhabitants were still hunter-gatherers who moved about with the seasons, but they grew a small crop of corn to give themselves a little food security.

This early corn was nothing like the large ears grown today. It had tiny ears with small kernels and resembled a modern crop known as Argentine popcorn. Its ears were only slightly bigger than those of teosinte. Nevertheless, scientists know this corn was domesticated, because it had kernels that could not release themselves from the cob; it could be reseeded only when humans removed the kernels and planted them. Cob sizes increased; between 500 B.C.E. and 1 C.E. cob length doubled in size.

Corn gradually spread through the Americas. The same small, primitive corn appeared in northern South America 1000 B.C.E., near the Pacific coast in Ecuador between 1200 and 800 B.C.E. and along the Orinoco River in Venezuela about 800 B.C.E. People in the southwestern United States were growing corn by about 1000 B.C.E. Small-kernelled corn reached the mountains of Peru by 450 C.E. Corn was not initially a staple of most peoples' diets; historians believe that much of the earliest domesticated corn was used to brew beer. As the years went by, however, corn provided an increasingly larger share of the calories of many American diets. Corn can be eaten whole, from the cob, but it was most important dried, which made it a source of food that could be stored year-round. People used stone mills to grind it into cornmeal and made this meal into flat bread or porridge. Corn is not an especially nutritious grain because it lacks two essential amino acids (the building blocks of proteins). Early Americans solved this problem by adding ashes to cornmeal to increase the niacin content and by combining corn with beans.

Beans form the second component of the trinity and supplied the protein that corn lacked. Lima beans appear to have been domesticated first, followed by the beans now called common beans, which include navy, kidney, and red beans, among many others. Ancient common beans evolved into the more than 100 types of domestic beans known today. Common beans and the lima beans were all widely cultivated in the Americas long before Europeans arrived. Scientists can tell that the beans were domesticated because, just as with domesticated corn, these beans cannot expel their own seeds; humans must do that in order to plant the next crop. Beans appear to have been domesticated later than corn. Historians had long theorized that corn and

beans were domesticated simultaneously, but that does not now seem to have been the case.

Mexican and Andean Americans domesticated lima beans independently of one another. Historians currently believe that people in the Andes may have started growing lima beans around 2000 B.C.E. Earlier research into this area led to speculation that humans may have domesticated limas around 5600 B.C.E., but these dates are now considered inaccurate. The Andean lima was a large-seeded variety. It had spread along the Pacific coast of Chile and Peru by about 400 B.C.E. The smaller-seeded Mexican lima bean appeared later, around 800 C.E. Large-seeded lima beans predominated at higher altitudes, while small-seeded varieties grew at lower altitudes. Lima beans are high in protein and fiber; people ate them fresh or dried them to save for later. They cooked dried beans by boiling them.

To trace the ancestry of various types of common beans, scientists have analyzed the protein content of domestic and wild beans in Mexico, Central America, and South America. They discovered that common beans were domesticated twice, in two different places. One type of bean was domesticated in Mexico, and another type was domesticated in the Andes. The earliest known domestic common beans were grown about 300 B.C.E. in Mexico. Common beans, similar to lima beans, provided necessary protein to ancient diets, especially when combined with corn. Common beans keep well when dried, so people could count on eating them year-round.

Squash formed the third component of the trinity. Humans cultivated several varieties of squash that still exist today as acorn, spaghetti, and patty pan squashes; pumpkins; and zucchini. Green and yellow squashes came from the eastern United States, and orange pumpkin squashes came from Mexico. Historians know little about the process by which humans domesticated squashes. Some experts believe squash cultivation may have occurred simultaneously with corn cultivation, perhaps around 3000 B.C.E.

MESOAMERICAN CIVILIZATIONS

Agriculture facilitated the rise of the great Mesoamerican civilizations, which built large cities with complex bureaucracies and religions. The Olmec lived on the coast of the Gulf of Mexico between 1500 B.C.E. and 400 C.E. They worshipped a rain god, a sign that rain was extremely important for growing their crops. The city of Teotihuacán, near modern Mexico City, was inhabited from 150 B.C.E. to 750 C.E. In its heyday it was the size of Rome. Its inhabitants also worshipped a weather deity, a fanged storm god who would release the rains to grow the crops of corn, beans, squash, and peppers.

The Maya, a civilization that lasted from about 1800 B.C.E. to the 17th century C.E., had a vast empire that encompassed parts of Guatemala, Mexico, Honduras, and Belize, with several regional capitals. Their kings and bureaucrats oversaw a large population of citizens, most of them farmers. To feed the population, Mayan farmers maintained vast permanent

plantings that included raised fields, terracing, canals, and other irrigation systems. The raised fields and the canals were constructed together; when the farmers dug out the canals, they dumped the excess dirt onto the fields. This provided the crops with a steady source of water and kept them away from floods. The canals were a valuable food source, too; farmers allowed wild turtles and fish to live in them and caught them for meat. The Mayan priests maintained a complex calendar that helped farmers keep track of the solar year. This calendar told farmers when to plant their crops and when to harvest them. It helped farmers plan their year so they could produce the best possible crop.

Despite the fact that about 70 percent of the Mayan people worked as farmers, Mayan farming never produced the vast surpluses of grain that farmers in other areas achieved. The damp climate made it difficult to store corn for more than a year. The Maya had no domestic animals to help them plow and instead had to do all their work by hand. Corn, the largest crop, contains little protein, and the Mayan diet had few other protein sources; as a result, most people were malnourished.

THE ANDES: QUINOA, POTATOES, LLAMAS, AND GUINEA PIGS

People living in the Andes mountains of Peru developed their own crops and domestic animals suited to their dry climate and high altitude. They cultivated two crops not grown elsewhere, the potato and the grain quinoa. They also domesticated three animals: the llama, the alpaca, and the guinea pig. Andean Americans ate many types of wild potatoes; there is fossil evidence that people consumed wild potatoes as early as 10,000 B.C.E. in Chile. Potatoes were domesticated between 2000 and 1200 B.C.E. The people of the Andes cultivated four types of potatoes, one of which became the common potato eaten all over the world today. People of the Andes also cultivated the sweet potato. Archaeologists have found evidence of domestic sweet potatoes dating to about 2000 B.C.E. The sweet potato spread throughout the tropical portions of the Americas and was a staple of the Caribbean diet by the time Columbus arrived.

Quinoa is a grain that produces edible seeds. People began cultivating it from 2000 to 3000 B.C.E. It grows well in dry soils at high elevations and is quite hardy. Quinoa contains a complete set of amino acids, which meant that people did not have to combine it with a legume to get their necessary protein. It also contains fiber, iron, magnesium, and phosphorus. People boiled it like rice and ate it as a cereal.

Llamas and alpacas are four-legged animals related to camels. Their wild ancestors, the guanaco (for the llama) and the vicuña (for the alpaca), lived in herds with dominance hierarchies, making them easy for humans to domesticate. The process of domestication occurred gradually between 5000 and 2500 B.C.E. People used llamas and alpacas for both wool and meat. They also used llamas as pack animals on the high mountain paths. Historians believe humans may have

domesticated llamas and quinoa simultaneously. Llamas eat wild quinoa and pass the seeds onto the ground in their manure. When people began herding wild llamas and shutting them in enclosures at night, the llamas' manure would have contained both seeds to grow quinoa and natural fertilizer to help them germinate. After a successful crop of quinoa started growing, the farmers would move the llamas to another corral. The quinoa grew inside the enclosure, safe from grazing llamas.

The guinea pig was the third domesticated animal of the Andes. Hunter-gatherers between 5500 and 10,000 B.C.E. consumed a great deal of wild guinea pig meat. Between 2500 and 5000 B.C.E. people began keeping guinea pigs in their settlements to save the trouble of hunting them and ensure a steady supply of meat. Guinea pigs were ideal candidates for in-home domestication. They reproduce rapidly and prolifically, they eat table scraps, and they like to live in close quarters.

SOUTHWESTERN UNITED STATES

Agriculture first appeared in the southwestern region of the present-day United States about 1000 B.C.E. People living in caves in the mountains of New Mexico were growing corn and squash around 800 to 1200 B.C.E. Beans arrived slightly later, around 400 B.C.E. The tools and pots found with the fossilized remains of corn and squash indicate that the cave dwellers were not colonists from Mexico but instead local hunter-gatherers who made occasional trips south of the Rio Grande and returned home with seeds. Once agriculture arrived in the region, southwestern Americans adopted it quickly. Some historians believe these people had already domesticated some local seed crops such as little barley, amaranth, or chenopod, which prepared them for larger-scale agriculture with corn. Scholars agree it was certainly possible that foragers had discovered these local seeds and begun growing them deliberately, but so far no one has found changes in the forms of these local seeds that would indicate domestication.

The people of the Southwest managed to create farming practices that succeeded in a variety of environments and at different elevations, adapting their agriculture to local landscapes and wild animals. Early southwestern farmers lived in circular houses in small settlements. They kept their corn in underground storage pits and spent much of their time tending crops and grinding corn, which became an increasingly important portion of their diet as the centuries went by. Nevertheless, they continued to gather such wild plants as cactus, mesquite, grasses, pinyon, and agave. They hunted mountain sheep, mule deer, and pronghorn antelope. Agriculture did not become the primary means of sustenance for southwestern Americans until about the first century C.E. One reason this transformation took so long was the problem of irrigation. The southwestern United States has little rainfall, and it was a constant challenge to keep crops alive in the

arid environment. The earliest farmers used groundwater to irrigate their crops; they planted their fields near springs and lakes and counted on the high water table to keep the plants alive. Later farmers built irrigation canals and dams to hold water until they needed it for their fields.

EASTERN UNITED STATES

The Native Americans who lived in the eastern United States invented agriculture independently of those who lived in the Southwest. They domesticated their first plants between 2500 and 1500 B.C.E., focusing on local seed plants. The four so-called founder crops of the eastern United States were sunflowers, sumpweed (a plant related to the daisy and, grown for its seeds), goosefoot (related to spinach), and a small squash that provided seeds. This squash was the predecessor of the modern acorn squash and summer squashes.

All four of these crops were highly nutritious, comprising 17 to 32 percent protein, compared with wheat's 8 to 14 percent. Both sumpweed and sunflower seeds are high in oil content, providing healthy fats with dense concentrations of calories and vitamins. Despite their nutrition, though, these four crops could not sustain communities that survived solely by farming. All of the crops had disadvantages that discouraged farmers. Sumpweed, for example, is related to ragweed and causes hay fever and skin rashes; it also smells bad. None of the founder crops could produce anything like the agricultural surplus of wheat or corn. (Wheat comes from the Middle East and Europe and did not arrive in the Americas until it was carried across the ocean by European settlers during the 16th century. Consequently, Americans of that period continued to support themselves mainly by hunting wild game and gathering wild plants.)

Between 500 and 200 B.C.E. the eastern tribes began cultivating three more seed crops: knotweed, maygrass, and barley. All three of these plants have very small seeds that do not yield nearly the harvest volumes of major grains such as wheat. Although people supplemented their diets with these new grains, they still had to rely on wild food sources for most of their nutrition and calories. Would-be farmers had no other options. They could domesticate only those plants that already grew in the area, and none of the native species of the eastern United States lent itself to agriculture in the way wheat and barley did. Otherwise, however, conditions in this region were excellent for farming; the soil was rich and the water supply ample. The climate was pleasant and encouraged the growth of many plants. The people living in the region knew their local plants and did what they could to domesticate them. The Hopewell culture that existed in Ohio from 200 B.C.E. to 400 C.E. supported itself in large part with locally domesticated crops, but within the region there were simply not the resources needed to expand agriculture, so most societies remained small groups of hunter-gatherers.

Mexican crops did not reach the eastern United States until after 1 C.E. Corn arrived around 200 C.E., but it was not until 1100 that American Indians began growing the

nutritious Mexican trio of corn, beans, and squash. In many areas these three Mexican crops replaced local crops entirely. At that time the human population increased rapidly, as it typically does when societies settle down and adopt an agricultural lifestyle. People began building the larger towns that traditionally accompany the advent of large-scale agriculture.

FARMING IMPLEMENTS

All ancient American civilizations were Stone Age civilizations, meaning that they used stone to make most of their tools and had not yet discovered how to use metals. They also used wood and bone to make handles and tools, clay to make pottery, and straw to make baskets. The earliest American farmers used pointed sticks to dig the soil. As they became more expert at farming, they made more complicated tools such as hoes, usually with long wooden handles and stone blades tied on with leather cords. These implements were designed to make long days in the fields more comfortable and efficient, eliminating the need for farmers to get down on their hands and knees to work the soil. People probably used woven baskets to collect their crops at harvest time, and they stored dried corn and beans in clay containers. One important agricultural device was a kind of mill called a quern, a flat stone used for grinding corn. A person would place a handful of corn on the quern and use another stone to crush it into dust. This was a very laborious process, and women in ancient American agricultural societies typically spent many hours every day grinding corn.

AN ABSENCE OF DOMESTIC ANIMALS

Aside from Andean llamas, alpacas, and guinea pigs, as well as dogs in North America, Americans did not domesticate mammals. The Americas did not have any large mammals that could be used to plow fields. People had to do all the plowing and tilling by hand. As a result, American farmers tended to grow many plants in single fields, letting bean plants twine up cornstalks, for example; in contrast, wheat farmers in the Middle East and rice farmers in Asia tended to dedicate single fields to one grain crop.

Egypt

~ Hymn to the Nile, ca. 2100 B.C.E. ~

Hail to thee, O Nile! Who manifests thyself over this land, and comes to give life to Egypt! Mysterious is thy issuing forth from the darkness, on this day whereon it is celebrated! Watering the orchards created by Re, to cause all the cattle to live, you give the earth to drink, inexhaustible one! Path that descends from the sky, loving the bread of Seb and the first-fruits of Nepera, You cause the workshops of Ptah to prosper!

Lord of the fish, during the inundation, no bird alights on the crops. You create the grain, you bring forth the barley, assuring perpetuity to the temples. If you cease your toil and your work, then all that exists is in anguish. If the gods suffer in heaven, then the faces of men waste away.

Then He torments the flocks of Egypt, and great and small are in agony. But all is changed for mankind when He comes; He is endowed with the qualities of Nun. If He shines, the earth is joyous, every stomach is full of rejoicing, every spine is happy, every jaw-bone crushes [its food].

He brings the offerings, as chief of provisioning; He is the creator of all good things, as master of energy, full of sweetness in his choice. If offerings are made it is thanks to Him. He brings forth the herbage for the flocks, and sees that each god receives his sacrifices. All that depends on Him is a precious incense. He spreads himself over Egypt, filling the granaries, renewing the marts, watching over the goods of the unhappy. . . .

Where misery existed, joy manifests itself; all beasts rejoice. The children of Sobek, the sons of Neith, the cycle of the gods which dwells in him, are prosperous. No more reservoirs for watering the fields! He makes mankind valiant, enriching some, bestowing his love on others. None commands at the same time as himself. He creates the offerings without the aid of Neith, making mankind for himself with multiform care.

He shines when He issues forth from the darkness, to cause his flocks to prosper. It is his force that gives existence to all things; nothing remains hidden for him. Let men clothe themselves to fill his gardens. He watches over his works, producing the inundation during the night. The associate of Ptah . . . He causes all his servants to exist, all writings and divine words, and that which He needs in the North.

It is with the words that He penetrates into his dwelling; He issues forth at his pleasure through the magic spells. Your unkindness brings destruction to the fish; it is then that prayer is made for the [annual] water of the season; Southern Egypt is seen in the same state as the North. Each one is with his instruments of labor. None remains behind his companions. None clothes himself with garments, The children of the noble put aside their ornaments.

The night remains silent, but all is changed by the inundation; it is a healing-balm for all mankind. Establisher of justice! Mankind desires you, supplicating you to answer their prayers; You answer them by the inundation! Men offer the first-fruits of corn; all the gods adore you! The birds descend not on the soil. It is believed that with your hand of gold you make bricks of silver! But we are not nourished on lapis-lazuli; wheat alone gives vigor.

A festal song is raised for you on the harp, with the accompaniment of the hand. Your young men and your children acclaim you and prepare their [long] exercises. You are the august ornament of the earth, letting your bark advance before men, lifting up the heart of women in labor, and loving the multitude of the flocks.

When you shine in the royal city, the rich man is sated with good things, the poor man even disdains the lotus; all that is produced is of the choicest; all the plants exist for your children. If you have refused [to grant] nourishment, the dwelling is silent, devoid of all that is good, the country falls exhausted.

O inundation of the Nile, offerings are made unto you, men are immolated to you, great festivals are instituted for you. Birds are sacrificed to you, gazelles are taken for you in the mountain, pure flames are prepared for you. . . .

Men exalt him like the cycle of the gods, they dread him who creates the heat, even him who has made his son the universal master in order to give prosperity to Egypt. Come (and) prosper! Come (and) prosper! O Nile, come (and) prosper! O you who make men to live through his flocks and his flocks through his orchards! Come (and) prosper, come, O Nile, come (and) prosper!

Asia and the Pacific

~ Hymn to Goddess Earth, ca. 600 B.C.E. ~

1. Truth, greatness, universal order [rita], strength, consecration, creative fervor [tapas], spiritual exaltation [brahma], the sacrifice, support the earth. May this earth, the mistress of that which was and shall be, prepare for us a broad domain!
2. The earth that has heights, and slopes, and great plains, that supports the plants of manifold virtue, free from the pressure that comes from the midst of men, she shall spread out for us, and fit herself for us!
3. The earth upon which the sea, and the rivers and the waters, upon which food and the tribes of men have arisen, upon which this breathing, moving life exists, shall afford us precedence in drinking!
4. The earth whose are the four regions of space, upon which food and the tribes of men have arisen, which supports the manifold breathing, moving therein, shall afford us cattle and other possessions also! . . .
7. The broad earth, which the sleepless gods ever attentively guard, shall milk for us precious honey, and, moreover, besprinkle us with glory! . . .
11. Thy snowy mountain heights, and thy forests, O earth, shall be kind to us! The brown, the black, the red, the multi-colored, the firm earth, that is protected by Indra, I have settled upon, not suppressed, not slain, not wounded.
12. Into thy middle set us, O earth, and into thy navel, into the nourishing strength that has grown up from thy body; purify thyself for us! The earth is the mother, and I the son of the earth; Parganya is the father; he, too, shall save us! . . .
17. Upon the firm, broad earth, the all-begetting mother of the plants, that is supported by [divine] law, upon her, propitious and kind, may we ever pass our lives! . . .
19. Agni (fire) is in the earth, in the plants, the waters hold Agni, Agni is in the stones; Agni is within men, Agnis [fires] are within cattle, within horses. . . .
22. Upon the earth men give to the gods the sacrifice, they prepared oblation; upon the earth mortal men live pleasantly by food. May this earth give us breath and life, may she cause me to reach old age!
23. The fragrance, O earth, that has arisen upon thee, which the plants and the waters hold, which the Gandharvas and the Apsaras have partaken of, with that make me fragrant: not anyone shall hate us! . . .
25. That fragrance of thine which is in men, the loveliness and charm that is in male and female, that which is in steeds and heroes, that which is in the wild animals with trunks [elephants], the luster that is in the maiden, O earth, with that do thou blend us: not any one shall hate us!
26. Rock, stone, dust is this earth; this earth is supported, held together. To this golden-breasted earth I have rendered obeisance.
27. The earth, upon whom the forest-sprung trees ever stand firm, the all-nourishing, compact earth, do we invoke.
28. Rising or sitting, standing or walking, may we not stumble with our right or left foot upon the earth!
29. To the pure earth I speak, to the ground, the soil that has grown through the brahma [spiritual exaltation]. Upon thee, that holdest nourishment, prosperity, food, and ghee, we would settle down, O earth! . . .
36. Thy summer, O earth, thy rainy season, thy autumn, winter, early spring, and spring; thy decreed yearly seasons, thy days and nights shall yield us milk. . . .
42. To the earth upon whom are food, and rice and barley, upon whom live these five races of men, to the earth, the wife of Parganya, that is fattened by rain, be reverence! . . .
46. The serpent, the scorpion with thirsty fangs, that hibernating torpidly lies upon thee; the worm, and whatever living thing, O earth, moves in the rainy season, shall, when it creeps, not creep upon us: with what is auspicious (on thee) be gracious to us! . . .
52. The earth upon whom day and night jointly, black and bright, have been decreed, the broad earth covered and enveloped with rain, shall kindly place us into every pleasant abode! . . .
53. Heaven, and earth, and air have here given me expanse; Agni, Sûrya, the waters, and all the gods together have given me wisdom. . . .

59. Gentle, fragrant, kindly, with the sweet drink [kîlâla] in her udder, rich in milk, the broad earth together with [her] milk shall give us courage! . . .

62. Thy laps, O earth, free from ailment! Free from disease, shall be produced for us! May we attentively, through our long lives, be bearers of bali-offerings to thee!

63. O mother earth, kindly set me down upon a well-founded place! With (father) heaven cooperating, O thou wise one, do thou place me into happiness and prosperity!

Rome

~ Cato: On Agriculture, excerpt, ca. 150 B.C.E. ~

. . . Perform the vow for the health of the cattle as follows: Make an offering to Mars Silvanus in the forest during the daytime for each head of cattle: 3 pounds of meal, 4½ pounds of bacon, 4½ pounds of meat, and 3 pints of wine. You may place the viands in one vessel and the wine likewise in one vessel. Either a slave or a free man may make this offering. After the ceremony is over, consume the offering on the spot at once. A woman may not take part in this offering or see how it is performed. You may vow the vow every year if you wish. . . .

. . . Before harvest the sacrifice of the *porca praecidanea* [the hog offered in sacrifice before the harvest] should be offered in this manner: Offer a sow as *porca praecidanea* to Ceres before harvesting spelt, wheat, barley, beans, and rapeseed and address a prayer, with incense and wine, to Janus, Jupiter, and Juno, before offering the sow. Make an offering of cakes to Janus, with these words: "Father Janus, in offering these cakes, I humbly beg that thou wilt be gracious and merciful to me and my children, my house and my household." Then make an offering of cake to Jupiter with these words:

"In offering this cake, O Jupiter I humbly beg that thou, pleased by this offering, wilt be gracious and merciful to me and my children, my house and my household." Then present the wine to Janus, saying: "Father Janus, as I prayed humbly in offering the cakes, so wilt thou to the same end be honored by this wine placed before thee." And then pray to Jupiter thus: "Jupiter, wilt thou deign to accept the cake; wilt thou deign to accept the wine placed before thee." Then offer up the *porca praecidanea*. When the entrails have been removed, make an offering of cakes to Janus, with a prayer as before, and an offering of a cake to Jupiter, with a prayer as before. After the same manner, also offer wine to Janus and offer wine to Jupiter, as was directed before for the offering of the cakes and the consecration of the cake. Afterwards offer entrails and wine to Ceres."

► architecture

INTRODUCTION

Architecture is a human activity that combines a number of fields, including art, design, geometry, engineering, construction, and materials science (the science that studies the properties of materials, including, for example, their strength and durability). Architects draw on their knowledge of these fields to create structures for human use. In the ancient world these structures included not only homes but also a great many public buildings, including temples, tombs, government buildings, pyramids, granaries, theaters, athletic stadiums, and the like.

Archaeologists have few remains of prehistoric architecture to study, primarily because the earliest human-built structures were built with nondurable materials, so they have disappeared. The earliest architecture was a haphazard affair and consisted of homes that were built with whatever materials lay at hand. Thus, depending on local geography, prehistoric peoples built their shelters out of such materials as reeds, mud bricks, poles, logs, stones, or animal hides, or they found shelter in caves. These structures tended to be temporary because the earliest peoples were hunter-gatherers, so they moved about from place to place in search of food. There was very little “architecture” involved, and little attention was paid to the aesthetic qualities of the structure. The structure served a purely functional purpose—that of keeping out the wind, rain, and snow while providing the inhabitants with at least a minimal level of safety and security and storage for their few belongings.

True architecture did not develop until people began to lead more settled lives, staying in one place long enough to

make the construction of more permanent and aesthetically pleasing buildings worthwhile. Only when people turned to agriculture rather than hunting and gathering for their food did they begin to gather in ever-larger communities, forming the first hamlets, then larger towns, and finally cities where architecture flourished.

Thus, the development of agriculture had a profound affect on architecture. People gathered in communities began to develop more formalized belief systems, giving rise to organized religions and the temples where those religions were practiced. Further, because so many of the buildings found in places like Greece, Rome, and the Americas were so immense, they often took generations to build, requiring a settled, stable population of workers. Surplus food supplies, made possible only with agriculture, supported a class of priests as well as others who provided to city dwellers the fruits of civilization. Included would be poets and dramatists, who needed theaters for the production of their work.

Also included were classes of bureaucrats and civil servants, who ran the affairs of the community out of public buildings. The emergence of hereditary royal families gave rise to magnificent public buildings erected to demonstrate the power of the ruling class, and elaborate tombs, including the immense pyramids of ancient Egypt and Central America, ensured that royalty and members of the upper classes enjoyed a smooth trip into the afterlife. As society became more socially stratified, meaning that upper and lower classes of people developed, architecture became a way for the upper classes to design and build magnificent homes and villas that became a symbol of their status.

Architecture also provided more practical structures. For the military it supplied fortifications and walls along borders. For farmers it provided granaries, barns, and similar structures. For the upper classes, it furnished cookhouses, privies (toilets), bathhouses, gardens, terraces, and similar structures that enhanced the quality of life. Architects also learned to construct and position buildings in a way that in the 21st century would be called “environmentally friendly.” As firewood became more and more scarce because of the growth of cities and populations, architects learned to take advantage of the sun to provide warmth.

Architecture drew on the skills of numerous people. An architect had to design a building in a way that guaranteed it would last. He had to understand the properties of the materials he used to ensure that they were suitable for the building. As time progressed and as contact and trade between cities and empires developed, builders gained access to a wider variety of materials. Where stone was used, miners had to quarry, cut, smooth, and transport immense blocks. Builders had to organize masses of laborers to assemble the building, devise techniques for lifting heavy materials into place, and take care of such everyday chores as keeping track of the budget; in many cases they had to oversee slaves, making sure that they were fed and housed.

As architecture became more developed, builders had to understand such elements as drainage systems, and in time they learned to incorporate such features as arches, vaulted ceilings, domes, and so on. Stonemasons were highly skilled artisans who carved stone ornaments, including statues, that became part of the structure, and other artists painted murals and frescoes that enhanced the aesthetic appeal of the structure. City planners learned to arrange buildings in a way that increased their usefulness. For example, as cities grew and trade between cities and kingdom developed, architects arranged buildings in clusters surrounded by fortified walls and gates, to protect the population from marauders who might seize the city's wealth. Because it was not possible to move large amounts of earth, buildings had to be arranged around natural features of the terrain.

Because architecture was a community pursuit that required large numbers of workers and vast sums of money, most of the buildings that survive from ancient times were palaces for royalty, temples, or tombs. Royal palaces were a testament to the power and authority of the king or other ruler, and because they were as magnificent as temples, they served to remind the people that the ruler derived his authority from the gods. Temples were large and elaborate, much like the mosques and Christian churches built during the medieval period, to become a focus of worship for the particular god or goddess in whose honor the temple was built. Building such temples in parts of the world was considered a religious act. Tombs took many forms, in particular that of pyramids, but these pyramids and other public structures often served—or may have served—other purposes, such as those of scientific and astronomical observatories and calendars.

AFRICA

BY MICHAEL J. O'NEAL

Studies of the architecture of ancient Africa tend to feature most prominently that of ancient Egypt, located on the north of the continent adjacent to the Sahara Desert. The remainder of the continent, particularly in the context of discussions of ancient life, is generally referred to collectively as “sub-Saharan Africa,” or that part of Africa that lies south of the massive Sahara Desert.

Because of a lack of written records and because the kingdoms and nations of sub-Saharan Africa in general never achieved the prominence or lasted as long as ancient Egypt, not a great deal is known about the architecture of this vast region. Much of the architecture has disappeared, leaving archaeologists with fragments and ruins, often just foundations, to study. Often they are required to make inferences about ancient African architecture on the basis of limited evidence. Then, too, many ancient architectural sites were lost when the Great Aswān Dam was constructed on the Nile River, flooding vast tracts of land to form Lake Nasser. Nonetheless, archaeologists have discovered a number of intriguing monuments,

ruins, and, in some cases, intact structures that provide insight into the architectural skills of the ancient Africans.

Much of the architecture of sub-Saharan Africa was strongly influenced by that of the Egyptian dynasties. Just as ancient Egypt was the home of towering obelisks (a towering pillar that rises to a point), royal tombs, palaces, and the pyramids, so can similar structures, or their remains, be found in other parts of Africa as the influence of Egypt spread and grew. Influences can also be traced back to the Carthaginians and the Middle East.

ETHIOPIA

The early history of Ethiopia, sometimes called Abyssinia, is dominated by the kingdom of Axum. The kingdom originated in about the second century B.C.E. and reached the height of its power from the fourth through the seventh centuries C.E. Axum controlled most of modern-day Ethiopia as well as parts of Egypt, the Sudan, Eritrea, and parts of the Middle East, and its influence rivaled that of the empires of the Egyptians, Greeks, Persians, and Byzantines. It was a major trading nation, serving as a link between Asia and the Mediterranean region. It was also the first African state to issue its own coins. Archaeologists have uncovered the ruins of reservoirs, temples, and cities that attest to the influence of the kingdom, including the ruins at Yeha, a pre-Axumite kingdom. But perhaps the most intriguing remains from ancient Axum are its black granite obelisks.

Yeha lies in a remote part of what is called the Tigray region, several hours by car from the city of Axum. Visitors are willing to make the trip to see the remains of the Temple of the Moon, built in about 500 B.C.E. While little is known about the people who built the temple, the ruins themselves are striking. The roof and upper stories are missing, but the remains are nearly 40 feet tall. The inward-reclining walls are made of sandstone blocks that fit together with near-perfect precision; ancient Africans believed that the temple could be filled with water and not a single drop would leak out, despite the fact that no mortar was used to connect the blocks.

Axum is regarded as the successor kingdom to Yeha in that part of Ethiopia. The most prominent architectural site in Axum features its obelisks, carved beginning in about 400 C.E., which were among the tallest stone monuments in the ancient world. The largest one, which has fallen and lies on the ground in six pieces, would have stood nearly 110 feet high. The tallest standing obelisk is about 78 feet tall.

Archaeologists have long been puzzled by the carvings on this and other nearby obelisks. Although the obelisk was carved out of a single block of stone, it is covered with carvings that give it the appearance of having 13 stories, each “floor” with its own “windows” carved into the stone. At the base are carvings of “doors,” which even have locks and door knockers carved into them. Archaeologists are not certain about the purpose of the obelisks. That they were erected near tombs suggests that they may have been built as memorials to dead kings and queens and may have represented stairways

to heaven for the kingdom's rulers. In common with obelisks throughout the ancient world, they may have served as gigantic sundials, enabling people to tell time as the obelisk's shadow grew shorter and longer and changed position with the movement of the sun.

The tallest standing obelisk was recently returned to Ethiopia. Prior to World War II, Italy invaded Ethiopia, and the Italian dictator Benito Mussolini ordered the obelisk to be dismantled and taken to Italy. For many years the Ethiopian government asked the Italians to return it. Their request was finally granted, and in April 2005 the obelisk was loaded onto cargo planes and returned to its rightful home.

The Cathedral and the Ark of the Covenant Another archaeological site from the ancient kingdom of Axum is located just a few hundred yards away from the obelisks. Two Christian churches, both dedicated to Saint Mary of Zion, are enclosed in a walled compound. Between the two churches are the ruins of an ancient temple. According to legend, the area had been a swamp infested with evil spirits, but God came to the aid of the local people, who descended from the nearby hills and threw dust on the site to drive out the spirits. On this site were built shrines, and around these shines the kingdom of Axum gathered.

Then, in 331 C.E., Axum's king Ezana (whose reign began ca. 330) was converted to Christianity. In 372 he ordered the construction of a magnificent cathedral, the oldest Christian church in sub-Saharan Africa. The church was destroyed by Muslim invaders in the 1500s but has since been rebuilt. A Portuguese explorer, writing in the early 1500s, left behind a detailed description of the church, with its five long naves, vaulted ceiling, a choir, painted walls, and two surrounding walls. A major historical mystery surrounds the site. That such a massive church would be built in an area so distant from the center of the Christian world has suggested to some scholars that the church was built for a specific purpose: to house the Ark of the Covenant.

The Ark was a gold-lined chest. According to the Old Testament, the prophet Moses placed the stone tablets inscribed with the Ten Commandments into the Ark. In the centuries that followed, the Ark was the source of mysterious power. After it was moved from Mount Sinai, where Moses received the Ten Commandments, it was originally housed in the Holy of Holies, a chamber in the Jewish temple in Jerusalem. It later disappeared, and for generations historians, treasure seekers, archaeologists, and others have tried to find it. (The search for the Ark even formed the basis for one of the *Indiana Jones* movies.) Some believe it is housed in a mysterious "treasury" that is part of the cathedral site at Axum, where it has been guarded for many centuries.

Some scholars have theorized that the Ark is in Ethiopia because it was stolen and taken to Axum by Menelik, the son of Axum's most famous historical figure, the Queen of Sheba. According to this theory, the queen traveled to Jerusalem to meet King Solomon because she wanted to see firsthand

the results of his architectural skills, particularly the temple of Jerusalem. While she was there, she became pregnant by King Solomon, and after she returned to Ethiopia she had a son. Years later, her son left Ethiopia to be with his father but was driven out of Jerusalem by the jealousy of the city's elders. He left the city in the company of a number of the elders' firstborn sons, and according to this theory, either Menelik or the sons took the Ark with them. An alternate theory is that centuries later the Jews hid the Ark in Egypt to protect it from invaders. Later, after the kingdom of Axum converted to Christianity, church officials moved the Ark to Axum, where it has remained for 1,700 years. However, this is pure speculation, as no one has uncovered the Ark at Axum (or anyplace else, for that matter).

The City, Palaces, and Homes Archaeologists have uncovered and in many cases tried to reconstruct Axum's royal palaces and the homes of some of the kingdom's wealthy citizens. These structures consisted of tall pavilions mounted on high foundations. These foundations show that Axumite architecture favored walls that were not long and straight. Rather, the walls were indented at regular intervals along their length, creating recesses and salients (projecting segments of the wall) on the inside. Evidence suggests that most of these buildings were one or two stories tall.

Some of these buildings were of considerable size. The royal palace, called Ta'akha Maryam, is the largest that has been excavated. It measures nearly 400 feet by more than 260 feet. The pavilion in the center had nine rooms, all with roofs supported by columns and floors covered with flagstones. The palace also featured a central peristyle (an open area or courtyard surrounded by columns) and a number of four-column porticoes, or porches, with elaborate floral carvings at the octagonal bases.

This style was favored because the walls were made of loose, irregular rock bound together with mud. The "in and out" design of the walls made them stronger and allowed them to expand and contract with changes in temperature. The walls also featured an architectural device called a rebate, a continuous rectangular recess along the top or bottom edge of the face of stonework. Sitting atop each of these rebates was a flat stone that formed a small shelf. The purpose of these rebates was to help rainwater run off the surface of the mud walls, making them last longer. Further, they strengthened the walls and added an element of ornamentation. The walls were also strengthened by the use of granite blocks at each of the corners; sometimes an entire row of granite blocks was used, and granite was also used for features such as columns, capitals, stairways, and the like. In some buildings, wooden beams were used to give strength. These beams typically projected from the building at the ends.

These structures were surrounded by more modest homes, giving them privacy and helping to defend them from intruders. The larger buildings had carved pedestals made of granite, with capitals at the tops of columns. Flooring and

paneling were made of marble, and the homes had drainage systems and even brick ovens. In palaces, the kings dedicated thrones to the gods, including Mahrem, Meder, Beder, and Astar, and inscribed them with narratives of war.

The architecture of more common domestic buildings varied. Remains have been found of small round huts made of clay, with cone-shaped thatched roofs. Thatch may have been the most common roofing material, and it may even have been used on palaces and the homes of the wealthy. Other dwellings were rectangular with roofs supported by beams. Because only fragments of ruins have been found (except for foundations, which are more extensive), archaeologists have to make inferences from limited evidence about these and other matters.

THE PYRAMIDS OF NUBIA

The region called Nubia lay in the Nile River valley south of ancient Egypt. Most of what was Nubia is in modern-day Sudan, and a small portion lies in modern Egypt. The earliest inhabitants of the region were nomads, but by the beginning of the Dynastic Period of ancient Egypt (2920 B.C.E.), Nubia was an important trading center that provided Egypt with gold, ebony, ivory, exotic animals, and slaves.

As trade with Egypt increased, the region's power grew, but during the Middle Kingdom (2040–1640 B.C.E.) Egypt expanded into Nubia, which the Egyptians called Kush. The region remained politically disorganized until the first in a series of three kingdoms was established. The first, called the kingdom of Kerma, lasted from about 2400 to 1500 B.C.E. Kerma's kings accumulated enough power to build large walls, tombs, and other structures. During the New Kingdom, Egypt expanded farther into Nubia and built a new capital at Napata, which lasted from 1000 to 300 B.C.E. and was powerful enough to conquer Egypt, with its kings ruling Egypt as the Twenty-Fifth Dynasty (770–712 B.C.E.). After the Egyptians pulled out of Nubia, its capital centered on Meroë, which lasted from about 300 B.C.E. to 300 C.E.

In modern times a team of Swiss archaeologists excavated Kerma, the oldest African civilization other than Egypt. They found remains of a temple built of mud brick in about 2000 B.C.E. and funerary temple built in about 1600 B.C.E. The researchers have discovered tombs that were essentially man-made hills some 100 feet wide and 50 feet tall. Inside excavators discovered numerous skeletons, suggesting that when a ruler died he took a number of his followers with him into the afterlife. In one royal tomb were found the skulls of 4,500 cattle that analysis showed were brought from throughout the kingdom. Surrounding the city were monumental walls, with at least a two-mile stretch of military fortifications.

It was during the period when Napata was the center of the Nubian region that builders embarked on a program of pyramid building. This program continued into the Meroitic Period, beginning in 590 B.C.E., when the capital was Meroë. At three sites in the region are some 223 pyramids that functioned as tombs for royalty. The earliest ones were built at a site

called el-Kurru, and they include the tombs of King Kashta, his son Piye (who assumed control of most of Egypt), three of his son's successors (Shebaka, Shebitku, and Tantamani), and 14 queens. Unlike the practice of the Egyptians, who built much larger pyramids for kings than for queens, the Nubian pyramids for queens are only slightly smaller than those built for kings. The pyramid of Piye has been removed, but its foundation trench has been found, as well as 19 steps leading to a burial chamber cut into the bedrock below and covered with a corbelled masonry roof. (In a corbelled roof the masonry is set in courses, or layered rows, so that each course overhangs the previous one, forming a false vault or arch.) The tomb of Piye's successor, Shebaka, has a vaulted ceiling.

Later pyramids were built at Nuri after Taharqa, one of the last kings of the Twenty-Fifth Dynasty, moved there. His pyramid is much larger than the others, measuring about 170 feet square at the base and rising to as much as 160 feet high. This pyramid has the distinction of having been built in two stages. The first stage was covered with smooth sandstone. Over it was built a second, larger pyramid, but the earlier-phase portion projects out above the ruins of the later phase. The whole was surrounded by a nearby wall. The underground chambers of Taharqa's pyramid are elaborate. The pyramid is entered by an eastern trench, with three steps down to a door with a molded frame and a cavetto cornice (a concave molding shaped like a quarter circle). Through the doorway is a tunnel that opened into a large chamber with six large pillars. The pillars separated the burial chamber into a central nave and two side aisles, and each of these three segments has a vaulted ceiling. In addition to Taharqa, some 21 kings were entombed at Nuri, along with some 52 queens and royal princes. The pyramids for these rulers were built according to a consistent plan, and they were all larger than the pyramids at el-Kurru. Each has a chapel on the east side, along with a stela (a decorated stone slab) and relief decorations showing the king before the gods.

The largest Nubian pyramid site is at Meroë, located about 60 miles north of Khartoum. At this site, at least 40 kings and queens were buried over a period of about 600 years until 350 C.E. The site at Meroë, sometimes characterized as the largest archaeological site in the world, is divided into the South Cemetery, the North Cemetery, and the West Cemetery; the North Cemetery was built when the South became too crowded, and the West Cemetery was built for less important royal persons. The pyramids, made of sandstone, range in height from about 30 to 100 feet. Stripes of raised masonry framed each triangular side of the face the pyramids where they came together, and the corners of the upper fourth of the pyramids were rounded. As usual, a chapel was built against the eastern side. The early Meroitic pyramids were stepped, but those built later in the period were smooth, with wedge-shaped casing blocks positioned along each course. The core of these later pyramids tended to be poorly built with rubble.

The Nubian pyramids differ markedly from those of ancient Egypt, though the pyramids of the pharaohs probably

inspired Nubian builders. Like the pyramids of Egypt, they are built with stepped stone layers, or courses, but they are not as tall, ranging in height from about 20 to 100 feet, and they have a much smaller “footprint,” meaning that they do not take up as much ground—usually an area of about 25 feet square. They are much more steeply pitched, rising at an angle of about 68 to 70 degrees, so they appear more pointed compared with the Egyptian pyramids. At the base of the pyramids are small temples.

Mention should be made of another Meroitic site, the temple at Faras. Faras became an important town in the Meroitic kingdom in the third century C.E. On the west bank of the Nile stood a temple constructed during the reign of the Egyptian pharaoh Tutankhamen (r. 1333–1323 B.C.E.) as well as a chapel to the Egyptian god Hathor cut into the rock and probably built during the reign of Egyptian pharaoh Thutmose III (r. 1479–1425 B.C.E.) and enlarged under Tutankhamen and Ramses II (r. 1290–1224 B.C.E.). Today only ruins remain. The symmetrical temple included a square courtyard with a portico on two sides and two rows of columns. It also included a hypostyle hall with a sanctuary and 12 columns. (A hypostyle hall is one with a flat ceiling supported by columns.)

THE STONE PILLARS OF NAMORATUNGA

In southern Ethiopia and northwestern Kenya was a community of people called the Borana. Near Lake Turkana in Kenya archaeologists have studied a cluster of 19 magnetic stone pillars. These pillars are referred to as Namoratunga, a word that means “stone people” in the local language. Writing on the stones is markedly similar to writings found at other archaeological sites and thus indicates that the pillars were constructed in about 300 B.C.E.

What is intriguing about these pillars is that they seem to form an ancient calendar. The Borana developed a lunar calendar that was based on the positions and movements of seven stars or star groups in conjunction with the moon. The result was a calendar of 354 days and 12 months, with a leap month added every three years. The modern names of the stars and star clusters are Triangulum, Pleiades, Aldebaran, Bellatrix, Orion’s Belt, Saiph, and Sirius. According to Borana reckoning, a new year began when a new moon was observed in conjunction with Triangulum, the next month began when the new moon was seen in conjunction with the Pleiades, and so on. Each day had its own name, but since there were only 27 day names, the Borana started over when they arrived at the end of the list.

Astronomers and archaeologists have noted, though, that some of these stars and star clusters are invisible to the naked eye when they are too close to a new moon. Some researchers suggest that the 19 Namoratunga pillars were intended to mark the positions of these stars. Using statistical analyses, archaeologists have determined that there is only a small chance that the pillars could have marked the rising of the stars by chance. For them, this is strong evidence that

the cluster of pillars was an astronomical observatory and hence a calendar.

EGYPT

BY MICHAEL J. O’NEAL

Historians credit the ancient Egyptians with teaching humankind how to build. By trial and error over many centuries, the Egyptians learned how to design and build structures such as palaces, temples and temple gates, courtyards, and pyramids as well as homes. Until the rise of Egyptian civilization, people lived in makeshift structures made from whatever materials were locally available, including mud bricks. These structures did not last very long, so the communities in which they were built tended to be impermanent.

After the Egyptians, people constructed cities and homes that were fixed and settled. This led to a greater sense of homeland, of a specific place where people could remain permanently and develop the fruits of civilization. Permanent construction kept people in one place over a long period of time, as a structure was begun in the reign of one king and then continued during the reign of one or more of his successors. In many cases, by the time the structure was completed a century or more after it was begun, it was time to begin expanding or refurbishing it, so construction was an ongoing activity. The most famous architectural wonders of ancient Egypt are the pyramids, many of them located on the Giza Plateau and “guarded” by the Sphinx.

Probably the most recognizable element of ancient Egyptian architecture is the chain of some eighty pyramids and pyramid-like structures that stands like a row of mountains along the west bank of the Nile River. All are on the west bank because they were probably used primarily as tombs and the Egyptians buried their dead west of the Nile, in the direction of the setting sun. Although most are within about fifty miles of Cairo to the north, others can be found near Aswān to the south. Some were never completed, and most had to be dug out of the desert’s shifting sands by explorers and archaeologists. Most were constructed during the Old Kingdom, from about 2685 to 2180 B.C.E., and during the Middle Kingdom, from about 2125 to 1648 B.C.E.

THE STEP PYRAMID AT SAQQARA

The oldest surviving stone structure in the world is the Step Pyramid at Saqqara, the first pyramid to be constructed. It was built for the pharaoh Djoser sometime after 2700 B.C.E., during the Third Dynasty. It is called the Step Pyramid because its six tiers, each one smaller than the one beneath it, give the pyramid the appearance of a flight of stairs. The Step Pyramid represented a major shift in Egyptian architecture. This was essentially the first major building constructed of stone rather than mud brick. Further, the complex system of tunnels and chambers that lie beneath the pyramid itself suggest a major leap forward in the design and construction of buildings. Many archaeologists believe that the pyramid

underwent changes in design over time. It appears to have begun as a simple mastaba, a flat-roofed tomb with sloping sides. Later it was enlarged, and tiers of stone were added. At one time there were only two tiers, then four, and later six.

Although historians do not know much about Djoser, they do know a fair amount about the person who designed and oversaw the construction of the Step Pyramid. His name was Imhotep, and in later centuries he came to be regarded as a legendary figure, one who was almost godlike. It is known that he was Djoser's principal adviser as well as a scientist, physician, astrologer, sage, and poet. He founded a school of architecture that transformed Egyptian building from a collection of crude huts made of mud brick and thatch into a nation of lavish temples and palaces that were designed to last forever. His work provided the inspiration for Fourth Dynasty builders to construct the pyramids. An ancient Arab proverb states, "All things dread Time, but Time dreads the Pyramids."

The Step Pyramid consists not just of the pyramid itself. It also includes a complex of structures. The complex was originally surrounded by a limestone wall 34 feet high and 5,397 feet in length. This wall contained an area of about 37 acres with a number of buildings, terraces, and carved facades. In fact, many of the architectural elements of the complex are the first known examples of these elements. They include its colonnades (row of columns), porticoes (porches), hypostyles (the rooflines of a building resting on a row of columns), life-sized statues, and various types of moldings and cornices (the ornamented crowns of a structure, such as a column). The Step Pyramid itself is 197 feet tall and was constructed with almost 12 million cubic feet of stone and clay.

Other early pyramids include the pyramid for King Sneferu at Dashur, which was built around 2600 B.C.E. This pyramid is often referred to as the Bent Pyramid because about midway up there is a bend that makes it look as though the pyramid is bulging out. This bend was probably the result of a construction mistake, showing how difficult it was to make the sloped sides of a pyramid meet precisely at the top. The pyramid at Meidum is also attributed to King Snefru. Although this pyramid is slightly less than 300 feet tall, it sits on elevated ground, so it can be seen for miles around.

THE PYRAMIDS AT GIZA

The most prominent of the pyramids are those at Giza, built on a 1-mile-square plateau about 10 miles west of Cairo. From the top of nearly any building in Cairo, one can see this cluster of six pyramids, three large and three small. The ancient Greeks regarded this group as one of the Seven Wonders of the World. Over a period of perhaps 10 to 20 years during the 25th century B.C.E., King Khufu (sometimes referred to as Cheops, the name ancient Greek historians gave him), built the largest of the pyramids, the Great Pyramid. His successor, King Khafre (written as Chephren by the ancient Greeks) had a somewhat smaller pyramid built, though from a distance it looks as large as the Great Pyramid because it sits on higher ground. The third large pyramid was built by King Menkure

(or Mykerinos to Greek historians). Menkure had the three smaller pyramids at Giza erected for his queens.

The Great Pyramid at Giza is an architectural wonder. It occupies a site of some 13 acres—about seven city blocks—and it is level to within a small fraction of an inch. It was constructed of two and a half million stone blocks ranging in weight from 2 tons to 70 tons, with an average of 2½ tons. It is estimated that the Great Pyramid weighs 6.5 million tons. Over the period of construction, 100,000 blocks per year, or 275 per day, had to be cut, smoothed, and put in position—no mean feat, given that the pyramid consists of 201 levels that rise to a height of 485 feet. Originally, the Great Pyramid, covered with limestone, had a smooth, polished appearance. During the 14th century, however, the limestone was stripped off for use in buildings in Cairo; many of these buildings, made in part with limestone from the Great Pyramid, still stand.

The Great Pyramid appears to be solid, but in fact it contains a labyrinth of passageways and rooms. One passageway, called the "descending passage," enters the pyramid about halfway up and leads down to a chamber 600 feet directly beneath the apex. Angling off from this passageway is another, the "ascending passage," that leads up to the Grand Gallery, a room that is 28 feet high and 157 feet long. This gallery leads to the King's Chamber, where an empty sarcophagus (coffin) was found in the ninth century. The ceiling of this chamber consists of just nine stone blocks that together weigh about 400 tons. Another passageway leads to what is called the Queen's Chamber, so called because its ceiling is peaked, a common feature in queens' tombs during this era.

Considerable mystery has surrounded the question of why the pyramids at Giza were built. The usual explanation is that they were built as tombs for the pharaohs. No bodies or other objects typically included in tombs have been found in them, because over the centuries treasure hunters looted the pyramids. Nonetheless, most archaeologists agree that the principal purpose of the pyramids was to provide a home during the afterlife for the pharaohs. The Egyptians believed deeply in the concept of the afterlife. They believed that in addition to the physical body each person had a *ka*, a kind of replica or double of the body (not to be confused with the *ba*, or soul). According to the pharaohs, the *ka* did not die with the body—or at least it did not have to. It could survive if the deceased's body was protected from hunger, violence, and decay. To avoid decay, the body was mummified, that is, cleaned, wrapped, and treated with chemicals, and then buried in a human-shaped coffin. The function of the pyramids was to protect the body from hunger and violence. Because the pyramids were so tall and massive, with a complex system of shafts and chambers, they protected the body from intruders. Further, the chambers in the pyramids could be filled with jars of water, food, tools, and other objects to help the deceased on his or her journey into the afterlife.

Some historians, though, offer competing theories about why the pyramids were built. They believe that the pyramids were constructed for political purposes. The pharaohs saw the

need to unite the competing tribes of Upper and Lower Egypt, so the pyramids became a massive public-works project to give people pride in the nation's accomplishments. Some of the pyramids' blocks of stone even contain inscriptions from the workers, with names like "Enduring Gang" and "Vigorous Gang," suggesting that work groups took part in healthy competition over the work.

The pyramids have given rise to eccentric, if not fantastic theories. Some people believe that the pyramids are cursed, because a disproportionate number of archaeologists and others have died from illness or accident after working in them, and many others have suffered rashes, fevers, nausea, weakness, and other physical problems. Scientists, though, offer more prosaic explanations for these occurrences: that the sealed pyramids could house fungi or bacteria that cause illness or that the researchers could have been exposed to poisonous herbs, plants, or scorpions or to excessive amounts of radiation from uranium in the pyramids' chambers.

THE SPHINX

One of the most recognizable statues in the world is the Great Sphinx of Giza. The Sphinx, depicting the body of a lion and the head of a man, is the largest statue in the world made out of a single block of stone. It is believed to have been carved sometime during the third millennium B.C.E., most likely during the Fourth Dynasty (from 2723 to 2563 B.C.E.) Many historians believe that the head depicts King Khafre, and the Sphinx may have been built under Khafre's orders. The Sphinx is immense at 260 feet long, 20 feet wide, and 65 feet tall. It faces to the east and may have been built as a guardian for the pyramids on the Giza Plateau that lie behind it. An adjoining temple was constructed using blocks weighing up to 200 tons that were cut out during the carving of the Sphinx.

TOMBS

The ancient Egyptians revered the pharaohs as gods, so they built elaborate and permanent tombs to ensure that the pharaoh enjoyed a prosperous afterlife. In the earlier centuries of the Old Kingdom (roughly 2700 to 2200 B.C.E.), tombs for royalty consisted of simple mastabas. These tombs were not decorated in any way. It was not until the Third and Fourth Dynasties that pyramids were built to serve as tombs for the pharaohs. The Fourth Dynasty pyramids were built without decorations as well. Not before the Fifth Dynasty of the Old Kingdom were pyramids decorated, and they were more modest in size. The decorations consisted largely of hieroglyphic writing. This writing was intended to give the deceased instructions on how to have a safe journey to the afterlife.

The most elaborate tombs were built during the New Kingdom period (roughly 1600 to 1100 B.C.E.) in the Valley of the Kings and the Valley of the Queens. These tombs were built deep underground, primarily to hide them from tomb robbers. Robbery was a problem, for the tombs contained treasures such as vases, jewelry, gold masks, and similar items, often made of gold. These tombs were decorated with

detailed paintings depicting the journey to the underworld. The most famous of these tombs is that of King Tutankhamun, better known to the world as King Tut. Tutankhamun was a relatively minor king who died young after ruling for only about nine years, probably in about 1325 B.C.E. Little is known about his life. His tomb was discovered near Luxor, Egypt, in 1922 by the archaeologist Howard Carter. The find remains significant not because the tomb itself was very elaborate—the tombs of other kings hold more interest for archaeologists—but because robbers had never discovered it, so archaeologists recovered about 3,500 items from the tomb. Since then exhibits of these objects have toured the world.

TEMPLES

In modern life, the word *temple* is used most often to refer to a house of worship. In ancient Egypt, however, buildings that were called temples often served a number of purposes. Some were "mortuary temples," built to commemorate a dead king or to serve as a permanent residence for his soul, such as the so-called *ka* temples. Others were built primarily for political purposes. The temples at Abu Simbel, including one to Nefertari (1300–1250 B.C.E.) and one to her husband, Ramses II (1302–ca. 1210 B.C.E.), seem to have been built primarily to remind neighboring countries to the south of Egypt's greatness. Another class of temples, called Sed festival temples, was built to celebrate the king's jubilee. Others had several purposes, such as serving as administrative centers and fortresses. Even those that had primarily a religious purpose were not "houses of worship" like today's churches and temples. They were thought of more as houses for the gods and were built to serve the symbolic needs of these gods. People, though, did not necessarily assemble in the temples for any kind of organized worship conducted by priests.

Heliopolis Unfortunately, many of the temples of ancient Egypt are lost. Historians and archaeologists know about them primarily from surviving records or in some cases from ruins that indicate the size and overall shape of the temple. One example of a lost temple is that at Heliopolis, one of the three major cities of ancient Egypt (after Thebes and Memphis). Heliopolis, now covered by the suburbs of Cairo, was an important center for learning. In particular, it was a center for the study of astronomy, and its high priest was even referred to as the Chief of Observers (of the heavens). It is known that Heliopolis was the site of a magnificent "sun temple," or temple devoted to the worship of the sun gods Atum and Re-Horakhty as the source of all creation.

Archaeologists theorize that other sun temples built during the Fifth Dynasty were probably modeled after the one at Heliopolis. They know that six such temples were built, but to date only two have been discovered. One of these temples, at Abu Ghurob, was built by Niuserre, the sixth king of the Fifth Dynasty. This temple was constructed on a mound and surrounded by a limestone wall. At the eastern edge of the surrounding desert was a large pavilion with an elevated

passageway leading to a terrace. Inside, at the upper end, was a gate that led to a paved courtyard 250 feet across and 330 feet long. Additionally, the temple had a large rectangular podium that was exposed to the sun. Its sides sloped inward, and the structure was built out of limestone on a base of granite. On top of the podium was a limestone obelisk, or a tapered pillar with a pyramid at the top (similar to the Washington Monument in Washington, D.C.). This obelisk symbolized the sun god. An immense alabaster altar, built of a single huge circular block of stone, lay to the east of the obelisk. A small chapel was located at the base of the obelisk. At the sides of the entrance were two large basins and two stela (stone slab or pillar) made of granite.

OBELISKS

Obelisks, or tall tapered columns with pyramid-shaped caps, were a common feature of ancient Egyptian architecture. The

temple at Heliopolis began the trend, and most temples built afterward featured obelisks, typically one on either side of a temple gate. In some cases, a single obelisk, representing the creative power of the sun, was built in the center of a temple. Most weighed hundreds of tons, and little is known about how they were transported or put in place. The largest surviving obelisk, weighing 1,000 tons, was never completed and still lies in the quarry near Aswān.

THE TEMPLE AT KARNAK

The world largest religious structure is the temple at Karnak, located just north of the city of Luxor. Karnak is a modern name; at the time of its construction it was called Ipet-sut, a name that means “The Most Sacred of Places.” While much of the temple is damaged, parts of it remain intact, and it is one of the most popular tourist sites in Egypt. It is possible that the Temple of Ptah in Memphis was larger still, and numer-

Facade of the Great Temple of Abu Simbel (Courtesy of the Oriental Institute of the University of Chicago)

ous other temples in the Nile Delta region, now entirely lost, may also have been larger.

Karnak is actually a temple complex consisting of three main temples and several smaller outer temples. It occupies a site 247 acres in size and was built over a 1,300-year period beginning in about the 16th century B.C.E. Enclosed by tall brick walls are the three chief temples dedicated to the gods Amun (the sun god), Montu (the war god), and Mut (the mother goddess). The Great Temple of Amun, the major feature of the complex, was built during the reign of Ramses II.

Also considered a masterpiece of architecture is the Hypostyle Hall, begun during the reign of Ramses I, continued during the reign of Seti I, and finished by Ramses II. The hall is noted for its immense architraves (beams that extend across the top of columns, forming the lowest part of the entablature, the usually decorated area above the tops of columns). It is also noted for its windows with stone latticework. The ceiling is 82 feet high and supported by 12 columns. The walls are painted in earth tones; throughout are reliefs that depict scenes symbolic of creation. Covering the outer walls of the hall are pictures of battle scenes. In the courtyard outside the hall is a 70-foot obelisk erected by Tuthmose I and a 97-foot-tall, 320-ton obelisk erected by Hatshepsut, best remembered in ancient Egyptian history as the woman who challenged the notion that only men could be kings.

THE TEMPLE AT EDFU

One of the chief attractions of Edfu, a small city on the west bank of the Nile River, is the temple built to the sun god Horus. Although in many respects the temple is not especially beautiful, it holds a great deal of interest for historians because it is the most completely preserved and intact of all the ancient Egyptian temples. It was built during the Ptolemaic dynasty—the ruling period of the Greek family that controlled the region from 305 B.C.E. to 30 B.C.E. (and the most famous member of which was Queen Cleopatra). The temple itself was built over a period of time stretching from 237 B.C.E. to 57 B.C.E.

The temple is approximately 450 long, 260 feet wide, and 118 feet tall. It features columns, halls, stairs and a ceiling that are still largely in their original state, including the colors and decorations. In the courtyard stand statues, and there are two obelisks at the temple's entrance. Archaeologists are also interested in the remains of the ancient town that lie only steps away from the temple, including monuments that document the history of Edfu as an important provincial town.

HOMES

Virtually no homes survive from ancient Egypt. Archaeologists, however, know a great deal about ancient Egyptian homes, because when a homeowner died, a model of his home was often placed in his tomb, especially if the person was wealthy. Archaeologists have also excavated a village called Deir el-Medina. This was the village that housed the

workmen and their families as they constructed and decorated the rock tombs in the Valley of the Kings and the Valley of the Queens. While the homes themselves did not survive, archaeologists have been able to learn much about the size and layout of homes from the ruins.

Typically, homes were square and consisted of sleeping quarters and a living area. Kitchens were usually outside in the yard and often included a baking oven made of clay. The outside yard was also used as a shop for craftwork and as a pen for livestock. Many homes had storage areas underneath for food. Depending on how wealthy the family was, there could be a granary, stables for horses and livestock, and a threshing area where grain for baking and beer brewing could be produced. Inside walls were often painted with murals that depicted scenes from daily life. Of course, wealthy people had more lavish homes. They often occupied estates that included beautiful courtyards, gardens and ornamental ponds with fish, trees to provide shade, and a shrine to the gods. The insides of their homes typically featured high ceilings, intricately painted walls, and tall pillars.

Most homes had niches that held statues of gods and goddesses. Thus, a woman who wanted to bear a child might have a niche with a statue of the cat goddess Bastet, regarded as the goddess of fertility, or Taweret, the goddess who protected pregnant women. In general, homes were sparsely furnished. Again depending on the wealth of the homeowner, there might have been a bed made of a woven mat placed on a framework, a table for eating, and low stools for sitting; few chairs had backs. When an occupant bathed, he or she typically stood on a limestone slab while servants doused the bather with water; the water ran to a bowl below, which was later emptied by hand. Toilet needs were met in much the same way; waste was flushed with water to a container below or sometimes directly into the sand outside.

THE MIDDLE EAST

BY DAVID PETECHUK

The known history of advanced architecture in the ancient Near East dates back to around 3500 B.C.E. and can be traced to the Sumerians, who established a highly developed civilization in this area. The Sumerians also developed one of the oldest monumental architecture styles, called the ziggurat, a pyramid-shaped tower featuring a temple at the top. Despite the many different types of peoples who lived in the ancient Near East over the years and the constant shifting of centers of political power, the architecture of ancient Mesopotamia shows a certain amount of continuity or cultural uniformity of style.

What is known today about Mesopotamian architecture has been gathered from archaeological studies, ancient texts describing building practices, and pictorial representations of structures. For example, the Sumerians invented the cylinder seal to keep records of rulers who built various edifices and also, at times, to document building construction and

rituals associated with the building process. Cylinder seals are cylinder-shaped stones carved with decorative designs and engraved. These seals were used for a variety of purposes, including as a signature, to confirm a receipt, and to mark building blocks. They remained in general use throughout the area until the first millennium B.C.E. Some of the most notable cylinders providing architectural information about ancient Mesopotamia come from the late third millennium B.C.E. during the rule of King Gudea of Lagash (ca. 2150–2100 B.C.E.), who built the temple of Ningishzida and the temple of Geshtinanna. Although they did not normally contain information on common architecture and building practices, Sumerian cylinder seals have also recorded that houses in marshlands were built of reeds instead of the commonly used mud-baked brick made from local clay.

Most scholarly interest and available data on Mesopotamian architecture have focused on monumental buildings, such as temples and palaces. Temples represent the most enduring architectural monuments of the land, reflecting that culture's focus on serving and honoring the gods they worshipped. Less is known about houses and other structures, primarily because little stone was available for building and these mud-brick buildings deteriorated quickly or were routinely destroyed, with new structures built over the same sites.

ZIGGURATS

The most ancient and impressive monumental architecture of ancient Mesopotamia can be traced back to the Sumerians and is called a ziggurat. The name comes from the Akkadian word *ziqurratu*, which means “height” or “pinnacle.” These ancient towers were stepped structures that archaeologists believe served primarily as the bases for temples to the Mesopotamians' various gods. Archaeologists have also found that the process of building one of these structures was considered a religious act, which included frequent offerings to the gods and required that each worker contributing to its construction be a good and honest person.

Ziggurats evolved from the ancient Mesopotamian practice of building temples on platforms resting above the floodplain and providing a solid foundation on the damp soil. These platforms, or plinths, which date back to the Ubaid Period (ca. 6000–3800 B.C.E.), were built of mud brick, as were most structures in southern Mesopotamia because of the lack of wood or stone. During the third millennium B.C.E. the platforms became larger and higher. Eventually the decision was made to build temples that rose higher above the ground by constructing them on stepped, or terraced, platforms. This design may have stemmed from the practice of building on top of older temples and constructions. These platforms were completely solid throughout and allowed the ancient architects, who knew little at the time about how to keep tall, hollow structures standing, to build taller structures. The Mesopotamian equivalent of Egypt's pyramids, ziggurats were common in cities throughout Mesopotamia by approximately 2000 B.C.E.

In addition to the practical origins of ziggurats, archaeologists have developed several theories about social or philosophical underpinnings of ziggurat construction. For example, some new inhabitants came to Mesopotamia from a mountainous region in modern-day Iran, and archaeologists believe that ziggurats may represent a reconstruction of old mountain temples. Other theories include ziggurats as structures symbolic of a “cosmic mountain” from creation myths or as a bridge between the earth and heaven. This last theory is partly attributable to the ancient Tower of Babel described in the biblical book of Genesis, in which builders proclaim they will build a tower to “reach unto heaven.” There is little doubt that ziggurats were potent symbols. For example, some researchers theorize that trees and gardens were planted on ziggurats to make them represent a mountain that was visited by God and was meant to be climbed by the priests for ceremonial worship.

A typical ziggurat construction included a square or rectangular base, with the most common sizes being around 164 by 164 feet or 131 by 164 feet. Archaeologists also estimate that ziggurats were often 150 feet or higher, such as the one built over an older structure by Nebuchadnezzar II (ca. 605–561 B.C.E.), which had seven terraces, stood 231 feet high, and remains standing at 172 feet. One of the best-preserved ziggurats comes from the city of Ur in what is now Iraq. It had a base of 150 by 200 feet and reached a height of approximately 75 feet. The outer walls of early ziggurats seldom included architectural decoration such as moldings and cornices. Instead, the occasional adornment consisted only of depressions in or projections of brick that were alternately curved and rectilinear.

To allow people to ascend to the tops of ziggurats, about half the structures included stairs or a spiral ramp or path leading to each successive level, or concentric platform. The rest have no visible means of ascent. The temple towers were built with sloping walls believed to have been planted with trees or shrubs to make gardens. In addition, the Mesopotamians incorporated a unique technique that made normally straight, horizontal lines in buildings slightly curved, or convex, which made the overall structure seem softer or less rigid, especially when viewed from a distance. They were so accomplished at this technique that the human eye cannot easily discern the curve. Ziggurats were a prominent construction in Mesopotamia until around 500 B.C.E. and stretched from Babylonia in the south to Assyria in the north.

A notable ziggurat is the Choga Zanbil ziggurat, which rivaled the pyramids of Egypt in character and dimensions. It was built at the city of Dur-Untash by King Untash-Gal around 1250 B.C.E. The complex included three temples or places of worship and a number of courtyards that were paved with bricks. Glazed, kiln-fired bricks that gave off a metallic glimmer of blue and green extensively covered the ziggurat's walls. The design of ziggurat and temple included ivory mosaics and wooden doors decorated with opaque glass mosaics. In its current state the ziggurat towers 82 feet

above the plain; it is believed to have been 170 feet tall when first built.

Because it was restored at a much later date by King Nabonidus (r. 556–539 B.C.E.), one of the best-preserved ziggurats found in Mesopotamia was one built at the city of Ur by Ur-Nammu (ca. 2112–2095 B.C.E.). Constructed to honor the moon god, Nanna, it contained three stages, or platforms. The first rectangular platform measured approximately 205 by 141 feet. The entire ziggurat has been partially reconstructed to a height of about 36 feet. The structure's core was of mud bricks—unbaked bricks made of fine straw and clay and dried in the sun—which were then surrounded with more water-resistant baked bricks made of clay in a compressed mold. As was the tradition, almost all of these baked bricks were stamped with the name of the ruler, in this case Ur-Nammu. The exterior bricks were inclined to form a slope and included regularly spaced, flat buttresses (supports). The exterior walls on this ziggurat also included “weeper holes,” which were small gaps between the bricks that allowed moisture to evaporate from inside the structure. Vertical mud-brick drains were also built on the ziggurat's sides to drain rainwater. The ziggurat included three converging ramps in the first stage and a central stairway to the second stage. The access to the third stage is unknown, but it was probably another central staircase.

TEMPLES

Although archaeologists have no concrete evidence that a temple sat on top of the ziggurat at Ur, they know many ziggurats did serve as the base for temple buildings. Temples were also built on platforms or at ground level. One of the earliest known temples is a small square building uncovered at Eridu that dates back to ca. 5500 B.C.E. In addition to an offering table, it includes a niche and platform, most likely the resting place of a religious statue.

Most of the temples on top of ziggurats from the first period of Mesopotamian civilization, called the Protoliterate Period (ca. 3800–3000 B.C.E.), have been lost to time. Archaeologists have judged their appearance primarily on facade ornaments discovered at places such as Tell el-Ubaid, the ancient site that gave its name to the Ubaid Period. Most of the early ziggurat temples were small, single-roomed shrines, some measuring 80 by 40 feet. The ziggurat temples, like the bases, were made of mud brick and included some ornamentation, such as alternating buttresses and recesses built into the outside walls. Eventually they were designed with a long central sanctuary and various chamber rooms flanking both sides.

A good example of Protoliterate architecture is the White Temple (ca. 3200 B.C.E.) that sat atop the 40-foot-tall Anu Ziggurat at Uruk, which was named after the primary god, Anu. The temple itself measured 61 by 16 feet, indicating that it was meant for use by a small number of people, such as priests and perhaps certain important personages. The outer walls were whitewashed and contained niches and buttresses typical of

the temple architecture at that time. The building contained a *cella*, or central hall, and a stepped altar.

The temples' corners typically faced the cardinal points of north, south, east, and west, unlike the Egyptian pyramids, whose sides face the cardinal points. Although these began as modest structures, over time they were better planned and contained more intricate architectural designs. For example, during the Early Dynastic Period (ca. 3000–2350 B.C.E.) interior wall ornaments included a patterned mosaic of terracotta cones within the walls with the exposed ends covered in bronze or brightly colored. A temple in Uruk included similarly decorated brick columns, some of which were free standing. Facade ornaments were commonly used to break the uniformity of the outer brick walls. These include wooden columns covered in patterned mosaic stone or shell, copper-sheathed bands with decorations, and copper-covered lintels with designs, such as animals. In the Dynastic Period several of the most important temples were patterned after what is called a temple oval, an immense oval platform with a separate wall built around the platform and temple.

During the Neo-Sumerian Period (ca. 2100–2000 B.C.E.) many temples were built in the form of the *broad-cella*. In this architectural design the broad and shallow central hall could be approached only through a series of rooms or courts and surrounding halls. These courts and halls were typically laid in various floor plans designed to hinder access to the altar or statue of a god. Sometimes spaces were arranged around an axis that helped ensure that most worshippers glimpsed the deified ruler only from afar. Few, if any, of the common people could enter the main hall and approach the statue of the local deity.

PALACES

While much is known about the early ziggurats, considerably less is known concerning the early Sumerian palaces and other secular buildings. Archaeologists have discovered that as far back as the third millennium B.C.E. Mesopotamian notables lived in large complexes that often included lavish decorations. A Mesopotamian palace complex found at Ur included numerous courtyards and sanctuaries, a banquet hall, and burial chambers. These complexes were associated with the temples and shrines of the times and may have included facilities for workshops and storehouses.

Like most structures in southern Mesopotamia, the palaces were built out of mud brick and on platforms. Some were eventually built atop ziggurats. While little has been found to shed light on the earliest Mesopotamian palaces, archaeological excavations at Kish, today the site of Tall al-Uhaimer in Iraq, have shown that the buildings dating back to before 2000 B.C.E. included brick columns and simple, austere facades. Most palaces and other buildings probably had flat roofs supported by the trunks of palm trees. Nevertheless, architectural historians believe the ancient Sumerians also knew how to make a simplified support system known as the corbelled arch and corbelled vaulting. The arch form uses

The ruins of Persepolis (in modern-day Iran), the seat of the Achaemenian Empire of Darius I in the fifth and sixth centuries B.C.E.; terrace, throne hall, and palace are visible. (Courtesy of the Oriental Institute of the University of Chicago)

segments of stone or brick jutting out of a wall to span a space, such as a door or other opening. The corbelled vault uses the same technique to support the building's roof. Ancient Sumerian architects also may have made common use of dome construction, as indicated by tombs found at Ur.

According to some observers the Neo-Assyrian Period (ca. 1000–626 B.C.E.), when the Assyrian Empire ruled over much of Mesopotamia, represents the high point of Mesopotamian architecture. Assyrian architecture was heavily influenced by ancient Mesopotamian architecture from the south, which had spread north as civilization expanded from the Sumer in southernmost Babylonia to Akkad in northern Babylonia and eventually to far-northern Assyria. However, unlike southern Mesopotamian architecture, Assyrian architecture also incorporated stone, which was more readily available in the region. As a result, Assyrian palace walls typically included sculptured and colored stone slabs called orthostats. These monumental vertical slabs were also used to line gates and entryways. The Assyrians also used a technique to make polychrome (multicolored) glazed bricks.

The palace complex of King Sargon II (r. ca. 722–705 B.C.E.) at his capital city of Dur Sharrukin, now Khorsabad, Iraq, was built within the city's inner citadel. Made of thick, mud-brick walls without windows, the palace featured doors opening onto internal courtyards of different sizes, including the Grand Entrance Court and the State Court. The throne room was situated between the State Court and a smaller court for women and children. Overall, the palace featured more than 200 courts and rooms, including public rooms, the king's apartments, and a freestanding, seven-level ziggurat with a temple complex. The vast palace complex covered approximately 1,000 acres, and many of the rooms and courtyard walls were covered with intricately sculpted decorations on stone slabs. For example, on the facade of the northern part of the palace Sargon II is shown welcoming a high official. Other sculpted walls depicted the king's military and civic accomplishments.

King Sennacherib, who ruled Assyria from about 705 to 681 B.C.E., decided to build the largest and most elaborate Assyrian palace ever known, which he referred to as the "Palace without Rival." Built on a platform close to the

Teblitu River, whose course Sennacherib had changed to accommodate his building site, the king's palace incorporated mud-brick stone and precious materials, including ivory and cedar brought from the forested mountains of Lebanon. It included large columns of bronze or cedar. The walls were lined with slabs of gypsum alabaster brought from Assyrian quarries and used because the soft stone was more easily carved than other types of stone in the area. The doorways included stone statues of human-headed winged bulls and lions as guardians on either side. Smaller statues were also used to help support columns. In addition, numerous stone reliefs of spirits and animals decorated the palace walls and were meant to protect the king from evil. The palace contained more than 70 halls and chambers, most lined with stone panels depicting the king's many accomplishments.

During the short-lived Neo-Babylonian Period (ca. 625–539 B.C.E.) builders combined both northern and southern architectural approaches and methods, including the polychrome glaze popular among the Assyrians. The Chaldeans, who made enameled baked bricks by applying a colored paste before baking, used these bricks for the exterior of their palaces and temples, often completely covering the faces of the structures with them. Their success in producing these bricks is evidenced by the fact that the remains of the brilliant blue, white, black, yellow, and red enameled bricks have maintained their brilliancy to modern times. Some of the bricks included floral designs and animal figures. The inside of the Chaldean palaces were also heavily decorated with murals. Another decorative technique applied to the inner walls was a thick layer of clay stucco, in which dry cones of baked clay were buried within the wall. The cones were visible on the wall's surface at regular intervals and covered with various colors. In addition, the cones' heads were separated by colored geometrical lines.

During the Persian Empire (ca. 538–331 B.C.E.) many of the Mesopotamian techniques were still being used in Near Eastern architecture. By this time, however, the Persians had incorporated the extensive use of columns, as evidenced by the famous complex of palaces at Persepolis (518–460 B.C.E.), in which the throne room alone had 100 columns. Founded by Darius the Great, who reigned in Persia from 521 to 486 B.C.E., the palace was not completed until approximately 100 years later by Artaxerxes I, who reigned from 464 to 424 B.C.E. One reason construction took so long was that the construction of buildings could not even begin until a complex platform was completed, a technically difficult project because it was inserted into an irregular and rocky mountainside. The palace complex was designed not only as a seat of government but also as a showplace and center for receptions and festivals. The northern part of the palace was meant primarily for officials and included the Hall of the Apadana, the Throne Hall, and the Gate of Xerxes. The rest of the complex included the Palaces of Darius and Xerxes, the Harem, the Council Hall, and other such facilities.

By the time of the Sassanians, who can be traced back to around 250 B.C.E., architects began using rough-hewn stone to construct their palaces. At places like Firuzabad and Sarvestan the palaces featured triple aivans, which were huge, open-air entrance halls that led to reception halls, beyond which were situated the monarch's residential quarters. The Sassanians also made extensive use of stucco, which accounts for the loss of architectural remains of these triple aivans, whose existence is based on period literature. Also worth mentioning is the Palace of Shapur I, who ruled from 241 to 272 C.E. Found at Ctesiphon, southeast of the modern city of Baghdad, the palace features the largest single-span arch in the world.

HOUSES

The earliest known dwellings in Mesopotamia consisted of round, mud-wall huts sunk into the ground with an entrance and a hearth. In what was the northern region of Mesopotamia archaeologists have discovered huts dating to the ninth millennium B.C.E. sunk into the ground with stone pillars made out of plaster. Many houses connected to the Marsh Arabs and their reed culture were also built of tall reeds. These reeds were staked into the ground in two parallel rows with their tops tied together and covered with matting. A similar, more complex technique is still used in rural sections of modern Iraq.

Outside the marshlands, however, houses were built of mud bricks and mud plaster. Typically, house construction varied according to the socioeconomic status of the occupants. The poorer people lived in single-story houses of reinforced mud brick with floors of packed earth or mud bricks. These houses were sometimes merely circular huts supported by a center post. As building techniques progressed, however, those higher on the socioeconomic ladder had much grander living quarters that were two and sometimes even three stories high.

Based on archaeological excavations at Ur, the typical "upper-middle-class" home of around 2000 B.C.E. was multistoried and built around an open-air courtyard, which allowed light to enter the windowless rooms. Typical ground-floor areas included a kitchen with a fireplace, a long, narrow reception room where guests were received, a chapel with an altar, and a tomb under the pavement or ground. The open-air yard probably included storage sheds or stalls for sheep, goats, and other domestic animals. The home's second story was reached by stairs, sometimes leading to a wooden balcony supported by columns. This balcony usually extended around the entire central courtyard, and the second floor usually consisted of bedrooms. Despite this luxurious space for that era, a ladder was often used so that people could sleep on their rooftops on hot summer nights. The roofs were buttressed with timbers packed with mud. Eventually these houses also included a bathroom just off the courtyard. For most houses the bathrooms were small enclosures with a central drainage hole paved on each side with bricks where people would place their feet and squat.

CONTRIBUTIONS TO ARCHITECTURE AND THE HANGING GARDENS

Architecture in the ancient Near East was advanced by the region's various rulers for dual purposes. The earliest of the larger buildings were devoted primarily to religious expressions. But large ziggurats and palaces also provided rulers with the opportunity to showcase their power and achievements.

Over time Assyrian kings, among others, began to use architectural design and city planning to further their concerns with warfare and trade. For example, cities were often circled with heavy walls and powerful gates. In one city built during King Sargon II's reign, the main gate was designed as a fortress built over the city wall with the primary citadel rising over the wall at the city's rear. Later the Babylonians borrowed from this approach to build royal palaces over the city walls. During the Neo-Babylonian Period architects designed a fortification around that city that included a double line of walls and a moat that was fed by the Euphrates and through which boats could enter the city under gatehouse bridges.

Considering the materials readily available to the ancient architects of the Near East, architects at the time revealed a high standard of originality and design. For example, the use of the dome can be traced back to mud huts built in Mesopotamia at around 4000 B.C.E. Later, the Sassanians made a major contribution to world architecture through their propagation of the dome on squinches (small arches built across the interior angle of two walls) above a square hall.

The Mesopotamians are also credited with developing the arch, and the earliest-known keyed arch was unearthed at Nippur, which is known as the ancient holy city of Mesopotamia and dates back at least to 2200 B.C.E. It is only through the use of keyed arches that architects could make large openings in walls and buildings. The Mesopotamians' use of brick led them to develop the pilaster and the column as well as frescoes and enameled tiles. Another example of architectural advancement included the *bit-hilani*, a portico entrance hall built with a stairway approach that is flanked by pillars, developed by the Hittite civilization ca. 1600 B.C.E.

A discussion of ancient Near East architecture would not be complete without mention of the fabled Hanging Gardens of Babylon, one of the Seven Wonders of the Ancient World. Although no concrete evidence of their existence has been uncovered, archaeologists believe they were probably built by Nebuchadnezzar II along the banks of the Euphrates River to please a wife or concubine who had lived in the lush mountain areas and was made homesick by the sun-baked plains of southern Mesopotamia. Interestingly, written accounts of the Hanging Gardens do not come from Mesopotamia but from foreigners who had visited Babylon or heard of the gardens. According to the Greek geographer Strabo (ca. 62–24 B.C.E.), writing in the first century B.C.E., the structure “consists of vaulted terraces raised one above

another, and resting upon cube-shaped pillars. These are hollow and filled with earth to allow trees of the largest size to be planted. The pillars, the vaults, and terraces are constructed of baked brick and asphalt.” This green, forested, artificial mountain was described by the Greek historian Diodorus Siculus (ca. 90–30 B.C.E.) as being 400 by 400 feet and reaching more than 80 feet in the air. Some accounts indicate that the structure, which was probably similar to a ziggurat, may have been as high as 320 feet.

ASIA AND THE PACIFIC

BY MICHAEL J. O'NEAL

Architecture has often been referred to by the fanciful phrase “concrete music,” suggesting in a poetic way that pleasing architecture makes more permanent the beauty of music that would otherwise disappear. Because architecture, at least during ancient times, was a collaborative effort involving many architects, builders, and craftsmen, it came to express the vision and values not just of an individual architect but also of the culture that shaped that vision and those values. That ancient architecture is the expression of a culture rather than of a person makes it of particular interest to historians and archaeologists.

Nowhere is this truer than with the architecture of ancient Asia, particularly China and India, where architecture combined function with great attention to form, beauty, and harmony with the environment. Because portions of large numbers of buildings and other structures from these and other Asian countries have been preserved throughout the centuries, architectural historians have detailed insight into the designs, materials, construction techniques, and functions of ancient Asian architecture. What they have found is a great degree of adaptability, as architects were able to use materials and methods that were available to them in their particular regions of the world.

Any tour of the architecture would begin in China, which produced one of the world's oldest and most accomplished civilizations. Indeed, the influence of ancient Chinese architecture was felt throughout Asia in such countries as India, Korea, Japan, and Thailand.

ARCHITECTURE OF ANCIENT CHINA

The construction of a building in ancient China began with the principles of feng shui, a term that means “wind” (*feng*) and “water” (*shui*). Feng shui consists of a set of principles that can be difficult for westerners to understand, though in modern life many westerners have been trying to incorporate these principles into the design, construction, and furnishing of their homes and even offices.

Feng shui is rooted in the ancient Chinese worldview that sought harmony and balance between the opposing forces of nature and between the physical environment and humans. The principles of feng shui were applied to the

Panoramic view of West Lake in Lin'an (modern Hangzhou), China, showing the curved roof feature thought to guard against evil spirits (Freer Gallery of Art, Smithsonian Institution, Washington, D.C., Gift of Charles Lang Freer)

selection of a building site, the design of the building, its construction, and the decorations both inside and outside. In contrast to Western architecture, which represented human conquest over the environment and separated the environment from human spaces, Chinese architecture stressed living in harmony with the heavens and the earth. Not only were individual buildings planned according to the principles of feng shui, but entire cities were laid out according to these principles as well.

The process began with a feng shui practitioner, a kind of diviner, who selected the most favorable site for a building or burial site. The diviner would apply principles from a number of different systems of thought. One of the most prominent systems included the concept of yin and yang, essentially opposing masculine and feminine principles. Another was called *wu xing*, a complex system of thought that saw nature as a series of cycles in which the five elements of nature existed in harmony with one another—water in winter, wood in spring, fire in summer, and metal in the fall, with earth dominating the transitional periods between these seasons. Finally, *bagua*, another highly complex system of thought, focused on changes in the natural cycle over time. *Bagua* (pronounced “ba-gwa”) helped the feng shui practitioner identify the nine areas of a home or building that corresponded with prosperity, fame and reputation, relationships, family, health, creativity and children, skills and knowledge, career, and helpful people.

The diviner would then try to achieve the most favorable chi (pronounced “chee”). Once again, the concept is difficult for westerners to grasp. In the Western scientific view of nature, at least until the findings of 20th-century physics, matter and energy were generally thought of as two different things. In Chinese thought they are considered in many respects the same. While the word *chi* is usually translated as “energy,” it also refers to the notion of matter on the verge of becoming energy and energy on the verge of materializing. The concept of chi was used in ancient Chinese medicine to refer to the vital life forces of the body. More generally, it referred to the most basic element of the physical world.

Ancient Chinese architects applied the same principles to construction that ancient Chinese healers applied to the body. The goal was to site a building in a way that achieved the most harmonious chi while avoiding evil chi. The diviner would focus on five fundamental elements of the physical world: *long* (dragon), *xue* (cave), *sha* (sand), *shui* (water), and *xiang* (orientation, in the sense of which direction something faces). These elements are self-explanatory except for “dragon,” which in ancient China was regarded as one of Twelve Symbols of Sovereignty. In this sense, the dragon symbolized the natural world and its ability to transform and adapt. Two dragons together but facing opposite directions were symbolic of yin and yang. The dragon was also a sign of royalty and thus of power.

To make a structure harmonize with nature, it was believed that the best way to orient it was facing southward toward a river or lake with a hill at its back to the north. In one major respect, this orientation had a practical function, for it shielded the structure from cold north winds. In laying out a city, a major goal was to locate the city’s central axis, often using mountain peaks to create a line that gave the city harmony and balance.

Three specific principles therefore dominated the form of ancient Chinese architecture. The first was that a building was to be symmetrical and balanced, in the same way that chi represented symmetry and balance in nature and in the human body. This meant that if a building were divided in half along a central axis, the two parts would be mirror images of each other. The second principle was that roofs were to be held in place by columns rather than walls. This allowed builders to incorporate a greater view of the landscape; the view from inside was not blocked by solid walls that enclosed the space and separated it from nature, and a more natural flow of energy from outside to inside could be maintained.

Finally, the roofs themselves were to be curved rather than straight. This principle reflected the ancient Chinese belief that curves repelled evil spirits, while flat roofs allowed evil spirits to enter the building. This principle explains why most

ancient and traditional Chinese buildings have something of a curved, swooped appearance, rather than the appearance of boxes, triangles, and other geometric shapes characteristic of Western architecture. One of the chief innovations of ancient Chinese architecture was development of the corbel bracket. A corbel is any kind of projecting support that extends outward from a building's roofline. The corbel can be decorated, and it was the use of corbels on ancient Chinese buildings that gave the roofs their distinctive style.

The most dominant form of architecture that survives from ancient China is imperial architecture, referring to structures associated with ruling dynasties. Rulers, of course, had access to immense funds to build huge mausoleums (tombs) and palaces, and they could command the efforts of literally thousands of architects and builders as well as slaves and prisoners of war to perform the actual labor. Although many ancient buildings in China were constructed of stone and even of metals, most were constructed with wood, which was plentiful. But because wood is a nondurable material, most of the ancient structures archaeologists have studied exist only in ruins. In many cases, archaeologists have only foundations to study.

Tombs and mausoleums were prominent structures in ancient China. For many centuries Chinese imperial rulers constructed elaborate tombs and mausoleums for themselves, and these structures are scattered about China since different dynasties ruled from different capital cities. Employing the principles of feng shui, they typically backed these structures up against hills and mountains, with the entrance looking out over a plain. Usually, a prominent feature was a *Shendao*, meaning "the Sacred Way." This was a broad, long entrance leading to the tomb. Guarding the tomb would typically be rows of statues of humans and animals. Along with the tomb would be other elaborate structures designed to enhance the dignity and power of the deceased.

Before arriving at his tomb, however, an ancient Chinese ruler would occupy a royal palace. As noted, these and other structures in ancient China were often built with wood, so they employed massive beams and posts that transferred the weight of the structure to the ground. The earliest such structures were painted primarily to protect the wood from the elements, but over time painting became much more elaborate, colorful, and decorative. One of the most famous palace complexes in China, built for the emperor Qin Shi Huang more than 2,000 years ago during the Qin Dynasty (221–207 B.C.E.), is called the Epanggong Palace. (*Gong* was the Chinese word for palace, though depending on the context it could also mean simply "home.") The complex's Front Palace was immense, capable of holding many thousands of people and covering an area of about 861,000 square feet. (By comparison, a football field, including the end zones, covers 57,600 square feet.) Another prominent set of palaces included those of the Western Han Dynasty (202 B.C.E.–9 C.E.), collectively referred to as Weiyanggong, which had some 40 palaces within an area measuring just 6.8 miles across.

Much of the imperial architecture of ancient China incorporated the number 9, which had special meaning. According to the principles of yin and yang, yin represented even numbers, while yang represented odd numbers. Odd numbers were thought of as masculine, while even numbers were considered feminine. To display their power (and masculinity), ancient Chinese emperors insisted on designs that incorporated 9, the largest odd number less than 10, and its multiples. Thus, for example, ancient temples and palaces were often built with nine sections, and gates were often built with various materials, including lumbar and stone, arranged in nine columns and nine rows. Another common feature on ancient Chinese palaces was the depiction of dragons and phoenixes. These figures were totems, or personal emblems, and they represented the emperor and his wife or consort. Columns, screens, walls, and other elements were painted or carved with representations of dragons and phoenixes.

Of nearly equal importance in ancient China were temples and other structures with religious significance, such as pagodas. It is estimated that during the Northern Wei Dynasty (386–535 C.E.), some 30,000 temples were built throughout China under orders from the emperor. Many of these temples were built with as much splendor as imperial palaces, and many were built in a shape that resembled that of a mushroom, suggesting the concept of rapid growth.

Like palaces, temples were extremely symmetrical, with the building balanced on a central axis and facing south. On the flanks of the temple proper were annexes and other buildings, again constructed with great symmetry and balance. Temples typically included an elaborate gate, a "heavenly king hall," and a library, as well as more practical elements such as dormitories, kitchens, dining halls, and rooms for receiving visitors. Also prominent in China are some 3,000 existing pagodas, which were built with various materials, including wood, stone, brick, iron, and bronze. Some of these pagodas are as high as 130 feet. Most are multistoried, and they were built as religious shrines, memorials, or temples. In many cases a temple was constructed below the pagoda.

One of the most famous Chinese architectural achievements is the Great Wall of China, the world's longest artificial structure at nearly 4,000 miles. However, the Great Wall that exists today is only one of five different walls built by the Chinese. The first, made primarily of rammed earth, was built during the Qin Dynasty in 208 B.C.E. Very little of this first wall remains intact, though archaeologists have discovered remains of it along with the remains of watchtowers constructed along its length. The wall was not built as a single project; rather, construction was a matter of joining together a number of regional walls primarily to mark China's northern boundary at the time. Most of the laborers who built the wall were slaves, prisoners of war, and political prisoners, and it is estimated that up to a million of them died during the wall's construction, giving the wall the nickname "the long graveyard." A second wall, built during the Han Dynasty (202 B.C.E.–220 C.E.) during the first century B.C.E., was

constructed in a similar way. It, too, has largely disappeared. The Great Wall that remains a tourist attraction in China was built under the Ming Dynasty over a 300-year period beginning in the 14th century.

ARCHITECTURE OF INDIA

Historians and archaeologists use the phrase *Indian architecture* to refer to the architecture not just of the nation of India but of the entire Asian subcontinent as well, including the modern-day nations of Bangladesh, Pakistan, and Sri Lanka. In ancient times, and even in modern life, these nations shared a culture and religion that gave rise to a common architecture.

The history of Indian architecture begins in the Indus Valley (roughly corresponding to the modern Indian state of Punjab) when, some 5,000 years ago, people migrated into the area and found a fertile, hospitable land. Archaeologists have discovered the remains of cities that were laid out with a degree of planning that would put to shame many modern cities, with defensive walls and streets arranged in a regular octagonal pattern, making it easier for carts laden with food and other materials to make turns. The remains of numerous houses have been found. These houses were built around a central courtyard that afforded privacy while also allowing light to enter the rooms constructed around it. The courtyard also provided a cool place for the family to gather during hot spells, yet it held warmth during colder weather. Long before the ancient Romans developed plumbing systems, the cities of the Indus Valley had sewage and drainage systems.

Roughly 3,500 years ago the cities of the Indus Valley, most prominently Mohenjo Daro, fell to nomadic Aryan invaders from the northwest. These invaders drove out the indigenous people, but rather than occupying their cities, the invaders preferred to live in forest hamlets. Although little of their architecture survives intact, archaeologists have studied ruins and have determined that the simple architecture of the Aryans influenced Indian architecture for many generations. Much of what is known about the architecture of this age, called the Vedic Age (ca. 1500–ca. 600 B.C.E.), is preserved in the ancient texts, the Vedas, that later formed the basis of Hinduism. It is known that the Aryans built homes with the abundant materials that lay at hand, including lumber and bamboo thatch. Their homes were circular and domelike, though later the homes expanded into a more rectangular shape. In time Aryan villages developed into small cities divided into quadrants and intersected by two main streets at right angles to each other. One quadrant was for the city's citadel, which guarded it from outsiders. A second was residential, a third was for merchants, and the fourth was for tradesmen.

A third phase of Indian architecture is associated with the rise of Buddhism. The connections between Buddhism and architecture, though, provide an interesting case study in the links between religion and other elements of a culture. During the Vedic period and up to about 500 B.C.E. the teachings of the Vedas had an impact on virtually every aspect of people's lives. The rigid caste system separating the social

classes of India emerged, and religion consisted primarily of pure ritual. At about this time two major religious reformers rose. One was the Buddha, or Siddhartha Gautama, who was born in 563 B.C.E. and founded the Buddhist religion. The other was Mahavira, the date of whose birth is uncertain but whose life probably overlapped that of the Buddha. Mahavira was the founder of Jainism, another major Indian religion and one that has many features in common with Buddhism. In both instances, the new emphasis was on the nature of the soul rather than on ritual observances.

Both of these key religious figures attempted to reform Vedic culture by lessening some of the emphasis on ritual. Buddhism turned out to be the religion that had the wider appeal, and it won the support not only of the region's mercantile classes but also of the king, Asoka the Great (r. ca. 273–232 B.C.E.), who declared Buddhism the state religion. Under Asoka, funds were provided to build monasteries throughout the region. Further, because the Buddha himself was the closest thing to a god among Buddhists, his relics became scattered throughout the land. The key point is that these religious developments gave rise to much of the architecture that developed in the Buddha's wake.

Accordingly, throughout India a large number of shrines were built in honor of the Buddha, many of them little more than piles of rocks purporting to contain a relic of the Buddha. In time, however, the people began to believe that these shrines needed to be improved, which gave rise to more elaborate stupas, or spherical configurations of stone, that reflected the growing influence of Buddhism. These stupas could be found throughout the country, and people visited them as shrines.

By about the second century B.C.E., though, the influence of Buddhism began to wane. India's rulers were returning to the teachings of the Vedas, and they found the Vedic caste system more congenial to their notions of power. After the reign of Asoka the Great and the decline of two major Indian ruling dynasties (the Kushans in the north and the Andhras in the south), Indian art and architecture underwent a severe decline. Buddhism, however, by no means disappeared. Merchants continued to support Buddhism, and they supplied most of the funds that allowed Buddhist monks to establish monasteries and centers of learning.

One of the most important of these centers was Sanchi, located near the modern-day city of Bhopal in India. Sanchi survives as a major pilgrimage site for modern Buddhists and as a tourist attraction for people the world over. The stupa at Sanchi is a domelike structure with a surrounding path and topped with a finial called a *harmika*. (A finial in this context is an ornamental projection from the top of a wall or column.) The domed shape of the stupa reflects the shape of the universe, and the *harmika* represented the Bodhi tree where the Buddha achieved enlightenment.

In addition to the main stupa are a number of other buildings that serve the needs of visitors and the monks who travel to the site to meditate and do penance. One, called the *vihara*, consists of cubicles, or cells, arranged around a central court-

yard. These drab cells evolved from the caves in which monks had lived in previous centuries. Another, called the *chaitya*, was a set of halls that could be used when the main outdoor stupa could not because of bad weather.

One of the interesting elements of the *chaitya* is that they were built in a manner similar to older Vedic architecture, but in stone rather than in wood. Thus, the *chaitya* have barrel-shaped vaulted roofs, entrances shaped like horseshoes, and railings. Archaeologists speculate that the craftsmen who built the structure were reluctant to give up the techniques they had used for building wooden structures when they turned to the use of stone. In fact, much of the cave architecture of ancient India, such as the caves at the city of Karle, look in most ways as though they have been carved out of wood, right down to the “joints” that were carved into the stone. Other early temples, such as the modest temple at Tigawa near modern-day Jabalpur, use a great deal of stone, including a stone slab for the roof, giving the temples an almost cavelike quality, though much of the stone is intricately carved.

These and similar structures were precursors to an era marked by the construction of magnificent Buddhist temples under the reign of the Gupta Dynasty, which reached the height of its power in about 400 C.E. During this period builders turned away from their “wood carving” approach to stone and began to employ techniques more suitable for stone and masonry construction. This gave rise to a style of architecture that was radically new. Until this time Indian architecture had been relatively simple and impermanent. The earliest Indians worshipped in the open, then in buildings constructed with reeds and bamboo, then in wooden post-and-beam buildings, and finally in stone stupas. Under the Gupta Dynasty, though, architects began to develop the core principles that led to more magnificent temples during the later medieval period.

One early Gupta temple is a small Shiva temple in the Jhansi district of India, in the town of Deogarh. (A Shiva temple was one dedicated to the Hindu god Shiva.) One noteworthy characteristic of this temple is that above the central worship area was erected a raised, pyramid-shaped structure that is estimated to have been 40 feet tall (much of the temple is lost). The temple also has four porticoes, or covered porches, one facing in each compass direction. The temple is also of interest because of the elaborate carvings on the exterior pillars.

ARCHITECTURE OF ANCIENT KOREA

Archaeologists have discovered the remains of Korean civilization dating back to the fifth millennium B.C.E. Among the remains are those of homes. The earliest homes on the Korean Peninsula were pits in the earth. Later homes used earthen walls with thatched roofs, and still later homes were made of logs.

Among the architectural sites that have been excavated is that of the city of Choson, which emerged in the fourth century B.C.E. and survived to the third century C.E. There

archaeologists have uncovered the remains of colonial headquarters buildings and tombs. Most of the official buildings were constructed of brick and wood, and their roofs were tiled. Tombs include the Tomb of the Painted Basket, a wooden structure with a single chamber and a large number of treasures. Tombs of kings and members of the upper classes have also been found in Koguryo, Kungn ae-song, and Pyongyang, which served as district capitals. In about 18 B.C.E. the city of Paekche was founded, and it, too, is the site of numerous building sites and tombs. Prominent among the city’s sites was a central pagoda with an entrance gate, a main hall, and other rooms laid out along a central axis, reflecting the influence of Chinese architecture.

ANCIENT ARCHITECTURE ON THE PACIFIC ISLANDS

Not a great deal is known about the architectural achievements of the peoples who inhabited the four major regions and some 25,000 islands that make up Oceania: Australasia (including Australia and New Zealand), Micronesia (including Guam, the Mariana Islands, and the Marshall Islands), Melanesia (including Fiji, New Guinea, Indonesia, and the Solomon Islands), and Polynesia (including Samoa, the Cook Islands, and Tonga). Settlement of these islands was a slow process over long periods of time, as people had to travel from far-flung locations by boat. Most of the region’s architectural record dates back, at the earliest, to about 500 C.E. However, the remains that do exist demonstrate an ability on the part of Oceanic peoples to adapt their architecture to their environment, using wood, coral, lava rock, reeds, and other materials that happened to be at hand on a particular island.

EUROPE

BY JAMES A. CORRICK

Ten thousand years ago the people of Europe lived a nomadic life as they followed game and searched for other food. These hunter-gatherers established temporary camps from which to hunt, fish, and forage. Their dwellings were as temporary as their camps and were easily assembled from materials found at hand, such as the wood and bark of trees, stones, and animal hides. These early shelters were the beginning of European architecture.

TENTS AND HUTS

The most common shelters for early Europeans were tents that were fashioned in a variety of shapes—circular, oval, rectangular, and square. Whatever the shape, each tent had a wooden frame from which hides hung to form walls. Sometimes stones were placed along the bottom of the hide walls to hold them in place. European hunter-gatherers also built wooden huts, which had the same variety of shapes as tents. The walls were wooden poles or stakes covered with bark, reeds, or hides in order to add further protection from wind and rain. Entry was through an opening left in the wall, which

was sometimes small and sometimes large. Some huts had stone foundations, while others built along riverbanks or lakeshores rested on platforms of brushwood, stone, or moss that served as protection from the often wet and marshy ground.

These tents and huts were generally small, probably meant for a single family. Some circular tents and huts in Scotland, for instance, were 13 feet in diameter, about the size of a small modern bedroom. A few larger structures did exist to house more people. Early Europeans would connect together two small tents with a long, hide-covered passageway to make a larger tent or to construct long huts up to 80 feet in length.

No matter the size, the interior of a tent or hut was not divided but rather formed a single dwelling space, one area of which was used for sleeping, another for cooking. If a shelter did not sit on a platform, its floor was often sunken and either left bare or covered with clay, bark, or brush. There was no chimney, and smoke escaped through entryways, gaps in the walls, or openings left in hut roofs and tent tops.

SETTLING DOWN

Agriculture appeared in Europe around 7000 B.C.E., and the migratory hunter-gatherers eventually became settled farmers and transformed their temporary shelters into more permanent buildings. This process took several thousand years to complete. By 2000 B.C.E. individual farmsteads and farming communities existed throughout ancient Europe. Within them were homes, barns, storage sheds, workshops, and cookhouses, sometimes all in the same structure but often in separate buildings.

Although elaborations and variations were eventually made to the design of these structures, the basic features remained constant throughout the ancient period. Some ancient Europeans who came under the influence of Greece and Rome, particularly those living in regions conquered by the Romans, adopted all or part of their architecture. However, even in Roman-controlled Gaul (roughly modern-day France), Iberia (present-day Spain and Portugal), and Britain (modern-day England), the more traditional architecture of ancient Europe remained the preference of many.

BUILDING SHAPES AND SIZES

The buildings of ancient Europe were commonly either circular or rectangular. Both kinds of structures were found all over the continent, although a specific region generally favored one design over the other. Thus many of the people of central and northwestern Europe built rectangular structures. Elsewhere, the circular house, or roundhouse, predominated, as it did in Britain even into the period of the Roman conquest in the first century of the Common Era.

The square was also a popular shape, and some oval-shaped structures existed. In northern France during the fifth millennium B.C.E. some buildings were shaped like trapezoids, which have only two sides parallel, unlike rectangles that have all four sides parallel. Again unlike the rectangle, in which each side is the same length as its parallel partner,

in the trapezoid one of the parallel sides is shorter than the other. The size of a building generally depended on its use: A house was larger than a storehouse, and a home meant for several families was larger than one intended for a single family. Accordingly, roundhouses varied in size from 15 to 70 feet across.

Rectangular buildings also varied in size. Small square buildings were 15 feet on a side, while larger rectangular structures averaged lengths of 100 feet. The latter were known as longhouses; they first appeared in central Europe sometime after 5500 B.C.E. and eventually spread to western and northern Europe, where they remained in use through the early centuries C.E. Longhouses were not only long, ranging from 33 feet to 246 feet in length, but they were also narrow, between 16½ and 23 feet in width. An average-sized longhouse could accommodate 20 to 30 people, either a large extended family or several smaller families, as opposed to smaller houses meant for a single nuclear family.

HOUSE EXTERIORS

Both circular and rectangular buildings served people as homes. Some of these ancient European houses had foundations of stone or wooden beams. River- and lakeside structures often sat on platforms supported by sturdy wooden posts a few feet or yards high; thus they were high enough to be above normal flood levels. A few houses in Italy actually were set on platforms erected over water, with supports for these platforms being as much as 30 feet in length, taller than many modern homes.

Most houses—indeed, most buildings of any kind—of ancient Europe, whether circular or rectangular, had wooden walls, though those in regions with few trees were made of stone and those in dry regions of bricks of dried mud. A few of the timber structures were log cabins, similar to those later favored by many American pioneers. More commonly, however, timber houses had walls of wattle stretched between upright posts and covered with daub for weather proofing. Wattle was made from vertical bundles of reeds or wooden stakes through which thin rods of wood were woven horizontally, while daub was a mixture of soil and clay along with grass, straw, animal hair, or dung. Dried daub was both hard and weather resistant. The upright posts were set at the corners of rectangular houses and evenly spaced around the circumference of roundhouses. The walls frequently had a coat of whitewash, made by crushing limestone or seashells and mixing with water. Whitewashing was both decorative, giving the exterior a glossy white appearance, and practical, since it further protected the walls from the effects of weather.

Rising from the top of the walls of most ancient European buildings were pitched roofs (typically two sided and sloped), which ascended at steep angles of 45 to 55 degrees and were generally covered in thatch, peat, or turf. Pitched roofs were needed because they allowed rain and snow to slide off rather than collecting on and possibly collapsing the roof. Some roofs had eaves, which were roof edges extending

beyond the walls so that dripping water or falling snow would not damage the walls.

A roundhouse's pitched roof was cone-shaped, rising to a peak. On rectangular structures one side of the roof might have been raised higher than the other, or the roof might have been double-pitched, that is, having two halves, each of which angled down from a central beam running the length of the house. At either end of the house, the two roof halves and the top of the end walls formed a triangle. This triangle might have been covered by further roofing or filled in with gables, triangular pieces of wood or wattle that rose from the tops of the end walls. Houses in parts of southern Europe, where conditions were drier and warmer, often had flat roofs, since water and snow accumulation was not a serious problem. Many of these roofs had an outer covering of dirt that often supported a rooftop garden.

For thousands of years most houses lacked windows and had only one doorway. After 800 B.C.E., however, houses with several entrances appeared. In Britain, for example, roundhouses of the last centuries B.C.E. and the first century C.E. had a main door that was flanked by two smaller entryways. Half-way around the circle was another large entrance. The main entrances, perhaps for religious reasons, faced east and west.

The entryway might or might not have had some sort of covering. In some ancient European homes entryways were left open or hung with a hide curtain. In Bulgaria in the sixth millennium B.C.E. a screen just inside the door provided privacy by blocking the view of anyone looking in from the outside. Many later houses, however, had wooden or wattle doors that pivoted on stone pins. The large entryways of British roundhouses in the ninth century B.C.E. had double doors. Some entryways were sheltered from rain and snow by a porch, a rectangular wooden frame with wattle walls and a flat or pitched roof. The porch was used at times to house animals such as pigs. Occasionally, to keep heavy rain, melting snow, or other groundwater from running into the house's interior, the bottom of the door did not reach the ground, and a step was provided to make entry easier. If the floor was dug below ground level, steps inside led down.

HOUSE INTERIORS

Inside ancient European houses the roof poles and rafters were left visible. Floors were often dug down a foot or more. They were made of beaten earth or were covered with animal skins, clay, paving stones, or wooden planks. Sunk into the floors of some buildings were clay- or stone-lined pits for storage. A rare house even had a shallow basement with a clay coating or stone lining. The interior walls were occasionally painted, as in German houses of the fourth millennium B.C.E., in which red and white zigzags streaked across a yellow background. If the walls were thick enough, as they were in some houses in Britain and Scotland, cupboards, shelves, and benches were cut into them.

Many houses, particularly in the early agricultural period, had a single room. In small rectangular buildings and in

most roundhouses, the room space was empty. However, many rectangular structures had several roof-supporting posts—sometimes in rows, sometimes staggered—breaking up the floor area. Buildings that lacked these posts had roofs that were fully supported by their frames, which in turn were supported by the walls. Among roundhouses, only the largest had roofs heavy enough to require support posts, and even they had a large, central, unbroken space because the posts, numbering 12 or more, were placed around the border of the room a few feet from the inner wall. Some roundhouses did have a central post that rose up to the roof and to which roof poles connected, but most of the floor area still remained free.

Commonly, in larger rectangular and circular houses partitions of wattle stretched between the support posts to divide the interior into two or more rooms. In a two-room house one room was used for cooking and activities such as weaving and tool making and repair, while the other was for sleeping. In buildings with many rooms the front chamber was a combined reception area and workroom, while other chambers served as a kitchen-dining room and one or more bedrooms.

In northern Scotland a special class of stone roundhouses, known as wheelhouses, had rooms formed by piers, stone supports that projected from the wall and ran from floor to roof to give the latter support. The piers also formed the walls of the rooms, each of which faced an open central space. These houses also had a stone hallway leading from the entryway into the house's center. The house's name comes from the wheel-like appearance of its interior: The house wall was the wheel rim, the piers were the spokes, and the central room was the hub.

Many homes housed more than just people. In regions with hard winters one room would contain stalls, mainly for cattle. In Scotland in the last centuries B.C.E. the space along the walls of roundhouses was sunken and paved with stone, probably as a pen for animals. Frequently one or more rooms had a loft, a partial second floor that was reached by ladder from the ground floor. Lofts had plank floors covered with wattle and made excellent places to keep food away from both domestic and wild animals. A few houses even had a complete second story. The same houses in Scotland that had paved sunken areas had a second floor supported by posts that served as the building's living quarters.

Without windows and often with only a single entryway to let in sunlight during the day, house interiors were quite dim, particularly in rooms partitioned off from the door. In a longhouse, for instance, which had its door at one end of the building, much of the interior was dark. The end farthest from the door was thus used for food storage and for housing livestock, the middle section for eating and sleeping, and the door's end for all activities requiring light.

Since chimneys did not exist in ancient European houses, the home's entryway allowed smoke from fires for cooking and heating to escape. Smoke also escaped through the roof. Much of the roofing material, such as thatch or turf, was porous enough to allow smoke to seep out. However, it was not

porous enough to let rain in, at least as long as the angle of the roof's pitch was great enough to allow water to flow off rather than through the roof.

FARMSTEADS

Many ancient European houses stood on isolated farmsteads, often the home of a single nuclear or extended family. The farmhouses varied greatly in size, ranging from a small roundhouse to a large longhouse. Surrounding the house, although in no particular pattern or order, were other structures that served a variety of purposes. Some were to house or pen animals. Farmsteads that raised cattle often supplemented or replaced the farmhouse stalls with a byre, or cattle stable. Many farms also had pens made of wattle for pigs, goats, and sheep, which in winter might have been housed in the human residence or in a barn. In terms of design and construction, byre and barn would have been like the main house, though probably smaller, particularly if the human dwelling was a longhouse.

In addition to animal enclosures, farmsteads had a number of storage facilities for wheat, barley, oats, and other grains. Early farmsteads dug pits that were then sealed with clay and covered with dirt. Beginning around 800 B.C.E. these pits were replaced by small storehouses, or granaries. Each wattle-walled granary, many of them rectangular even on farmsteads where the main structures were roundhouses, sat on a wooden platform supported by four to nine posts. The posts kept the stored grain out of the reach of animals.

A farmstead might also have had a cookhouse and a workshop for pottery making, weaving, and tool production and repair. Small buildings for storing tools and other equipment were sometimes present as well. There might even have been additional living quarters if the main house proved too small to accommodate a farmstead's human population. To keep domestic animals from wandering off, some farmsteads were fenced with a stone wall or a wooden palisade, which is a fence made of upright stakes. Many, however, were unfenced, relying on a ditch dug around the perimeter to keep the animals in. Beyond the fence or ditch were the fields for growing crops.

VILLAGE BUILDINGS

Along with solitary farmsteads, ancient Europe had many villages, some of which may have started as single farmsteads. Much the same sort of structures that were found on the farmsteads also were found in the villages, except in larger numbers. Thus there were houses, storehouses, byres, barns, and workshops. The houses of individual villages were often very similar to each other in size and design. For example, the houses in a village in Switzerland in the 18th century B.C.E. were small, rectangular buildings 13 to 16 feet long. All had wooden plank walls, and most had stone foundations.

Some communities even standardized their houses, as did a village in Poland in the eighth and seventh centuries B.C.E. This village had rows of two-room houses; each row

shared a single roof covered with reeds, and all the houses were the same size. The walls and floors were split logs, with clay and moss corking any gaps in the walls. One of the two rooms was a large common room for working, cooking, and eating, while the smaller one was a bedroom. Each house had a loft and a front porch.

Other ancient European communities displayed a range of houses of varying sizes, the smallest having only one room and the largest having several. The larger homes may have belonged to more prosperous villagers, or they may simply have been the residences of large families. Some ancient European houses were markedly different from the rest found in their villages. This difference may have indicated that their occupants were important members of their communities. In Britain in the second century B.C.E., for example, a number of houses, known as courtyard houses, probably belonged to prosperous or influential villagers. Each house had a rectangular, paved courtyard surrounded by a stone wall. Built into the wall were rooms, some of which were living quarters and others of which were for animals and storage. Some courtyard houses also had underground chambers.

HOUSE OF THE CHIEF

Some courtyard houses may have been the homes of village chiefs. Although few ancient European villages had special houses for their leaders, such dwellings did exist. A chief's house was not a palace, which ancient Europeans did not have. Instead, it was often the largest house in a village, frequently had more auxiliary structures associated with it than other homes, and sometimes was set apart from the rest of the village, either by being located a short distance from other homes or by being surrounded by a palisade.

In the sixth century B.C.E. central European village chiefs lived in compounds surrounded by double palisades, or a fence within a fence. In each compound was a smithy for metalworking and a large wooden house with a stone wall along one side. The chiefs' houses sometimes contained as many as four rooms. The doorway gave entry to a large central room where the chief probably conducted business. Off to one side was a large bedroom, and off to the other were a kitchen and a smaller bedroom.

Later, during the first century B.C.E. in Germany, at least one palisaded chief's compound included granaries and many animal stalls, indicating that much of the food production was under the chief's control. The compounds also enclosed small workshops in which villagers forged bronze and iron tools and weapons; made pottery and leather goods; and manufactured items out of wood, bone, and antler.

THE BROCH

In addition to being large and set apart, a chief's house was sometimes physically different from the homes of other villagers. One house located in France in the latter centuries B.C.E. had one end that was semicircular and may thus have belonged to a village leader. Among the most distinctive of

chief residences was found in Scotland from the first century B.C.E. to the second C.E. Known as a *broch*, this structure was a stone tower, of which some five hundred were built. Surrounding it were the houses of the rest of the village. Despite *broch* being Scottish for “borough” or “fortified place,” the structure was not a military post or fort but a fortified house, akin to the castles of the Middle Ages and the home of the local chief.

The *broch*'s wall, 15 feet or more in thickness, was actually two walls, which converged toward one another as they rose to a height that could exceed 40 feet. With some *brochs* the two walls sat atop a single solid wall; with others, they began at ground level. Passageways with wooden floors ran between the walls and were probably used for storage. The double-walled construction made for good insulation from the harsh northern winters. The *broch*'s entryway was a large tunnel that could be closed off with a heavy wooden door fastened by wooden bars. Beyond the door was a chamber, perhaps meant to house guards, and a stairway that led up to the wall passages. Tower interiors ranged in size from 18 to 40 feet in diameter. Built against the inside wall were several wooden or stone rooms, or cells, whose own walls sometimes contained cupboards and windows that looked out on the *broch*'s interior. Some *brochs* had a walled courtyard inside.

PUBLIC HALLS

In some ancient European villages, chiefs may have presided over village meetings, feasts, and other community activities in a public hall. Exceptionally lengthy longhouses, such as the 148-foot ones of central Europe, may have been such community halls. A different kind of longhouse found in Scotland, Britain, and northwestern and central Europe may also have been a village hall. These buildings differed from the usual longhouse in having rounded corners and being twice as wide, at about 40 feet. The interior was divided into rooms with partitions, and animals were apparently kept in stalls in some of these structures. It is also probable that, despite their communal nature, one or more families lived in these halls.

RELIGIOUS BUILDINGS

It is also possible that these halls were used for religious ceremonies. If so, they were among the few buildings that functioned for worship in ancient Europe, whose people preferred outdoor sacred sites. Occupying Romans did build temples, but these were for their own use. Only on the island of Malta between 3600 to 2500 B.C.E. did large temples appear in ancient Europe. Built in groups of two, three, or four, these temples had walls made of limestone covering a core of dirt and broken rock. A large entryway led into a central passage, off of which were three to six semicircular chambers. Floors were covered with crushed limestone or paved with stone. At least one temple had stairs leading to the roof, which was probably flat and made of clay-coated wood. Another temple had red-painted walls. Other religious structures in Europe for the next several thousand years were generally simpler affairs

than those of Malta. Some villages had a shrine that was a house set apart from the rest and left vacant except for human and animal figurines.

In the last centuries B.C.E. and the first centuries C.E. the Celts built both shrines and temples. A Celtic shrine built during this period was a small structure with a pitched roof and gables supported by posts. The structure lacked walls and was surrounded by a palisade and a ditch, across which was a wooden bridge. More elaborate were circular, stone Celtic temples found in southern France. Influenced by Greek architecture, each temple had a colonnaded portico, a porch with regularly spaced columns. The portico surrounded a *cella*, or sanctuary. The latter always towered over the portico and was paved with stones arranged in geometric shapes.

GREECE

BY MICHAEL J. O'NEAL

For generations of tourists, a visit to Greece has meant touring architectural ruins in Athens and other sites throughout the country. Even those who have never visited Greece are likely to recognize the names of some of the most famous sites, such as the Parthenon, for these buildings are tangible reminders of the beginnings of Western civilization. Greek builders inspired and taught the later builders of the Roman Empire (31 B.C.E.–476 C.E.); the Romans copied Greek architecture extensively, and many of their surviving buildings provide insight into the methods and materials of Greek architects. Indeed, much of what archaeologists know about Greek architecture comes from their knowledge of later Roman architecture. Still today, modern buildings are sometimes built in the Greek Revival style, suggesting that they copy many of the features of ancient Greek architecture.

Interestingly, the architects of ancient Greece were not regarded as artists, as prominent architects in modern times are. An architect was seen as a combination of skilled tradesman, contractor, and builder. The state—or sometimes a wealthy individual—hired an architect to complete a building project. He designed the building, hired the necessary laborers, acquired the materials, and kept track of the budget. In many instances, the name of the architect is not even known. Only later, during the Hellenistic Period from the fourth century into the first century B.C.E., did architects come to be thought of as artists in their own right.

THE ROOTS OF GREEK ARCHITECTURE

The ruins that survive date primarily from the late Classical and the Hellenistic periods of Greek culture. Historians cite the Persian Wars (480–448 B.C.E.) as the beginning of the Classical Period of Greek art, which extended to the death of Alexander the Great in 323 B.C.E. The Hellenistic Period began with Alexander's death and extended to about the first century B.C.E. Like Greek civilization generally, though, Greek architecture did not spring out of nowhere. The centuries before the Classical Period are called the Archaic

Period, which began in roughly 600 B.C.E. During the Archaic Period and the earlier part of the Classical Period, structures were built primarily with mud brick, clay, and wood. These materials are not very durable, so virtually nothing remains of them, nor are there any surviving written descriptions of them. Only in the Classical Period did architects and builders begin to use more durable stone so that many of their buildings survive, at least in part.

Archaeologists, though, have excavated sites from earlier Bronze Age civilizations around the Aegean Sea, including such sites as the cities of Knossos, Mycenae, and Troy. (Bronze Age refers to the period in history beginning in about 3000 B.C.E. when bronze, an alloy of tin and copper, was widely used for tools and other purposes.) These were the very earliest civilizations that can be called Greek, flourishing from about 3000 to 1200 B.C.E. The first of these, the Cycladic culture, rose during the Early Bronze Age (about 3000–2200 B.C.E.). The second was that of the Minoans, who flourished from about 2700 to 1450 B.C.E. on the island of Crete. The third, the Mycenaean, rose during the Late Bronze Age, from about 1600 to 1200 or 1100 B.C.E. and provided the setting for such literary works as the epics of Homer. The Mycenaeans occupied an area of the Greek mainland south of what would become Athens. Surviving from each of these civilizations are remains of structures that give archaeologists clues about the roots of Greek architecture.

One of the most famous of these sites is Knossos, a city on the island of Crete. Archaeologists believe this site was the political capital of the Minoan culture. It was discovered in 1878 by an amateur archaeologist, who began excavating it then. In 1900 a British archaeologist purchased the entire site, and with the help of a team of archaeologists he excavated and began reconstructing the palace of Knossos. Further study revealed that humans began inhabiting the site in about 7000 B.C.E. The population grew until it numbered from 5,000 to 8,000 people in the years 1900–1600 B.C.E. The community's central building, both for religious and administrative purposes, was the palace. Archaeologists' best guess is that the palace was built sometime between 1700 and 1300 B.C.E.

The palace is a wonder of ancient architecture. It occupies a site of some six acres and comprises 1,300 rooms. Among them are storage rooms that contained numerous large vases (called *pithoi*) used for food storage. Beneath the storage rooms were holes used to store valuables. The five-story-high palace also had running water and a sewage system. Its porticoes (porches) and airshafts provided ventilation and allowed the building to catch sea breezes to remain cool during the hottest weather. The plaster walls of the palace were decorated with numerous frescoes. These frescoes were in a state of decay and were reconstructed by Piet de Jong, a 20th-century artist who specialized in fresco reconstruction. The Throne Room has an alabaster throne that was built into the wall and flanked by carvings of mythological animals.

At the end of the Bronze Age, architecture in effect “disappeared” from ancient Greece. It reemerged during the

seventh century B.C.E. It was at about this time that Greek civilization began to flourish. Greece became more prosperous, and a more urban culture developed. This gave rise to cities and the buildings that filled them.

FEATURES OF GREEK ARCHITECTURE

Most ancient Greek buildings were either cube shaped or had a rectangular footprint. Public buildings, such as temples, were constructed primarily of limestone, an abundant building material in ancient Greece. Architects would probably rather have built using marble, but marble was expensive, hard to transport, and not readily available; the only marble available had to be transported from Mount Pentelus and Attica or from a few of the Greek islands. Marble was used, though, for decorative and structural components in some of the most important buildings, including the Parthenon.

Most buildings were flanked with a colonnade, or a row of columns. Sometimes the colonnade was just at the front entrance, but other times it was on all four sides. Many buildings, too, had a portico, or a covered porch supported by columns. In general, Greek buildings did not have arches or domed roofs, so all the buildings had a squarish appearance; only later did the Romans add arches and domes to their buildings. Roofs consisted of wooden beams covered with tiles, usually made of terra-cotta, or unglazed clay. (Terra-cotta, meaning “burnt earth,” is the material used to make modern flowerpots; the word also refers to their brownish-orange color.) Some buildings were roofed with marble tiles.

A common feature of Greek buildings was their low-pitched roofs. (The Greeks did not have to worry about snow building up on roofs, so the roofs did not need a steep pitch, or angle, for snow to fall off.) At each end of the building was a pediment, or a triangular area under the angle of the roofline. Pediments were typically filled with stone statues. Many buildings, too, featured an entablature. This term refers to a horizontal row of stone blocks under the roof between the tops of the columns that supported the building. The entablature provided an “easel” for sculptors, who carved friezes on them, or sequences of carvings that often told a story. These friezes often alternated metopes and triglyphs. A metope was simply a pictorial panel; a triglyph was a group of three projecting vertical blocks that separated the metopes.

FORMS OF GREEK ARCHITECTURE

A theater could be found in nearly every Greek town of any size. These theaters were used not only for dramatic performances but also for official meetings. The origins of Greek drama lay with religious ceremonies, but by about the sixth century B.C.E. drama came to be regarded as one of the highest forms of art, and the plays of such dramatists as Sophocles (ca. 496–406 B.C.E.), Aeschylus (525–456 B.C.E.), and Euripides (ca. 484–406 B.C.E.) are still performed throughout the world. The theaters were typically built into a hillside with tiered seating arranged in a semicircle. Behind the stage area was a low building used for storage and as a place where the

FROM ANCIENT GREEK HISTORY TO ROMAN MYTHOLOGY

A widely known story from Roman mythology is that of Daedalus and his son, Icarus. Icarus flew too close to the sun with wings his father had made. The sun melted the wings, and Icarus fell to his death. This myth has a strong connection with the palace at Knossos.

After the spread of the Roman Empire, the legend grew up that the palace, because of its large number of rooms and confusing layout, was the labyrinth King Minos had built to house the Minotaur. The story goes as follows. Minos, the king of Crete, boasted that the gods would grant him anything he wished. He believed that the sea god Poseidon would give him a magnificent bull if he offered an appropriate sacrifice of one of his own bulls. When a white bull miraculously emerged from the sea, Minos sacrificed a bull to Poseidon, but the bull was inferior. Poseidon was annoyed, so he caused Minos's wife, Queen Pasiphaë, to fall in love with the white bull. To consummate her love for the bull, she enlisted the support of Minos's chief builder and architect, Daedalus. Daedalus's solution was to build a wooden cow into which Pasiphaë could be lowered. Later, to everyone's horror, Pasiphaë gave birth to a creature that was half-man and half-bull, called the Minotaur.

Minos was eager to hide this evidence of his wife's infidelity. He consulted with the oracle at Delphi, which counseled him to build a labyrinth where he could hide the Minotaur. That labyrinth, according to Roman myth, was the palace at Knossos. Later, Minos's son was killed by the Athenians, leading to war between Crete and Athens. With the help of the god Zeus, Minos won the war. To put an end to the conflict they were losing, the Athenians agreed to provide Minos with seven stalwart young men and seven maidens every nine years. These people would be sent into the labyrinth, where they would be consumed by the flesh-eating Minotaur. Eventually, the Athenian hero Theseus killed the Minotaur with help from Minos's daughter, Ariadne.

Minos later learned that Daedalus had helped Pasiphaë in her wickedness. In anger he imprisoned Daedalus and his son, Icarus, in the labyrinth, but Pasiphaë got them out. Daedalus and Icarus wanted to flee Crete, but they knew that doing so would be impossible, for the king had all the harbors watched. Accordingly, Daedalus made wings out of feathers that were held together with wax so the two could fly away. He and Icarus flew north, but Icarus was so intoxicated with his ability to fly that, despite his father's warnings, he flew too near the sun. The wax in his wings melted, and he fell to his death in the sea near an island that was named Icaria in his honor.

actors could dress. The theater at Epidaurus is one of the best-known Greek theaters, and it survives almost entirely as it was when it was built beginning in the fourth century B.C.E.

Greek towns of any size were also likely to have a gymnasium, often with an attached *palaestra*, or facility for training in wrestling and boxing. The *palaestra* had a fairly standard architectural style. Surrounding a rectangular open-air court were colonnades. Adjoining rooms served a variety of functions, including bathing, storage, and socializing. One of the most famous surviving *palaestrae* can be found at Olympia as part of the original site of the Olympic Games. The famous arena at the University of Pennsylvania in Philadelphia is called the Palestra, named when it was completed in 1927 by one of the university's professors of Greek.

Other common architectural forms include the *tholos*. This was a circular building used for religious purposes. The *tholos* at the city of Delphi, built to honor the goddess Athena in about 380 B.C.E., is one of the best examples. The *propylon* was a porchlike structure that typically served as an entrance to the grounds of a temple; one of the best preserved is the *propylon* at the Acropolis in Athens, built from 437 to 432 B.C.E. The *bouleuterion* was a council chamber found in many towns that also served as a courthouse. Finally, the *stoa* was a narrow hallway often found in the commercial districts of

Greek towns. The *stoa* consisted of a narrow hall with an open colonnade, where merchants would set up shops. In Athens the Stoa of Attalus has been completely restored.

Many of the best surviving examples of Greek architecture are temples. These temples, though, did not serve the same function as modern-day churches, temples, or mosques. Generally, the altar was placed outside in a sacred area called the *temenos*. The temple itself served more of a storage function for offerings made to the local god, artwork, and a treasury. Inside the temple was a *cella*, or an inner room or sanctuary that housed the statue of the local god and was typically surrounded by a row of columns. The most famous example of a surviving temple is the Parthenon in Athens, built from 447 to 432 B.C.E.

ORDERS OF GREEK ARCHITECTURE

Archaeologists, architects, and art historians have identified three main orders, or styles, of ancient Greek architecture. These styles can be seen on modern buildings, including those in the United States. Government buildings, courthouses, and even homes, many of them built in the early years of the United States, incorporated the Greek orders, in large part because Greek architecture for early Americans symbolized the birth of democracy. Wanting to incorporate democratic

ideals into American life, early American architects tended to copy the Greek orders.

As these styles evolved, the goal for Greek architects was to find pleasing proportions. They wanted to ensure that each part of the building was proportioned in relation to the other parts to achieve a perfect form. Thus, they constantly experimented with these forms. In earlier centuries the forms were fashioned primarily out of wood; during the Classical Period stone was the favored building material. Since many buildings had religious significance, the Greeks wanted them to last forever and have the ability to withstand earthquakes. Because so much depended on the buildings' supports, a great deal of attention was paid to the columns. These columns consisted of a number of parts; from bottom to top, they included the pedestal, base, shaft, and capital. Resting on the capital was the horizontal architrave (a beam that extends across a row of columns). Above the architrave was the frieze carved on the entablature, and on top of that was the cornice, or projecting moldings that allow rainwater to flow off the top of the building.

The first of the orders, the earliest to develop (in about the seventh century B.C.E.), is called the Doric, a term the Greeks

themselves used in the belief that this style of architecture descended from the more ancient Dorian culture. The ancient Romans regarded the Doric style as the most masculine. The distinguishing features of this style are that the columns are thick and sturdy and the capitals, or the tops of the columns, are plain. The ancient Greeks believed that a man's foot was one-sixth his height, and they used this proportion in Doric columns. The Doric style of architecture can be seen in the Parthenon in Athens, the Temple of Hera at Paestum, and the Temple of Apollo in Corinth.

The second order of Greek architecture was the Ionic, which developed about a century later. Its distinguishing features are that the columns are more slender, about eight times the width at the base, and the capitals are ornamented with spiral scrollwork called volutes. The Romans thought of the Ionic style as more feminine, with the scrollwork representing a woman's hair and the vertical fluting (concave, semicircular grooves) of the column representing the folds of her gown. The Greeks themselves saw this distinction. The Ionic style was prevalent in regions that were urban and sophisticated. The people saw this style of architecture as refined and elegant. In contrast, the people in regions where the Doric order predom-

The theater at Epidaurus, Greece (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

inated were more rural; they preferred what they considered the sturdier, more “manly” Doric style. They resisted Ionic architecture because they saw it as symbolic of the dominance of Athens over the other city-states of Greece. A good example of the Ionic style is the Temple of Apollo at Didyma with its 122 enormous columns (only two of which survive).

The Doric and the Ionian are regarded as the two main styles of Greek architecture. A third order, though, called the Corinthian, emerged from the Greek city of Corinth. This style was an evolution of the Ionic, for it features columns that were even longer and slimmer than Ionic columns. The distinguishing feature was elaborate and detailed carvings on the capital. These carvings were of the leaves of the acanthus, a plant that grew in the Mediterranean region. Because the Corinthian style was more detailed and “fancy,” it came to be associated with luxury and wealth. The reason the Corinthian style is not considered a major style of Greek architecture is that few buildings in Greece adopted the style. Later, though, it was commonly used in Roman buildings, including the Pantheon.

ANCIENT GREEK HOMES

Because the houses of ancient Greece were generally built with inferior materials, archaeologists do not have very many complete or nearly complete houses to study. The generalizations they make about Greek homes are pieced together from contemporary descriptions and from the remains of housing sites that have been excavated. These sites are found primarily in Athens and the northern Greek city of Olynthos. One exception is a house that has been excavated in the town of Vari, located southeast of Athens. This is the best-preserved house archaeologists have had to work with, and while it was a farmhouse, evidence suggests that houses in the cities were similar.

These sites provide evidence in the form of floor plans. Also, the remains of artifacts provide evidence of the use to which rooms and areas of the house were put. For example, the existence of a drain suggests that an area was used as a bathroom, while chips of a substance like marble suggest that an area was used as a workshop by a stonemason.

A number of factors influenced the design and construction of Greek homes. In Athens many houses were irregularly shaped because the streets of ancient Athens were extremely narrow and crooked. In earlier centuries people had built crude homes on sites that gave them access to water and that followed the natural contours of the land. Later, when Greek civilization was at its height and new homes were being built over the old ones, little effort was made to impose more order on the layout of the city.

Further, efforts were made to build housing in places near to where Athenians worked. Thus, many homes were built in and around the industrial district of the city. The streets were made of hard-packed earth, sometimes covered with gravel. Water was brought in by conduits carved in the rock or sometimes by terra-cotta pipes, though water often

had to be carried to the home from public fountains. The remains of many cesspools have been found, suggesting that waste was removed by channeling it into these pools. In some places, drainage ditches were constructed; some were simply conduits carved into rocks, but some were elaborately constructed with floors, walls, and even slab ceilings.

Greek houses tended to be of poor quality. Even the better homes were made primarily with stone and mud, not the limestone that was used for public buildings. The foundation of the house consisted of irregularly shaped rocks that were simply piled in place. The exterior walls were made with mud brick, sometimes coated with lime. These walls were thin and rickety—so much so that burglars, rather than coming through doors or windows, simply knocked holes in the walls to gain entry; in fact, a common Greek word for *burglar* literally meant “wall digger.” In some cases, the thickness of the surviving foundation suggests that the house might have been of two stories. While most homes, especially those built before about 500 B.C.E., were small, in later years larger and more luxurious homes were built. Many were built in the countryside, where wealthier Athenians would go in the summer to escape the city’s heat, as well as the smells, insects, rats, and disease caused by garbage piling up in the streets.

An almost universal feature of Greek houses was that they were built around a central open courtyard. Rooms were adjacent to the courtyard on all four sides, though the homes of poorer people generally consisted of just one room divided by partitions. Many had a veranda that provided shade and protection from the rains. The interior walls were generally coated with whitewashed plaster, and the homes of wealthier people were decorated with frescoes. Either animal skins or reed mats covered floors of hard-packed earth, and small stones were often used to create mosaics on the floors. Small windows were positioned close to the ceilings to admit light but keep out the heat of the summer sun. Roofs were generally made of terra-cotta tiles over wood. Wood, though, was expensive and hard to obtain. Only the wealthy could afford wooden shutters over the windows and wooden doors; when people in the countryside fled during outbreaks of war, they often took their wooden doors and shutters with them.

Another feature of Greek homes was that many had separate quarters for men and women. Greek husbands believed that their wives and daughters had to be shielded from public view. Thus, if they could afford to do so, they constructed homes with a separate area for women either at the back of the house, away from the street, or on the second story. This area was called a *gynaikieion*. Similarly, men had their own quarters, called the *andrôn*, typically located on the north side of the house, which stayed cooler. Many men used this area of the house to entertain male friends.

Few examples of what could be called apartment houses have been found. A notable exception is the port town of Piraeus, where apartment blocks called *synoikiai* were occupied by the poor and foreigners. These apartments, though, were often death traps because of earthquakes and fires.

ROME

BY FRANCESCA C. TRONCHIN

The remains of Roman architecture are enormously varied, from the most humble one-room home in Pompeii to impressive amphitheaters in Rome, France, and North Africa. Like Greek buildings, the surviving Roman structures have had considerable influence on architecture in the Western world and beyond. Although a great many Roman structures survive, the record geographically favors the architecture of the city of Rome itself. The eruption of Mount Vesuvius in the year 79 C.E. not only destroyed the cities of Pompeii and Herculaneum but also preserved a great number of private houses as well as public and religious buildings. These sites offer a very good picture of what Roman cities looked like, but only for the earliest phases of the Roman Empire. Other regions like North Africa, the Middle East, and central Europe are helping to complete the picture of Roman architecture, both in the heart of the empire and in its far-flung provinces.

In addition to the archaeological evidence, some ancient texts reveal a good deal about Roman buildings and their design. One written resource in particular—the *Ten Books on Architecture* by Marcus Vitruvius Pollio—is a very useful tool in the study of Roman structures, engineering, decoration, and even city planning. Vitruvius was an architect and an engineer living in the first century B.C.E., and he dedicated his comprehensive treatise to the emperor Augustus. While Vitruvius's writings are very helpful, he primarily described the state of architecture in his own time and a few centuries before. To learn about later periods in Roman building, one must look again to the physical remains as well as to a few surviving pieces of ancient texts by writers in later periods.

Vitruvius was, like most Roman architects, more than simply a designer of buildings; he was also an engineer and was knowledgeable about landscape design and art. Although Roman architects were skilled in a great many areas, few of their names survive to our day. In antiquity it was more important that the name of the person who commissioned and paid for a building be preserved, rather than the name of the person who designed and constructed it. Vitruvius, among other ancient writers on architecture, described the importance of symmetry, harmony of forms, durability, utility, and beauty in buildings. These are principles that can be observed in many surviving Roman structures.

Although Roman designers borrowed heavily from Greek architecture, they made considerable contributions in construction and style. The arch and vault were perfected by the Romans. Concrete was essentially discovered in the Roman period and exploited by the architects of the time. The Romans also introduced new building types like the amphitheater, bath, and apartment building (called an *insula* in Latin). The Markets of Trajan in Rome, built between 110 and 112 C.E., could be regarded as the first multistoried shopping mall in the world.

DESIGN AND MATERIALS

Among the earliest building materials in Roman Italy were mud brick and tufa, a local volcanic stone. Both eventually fell out of use for the most part, but for different reasons. Tufa was a sturdy and readily available stone, but it was not well suited to the kind of fine decorative carving favored by Roman architects. Mud brick had been used for millennia throughout the Mediterranean region, but it is only a semi-permanent material. The kiln-fired bricks that came into use during the first century B.C.E., in conjunction with concrete, proved to be much more durable; many of the Roman buildings that survive are made of this combination of fired bricks and concrete. Eventually travertine (a type of marble from quarries close to Rome) became an important material for Roman buildings. With the discovery of beautiful and pure white marble in northwestern Italy during the life of Julius Caesar (100–44 B.C.E.), builders came to favor that type of stone for luxurious buildings in Rome and elsewhere. In various parts of the Roman Empire different building materials were exploited because of their availability as well as their suitability to the local climate.

The earliest Roman buildings were frequently decorated with terra-cotta statuary, evidence of a strong relationship to the Etruscan civilization of central Italy. Vitruvius describes the reliance of Roman architecture on Etruscan design. Not only did the Etruscans use terra-cotta statues on their buildings, but they gave their temples a strong focus on the front of the building as well. This design is very different from that favored by earlier Greek architects, and it came to be adopted by Roman builders.

Like much of Roman art, Roman architecture was eclectic. Designers borrowed styles from both the Etruscans and the Greeks, and many architects working in Rome just before the days of the empire (beginning in the first century B.C.E.) and shortly afterward were Greek or of Greek descent. The Romans used innovative materials such brick and concrete throughout the empire, but they almost always used Greek architectural forms to decorate building exteriors. For example, the facade of the Colosseum—Rome's monumental amphitheater—is decorated with columns in the Greek Doric, Ionic, and Corinthian orders. (The “orders” made up an organizational system of Greek architecture.) Beginning in the second century C.E. materials and styles showed an Eastern influence, such as with the importation of Proconnesian marble from modern-day Turkey and in the use of various architectural details native to other Eastern provinces.

The Roman architects combined Greek, Etruscan, and other design elements in new and original ways, as in the Temple of Portunus in Rome. The building has the Etruscan features of a high supporting platform, a porch with columns, and a focus on the front of the building. The freestanding columns at the front and half-columns at the sides and back, however, show a reliance on Greek examples. The combination of different forms gave the temple its distinctly Roman flavor.

Concrete—a mixture of lime, volcanic ash, stones, a binding agent, and water—had been in use on a minor scale in Mesopotamia, but Roman architects perfected the material. Concrete had advantages over previous architectural materials, such as cut stone, in that it was exceedingly strong and flexible and was faster and cheaper to construct. The Romans' first use of concrete dates to the late third century B.C.E. Concrete allowed Roman architects to improve upon a feature that had been used by the Greeks and Etruscans: the arch. The arch is a highly stable structure that transmits and bears weight very effectively. Arches can accommodate a wider span than more traditional architecture, which uses simple vertical and horizontal supports, and the strength of concrete allowed for even wider spans. The use of poured and shaped concrete to create arches imparted a greater flexibility of form as well. When arches are extended, they create a barrel vault, like a semicylindrical ceiling over a corridor.

Roman architects used concrete and the structures of the arch and barrel vault to create new types of buildings. The Sanctuary of Fortuna Primigenia at Palestrina in central Italy is an early example of the creative and complex use of concrete vaults. The Pantheon in Rome, however, is perhaps the most spectacular example of concrete construction. It was the largest dome in the world until modern times. The Pantheon survives almost completely intact, allowing visitors to gain an exceptional sense of occupying an ancient space.

Although visitors to Rome and other ancient Roman cities in modern times see large sections of brick-faced concrete walls that still stand, in antiquity these walls were frequently covered with other materials, usually to give a richer appearance. Stucco was often employed to cover the walls and could be enhanced with thin layers of the fine plaster that was a suitable surface for fresco painting. Both interior and exterior walls could be plastered and painted. In more costly buildings, thin slabs of marble and other stones were used to cover the concrete walls and therefore give the illusion that the entire building was made of more expensive materials. White marble was particularly popular for these panels, probably because of the associations with more ancient and venerable Greek buildings (which were actually made of solid marble in many cases). The emperor Augustus is said to have boasted that he transformed the city of Rome from a brick one to one made of marble. This statement is partly true, since a great many buildings were constructed in the city during Augustus's reign, frequently faced in white marble.

Colored marble was also popular for revetment panels (decorative thin slabs of stone) as well as entire columns and pavements for floors. These stones came from all corners of the Roman Empire. Yellow stone veined with purple came from Tunisia, green "serpentino" from southern Greece, red-purple porphyry from Egypt, and the Phrygian white and purple stone from what is now Turkey. These colored stones, in combination with glass and terra-cotta, could also be used in small cubes, or tesserae, to make mosaics. Mosaics were

used as beautiful and durable floor coverings in private homes and public buildings alike.

ROMAN TEMPLES

The Romans most frequently worshipped their gods and goddesses at temples. Roman cities were full of small and large temples, which could also be dedicated to deified emperors. Most Roman temples were rectangular in plan; stood on a high, stepped podium; and had one entrance at the front of the building. A columned porch, topped by a pitched roof (two sided and sloped) and pediment (the triangular section just below a sloped roof, which sometimes contained sculptural decoration), drew attention to the doorway. This is a departure from the design of Greek temples, which typically had colonnades (rows of supporting columns) along all four sides, creating the illusion that no particular side was more important than the others. The interiors of Roman temples were occupied by statues of a deity as well as expensive gifts that had been dedicated to the god or goddess. Some temples were round in plan, also with a single entrance.

The Pantheon, constructed between 118 and 125 C.E., is the quintessential example of this kind of temple. Dedicated to the 12 major Roman gods, the Pantheon is entered through an impressive porch supported by enormous granite columns. The domed interior of the Pantheon alludes to the canopy of the heavens and the orb of the world. In the eastern part of the empire, especially after the second century C.E., temple design became even more innovative. The Temple of Venus at Baalbek (in modern-day Lebanon) combines traditional aspects such as the high podium and single entrance with a scalloped roofline and unique five-sided Corinthian column capitals.

THE FORUM

Every Roman city had at its heart a forum. This was a place for commercial, legal, political, and religious activity. A forum was essentially an open plaza, usually in the center of a town. The open space was usually a rectangle marked by colonnades or porticoes (covered entrances or walkways) on three sides, with a major temple occupying one of the short sides of the plaza. The forum was frequently decorated with commemorative statues of military and political leaders and other historic monuments. Arches, sometimes celebrating military triumphs, could stand as monumental portals into the forum. Arches celebrating the various victories of the emperors Augustus, Tiberius, and Septimius Severus stood in the main forum in Rome. Porticoes provided shade for visitors to the forum, who met friends and business associates there for meetings. Administrative and political buildings like the Senate house and record building were also located in the main forum of a city.

Basilicas were multipurpose buildings common in the Roman forum. A basilica was usually a long and narrow rectangular structure with a wide central aisle and narrow side aisles separated by rows of columns. Magistrates and

Engraving of the Roman Colosseum by Antoine Lafréry (© The Trustees of the British Museum)

judges could preside over trials or other business on a raised platform at one end of the interior, called a tribunal. Court cases would be heard in basilicas, though less-important trials could be carried out in the open space of the forum itself. In some cases, as in the Basilica Julia in Rome's main forum, small shops occupied the front section of the ground floor.

In the main forum of a Roman city, a major temple stood at the short end of the oblong open space of the plaza. This placement focused visitors' attention on the temple. The temple was usually dedicated to three of the major gods in Roman religion: Jupiter, Juno, and Minerva. Other temples could also be present in a forum, especially if they were dedicated to the protective deity of the city or to a deified emperor.

THE ARCHITECTURE OF ENTERTAINMENT

Some of the greatest innovations of the Roman architects were the buildings designed as entertainment venues: baths, theaters, and amphitheaters. Although Greek builders had constructed their own baths and theaters, the Romans improved upon their forms and monumentalized them. The amphitheater, used for gladiatorial combat and hunts, is a Roman invention.

The ritual of visiting a bath in the Roman world was significant. It was not merely a place to clean oneself; it also allowed visitors to exercise in the *palestra* (an open space for ball games, stretching, and running), have a massage, meet with friends or colleagues, read a book, stroll in a landscaped garden, or hear a concert. Some luxurious private homes had bath suites, but most Romans visited a public bath. Many cities had more than one bath; Pompeii had at least four at the time of its destruction. One of the largest bath complexes ever built was the Baths of Caracalla in Rome, constructed in the early third century C.E. The site measures 390 by 740 feet, just slightly smaller than Giants Stadium in New Jersey.

Most baths had three main rooms, named for the temperature of the environment: a *frigidarium* for a cold-water dip, a *tepidarium* for a swim in warm water, and a *caldarium* for a hot bath. A *laconium*, like modern saunas, offered a steamy place to sit and work up a sweat. Bath buildings were usually arranged symmetrically with the hot, warm, and cool rooms in a row. The *caldarium* would be situated closest to the furnace that was used to heat the entire structure. The floors and walls of many baths were heated by a hypocaust. In this system, the floors were raised on small brick piers and

hot air was directed into the open space. Public and private baths alike were usually sumptuously decorated with multi-colored marble revetments, elaborate mosaics, and statuary. A Roman bath should not be confused with a latrine; these public restrooms were situated in many parts of a city and were not always associated with a bath building.

While both Greek and Roman theaters were used for theatrical performances, they were very different in design. Greek theaters were typically cut into a hillside to accommodate the sloped seating area; Roman ones were freestanding, thanks to the use of concrete vaulting. The earliest Roman theaters were only temporary, erected for religious festivals. These short-lived structures, however, could be quite elaborate, like the one erected by Marcus Aemilius Scaurus in 58 B.C.E. Although it was dismantled after a month of use, it could hold 80,000 spectators and was made of at least two kinds of marble. Roman theaters resembled Greek theaters with their tiered seating, but they had a semicircular orchestra (the place where the actors stood) instead of a circular one. The stage building behind the orchestra and facing the audience in a Roman theater was usually elaborately decorated with columns and statues in niches. The theaters at Orange in France and Mérida in Spain are very well preserved and represent the standard type of Roman theater.

DOMESTIC ARCHITECTURE

Ancient Roman homes were almost as varied as modern dwellings. Some members of the lower classes lived in a single room or a dimly lit apartment in an *insula*, an apartment building. The wealthiest Romans enjoyed vast estates with many different types of structures as well as fountains, gardens, and bath suites. Much of the city-dwelling population lived in a *domus*-style (single family) house, of which Pompeii gives us many examples. In middle- and upper-class houses decoration played a significant role, and frescoes, statuettes in marble and bronze, and mosaics frequently created a sumptuous atmosphere.

The *domus* was very popular in Roman Italy but less so in the provinces. Vitruvius describes the origins of the *domus* as well as its typical plan and types of rooms. The *domus* probably grew out of the designs of Etruscan homes, but Roman architects experimented with new and borrowed forms, elaborating on the earlier forms. *Domus* structures were like modern townhouses in that groups of these homes could occupy an entire city block, and they shared walls. There was a strong focus on the interior of the house, as few windows could be opened up to the exterior. The circulation of light and air was a major concern for the designers of the *domus*, and the houses incorporated a number of innovative features that allowed for the illumination and ventilation of interior spaces. Since artificial lighting in the ancient world was largely created by the use of oil lamps with open flames, many architects attempted to bring as much natural light into the house as possible, for fires were frequent and could be devastating in densely populated cities. Elaborate wall paint-

ings enlivened the interiors of these buildings with images from classical mythology, landscapes, cityscapes, or imitations of marble revetments. Floor mosaics, either patterned or with figural scenes, also adorned Roman homes. The *domus* frequently had more than one story, as evidence from Pompeii and Herculaneum demonstrates.

A typical *domus* was entered through a narrow doorway followed by a hall called a *fauces* (Latin for “throat” or “jaws”). Once in the *fauces*, a visitor was often presented with an axial view through the house. Many homes in Pompeii and Herculaneum preserve this vista from the front door through rooms called an atrium and a *tablinum* and on toward a garden in the rear of the house. The atrium was an important room, used for the display of portraits of family members and the reception of guests. A rectangular opening in the roof of the atrium—a *compluvium*—admitted light into the house and directed rainwater to a shallow pool (*impluvium*) below. The rainwater could be stored in an underground tank and used for cooking and cleaning. Although allowing rain into the home seems strange, it was essential in a time when indoor plumbing was rare or nonexistent. (Eventually many Roman cities came to have quite sophisticated water systems that allowed for running water in private homes.)

Four to six small bedrooms called *cubicula* opened into the atrium from the sides. *Alae* (Latin for “wings”) were open rooms off the atrium that had a number of purposes, frequently serving as storage or work spaces. At the far end of the atrium was the *tablinum* that could be likened to a “home office,” where the head of the household met with colleagues and clients. Beyond the *tablinum* was the more private area of the home, which frequently included a porticoed landscaped garden with statuary and fountains as well as a *triclinium*, or dining room. The *triclinium* takes its name from the Greek words meaning “three couches,” referring to the ancient use of couches, instead of chairs, for dining. The rooms beyond the *tablinum* functioned as reception and entertainment areas for guests. A Roman *domus* usually had a very small kitchen (sometimes with an adjacent latrine) with wood-fired stoves and braziers (a type of grill). Vitruvius describes a symmetrical and axial *domus*, but a great number of variations on this plan exist, demonstrating a variety of personal needs and tastes of the homeowners. The use of a peristyle—a garden surrounded by columns—as well as beautiful decoration inspired by more ancient works of art are two examples of the Greek influence on Roman domestic architecture, alluding to the highly decorated public spaces of Greek cities.

Although many Romans must have enjoyed the relative luxury of living in a beautifully decorated and spacious *domus*, the vast majority of urban residents lived in an *insula*. These multistoried structures were prevalent in large and densely populated cities like Rome and Ostia. *Insulae* were usually about four stories high, opened on to a multifunctional courtyard, and comprised individual units that were rented by the residents. The *Insula of Diana* at Ostia (built around 150 C.E.) is an interesting example of this building type; the

ground-floor apartments were well appointed and large, while the units on the upper floors were smaller, some having only a single room. The most desirable apartments were on street level rather than up several flights of stairs. Most *insulae* were dark and uncomfortable, judging from the ancient written descriptions of them. Authors report the cooking odors of other tenants, rats' and pigeons' nests, leaky roofs, and noisy neighbors. The only latrine in the building was on the ground floor, near the entrance to the *insula*. Fires were common in these apartment buildings, especially because most residents did their cooking on braziers in the hallways of the building. Concrete construction and strict building codes in some cities alleviated some of these dangers.

At the other end of the spectrum of domestic architecture from the *insula* was the villa. While some villas were simply large, but modest farmhouses, many were the luxury estates of the very wealthy. Most Roman elites would have more than one home, and villas in the countryside and at the seaside were very popular. The structure of an extra-urban or suburban villa varied greatly throughout the empire but was generally spacious and well decorated. Some villas included smaller versions of the amenities found in cities, like baths, theaters, and libraries. The villa of the emperor Hadrian at Tivoli outside Rome was, in fact, like a small city enriched by pools, gardens, covered walking paths, and at least one temple. Although it was commissioned by Hadrian in the first quarter of the second century C.E., it apparently served as a villa for later emperors who enjoyed all its luxuries and tranquility outside the busy city of Rome.

Other emperors constructed impressive and grandiose villas within the city, which were actually urban palaces. Domitian, who ruled from 81 to 96 C.E., commissioned the architect Rabirius to build a three-part complex on the Palatine Hill in Rome. Like many villas, the palace was multi-functional and included spaces for entertainment, official business, and residential use. The public wing of the palace even included a basilica where Domitian could preside from an elevated tribunal under a vaulted niche.

LATER INFLUENCE

The remains of Roman architecture have been enormously influential in Western culture. Many of the government buildings and memorials in Washington, D.C., for example, exhibit distinctly Roman forms and decoration. This long afterlife of Roman style and structure is well deserved, for the ancient architects created new types of structures, improved and expanded upon the use of various materials, and combined the influences of other cultures into a useful and attractive architectural vocabulary.

THE AMERICAS

BY JULIA MARTA CLAPP

The geographical regions of North, Central, and South America are distinguished by profoundly diverse climates. Ancient

Andeans lived in arid areas and tropical ones, at sea level and in mountainous areas. The region known as Mesoamerica included wetlands and dry land, civilizations located at high altitudes and those positioned near bodies of water. Mound builders in North America lived in the flat, temperate climate of what is now the eastern United States. Ancient American architecture is both specific to its environmental conditions and universal among varying peoples and eras.

For ancient Americans, religious ritual was at the center of cultural life, and this was reflected in their architecture. Many of the structures that remain are public buildings, plazas, and temples where ceremonies and rituals were performed. The construction, decoration, and even cardinal orientation of these buildings were symbolically related to religion and cosmology. The importance of symbolism cannot be overstated in ancient American culture.

THE OLMEC

The region known as Mesoamerica included the southern half of present-day Mexico and extended approximately to present-day Costa Rica. Generally recognized as the oldest civilization in Mesoamerica, the Olmec lived in Mexico along the southern coast of the Gulf of Mexico. Far less is known about the Olmec than about later groups. Some estimates locate the birth of the Olmec civilization possibly as early as 1500 B.C.E., but there remains some variation in the group's dating. Its decline is generally located at 400 B.C.E., spanning the Early and Middle Preclassic eras.

The earliest Olmec cities were San Lorenzo (1500–1200 B.C.E.) and La Venta (1200–400 B.C.E.). At Olmec archaeological sites, evidence remains of housing and royal compounds as well as ceremonial and civic structures. While La Venta and San Lorenzo are best known for their spectacular colossal heads made of basalt, there is also evidence of great architectural structures. San Lorenzo has remains of both grand and modest housing structures, which indicate that Olmec society—not unlike much of Mesoamerica—was profoundly hierarchical. Houses were constructed by assembling pole-and-thatch systems to create walls and roofs, which is similar to modern-day techniques used in the area. The Olmec also constructed buildings with compacted earth.

Archaeologists have discovered what is now known as the Royal Compound, an elite residential area for Olmec rulers. The compound's Red Palace included a workshop where stone sculpture was produced. The Red Palace features basalt roof supports, gravel floors, and mud walls. For unknown reasons, the workshop ceased production in about 1200 B.C.E., but the compound contains the remains of much sculpture. Archaeological research uncovered a collection of basalt stones that, based on their shape, are believed to have once formed an aqueduct to the Royal Compound. It is possible that the aqueduct was used to bring fresh water to the city's inhabitants. The construction of the aqueduct as well as monolithic sculpture suggests that the Olmec were quite advanced in the fields of mathematics and engineering. Because

pre-Columbian Mesoamericans did not use horses as beasts of burden, basalt stone was moved solely by human effort from the neighboring Tuxtla Mountains. Basalt, therefore, would have been used only for elite buildings or other monuments of particular sociopolitical importance.

Throughout pre-Columbian Mesoamerica, civilizations also engaged in what is commonly referred to as an ancient ballgame, which was played on a large, outdoor rectangular court, with high walls along either side. The ball was made of rubber, which was abundant along the Gulf Coast. An ancient example of what is believed to have been a ball court remains at San Lorenzo.

The Olmec city of La Venta rose in prominence with the decline of San Lorenzo and had a relatively large population until its own decline. The city's layout seems to have been divided into two halves, partitioned by the Central Plaza. As ritual practice was central to Mesoamerican public life, it is likely that the Central Plaza was the site of such practice and was therefore the heart of Olmec life at La Venta. The city's most impressive monument is the Great Pyramid (also known as Complex C), a stepped pyramid located near the Central Plaza. Rising about 105 feet above the ground, the Great Pyramid is larger and reflects more impressive engineering than other monuments of its era. Archaeologists have not determined its purpose, though scholars have put forth at least two possibilities. First, the building may be a funeral monument, storing remains or offerings (similar to the pyramids of the ancient Egyptians). Second, the pyramid might have served as a site for ritualistic ceremony. This theory is supported by the discovery of two several-ton, monolithic thrones on the south side of the building. Archaeologists also found other stone monuments near these thrones, which at some point were intentionally destroyed and buried in a ritualistic act.

Another significant discovery at La Venta was Tomb A, which was made of basalt stone carved into numerous six-foot-tall columns. These were then arranged tightly like dominoes. Marking the entrance to the tomb were five more columns that leaned diagonally against the horizontal stones. Packed mud and flagstones covered the earthen floor inside the tomb. Beneath the flagstones were burial offerings.

Other architectural complexes at La Venta contain similar mounds and plazas whose functions remain unknown, as well as a ball court, ruler residences, ritual areas, and stone monuments. The Olmec remain largely mysterious to current-day scholars; many of their buildings, sculptures, and monuments were damaged or destroyed during the civilization's downfall, and all have been vulnerable to several millennia of erosion in the Gulf Coast's tropical climate.

TEOTIHUACÁN

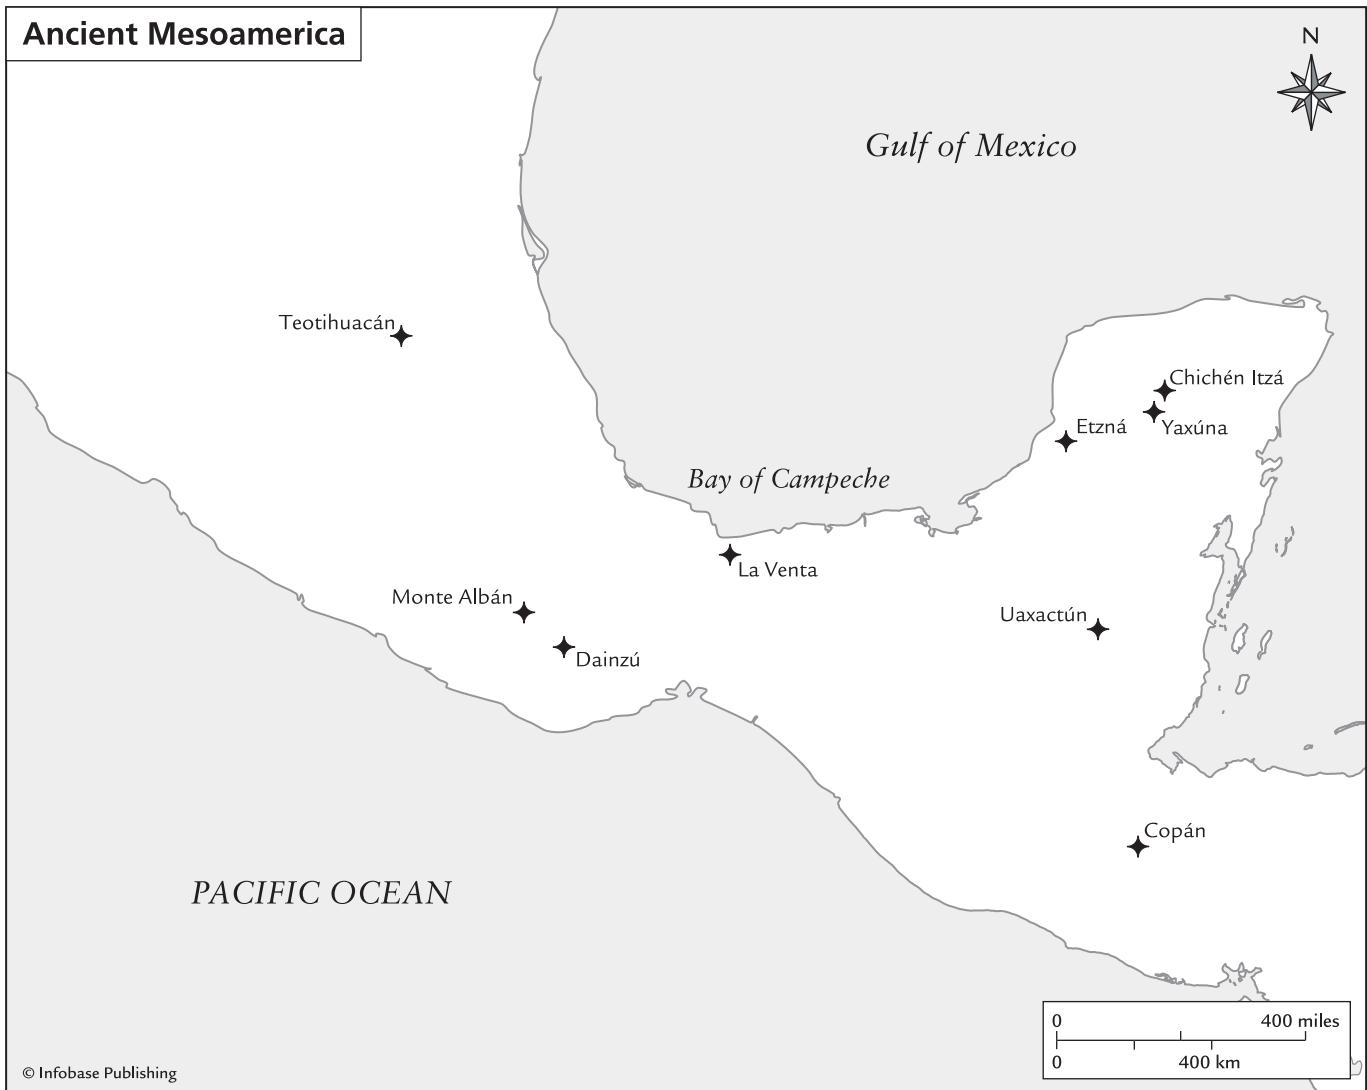

Teotihuacán was the largest, most powerful city in pre-Columbian Mesoamerica. It was located in the Teotihuacán Valley, about 25 miles from modern-day Mexico City, and covered eight square miles. Its population was perhaps as

much as 200,000 people during its peak, placing it among the top 10 largest cities in the world during its time. Teotihuacán was occupied to a degree during the Early Preclassic Period (1800–1200 B.C.E.), but the bulk of its building activity occurred centuries later. Teotihuacán's greatest structures were completed before 300 C.E. (the Classic Period), contemporary with the early Maya. Surrounding its central structures were living compounds of varying sizes.

Teotihuacán was designed on a grid system, the centerpiece of which was the Avenue of the Dead, a boulevard extending several miles across the city. Much city planning, especially that of the Avenue of the Dead, probably took place between 150 and 200 C.E. The Pyramid of the Moon stands at one end of the Avenue of the Dead, against the backdrop of the inactive Cerro Gordo volcano. Its position in front of the volcano is strategic, as its massive presence (700 feet long and 200 feet tall) echoes that of the Cerro Gordo, suggesting a spiritual relationship between man-made structures and the land. Many Mesoamerican pyramids were designed to imitate the natural form of mountains. The Pyramid of the Moon, which was rebuilt several times during the era of Teotihuacán, also has at its base evidence of another pyramid as well as an open courtyard.

Teotihuacán's oldest structure, the Pyramid of the Sun (constructed between about 50 and 125 C.E.), is located along the eastern side of the Avenue of the Dead. One of the largest structures in pre-Columbian Mesoamerica at over 200 feet tall, the Pyramid of the Sun has five levels and an enormous staircase. Builders constructed the pyramid in several phases, the second of which was around 225 C.E. The pyramid was built over a cave that had been formed by a lava tube; the cave is 330 feet in length (with portions enlarged by human effort) and located 20 feet beneath the pyramid. The cave's floor was covered with basalt stones and its walls with mud. Inside the caves archaeologists have discovered U-shaped troughs similar to the aqueducts at San Lorenzo and which likely served a similar purpose. Caves are extremely important in pre-Columbian Mesoamerican origin myth, so the Pyramid of the Sun's location is particularly significant and would have been directly linked to religious practice in the city. It was arguably the religious and sociopolitical heart of the city—the most important building in Teotihuacán.

At the other end of the Avenue of the Dead, 2 miles south of the Pyramid of the Moon, is the Ciudadela complex, constructed in about 150–300 C.E. The Ciudadela's plaza is roughly 144,000 square feet, and it houses the relatively small Temple of the Feathered Serpent. This temple is distinguished primarily by its *talud-tablero* construction, a style of architecture that is characterized by a system of sloping and vertical surfaces. Archaeologists have speculated that the *talud-tablero* method of construction may have been developed several centuries earlier in nearby Tlaxcala, where *talud-tablero* buildings have been dated to 300–100 B.C.E. While Teotihuacán's architectural influence has been widely noted

Major architectural sites in ancient Mesoamerica include La Venta, Monte Albán, and Teotihuacán.

in other cities, particularly those of the Maya, it is important to remember that the city was also influenced by others.

The temple is dedicated to Quetzalcoatl, the feathered serpent deity who remained vital to Mesoamerican spiritual life through the time of the Aztecs. The Temple of the Feathered Serpent features more decoration than the Pyramids of the Sun and Moon. Its facade is ornamented by continuous scaly reptile carving that wraps around all six levels and by large protruding heads of various beasts. The temple commemorates warfare, and evidence of human sacrifice—practiced widely in Mesoamerica—has been found at the foot of the temple.

Other architectural remains have been found at Teotihuacán, and they have enabled archaeologists to create a relatively complete portrait of the layout of the city. Teotihuacán boasts residential complexes and large open plazas. The city also has preserved murals, mostly containing religious or moral content, that were painted on the horizontal facades.

The feathered serpent encircling the Pyramid of the Feathered Serpent was painted as well.

THE MAYA

The Mayan civilization of Mesoamerica is believed to have begun around 500 B.C.E., though it is best known for its Classic Period art and architecture of 250 to 650 C.E. In the Preclassic Period the Maya were also active builders, as settled community life requires buildings for domestic, ceremonial and civic activity. Among the buildings that characterize Mayan architecture are pyramid temples, housing complexes and plazas, as well as the ball court, which the early Maya built with sloped sides. Overall, these structures adapted to the variable landscape and were organized in a less systematic way than other Mesoamerican cities, which were based upon the grid system. For example, as Teotihuacán's rational planning was similar to that of contem-

porary New York City, Mayan urban planning was more akin to the winding cities of old Europe. Furthermore, the Maya created no standardized or universal design among their disparate cities; architectural style arose from local preferences. However, because they built with sensitivity to their environment, cities with similar ecological conditions did tend to resemble one another. Mayan architecture did not distinguish greatly between buildings' functions, and buildings probably served more than one purpose.

Also noteworthy in Mesoamerican architecture was the Maya's use of corbeled vaulting, a system in which the stones of two opposing walls are laid horizontally with increasing proximity until they meet in an inverted V-shaped arch. It is interesting to note that the corbeled vault was also in use by the ancient Mycenaeans in Greece. Stone was not the only building material; the Maya also constructed flat roofs with wooden beams and stucco. It is important to remember that any ancient Mesoamerican building was constructed solely through human labor, so stone blocks of all sizes were quarried, gathered, and placed atop pyramids without the help of animals or modern machines. Many early Mayan buildings were constructed by the use of projecting supports that were inserted into fitted openings. Onto this framework the Maya applied stucco to decorative effect, often in the form of large gods' heads.

One of the most notable Early Preclassic Mayan edifices is known as Structure EVII, at Uaxactún. Structure EVII is a six-level pyramid whose facades correspond to cardinal directions. It was the largest of three pyramids that formed the "E-Group." Each side has several staircases: One is central and reaches the top level, and it is flanked by narrower, shorter staircases and enormous carved masks. Structure EVII was probably used for ceremonial or ritualistic purposes, and its position in relation to the sun also indicates that it functioned as a sort of sundial.

Staircases are a hallmark of Mayan architectural design, and later temples boasted extremely tall staircases that required no small degree of athleticism to mount. In addition to the more characteristic staircases, the archaeologist Charles Suhler discovered a Late Preclassic Mayan platform with a curious staircase in the city of Yaxúna, which is about 12 miles from the famous Mayan site Chichén Itzá. The means to ascend Structure 6E-120 were buried within the building: a series of internal corridors and chambers that ultimately yielded a trapdoor leading to the apex of the structure. This style, which endured throughout the Classic Period, is significant. It has led archaeologists to conclude that for the Maya, the process of ascending a structure was at least as important as arrival at the top. In other words, the Maya placed ritualistic significance on the act of ascension.

The triumvirate arrangement of the E-Group pyramids was common in Early Classic Mayan architecture, and it is seen again at Uaxactún in a different grouping. The A-Group was built early in Uaxactún's history, and it was a relatively simple arrangement of three. Over the course of 500 years,

this basic assembly was greatly expanded upon, ultimately resulting in an extravagant complex in the Late Classic Period.

OAXACA

The Valley of Oaxaca in Mesoamerica has a rich architectural history that dates back to the 14th century B.C.E. and culminates with the great civilization of Monte Albán. The most commonly excavated buildings have been housing structures, which in the period of 1150–850 B.C.E. were constructed with wattle and daub, in which a wooden lattice structure is covered with packed mud, clay, and other materials. This method was also used during the Neolithic (7000–2000 B.C.E.) in Western Asia, Central Europe, and North America. Around 900 B.C.E. builders in this era made simple pyramids in the forms of platforms made of (and filled with) earth. These constructions had several layers and a staircase.

Home to the Zapotec, Monte Albán began its development in the Middle Preclassic around 500 B.C.E. and reached its apogee during the Classic Period, finally coming to an end concurrent with the Maya (ca. 900 C.E.). The most significant early structure from the earliest settlement at Monte Albán is a stone platform that housed what is now known as the Temple of the Danzantes (dancers), so named for its decorative carvings of loose-limbed figures. About 140 large blocks of stone were carved with the *danzantes* and arranged as part of the temple. Another set was incorporated as part of another structure at Monte Albán, which is called Building or Mound J. Art historians have recently reinterpreted the *danzantes* as prisoners of war, leading to the conclusion that the Temple of the Danzantes was a war memorial.

Building J was also built during the Preclassic Period, probably sometime between 150 B.C.E. and 150 C.E. Two sides of this stone-faced structure meet to form a westward-pointing triangular shape that is similar to an arrowhead. Scholars now believe that owing to its orientation Mound J held astronomical significance. The building also incorporates inscriptions and date symbols carved in stone in the Zapotec language, which provides insight into this early culture. Also during this period Monte Albán developed a system of standardization of buildings, in which various building functions yielded particular design.

Around the time that the hilltop city of Monte Albán was coming into being (ca. 500–150 B.C.E.), neighboring Oaxacan cities, such as Monte Negro, exhibited architectural practices that were seen in early Monte Albán as well. The buildings at Monte Negro were multichambered and reflected the hierarchy of society in their grandness and complexity. They boasted column supports, wattle-and-daub and adobe construction, courtyards, and drains. Other cultures also used adobe during this time, including the ancient Sumerians and Babylonians.

SOUTH AMERICA

The west coast of South America is home to what are known as Andean cultures, including pre-Inca civilizations such

as the Chavín (900–200 B.C.E.), Paracas (600–175 C.E.), and Moche (100–600 C.E.) cultures. The ecological environment on the west coast of South America is varied and intense, with extremely dry areas as well as dense, tropical zones. Traces of human activity have been located as early as 10,000 B.C.E. in this part of South America. The Preceramic Era (3000–1800 B.C.E.) saw the first evidence of architectural endeavors. As did Mesoamericans, Andean people during this period created temples and plazas, which were often reworked over time. An example of such expansion is found in the city of Kotosh (settled ca. 2450 B.C.E.), which is northeast of modern-day Lima. Architecture at Kotosh is characterized by mound buildings, which were topped by small stone temples, such as the Temple of the Crossed Hands, which includes adobe reliefs of two crossed arms.

Community effort in building was important in Pre ceramic Andean culture, in contrast to that of the ancient Egyptians, who are believed to have used forced labor to build their monuments. In Andean culture, community identity was central to cultural tradition, so building labor was not compulsory. This makes the endeavors of this early period especially astonishing, considering their organization and accomplishment. This ethos of community remained part of Andean culture throughout pre-Columbian times.

The architecture of this period was characterized by circular or rectangular open-air plazas, which reiterate the importance of Andean community life. The site of Salinas de Chao features rectangular platforms, terraces, and plazas (some of which were underground), generally made of stone, bound by mortar, and covered with clay. Two plazas now called Unit A and Unit B had stairs leading from the complex to a subterranean plaza, as well as incised and painted clay friezes on its walls.

The largest Preceramic site, called El Paraíso, dates to ca. 2000 B.C.E. Its complexes are built with 100,000 tons of stone, which is a particularly astonishing feat of construction. El Paraíso has two buildings that are situated parallel to each other at opposite ends of the plaza. There is also a large complex called Unit 1, which has been excavated and explored. The complex has 16 rooms and a red-painted chamber of unknown purpose.

In the first millennium B.C.E. the Chavín culture created great platforms that had relief carving. Cerro Sechín, a site on a granite hill at Sechín Alto, boasts a platform of 12 stories that is dated between 1700 and 500 B.C.E. and was expanded until about 200 B.C.E. The platform was completed in a series of several phases that gradually increased in size and complexity. It included a wall of stone and clay, granite slabs, columns, and a system of aqueducts to conduct water. Granite slabs that surround the structure are carved with figures of mutilated warriors that have been linked thematically (though not with historical evidence) to the *danzantes* of Monte Albán. It is possible that Cerro Sechín's symbolic significance was similar to that of other war monuments of the ancient Americas.

The site Chavín de Huántar is one of the greatest of the Chavín Period. The site's location is strategic and advantageous, as it sits near two rivers and two mountain passes, near the coast and near the jungle. The Old Temple is built in the form of the U-shape, which was characteristic of Chavín architecture. It contained rooms and passageways (some hidden), air ducts, and a sunken platform that would have accommodated several hundred people. The temple's Sunken Circular Court has a wall of stone slabs with finely carved jaguar and human figures. The jaguar, which sometimes assumed human characteristics, is an important and pervasive motif in early art of South America and Mesoamerica. Also impressive are the more than 40 monolithic heads that protrude from the upper walls of the temple. The temple is built around a lancelike sculpture called the Lanzón, which is one of the site's earliest-dated objects. The carved figures and the Lanzón were symbolic and related thematically to the rituals that took place at the temple.

The Ica Valley has provided evidence of architectural developments from the Paracas culture. At Animas Bajas archaeologists have found rectangular mound structures that contained many rooms, ramps, and earthen foundations covered with adobe bricks. As with many buildings and sites in the ancient Americas, there is evidence of remodeling and expansion. Other sites in the area include housing terrace units made of adobe or stone brick.

The later Paracas site of Animas Altas shows a more sophisticated architectural program, also including walled fortification. Major monuments found at the site are 13 large mounds constructed of two levels with rooms, storage units, patios and corridors. These are built over an earth foundation on which adobe bricks are stacked and bonded with adobe mortar; occasionally, grassy materials fill the spaces between the bricks. Some of the walls at Animas Altas have been decorated with low-relief carving of mythological creatures, incorporating both serpentine and catlike features and references to birds and water. All of these characteristics would have had religious or cosmological significance to the inhabitants of this area.

NORTH AMERICA

Little is known about different varieties of ancient architecture in North America. In the region now called the eastern United States, most of the structures archaeologists have identified were burial mounds. This tradition lasted for more than two millennia in North America. In the era 5500–3000 B.C.E. in the lower Mississippi area, the earliest mound structures were in present-day Louisiana. The Watson Brake Mound Group (3900–3300 B.C.E.) comprises 11 earthworks connected by a terrace and plaza. They are constructed of earth and have a conical shape.

The largest and most elaborate earthen mounds of the second millennium B.C.E. are found at Poverty Point (1730–1350 B.C.E.), which overlooks the Mississippi River floodplain in northeastern Louisiana. This structure was more

complex than the hill-like mound structures built elsewhere. Schematically, its design resembles an amphitheater: It is a semicircular structure formed of six concentric, 100-foot-wide earth platforms divided by five 35-foot-wide radial passages between. Archaeologists believe that housing structures were built on the platforms. Another type of mound was built slightly northeast of Louisiana at Sapelo Island in Darien, Georgia. The Sapelo Island Shell Rings are large, enclosed circular mounds built of oyster and other oceanic shells. This is one of several similar structures and dates to about 2170 B.C.E.

The Adena culture (1000–100 B.C.E.) also built conical burial earthen mounds. They were composed of packed earth upon foundational buildings, and they sometimes included wooden tombs. This period was characterized by an increased importance placed on funeral ceremony and also trade. The emphasis on burial is especially seen in the Hopewell culture (200 B.C.E.–400 C.E.) of modern-day Ohio. This culture built circular or elliptical burial earthen mounds similar to those created by the Mississippian cultures nearly a millennium later. In fact, resemblance between the two cultures led the Mississippian mounds to be misidentified as Hopewellian until relatively recently.

The western Anasazi during the Basketmaker II Period (560 B.C.E.–700 C.E.) built rock-shelter sites in the last few centuries B.C.E. Archaeologists have found small settlements with hearths and storage spaces as well as burial and storage chambers lined with stone slabs.

► art

INTRODUCTION

Ancient human beings around the world painted on rocks. The purposes of these ancient rock paintings are not known. Archaeologists often suggest that they were religious works, because religion has been one of the most powerful motivators of artists. Perhaps the depictions of animals, humans, hunts, and war were intended to make hopes into reality. It was common in ancient cultures to believe that art was more than mere representation of something concrete, that an artistic depiction of something made it actual fact. That is, the act of creating art was simultaneously the creating of reality. For instance, the depiction of a bird actually created a real bird in the

world. Thus, the depictions of hunts could be attempts to make successful hunts reality.

This supernatural interpretation of ancient art—whether paintings or statues—makes sense of some but not all depictions. It does not account for the portrayal of a gored man on a European rock wall, of people dancing on Saharan rock sides, or of beings that are half animal and half human found in Egypt, Africa, and the Near East. Some African rock art was used during initiation rites to tell young people about their responsibilities as adults. In Inner Mongolia the rock paintings may have done no more than list the kinds of wild game found in an area. In Australia aborigines know what their ancient paintings mean: They are stories of creation and the arrival of humans in Australia, and the aborigines can translate the paintings for outsiders.

In addition to painting stone, ancient artists sculpted it. Many of the earliest artworks that archaeologists have found are small stone carvings of humanlike figures. Stone sculpture has usually been carved either fully in the round or in relief. In reliefs, carved figures project from a flat background. Egyptians and Kushites, from south of Egypt, were masters of relief carving, illustrating military victories or interactions between gods and humans on stone walls. These carvings featured stylized figures that appear flat to modern eyes but which were seen by ancient viewers to represent several perspectives of a figure. Reliefs were popular in the Near East and the Roman world for depicting military victories; the Romans developed the triumphal arch, which celebrated a great military leader with reliefs showing his victories.

The Egyptians may have been the first to create life-sized metal statues, dating to about 3500 B.C.E. Copper, a component of bronze, tends to hold bubbles, but it often can be found in nuggets; in Europe and northwestern North America it was sometimes pounded into shape, beginning in about 4000 B.C.E. in North America and perhaps later in Europe. Wherever people learned how to make it, bronze became the preferred metal for art, because it holds its shape better than other metals, even iron.

Another early medium for artistic expression was ceramics. It is not known how early people began making ceramics, but it dates back to at least the period of the last great ice age. Decorating ceramic vessels seems a natural activity for people, because human beings tend to like to have beauty in their lives. Thus, early ceramics often took on attractive shapes and were often painted. Advances in the technology of firing clay led to the development of glazes, which required high temperatures to melt. Glazes added luster to ceramics. Ancient pottery was not always intended to have practical uses such as storing grain or for carrying water. For instance, almost everywhere, people made ceramic figures, usually small. The figures sometimes served religious purposes such as acting as spiritual guardians for graves or as substitutes for human sacrifices. In many cases ceramic figures were toys, often in the shapes of animals and carts.

Wood was certainly used for sculpture in the ancient world, but wood decays, leaving mostly objects of more

durable substances such as stone and ceramics; a few ancient pieces survive, typically in dry climates. Written records tell of marvelous wooden sculptures in ancient India, and wood has long been favored for sculpture in Africa; both regions, however, have climates and insects that rapidly destroy wooden art. As with pottery figures, wooden carvings often were used for supernatural purposes, such as representing gods, but they also took the form of well-carved furniture, and wood was a favored medium for making dolls.

Glassmaking seems to have been intended originally for the making of jewelry. Glass beads, in particular, were very highly valued throughout the ancient world, with certain colors of glass sometimes being more highly valued than gold. Especially prized glass beads could travel through trade for thousands of miles, allowing archaeologists to use the ones they find to trace commerce among ancient peoples. Eventually, glass became a medium for household objects, and glassmakers became skilled at creating everyday objects such as vases and lamps into art objects such as dishes that looked like grapes or candlesticks that looked like vines.

A technique used to decorate objects was painting. Ancient peoples painted almost anything, probably because they loved color. Where a modern artist might leave a marble sculpture or bronze sculpture its natural color, ancient artists would paint the marble or bronze. The desire to create a painting for its own sake probably occurred very early among ancient artists, but aside from rocks, their paintings were usually on perishable materials such as wood, bark, bamboo, and silk. This means that a vast part of humanity's artistic history has been lost because the ancient paintings decayed or were destroyed. Sometimes the paints themselves contained acids that could eat through whatever was under the paint. From time to time, the paint lost flexibility as it dried and flaked away. For many ancient cultures art historians find only traces of paints that serve as clues as to the colors artists used. Occasionally, researchers get lucky, because in dry areas such as Egypt paint can survive in dark places, or ancient artists found a way to paint with durable colors, as the ancient Chinese did with lacquer.

Whatever form it took, ancient art was an expression of what ancient people valued and can tell modern people something about what the ancient people were like. In some cases, art is all that is left of a culture that passed from history thousands of years ago. The complexity of much ancient art speaks of people who were as complicated as modern people, and their work is sometimes unsurpassed by later artists.

AFRICA

BY KIRK H. BEETZ

ROCK ENGRAVING AND PAINTING

The earliest art to be found in Africa is on rocks. Dating the earliest rock art is difficult, but the oldest examples probably date to between 27,500 and 25,000 B.C.E. These pieces are

found in eastern and southern Africa and were the work of the San, sometimes called the Bushmen, who still populate parts of southern Africa. Their ancient paintings are found in caves and areas sheltered by tall rocks. The ancient San had a rich assortment of mineral pigments: white, black, red ochre, blue, yellow, and green.

Their paintings seem to have been mostly for ritual purposes, especially for coming-of-age rituals for youngsters in early puberty. The youngsters would be shown illustrations of their history, religious beliefs, and duties, and they would be told what behavior was expected of them as men or as women. The paintings often feature depictions of the eland, a large antelope, which was held sacred by the San. Outstanding examples of ancient San art are found in caves in Namibia, where the oldest paintings are found, and in Zimbabwe and South Africa.

In Namibia paintings probably accumulated over thousands of years, with styles varying from full-bodied depictions of people to impossibly thin, knobby characterizations. Both men and women and boys and girls are represented. They carry spears and bows and are usually unclad but sometimes wear belts and possibly loincloths. The modern African passion for body ornaments seems to date back to these earliest paintings, because portrayals of people wearing body paint, bangles on the arms, and bracelets are common. The figures sometimes wear masks. In paintings found in Kwa-Zulu-Natal, South Africa, the elands are huge, dwarfing the human figures. The humans vary in form from stick figures to broad-chested men and wide-hipped women. More recent rock paintings, perhaps from the early years of the Christian era, show a profusion of plants as well as humans and animals. Often the paintings are high off the ground—too high for a San adult to reach—but archaeologists do not know what the San used to help them reach so high.

Rock etchings and paintings of abstract designs, perhaps dating from 5590 to 2280 B.C.E., are found in Malawi and Zambia, but they do not appear to be San paintings and at present archaeologists have no idea who created them. There are ancient rock paintings of people and wildlife in Burkina Faso, Cameroon, Mali, Nigeria, and elsewhere in Africa south of the Sahara, but the cultures that painted them have yet to be identified. The best-known rock art in Africa probably is found in the Sahara, dating from 8000 to 3000 B.C.E. The art is found throughout the Sahara, from the west coast to the Nile River. It seems as though no large rock was left untouched by the ancient artists, and more than 40,000 etchings and paintings have been found. The art can be divided into periods based on style, subject matter, and carbon dating: Hunter Period (pre-6122 B.C.E.), Roundhead Period (6122–5095 B.C.E.), Herdsmen Period (5095–2780 B.C.E.), Horse Period (2780–600 B.C.E.), Camel Period (600 B.C.E. and later). Some datings put the end of the Herdsmen Period and the start of the Horse Period at 1500 B.C.E.

Many people are captivated by the Saharan rock etchings and paintings because they depict a Saharan environ-

ment that is very different from today's ever-growing desert. The painters lived in a Sahara that had many rivers and streams and much rain and was therefore lush with life. Animals flourished. The paintings show both dark-skinned and light-skinned people, often mixing together. Mineral pigments, charcoal, and burned bone were used to create such colors as white, black, red, yellow, purple, and green. The paintings show rituals, community activities, hunting, wars, and dancing. People usually are portrayed realistically, although during the Roundhead Period figures with circular or oval heads were common; they may have been wearing a kind of headdress that held hair in a net, or they may have been wearing masks. By about 6500 B.C.E. the wet era of the Saharan regions had peaked and thereafter declined. Lush wetlands became grasslands. By 3000 B.C.E. the Saharan peoples were being forced out of their lands by desertification, and the Egyptians fought fierce wars against peoples from the west called Libyans, who were seeking to occupy the farmlands of Egypt.

It is unclear how much the rock art of the Sahara influenced African art south of the Sahara. The spiral image common in African art appeared in the Sahara in about 6000 B.C.E. and may have spread from there. The spiral usually consists of a dark line twisting out from a central point. It also shows up in jewelry as wound wires. Sometimes, especially when carved or represented in ceramics, its outward end is given the head of a snake. In some African cultures the spiral signifies eternal life. When worn as a pendant, it can represent the wish for a long life for the wearer. It also may represent the eternal existence of the soul when included in burial objects.

Many of the problems in tracing influences of the early Saharan artists stem from the climate of Africa and its cultural history. Outside of the Sahara and some areas in the south, Africa is wet. Most African art has been rendered in wood, but in tropical Africa wooden objects rot in fewer than 50 years; some African cultures have made it a regular part of their lives to replace wooden objects every few decades. Moreover, few ancient Africans had written languages, and for the few that did have writing, the writing has not yet been interpreted. In addition, many African cultures have migrated often during the past 5,000 years, and only recently have anthropologists started reconstructing the paths of those migrations.

Given Africans' ancient passion for jewelry, it would be reasonable to assume that gold, which does not corrupt like most other metals, would preserve some of the history of their art. But Africans have a long tradition of melting old gold jewelry to make new gold jewelry, and many of the gold artifacts left in graves have been looted. Thus historians do not have a consistent record of art objects to trace the development of cultural art traditions; there is little written record describing the art that no longer exists; and when ancient African art objects are found, the people living near the objects are not necessarily the culture that made them and have little

Petroglyph of animals and people at Tassili, Algeria, in North Africa (© Board of Regents of the University of Wisconsin System. Photographer: Jeanne Tabachnick)

idea of who did. This means that the history of the art of ancient Africa is very fragmented and incomplete.

NUBIA

Nubia is a term often used to lump together several different cultures that occupied a region just south of ancient Egypt. Second to Egypt, this region is where the most African art has been found. The earliest sculpture dates from about 4000 B.C.E. and comes from just south of ancient Egypt. It consists of clay figures, including a small, fat female figure, which may be a fertility figure. A large clay head of a hippopotamus that appears to have been broken off a bigger figure suggests that the early Nubians made large sculptures as well as small ones. When Egypt expanded its influence southward, this ancient Nubian culture moved southward, probably to get out of the way. By 2600 B.C.E. it seems to have been in decline, because of Egypt's military pressure. After about 2600 B.C.E. there is a gap to about 1900 B.C.E. in the archaeological record for Nubia; at one time this was thought to represent a different culture from the earlier one, leading to the early culture's being called A group, the middle or missing culture B group, and a culture starting in 1900 B.C.E. C group. At present these three groups are thought to be illusions, and archaeologists believe that from 4000 B.C.E. to about 900 B.C.E. there was one continuous culture, with the supposedly missing group being one whose ancient relics archaeologists have not yet found but may find someday.

Between 2150 and 1900 B.C.E. Nubian culture just south of Egypt may have mixed with a culture from farther south, forming the kingdom of Kerma, named after its capital city,

which was beside the Nile River. Numerous ceramic figures have been found from the Kerma culture of 1900–1550 B.C.E. Figures tend to be small, in the 3- to 5-inch range. They depict humanlike forms with animal heads and what may be fertility goddesses with broad hips and thick thighs. The figures are carved with patterns of lines and dashes that may represent body paint. Most figures have lines around their necks, and some have dots across their chests that suggest jewelry. Breechcloths, a strip of cloth that hangs between the legs from a waistband, seem to be the common garb. There are also depictions in ceramics of animals that may have symbolized religious ideas.

By 1650 B.C.E. Kerma had extended its dominion nearly to the first cataract (rocky outcrop) on the Nile River, north of where the Aswān Dam is today. Between 1504 and 1492 B.C.E. the pharaoh Thutmose I invaded Kerma, sacked the capital city, and continued hundreds of miles south beyond Kerma's lands, seizing much of the rest of Nubia. Only in the far south of Nubia did the Nubian culture survive. The Egyptians built huge monuments, such as the temple at Abu Simbel, using enslaved Nubians, to remind Nubians who were their masters. Only in 1070 B.C.E. did Egypt withdraw from Nubia.

KUSH

In about 900 B.C.E. a kingdom the Egyptians called Kush was founded in Nubia. Its capital was the city of Napata, which was beside the Nile River in what had been the south of the Kerma kingdom but was near the northern limits of the new kingdom of Kush, which extended far to the south, encompassing most of the White Nile and Blue Nile rivers. In 712 B.C.E. Kush conquered Egypt, establishing the short-

lived Twenty-Fifth Dynasty of Egypt. During this period Kushite artists blended Egyptian art styles into their own. When large buildings were constructed, sculptors created large reliefs (carvings with figures projecting out from a flat background) depicting gods the way the Egyptians did, with human bodies and animal heads, wearing Egyptian-style black wigs but Kushite clothing. Some reliefs portray kings wielding swords and others show prisoners taken in war. The Kushite carvings of people are notably chunkier than Egyptian carvings, with heavier legs and broader shoulders, resulting in a style influenced by Egypt but uniquely belonging to Kush. In the 700s and 600s B.C.E. Kushite bronze statues were exceptionally sophisticated, portraying people realistically. Small sculptures still have color on them, showing that they were painted realistically.

In 663 B.C.E. Kush was forced out of Egypt by an invasion into Egypt from Assyria. In 593 B.C.E. Egypt invaded Kush, sacking Napata. The kings of Kush moved their capital south to the city of Meroë, and there they reigned from about 590 B.C.E. to 350 C.E.; Nubian art flourished. Meroë is located on the Nile River south of where the Atbara River flows into the Nile and lies on an ancient north-to-south trade route. It is famous for its more than 60 steep pyramids marking the tombs of Meroite kings. Many of them were 50 to 100 feet in height when new, though ones built in the last 200 years of the kingdom were about 13 feet in height.

Although the royal tombs were looted by grave robbers, the robbers occasionally missed spectacular golden jewelry. Some bracelets feature inlaid glass in abstract designs or in depictions of a four-winged goddess. Egyptian influence can be seen in the clothing of some of the figures and in beads shaped like scarab beetles. Rings are elaborate, sometimes wide enough to cover two or three upper knuckles. Small figures of animals may have represented gods meant to protect the dead, and snakes were probably symbols of the Meroite kings and queens.

Meroite sculptors had contact with Greek and Roman sculptors as well as Egyptian ones, and they incorporated Greek and Roman styles into their own, creating freestanding sculptures in sandstone. A bust of the deceased from a Meroite tomb from 100 to 200 C.E., in the Sudan National Museum in Khartoum, shows the mixture of influences and its unique result, with hair tied down in rows, a Greek-like pose, and an Egyptian-like nose but with slitlike eyes that are African in style, as well as an overall composition of features identifying the figure as a Meroite and no one else. Another example is the Venus of Meroë from the 100s to 200s C.E. She is missing most of her legs but still is almost a yard in length. She shows the influence of Roman sculpture in her body proportions and gives the appearance of soft plumpness. She was painted a reddish brown.

AXUM

To the southeast of Kush, in the highlands of Ethiopia, a nation arose out of the mixing of Sabeans from southwest

Arabia and local Africans in about 500 B.C.E., and they spoke and wrote in the Sabean language. The city of Axum was built on trade, shipping African goods off to the Near East and the rest of Asia and importing goods from the Near East and southern Asia. It was a major trading center by the dawn of the Christian era; by 350 C.E. it was capital of a kingdom that included Yemen and Meroë. When the nation converted to Christianity at about that time, Christian images influenced its art.

Stone sculptures from as early as 1500 B.C.E. have been found in the area of the city of Axum. One of a lion, in the National Museum of Ethiopia in Addis Ababa, is covered with Sabean inscriptions, indicating that Axum had a long cultural history before its emergence as an empire in East Africa. By the 400s B.C.E. Axum was producing sculptures in stone in its own national style: Human figures were stiff, with stylized faces rather than portraits of individual people, and altars were marked by the symbols of the gods they served.

The most impressive of Axum's sculpture began to be carved in the 300s C.E. These were stelae, or large upright stones carved with images, the tallest of which was 108 feet high; the tallest still standing is 22 feet high. More than 200 stelae have been found. They were carved to look like tall buildings, with doors at their bases and upper stories with windows and columns. From a distance they appear to be actual buildings. They were built to mark tombs. An older tomb built to resemble a house stands near some of the stelae, and it is possible they evolved out of earlier, smaller imitation houses. The stelae show some influence from Arabian and Indian sculpture. Other works from the 300s to 500s C.E. are Christian symbols such as silver crosses.

WEST AFRICA

Westward across Africa from Nubia and Axum, in Nigeria at a tin mine at the village of Nok, stone tools and pieces of ceramic sculptures were found in 1928: a human head, a monkey's head, and a foot. Apparently, the tools and sculptures had been washed into a gully by rain, and the sculptures had been broken apart in the process. The heads showed signs of having been broken off from larger sculptures. In 1943 more ceramic heads were found, mostly by accident. In the late 1950s these sculptures were identified as being from one culture located near the Niger River in a 60,000-square-mile area. This culture was dubbed Nok, after the village where its artifacts were first found.

Exactly when the Nok culture flourished is uncertain, with its beginning being placed either in the 700s B.C.E. or the 500s B.C.E. It seems to have ended in the 200s C.E. The origins of Nok culture are likewise uncertain. Some historians believe the Nok were influenced by people from the Sahara, either nomads or possibly Romans. Others suggest a movement westward of the arts and skills of Kush, especially during the period when Meroë was the capital of Kush. It is possible that the Nok people developed their art on their own.

Nok sculptures are so far the earliest sculptures in the round found in sub-Saharan Africa, meaning that they are fully three-dimensional and are modeled on all sides. A head that was being used on a scarecrow in the village of Jemaa in 1943 now resides in the National Museum in Lagos, Nigeria. It dates from the 400s B.C.E., and it could be either a man or a woman. Its hair is pulled back in tight rows, even over its ears. Its eyebrows appear to be woven into tight lines. The lips are full, and the nose is broad and flattened. It is broken off at the neck. Enough sculpted body parts have been found to indicate that the head was attached to a complete, life-size body. Its pupils, nostrils, and mouth have holes that probably were made to allow moisture to escape during firing (baking at high heat).

There is much variety in Nok sculpture. There are bearded men with tall headgear and bare-breasted women with high foreheads and heavy, ponderous bands of necklaces. Some figures are crude and barely recognizable as humans, while others are well proportioned and detailed. The Nok made many small figures that are less than two feet in length. These figures include depictions of humans sitting or kneeling as well as animals. Sculptures of monkeys appear to have had religious or magical importance. Archaeologists speculate that the figures were once parts of tombs or rested on wooden altars that decayed; they believe that water eventually washed away many of the ancient sites, so that most Nok art is not found where it originally was made. Some archaeologists believe that the Nok culture did not disappear but instead moved from Nigeria to the southeast, becoming the Yoruba culture, known from the late Middle Ages. Other archaeologists disagree with this view, believing the Yoruba culture to be separate from the Nok.

Much of the history of African art is no more than frustrating hints of what may have existed. For instance, the kingdom of Wagadu may have existed in West Africa from the Atlantic Ocean eastward to rivers that flowed into the Niger River, possibly in the 200s to 100s B.C.E. There are a few accounts of Wagadu kings dressed in fabulously colorful robes and of people wearing beautiful jewelry, yet no remains of the Wagadu have been found. The Wagadu kingdom was succeeded by the kingdom of Ghana, which was described by Arabs in the Middle Ages but which arose around 1 C.E. The Ghanians sculpted ceramic snakes, which featured in their creation stories.

South of the kingdom of Ghana in the region of the Volta River lived the Akan-speaking culture, which survives in modern times. The ancient Akans were probably animists, people who believe that the universe is full of spirits and that plants, animals, and even inanimate objects can have spirits. Their culture arose during the first millennium B.C.E. It is possible that they made ceramic busts of people and that by 500 C.E. they were making gold jewelry.

Farther south, on the African coast at the Niger River delta, were the Igbo-Ukwu people, for whom a small number of relics have been found. In about 500 B.C.E. the Igbo-Ukwu

people learned to smelt copper. They eventually mastered the making of bronze, perhaps learning this skill from Berber traders from the Sahara. Almost nothing is known about the Igbo-Ukwu, except that they made metal sculptures in a style uniquely their own and that by about 800 C.E. they were making exquisitely detailed pots and small busts. A pendant of a human head, in the National Museum in Lagos, has scarification on its scowling face. Scarification is the deliberate scarring of skin to create decorative patterns. Especially mysterious is the carefully detailed and assembled bronze sculpture of a leopard skull, also housed in the National Museum in Lagos.

CENTRAL AND SOUTHERN AFRICA

South of Lake Chad lived the Kanem-Borno culture. Agriculture began in the region in about 1,000 B.C.E., which probably marks the beginning the Kanem-Borno culture. The Kanem-Borno people made ceramic vessels about four feet in height for storing grain and for burying people as well as pottery for everyday use. They made numerous ceramic sculptures of humans and animals. The human sculptures may have been used in ancestor worship. The animals include sheep, cattle, and antelopes. Dating is uncertain for these sculptures, though one of a sheep may be from the 500s C.E. It is not known when the Kanem-Borno people learned to cast metal, but early examples of jewelry of brass and iron show they had mastered the lost-wax technique. (In this technique clay is molded around a wax sculpture, the clay is heated until the wax melts, molten metal is poured into the empty mold, the metal cools, and the mold is broken to reveal the metal sculpture.) They manufactured beads of quartz and glass. For much of central and southern Africa, ancient art is either lost, probably because it was made of wood or has yet to be discovered.

JEWELRY

It seems that Africans universally have loved wearing jewelry. In Africa every part of the body can have jewelry, and even in Africa's earliest art people are portrayed wearing jewelry. Egyptians were famous throughout ancient Asia for their beads, and Africans south of the Sahara imported beads from Egypt. The oldest African-made glass beads probably came from South Africa, but the date is uncertain. By about 300 B.C.E. Africans wore a wide variety of beads: glass ones from Egypt or ones they made themselves, clear and carnelian quartz ones, ones made from seashells, and ones made of polished ceramics. By 300 C.E. Africans were importing beads from Europe, the Near East, and India. The beads were often balls, but they could be rectangular, diamond-shaped, or shaped like animals—just about any shape.

Beads were woven into men's and women's clothing and often into their hair. They sometimes symbolized good health or prosperity but mostly were valued for their beauty. Beads often were set into jewelry, and glass beads in Nubia were set into bracelets so they glittered from any angle. The metals gold, silver, bronze, brass, copper, tin, and iron were used by

different cultural groups to create jewelry. The type of metal usually depended on its availability. Gold was typically the most-prized metal; in West Africa, however, silver was preferred because it symbolized purity—gold was thought to be impure. For anyone studying the history of jewelry, there will always be the frustration caused by the African custom of melting down old jewelry, especially gold jewelry, to use the metal to make new jewelry. This tradition means that sculptures showing people wearing jewelry and jewelry placed in graves are often the only sources of information about what ancient Africans wore.

Jewelry often identified a person's place in society. The size and weight of an anklet sometimes expressed a woman's wealth. In the Congo ivory or bone jewelry with human heads with three points sticking out would indicate that the wearer was a king. Jewelry had practical value. For example, hairpins could be made of metal or ivory; they would hold sometimes elaborate hairdos in place, and their length could speak of a wearer's social status.

Perhaps as ancient as the Nok culture are leg ornaments in the shape of snakes. Worn lengthwise and usually made in bronze, the ornaments are bars with coils and snake heads, and modern cultures wear them to ward off real snakes. Bronze bracelets shaped like snakes have been excavated near the Cross River in Nigeria. Anklets, armlets, and bracelets in the shape of coiled rope have been found throughout central Africa. Some items weigh several pounds and probably were worn only to show the wearer's status.

EGYPT

BY MICHAEL J. O'NEAL

The ancient Egyptians had no word for *art*. Artists were mindful of the aesthetic properties of their creations, but they had no abstract word that was understood as art, and no one thought of their creations as art in the modern sense of the word. When they created items, they did so almost always with either a practical or religious purpose in mind. Practical items, like bowls and other vessels, were used in the home for everyday purposes. Religious art commonly depicted gods and goddesses as well as the pharaohs, who were seen as divine. It was created to serve a spiritual purpose, most often to honor the gods, to ensure a continuous connection between the physical and spiritual worlds, or to help a deceased person on his or her way into the afterlife.

Egyptian artists worked within a limited range of subject matter. Ancient Egyptian culture valued conformity rather than individualism, so there was little room for innovation, experimentation, or personal idiosyncrasies—features usually thought of as characteristic of art. Most forms of artwork, especially larger pieces, were produced by teams rather than individuals. That said, the best, most artistically pleasing objects that survive from ancient Egypt feature carvings and paintings that seem to be present solely because they are beautiful. In other words, they are works of art.

ARTISTIC CONVENTIONS

Ancient Egyptian artists adhered strictly to a set of rules and conventions. These rules did not change dramatically over a period of three thousand years. Painting and drawing made use of simple lines and shapes and broad areas of color. Male figures were always darker than female figures (perhaps reflecting the fact that women stayed indoors more than men and thus were not burnished by the sun). The size of a figure reflected its relative importance; men were always larger than women, and the pharaoh was always larger than the other figures and equal in size to the gods. Pharaohs were always shown with their symbols of power, and other symbolism was strictly maintained: blue represented the Nile River, red symbolized power, and yellow represented the sun (and hence the sun god). Commoners were always portrayed with either two left or two right feet. Depictions of animals, too, were symbolic; for example, a falcon's head represented the sky god Horus, and a jackal's head represented Anubis, the god of funeral rites. By adhering to these rules, Egyptian artists created a sense of order and continuity. Rarely did Egyptian art attempt to create an impression of chaos, despair, or other dark elements of life.

In portraying the human form ancient Egyptian artists made use of what is called the canon of human proportions. They started with a square grid that, for standing figures, included 18 "units." Two were used for the face, 10 for the area from the neck to the knees, and six from the knees to the bottom of the feet. For seated figures a 14-square grid was used. This way of proportioning the human body remained remarkably consistent throughout Egyptian history and was used to guide the artist not only in making statues but in creating paintings and relief work as well.

THE ORIGINS OF EGYPTIAN ART

This history of ancient Egyptian art began millennia ago, long before the time of the pharaohs, the great temples, and the pyramids. In the Nile River valley archaeologists have discovered late Stone Age cliff drawings created by the valley's first inhabitants that date back to the eighth millennium B.C.E. These drawings show scenes from everyday life, including wild animals, hunting, herds of domesticated animals, and boating. Archaeologists have also discovered such items as pottery and carved stones and ivory, often placed in graves. Also discovered have been small statues of animals and people. Sometimes the figures of people had grotesquely large genitals, suggesting that these pieces were part of rituals surrounding a fertility cult.

Later, during the Predynastic Period, or the centuries immediately before Egypt was united under the rule of the pharaohs during the Dynastic Period, painted scenes on pottery became more common. Also, artists began to practice some of the artistic forms that became common in Dynastic Egypt. Many of the art objects they created were for ceremonial purposes, including knives with ivory handles, palettes (vessels

made of stone or wood and used for various purposes), and maces (ceremonial staffs). These objects, often used as votive offerings (gifts made for the gods), played an important role in religious rituals, and their possession helped define the status of a person in the social order.

Many of these kinds of items have been found in and around the temple at Hierakonpolis. In fact, this temple and its environs have been a treasure trove for archaeologists and art historians. A partial list of “firsts” and “onlys” from this temple includes such large structures as the first tomb cut into stone, from about 3100 B.C.E.; the earliest painted tomb, depicting a funeral procession; the earliest preserved royal palace, from about 2900 B.C.E.; and Egypt’s earliest temple, dating to about 3400 B.C.E. Notable statuary includes the oldest life-size statue of a human; the earliest large-scale metal statuary, including a life-size statue of the Sixth Dynasty (2323–2150 B.C.E.) king, Pepi I, and his son; and the oldest known stone statue of a named person, King Khasekhemwy of the Second Dynasty (2770–2649 B.C.E.). The first mummies, from about 3600 B.C.E., also come from this temple, as do Egypt’s earliest masks, made of pottery; the oldest-known cult image, a golden hawk head of the god Horus; and the largest flint knives made in Egypt, along with huge bowls, maces, and other items. There are a number of other interesting items, including the earliest surviving house in Egypt, from about 3600 B.C.E.; the first preserved beard; Egypt’s earliest beer brewery; and the first evidence of hair extensions and henna hair dye.

PAINTING

Most of the painting that survives from ancient Egypt is found on pottery and stonework. Paintings have been found on relief stonework, but many paintings have also been found on flat stone. Unfinished paintings have given art historians clues about how painters worked. Evidence suggests that skilled draftsmen marked out the areas to be painted by making sketches with red paint and then making corrections with black paint. In the Middle Kingdom (2140–1640 B.C.E.) painters began to use a system of grid lines to plan out the composition—in representing humans, the canon of human proportion referred to earlier. These grids would then aid the painter in maintaining proportions as the painting was sketched in. Sometimes the lines were etched in using a straight edge, but often they appear to have been done with red chalk lines made with a string that was stretched tightly and then snapped against the surface (in the same way that modern builders “snap lines” on the floor when marking out the interior walls of a house under construction).

Once the plan of the composition was in place, artists made a sketch using fine brushes, similar to the brushes used for writing. Brushes were made with reeds cut at an angle and split to produce bristles. To apply the paint, more substantial brushes were made with fibrous wood. A typical brush was made of twigs that were tied together; the ends were then pounded to break the fibers into bristles.

Pigments were made from local minerals that could be found in the deserts surrounding the Nile River valley. White paint was made with gypsum (calcium sulfate), “whiting” (calcium carbonate), or huntite, a chalky white compound of calcium and magnesium. Soot and charcoal were used to produce black, and iron oxide (rust) produced a range of yellows and browns. Various other minerals, including realgar (arsenic sulfide), orpiment (arsenic trisulfide), jarosite (potassium sulfate and iron sulfate), azurite (copper carbonate), and malachite (also copper carbonate), were mixed to produce other colors, including blues, greens, reds, and yellows. Many of these compounds are unstable in light, and the colors have faded over the centuries.

Most surviving painting can be found on the walls of tombs and temples built at the behest of royalty, though similar work was increasingly part of private tombs and houses beginning in the Eighteenth Dynasty (1550–1307 B.C.E.). The Egyptians believed that painted scenes in tombs would help ensure the continuity of life. In temples they believed paintings preserved the memory of the accomplishments of the pharaohs and, by depicting rituals, would serve as a visual record that would ensure that important rituals were later performed. While many examples of fine relief painting could be cited, art historians often point to the painting found in the tomb of Mentuhotep II (r. 2061–1991) at Dayr al-Bahri and to the carvings found in the shrine to Sesostris I (r. 1971–1926) in Karnak as particularly superior examples.

One feature of ancient Egyptian painting that strikes modern viewers is the lack of three dimensions. Most later painting, beginning in Renaissance Europe, creates the illusion of a third dimension, depth, by arranging the elements of the composition and altering their size so that some are in the viewer’s foreground and others in the background and objects themselves have a sense of depth. Egyptian painters, in contrast, remained happy with flat, two-dimensional paintings and drawings. Further, more modern painting creates the sense that the objects are viewed from a single perspective. An Egyptian painting, in contrast, employs multiple perspectives.

Modern viewers, too, are often struck by a kind of oddity in the way human figures are represented in Egyptian painting. Rather than giving the figures naturalistic poses, the paintings seem almost to be made of a collection of parts. Thus, for example, the head might be in profile, but with a full “frontal” view of an eye. The shoulders may then be rendered frontally, but the legs and buttocks may again be in full profile.

No discussion of painting would be complete without mentioning the illumination of papyrus manuscripts. Papyrus is a form of paper made from the reeds of papyrus plants. Beginning in about the Eighteenth Dynasty, artists started to include small drawings and paintings on official and religious documents. Among the best examples of this type of work are the illuminations of the Book of the Dead by a scribe named Ani in the Nineteenth Dynasty (about 1250 B.C.E.).

Banquet scene, fragment of wall painting from the tomb of Nebamun, Thebes, Egypt, Eighteenth Dynasty, around 1350 B.C.E. (© The Trustees of the British Museum)

SCULPTURE

Because sculptures are made of stone or other durable materials such as ivory, many from ancient Egypt survive intact. Most sculptures were created for one of two purposes. One was to be placed in tombs, and the other was to serve as a votive offering in temples. Overall, the purpose was not realistic representation; particularly in the case of tomb art, it was expected that no one would ever see it. Rather, the purpose was to preserve an idealized image of the individual in death when he or she stood before the gods. Accordingly, the emphasis was on idealized types rather than individual portraiture.

Egyptian sculptors worked with a variety of materials. Generally, sculptures were made with soft stone. The most easily obtained was limestone, which could be found in the cliffs on both sides of the Nile River. Other soft stones included alabaster (calcite), sandstone, graywacke (a dark gray sandstone sometimes mixed with bits of quartz or feldspar), and schist (a crystalline rock that can easily be split along parallel planes). Egyptian sculptors also worked with harder stone, including basalt, granite, granodiorite (a granular

rock with characteristics of both quartz and granite), diorite (a crystalline rock containing a number of minerals), and quartzite (a type of sandstone). Sculptors shaped softer stone using stone tools and copper chisels. Harder stone was shaped by hammering it and using abrasives made from still-harder stone.

Whichever type of stone the artist used, it was often covered in plaster and painted; in some cases it was painted without plastering. Frequently, though, the stone was left unpainted because of its color symbolism: black stone symbolized the life-giving silt left behind by the flooding of the Nile; reds, golds, and browns represented the sun; and green represented vegetation and the emergence of new life.

Sculpture included not only statuary but also relief carved into the surface of stone. Relief work was of two types. In raised relief, the background is cut away, leaving the figures standing out from the surface of the stone. (A modern coin is a good example of raised relief.) In sunk relief, the opposite is done: the background is left as it is, and the figures are carved into the stone. Typically, the outside walls of a temple or tomb used sunk relief, where sunshine and shadow had the effect of

enhancing the figures. In contrast, interior walls more commonly used raised relief.

Wood was also used for sculptures, though most of the wood had to be imported. Some common woods included tamarisk, acacia, and the wood from fig trees as well as a variety of pine from Syria. Wood was shaped with knives and adzes and polished with rubbing stones. Some pieces were made with single chunks of wood, but many were made with pieces or strips that were joined. Sometimes the wood was painted, but often it was left in its natural state, especially if the quality of the wood was high.

Metal, too, was a common medium, especially arsenic bronze (an alloy of arsenic and copper) in the Old Kingdom (2575–2134 B.C.E.) and bronze (an alloy of tin and copper) beginning in the Middle Kingdom. Gold and silver were highly valued. Although today gold is regarded as the more precious metal, in ancient Egypt silver's rarity made it the more precious metal compared with gold, which was used extensively.

During the Old Kingdom some characteristic types of statuary began to emerge. One of the most common was that of a man standing with his left leg advanced slightly forward. Another common form was a seated man. While fragments of wooden statues of the first type survive from the city of Saqqara and date to the First Dynasty (2920–2770 B.C.E.), more impressive examples include a statue of King Djoser of the Third Dynasty (2649–2575 B.C.E.) in the temple complex at Saqqara and the statue of King Menkaure II and Queen Khamerernebtu of the Fourth Dynasty (2575–2465 B.C.E.) from the pyramid complex at Giza. During the Old Kingdom the convention of “frontality” was established. This term refers to the convention of always having the figure facing to the front, even if the figure is in motion, perhaps walking. Many sculptures were housed in enclosed niches and alcoves, so it made sense to have the figure face to the front so that viewers could see the face and interact with the figure more readily.

During the Middle Kingdom sculpture became more realistic, and many statues from this period appear to be portraits rather than idealized types. Many portray royalty, including such figures as Sesostris III and Amenemhet III. Sculptors during this period began to use the sphinx—with the body of a lion and the head of a king—to create an image of the pharaoh as the protector of Egypt. The most dramatic example is the huge Sphinx on the Giza Plateau, the site of the Great Pyramid. Another good example is the statue of Amenemhet II. In addition to royal figures, some statuary appears to have been commissioned by private individuals. Many of these pieces show the figure seated, standing, or in many cases squatting and often wearing a cloak. Some of the statues are entirely cubical, with the figure portrayed with his or her knees drawn up. These types of statues are called block statues.

During the New Kingdom (1570–1070 B.C.E.) the art of sculpture rose to new heights. Art historians regard many of the statues that survive from this period as among the most accomplished works of art the ancient world produced. Again, many of the statues were created to honor a pharaoh. Particu-

larly well known are the statues of Hatshepsut and Thutmose III. Hatshepsut, an 18th Dynasty pharaoh, remains famous in part because she was a woman. In order to legitimize her rule, she dressed as a man and was even known to wear a false beard. Her statue, housed at the Metropolitan Museum of Art in New York City, is clearly that of a powerful ruler, with all the trappings of authority rather than the subordinate, domesticated woman most often portrayed in Egyptian art.

New Kingdom pharaohs commissioned a number of so-called colossal sculptures. Many of these extremely large sculptures were housed in funerary temples. Perhaps the best known is the colossus of Ramses II, located now in a special museum built to house it near the village of Mit Rahina in Egypt. Although the statue is unfinished, modern sculptors and art historians remain in awe of the work. It portrays the pharaoh lying down. Even without feet, the statue is nearly 34 feet long and carved out of a single block of limestone. Modern artists point out that even with mechanized carving, grinding, and sanding tools, creating a statue that achieves the anatomical perfection of the Ramses statue would today be a long, painstaking process. They marvel, then, at the ability of teams of Egyptian artists to achieve the results they did using far less sophisticated tools.

A pair of statues inspiring similar awe can be found in Thebes at the entrance to a mortuary temple built by Amenhotep III, an Eighteenth Dynasty pharaoh. Both of these statues of Amenhotep III are 75 feet tall and carved out of single blocks of stone. These works are called the Colossi of Memnon because the ancient Egyptians associated the statues in legend with King Memnon, the son of Eos. Because of a crack in the stone, one of the statues emitted a soft moan when it warmed in the morning; according to the legend, this sound was Memnon greeting his mother. (Later the Romans attempted to “fix” the stone, and the sound was no longer heard.)

THE AMARNA PERIOD

Generalizations about the reliance of Egyptian artists on fixed conventions and rules do not apply strictly to the Amarna Period, during and just after the reign of Akhenaten in the late Eighteenth Dynasty, in the mid-1300s B.C.E. The period is called Amarna, from El-Amarna, the name of a modern city that has been built over the site of a new capital city Akhenaten had built in dedication to the sun god. Scholars conclude that art in Egypt changed because the nation was in a state of turmoil during Akhenaten's reign. He was very much a religious and social revolutionary, and he violated many of the conventions that had dictated the behavior of the pharaohs for centuries. After his death Egypt returned to normal, and the aberrations of Amarna Period art disappeared.

Amarna Period art was different because it conveyed more of a sense of motion and vitality than conventional Egyptian art. Instead of being posed formally, figures were often portrayed in motion. Figures appeared in groups, and depictions of the pharaoh and his family were naturalistic and informal. For some reason a great deal of attention

was paid to the portrayal of hands and feet, right down to the details of the fingernails. Many of the representations of Akhenaten himself, as well as others from the period, strike the modern viewer as bizarre, with elongated heads, distended bellies, and thin limbs. Representations of his queen, Nefertiti, suggest that she wielded as much power as her husband, in part because images of her were the same size as those of Akhenaten.

OTHER ARTS

Pottery was not considered an art form in ancient Egypt. Although there are examples of pottery with human or animal figures, and a few were made in the form of animals, most of the surviving pottery was purely functional. Historians know that during the Eighteenth and Nineteenth Dynasties, floral designs appeared on high-quality pottery, but none of this pottery survives.

Egyptian artists did, however, exercise their skills on a type of pottery called faience. The term is used to refer both to the materials from which the piece is made and to the piece itself. In ancient Egypt faience consisted of silica made of sand, crushed quartz, or sometimes crushed pebbles in water. Lime was added to make the materials adhere, and ground copper provided color. After the piece was formed, it was coated with a mixture of soda, lime, and silica. Most of the pieces that survive are a rich blue-green because the coating also contains copper, though other pieces are black, brown, red, yellow, and white. The piece was then fired in a kiln to produce a glassy surface. Faience was used to produce a range of items, including scepters, bowls, beads, amulets (a charm against evil), scarabs (beetles used as charms), goblets, and small statues. It was also used to make decorative tiles, such as those found in the Step Pyramid of Djoser at Saqqara. One of the most famous pieces of faience is a blue hippopotamus nicknamed “William” in the New York Metropolitan Museum of Art.

The ancient Egyptians were accomplished jewelers. Although they did not use precious stones such as diamonds, they used a wide range of semiprecious stones, including agate, turquoise, lapis lazuli, feldspar, garnet, jasper, amethyst, and carnelian. Bracelets were found in the tomb of Djer, a First Dynasty king, and from the Fourth Dynasty came bracelets belonging to Queen Hetepheres. The most spectacular jewelry, however, dates from later dynasties, including the collection of jewelry belonging to Queen Ahhotep of the 18th Dynasty and the large collection found in the tomb of King Tutankhamen (“King Tut”) of the Eighteenth Dynasty.

Glassware was known during the Predynastic Period, but it did not become an independent form until the 18th Dynasty. Glass was used to make small vessels, such as cups and flasks, as well as for beads and amulets. Glass thread was often applied to the objects for decoration, and some had gold rims. Glass was also used as an inlay. Perhaps one of the most widely recognized pieces of ancient Egyptian art, the funerary mask of King Tutankhamen, is made of gold with colored-glass inlay.

Artwork was produced with a number of other materials as well. The ancient Egyptians were accomplished metalworkers, and many pieces made of copper and bronze survive. These include jugs and bowls, as well as metal statues. Some were made by pounding the metal, while others were made from castings. One of the most famous pieces of metalwork is the life-size statue of King Pepi I from the Sixth Dynasty, made of pounded copper plates affixed to a wooden core. Gold, more easily found in ancient Egypt than silver, was widely used for many purposes, including jewelry, vessels, furniture, and inlay, and it was frequently pounded into thin gold leaf for decorative purposes. Again, the most impressive display of gold objects comes from the tomb of King Tutankhamen.

Among less durable materials, wood was used not only for statues but also for cabinetmaking and furniture. In the tomb of King Tutankhamen, archaeologists found a wooden chest with an ivory veneer and 33,000 pieces of ebony and ivory inlay. Ivory and bone were also used to produce small statues, often of creatures such as grasshoppers and gazelles.

THE MIDDLE EAST

BY TOM STREISSGUTH

Ancient Mesopotamia comprised different ethnic groups and cultures located along the Tigris and Euphrates rivers in what is modern-day Iraq and parts of what are now northeastern Syria and eastern Turkey. In this region archaeologists have discovered remains of human habitation dating back more than 100,000 years. The ancient Mesopotamians were among the first to develop farming, build an urban civilization, and create a distinctive artistic style.

Historians classify Mesopotamian art by periods named after important excavation sites and kingdoms, with the earliest being the prehistoric sites of Hassuna, Samarra, and Halaf, all preceding 5000 B.C.E. Following these eras are the Ubaid (fifth millennium B.C.E.), Uruk and Jemdat Nasr (4000–2900 B.C.E.), Early Dynastic (2900–2340 B.C.E.), Akkadian (2340–2100 B.C.E.), Babylonian (1900–1600 B.C.E.), Assyrian (1400–612 B.C.E.), and Persian (to 637 C.E., the date of the Islamic conquest of Mesopotamia). Many of these periods overlap according to location, and many have subcategories covering more specific times and places. Excavations of Mesopotamian cities at different levels reveal a constant flux as local dynasties conquered, rose, and fell from power and as sculptors, painters, metalsmiths, and jewelry makers learned new methods and styles to apply in their work.

THE GODS AND SPIRITS OF MESOPOTAMIA

Despite many wars and political upheavals, ancient Mesopotamian art has distinctive and constant themes. The gods of Sumer (in southern Mesopotamia) and Akkad (near what is now Baghdad in Iraq), each with their particular attributes, symbols, and familiar groups of demons and spirits, are found

across the millennia in the work of Mesopotamian artisans. Each major city had its patron deity, which was depicted in ceramics and sculpture and featured in temples decorated with statues and paintings of the god. Some of the more important Mesopotamian gods were the sky god, Anu, worshipped in Sumer; the fertility goddess, Inanna, of Uruk; Nergal, the god of the underworld; and Ishtar, a goddess associated with the planet Venus, love, and war. There were also gods of the moon (Sin) and of the sun (Shamash). These deities were shown in anthropomorphic (human) form, along with important symbols of their power and attributes.

Shamash, for example, is shown near a disc representing the sun. Sin appears near a crescent symbolizing the moon, and the goddess Ishtar is depicted with an eight-pointed star. The water god, Er, is most often shown with streams flowing from his shoulders or from a jar. Adad, the god of storms, appears with a lightning bolt and stands on the back of a bull. A goddess of healing, Gula, was associated with the figure of a dog. The messenger of the gods, Ninshubur, holds a staff in his hands, and Nusku, the god of fire, holds a lamp or flame. Marduk was the principal god of Babylon. He was originally a god of the earth and of agriculture, and he appears with a spade in the shape of a triangle. Assur, the god of the powerful realm of Assyria, wears a horned headdress and a staff or spear as a symbol of his office.

Mesopotamian artists also relied on a large repertoire of minor spirits, usually taking the form of a familiar animal. Lions were a favored species and appear winged, half-human, and with their maned heads atop the form of a powerful bird with long talons. Bulls are shown with their horns and often in the form of half-man, half-bull. Other familiar animals are snakes, turtles, scorpions, sheep, goats, and horses. The evil goddess Lamashtu, daughter of Anu, had the head of a lioness, the ears of a donkey, and the feet and talons of a bird. Lamashtu commonly stands on top of a donkey, holds a pair of snakes in her hands, and nurses a pig or a dog.

PREHISTORIC ART

Clay figurines in a rounded female form date to the early Neolithic Period (10,000-3,000 B.C.E.) and are the earliest works of art from Mesopotamia. These were found in great number at Hassuna, a site that gave its name to a period of art dating to about 5800 B.C.E. Statuettes and household vases carved in clay and alabaster have been uncovered in graves near Samarra, which lent its name to the following period, of the late sixth millennium B.C.E. These figures were decorated with stone necklaces and shells for eyes. Samarran artisans also created new geometric, human, and animal forms for use on their finished pottery. Halaf works, from 5300 B.C.E. to about 4500 B.C.E., display religious symbols, such as a double ax head and the stylized head of an ox.

The first cities of Mesopotamia were built in the plains between the lower Euphrates and Tigris rivers, the region known as Sumer. Trade and a centralized government brought about the invention of cuneiform writing, in the form of angular

marks made with sharpened reeds (*cuneus* in Latin) on wet clay tablets. Sumerian palaces were decorated with elaborate friezes, horizontal wall paintings that depicted royal processions and mythological scenes.

ART OF THE SUMERIANS

During the Uruk Period, named for an important Sumerian city, sculptors began working in new materials and giving their figures a larger and more lifelike appearance. Using a flat wall or a finished ceramic piece, they carved away the smooth surface to create geometric or figurative art in a technique known as bas-relief. Artists of this time began moving away from conventional shapes and styles to give their figures individual characteristics and emotions. Nevertheless, Mesopotamian art remained two dimensional, with the human body and animals portrayed in flat profile against a patterned background, as in the wall paintings of ancient Egypt.

The famous Warak vase, found at the site of Uruk, is carved of alabaster and shows four different designs on parallel horizontal bands known as registers. The bottom band shows a row of barley and palm plants, and above is a line of rams and ewes. At the next level appears a procession of men carrying jugs and baskets, and at the top is a lord or king attended by servants and a temple priestess. The Warak vase displays the dedication of the Sumerians to Inanna, the goddess of fertility and of the fruit of the land. It also serves as a textbook example of Mesopotamian pictorial style, in which a scene or story is depicted in registers against a flat, stylized background and in which figures are given importance according to their size, position, and the detail of their clothes and adornment.

Metalsmiths of this time began mastering new techniques of casting and shaping copper, bronze, silver, and gold. The lost-wax process allowed artists to form a desired figure out of wax, surround it with clay, and then fire the clay to melt the wax. The result is a hollow, hardened clay mold into which molten metal is poured; after the metal cools and hardens, the mold is broken away to reveal the finished piece. Mesopotamian smiths brought the art of lost-wax casting to a very high level, creating jewelry, statuettes, and other objects that could also be etched and engraved in minute detail.

In the Uruk era the Sumerians raised stepped temples known as ziggurats, used to bring the kings and priests closer to the gods of the heavens. The ziggurats served as symbols of the power and wealth of the kings who raised them. The exterior walls were elaborately decorated with horizontal friezes, and the interior featured paintings of scenes from mythology and religious symbolism. The Sumerians also gave detailed attention to the burial of their monarchs. The Royal Cemetery at the city of Ur has provided archaeologists with the largest single treasure of ancient Mesopotamian art in existence. Nearly two thousand graves were unearthed at this site in the 1920s, many of them containing valuable worldly goods

meant to accompany kings and queens to the afterlife: jewelry in gold, lapis lazuli, carnelian, and other semiprecious stones; gold and silver crowns and other personal adornments; bowls of alabaster and silver; and thousands of cylinder seals. The fabulous Great Lyre found at Ur is made of bitumen and lapis lazuli, and it displays the head of a bearded bull cast from a large mass of solid gold.

The cylinder seal emerged during this time as a practical tool as well as an important artistic medium. A seal was a small, carved cylinder that could be rolled across a wet clay tablet or sheet of papyrus to show possession or to record a document or transaction. A seal was made of stone, fired clay, bone, or ivory; when rolled across a document, it left a long rectangular impression showing a simple geometric design, banqueting scene, religious symbols, or a god or gods in a variety of aspects and poses.

Artists of the Early Dynastic Period that followed Uruk worked in a familiar style in their statuary, paintings, and cylinder seals. Statuettes from a temple site at Tell Asmar were given very large eyes, which were originally inlaid with semiprecious stones; the eyes symbolized fervent devotion of ordinary worshippers to the god of the temple. Square stone plaques attached to the temple walls showed banquet scenes in bas-relief. Historical scenes of battle and victory were carved into stelae, freestanding blocks of stone that carried inscriptions, proclamations, or human figures. Sculptors also carved portraits in stone of kings, scribes, and administrators, each with individual expressions and features.

King Gilgamesh of Uruk, who reigned in Sumer around 2500 B.C.E., became the central hero of the Epic of Gilgamesh, a poem of 3,000 lines that survives as one of the world's oldest works of literature. For the next two millennia the Gilgamesh epic provided artists of the region abundant subject matter in their sculpture, paintings, and cylinder seals.

AKKAD AND BABYLON

The conquest of Mesopotamia by King Sargon in 2340 B.C.E. established the Akkadian Dynasty. Sumerian cities declined in importance as Sargon united the northern and southern regions of Mesopotamia for the first time. The art of Mesopotamia also underwent important changes. Humans and animals gained prominence by being set against plain backgrounds, rather than serving as simply another useful motif in a repeating pattern. Seal and jewelry engravers showed much greater skill in bringing out realistic features of the head, face, and body and in depicting life-like emotions. The stelae and bas-reliefs of the Akkadian Dynasty honored the achievements of their kings, who are shown engaging in battle, taking prisoners, and driving their enemies from the field. Artists began using diorite, an extremely hard gray stone that could be polished to a glossy sheen, for their monumental sculptures. Akkadian metalsmiths skillfully cast sculpture and vases in silver, copper, and gold, and they created ceremonial weapons and tools that carried symbols of the ruler and the gods.

Human-headed winged bull from the palace of King Sargon II (721–705 B.C.E.) at the Assyrian capital Dur-Sharrukin (modern-day Khorsabad, Iraq) (Courtesy of the Oriental Institute of the University of Chicago)

The Kassite Dynasty that rose in the 16th century B.C.E. is best known for a series of *kudurrus*, or boundary stones, which became an important medium for commemorative inscriptions and in which the figures of the gods were replaced by familiar emblems.

The fall of Akkad ushered in a period of weak political control but important artistic advances in Mesopotamia. Artists mastered the human form, rendering movement with great realism and decorating the body with elaborately designed and draped clothing. The reign of Hammurabi of Babylon, which lasted from 1792 to 1750 B.C.E., left as its most enduring monument a code of laws carved into a tall, diorite stele, which as both a social and artistic artifact has become the most famous single work of ancient Mesopotamian art. In the Stele of Hammurabi, the king stands before the sun god, who presents a ring and staff to the king as symbols of his sovereignty. French archaeologists unearthed the stele at Susa, in what is now Persia, where the ancient Elamites had taken it after the conquest of Babylon in the 12th century B.C.E.

ASSYRIA

As Babylon grew weaker, the realm of Assyria rose in northern Mesopotamia and spread its authority over the mountains of Asia Minor and the valleys of the Tigris and Euphrates. The kings of Assyria ordered the carving of enormous bas-reliefs to celebrate their military victories and

their rule of much of the Middle East. Made from marble and limestone, these friezes were placed along the walls of temples and palaces, in throne rooms and hallways, and in staircases and reception halls.

One of the largest groups of wall reliefs survived at monumental buildings raised by King Ashurnasirpal II (r. 884–859 B.C.E.) at the royal city of Nimrud. In these horizontal slabs the king is shown hunting, battling, and winning victories with the blessing of the gods. Foreigners are shown humbly bearing tribute, while inscriptions recount the king's name and titles and his many conquests. In all these works the sculptors achieved great detail in clothing and in the rendering of faces and limbs. Assyrian artists also celebrated the kings' achievements with freestanding obelisks (large pillars), which were decorated on all sides, and marked their conquests with carvings in natural rock located at the physical limits of the empire.

Monumental sculpture and reliefs also survived at the palace of Sargon II at Khorsabad and of Sennacherib (who reigned from 704 to 681 B.C.E.) at Nineveh, the last Assyrian capital. Archaeologists of the 19th century uncovered nearly two miles of wall reliefs within 70 different rooms at Sennacherib's enormous palace, which was burned by a conquering army and then buried by new construction that took place in the following centuries. The subjects, as in the other Assyrian sites, were processions of tribute and military campaigns, with inscriptions on the walls recounting the victories of the king.

Under the later Assyrian kings, wall paintings replaced friezes in stone in many monuments and public buildings. Colored pigments were mixed and applied to whitewashed plaster on interior spaces, while glazed and painted bricks were used on exterior surfaces. These paintings depicted hunting and battle scenes, royal parades and processions, symbols of the king and the gods, mythological beasts, and various repeated geometric and abstract designs. The Ishtar Gate, an entrance to the city of Babylon, dates to about 575 B.C.E. and was built during the reign of Nebuchadnezzar II. The gate was made of tiles fired in a deep blue glaze and decorated with bas-reliefs of bulls and dragons. A Processional Way, which began at the gate and led to the city's royal palace, showed a series of lions carved in relief.

PERSIAN DYNASTIES

The Achaemenid Dynasty of Persia conquered Mesopotamia in the sixth century B.C.E. The Achaemenids claimed to be the heirs of the mighty Assyrians and drew on the monumental style of Assyria in their palaces and temples. At the palace of Susa, built by the Achaemenid King Darius I, artists rendered human-headed lions underneath a winged disk in bas-relief on the palace walls, made from glazed, multicolored bricks. At Persepolis large friezes depicted processions of courtiers and men bearing tribute to the king. Colossal animals—bulls and griffins and other mythological beasts—were carved in stone or cast in bronze to guard the entrances to the palace.

In 331 B.C.E. the Macedonian general Alexander the Great defeated King Darius III of Persia at the Battle of Gaugamela. Alexander died in Babylon a few years later, but his victory over the Achaemenid ruler ushered in the Seleucid Dynasty, founded by his general Seleucus. The Seleucids reigned for less than a century in Mesopotamia, while the gods and myths of the Greek world were taken up by the region's sculptors and metal engravers. Very few complete works of art survived, as sculptures in bronze were later melted down and their scarce metal recovered for new works. Seals of the time showed Greek gods and Seleucid rulers as well as important symbols such as the anchor and horse head, the personal emblem of Seleucus.

The Parthians overthrew the Seleucid Dynasty in the middle of the third century B.C.E. They were followed by the Sassanian Dynasty, which was established in 224 B.C.E. and endured until the Islamic conquest of Mesopotamia in 633 C.E. The palace at the Sassanian capital city of Ctesiphon in central Mesopotamia is best known for elaborate decoration in stucco on the interior walls. Colorful floor mosaics found in Sassanian palaces portrayed women dancing, making music, and weaving garlands. The art of metalsmithing also reached a zenith during the dynasty, which left behind no paintings and very few portraits in sculpture, while life-like portraits of the rulers, imitating a style introduced by the Macedonians, were created for coins of the realm. Sassanian artists mastered the art of detailed engraving in a variety of techniques, including chasing, embossing, and cloisonné enameling, applied to silver and gold cups, bowls, ewers, plates, and dishes. They used as their subjects the royal banquets, hunting scenes, and mythical beasts that were ancient traditions in Mesopotamia. The elaborate, repeated designs and borders of Sassanian art in stone and metal had a strong influence on subsequent Islamic art. Sassanian artistic style also traveled to the Byzantine Empire, which survived the fall of Rome in Eastern Europe and Asia Minor, and to central Asia and China.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

INDIAN PAINTING

The earliest paintings in India are probably ones found on large stones and rock faces, mostly in central India, in the region of the city of Bhopal. They depict humans and animals and are all thought by archaeologists to have been painted after 5500 B.C.E. The earliest ones show people as stick figures wearing only loincloths and animals that sometimes have abstract designs on their bodies. The humans appear to be hunting the animals with spears and bows and arrows. Later rock paintings show humans riding horses and wielding swords and shields. The innards of animals are sometimes depicted, a style also found in rock paintings in faraway Borneo and Australia.

Few other paintings in India and southern Asia survive from before the 200s C.E. because surfaces such as wood and silk and other fabrics, which were used for painting, decay quickly in wet climates and are subject to destruction by fire. In India the second-earliest surviving paintings are found on walls in cave temples at Ajanta; they are fragmentary because much of the paint has peeled off over the centuries. Cave X of Ajanta houses the earliest painting that dates from the first century B.C.E. It depicts the life of the Buddha and is so richly presented that the mural suggests that painting had become a highly sophisticated art form much earlier in history. Much better preserved are paintings in Cave I from the 400s C.E. In these paintings, human beings and gods are sometimes serene, sometimes joyful, and always surrounded by activity, suggesting that life is an enterprise rich in spiritual and physical pleasures that people who set free their inner vitality can enjoy.

INDIAN SCULPTURE

The roots of Indian arts probably reach back to the Harappan civilization of the Indus River region (ca. 2600–ca. 1500 B.C.E.). Metal casting emerged early in Harappan culture, perhaps 2300 B.C.E., and it was already highly developed, suggesting that the Harappans learned how to make bronze and other metal figures from Mesopotamians. Most Harappan castings have been found in the ruined city of Mohenjo Daro. Perhaps the most spectacular artifact is the copper image of a young woman housed in India's National Museum in New Delhi. Dating from before 1750 B.C.E., she is 5½ inches tall, missing her feet, and clad only in bangles and a necklace. She features the wide nose and thick lips typical of the Harappans and may represent a dancing girl. She is in a relaxed, languid pose, as if waiting for something, and the figure presages the graceful ancient Indian style to come.

The Harappan culture began to decline between 1900 B.C.E. and 1800 B.C.E. After its fall to natural disasters and an Aryan influx around 1500 B.C.E., the primary influences on Indian art were remnant Harappan populations southeast of the Indus River and the Greeks. The Aryan tribes that invaded the Harappan lands in the Indus Valley spread through northern India. Little remains of Indian art from about 1500 B.C.E. to about 500 B.C.E., though Indian writings indicate that the period was a colorful one for the arts. Perhaps most artworks were made with perishable materials such as wood, which rapidly decayed in India's wet environment.

A new sculptural tradition began in India from the influence of a Hindu prince named Siddhartha Gautama. Born into the warrior caste (one of four social divisions in India), Siddhartha lived from about 563 to about 483 B.C.E., and he became known as the Buddha. He traveled through the northeastern kingdoms, urging people to forsake their desires, and he formed the first Buddhist order of monks. At first Buddhist sculptures focused on symbols, but in the 200s B.C.E. artists began sculpting realistic portraits of the Buddha, starting an artistic tradition that would shape much of the art and taste of Asia and the Pacific.

In 326 B.C.E. Alexander the Great conquered much of northwestern India. He brought with him Greek culture, including artists. In 321 B.C.E. a general of the Nanda Dynasty, Chandragupta Maurya, overthrew the Nanda government and defeated the Greek state that had been created by Alexander in the northwest of India. The Maurya Dynasty (321–185 B.C.E.) featured great empire builders in its first three rulers, who expanded their nation to cover most of the Indian subcontinent, but in 261 B.C.E., Chandragupta's great-grandson Asoka had a crisis of conscience after seeing the misery his conquering had caused, converted to Buddhism, and made his nation a pacifist state. Thereafter its power and territory waned, yet the Mauryans initiated a great age of stone sculpture.

Greek-style sculpture was immensely popular, especially for portraits, and Greek sculptors found ready work in the

Schist head of the fasting Buddha, from Rawalpindi District, Gandhara, Pakistan, second to third century C.E. (© The Trustees of the British Museum)

Maurya Empire. In India, Greek artists would carve standardized torsos of men and women, leaving off the heads, and would later supply heads when orders for individual portraits were made. Thus were made numerous portraits of wealthy Indians that had identical Greek bodies. Indian-style sculptures were also common, especially for public works. Such an example from about 200 B.C.E. is in the Patna Museum. It is a depiction of a *yakshi*, a female spirit that protected the wealth of the earth. At 5 feet, 4 inches tall, it has a lifelike height, but its curves are exaggerated, creating fluidity in its pose and suggesting it might step forward, alive. Its clothing and other physical features are done in fine detail, and it glistens with Mauryan gloss, a smooth, highly polished shiny surface that was unique to the Maurya Era.

The Buddha's death sparked another kind of sculpture that came into full flower during Asoka's reign. Burial hemispheres of dirt, called *stupas*, had been in use on a small scale for the interment of important people, but the Buddha's ashes were divided into eight large stupas after his death. A fervent convert to Buddhism, Asoka had seven of the stupas opened, and he divided the remains among 84,000 new stupas throughout India. The finest of these is the Great Stupa in Sanchi in central India. Originally a mound of dirt 25 feet tall and 60 feet across, the dirt was covered by bricks and surrounded by temples and gates. The stone gates date from the first century B.C.E., and they mark the end of the major building period for the shrine. Sculpting the stone as if working in wood, artists adorned the gates with a dazzling number of figures so that the pillars and crossbeams appear to be crawling with life, including graceful figures of women who exemplify inner vitality. Indians loved depictions of life, and their architects believed that no public building was complete without depictions of women.

Thus, for Indians buildings became works of art. They built towers abounding with sculptures of trees, plants, animals, and stones, making the entire structure a sculpture on a grand scale that was meant to emulate mountains. These towers represent a Buddha-like climb to enlightenment. The ascendancy of Buddhism did not last for long in India, and by the 100s C.E. Hinduism was reasserting itself. New Hindu towers were adorned with sensuous images of gods, goddesses, nature spirits, and people, usually naked and almost always graceful and lively; these towers represent the phallus, symbolizing creative power.

Buddhism inspired another spectacular form of sculpture. In Bihar, near Nepal, Asoka displayed his religious tolerance by having rooms carved into huge rocks so that a non-Buddhist sect of ascetics could meditate in them during the rainy season. The interiors of the rooms are carved to look like the interiors of wooden, thatched houses. They would inspire great Buddhist structures elsewhere in India. Good examples of their development can be found in the Western Ghats mountain range, where thousands of rock structures were carved into the mountainsides and cliffs. The first structures were Buddhist monasteries, begun in

150 B.C.E. These were followed by temple complexes, carved by iron tools into rock faces, with one temple having a hall 124 feet long. The main structural elements were made to look like wood, as if the monastery or temple were wooden. The walls were carved with scenes of the Buddha's life and teachings. Dancers, preachers, kings, and bodhisattvas were depicted on pillars and walls as well. Bodhisattvas were people who could have ascended to oneness with God but who chose to put off their salvation to help other human beings reach nirvana—a state of blessedness or union with the godhead. As Hinduism returned to dominance in India, caves were carved to become Hindu temples where even lower castes would worship. They feature lush statues of nature deities, often monumental in stature. At Elephanta Island a three-faced statue of the god Shiva from the 500s C.E. is 17 feet tall and situated so that light from the entrances to the cave falls directly on the faces.

The Indian style of sculpture, especially when connected to the Buddhist or Hindu faiths, spread throughout Indochina and eventually to the main Indonesian islands, reaching Java in about the 700s C.E. The Indian painting style also spread, though surviving examples in Indochina tend to date from the 1200s C.E. In the 100s and 200s C.E. Buddhist evangelists brought Indian sculptural and painting traditions to China, which already had a well-established painting tradition of its own.

CHINESE PAINTING

The earliest known paintings in China are from Inner Mongolia. Consisting of mineral pigments drawn on stone, they are on large rocks and sheer rock faces, all in the open; none so far have been found in caves. The paintings depict animals and stick-figure people, and they include elephants—creatures that became extinct in the area before 8000 B.C.E. Such rock paintings continued to be created among illiterate peoples in this region until about 200 B.C.E. They may have been created to give the painters magical powers while they were hunting, or they may have had more prosaic uses, such as telling travelers the kinds of game that could be found nearby.

Lacquer at first came from the resin of the lacquer tree (*Rhus verniciflua*), yielding a glossy black paint that was highly durable. During the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.), Chinese painters began experimenting with pigments in lacquer to give it color, and vivid yellows, reds, and browns still survive. Archaeological finds suggest that lacquer may not have come into widespread use until the Warring States Period (453–221 B.C.E.). From the 400s B.C.E. on, lacquer was used for decorative art on chests, furniture pieces, walls, doors, and other household surfaces. This must have made homes brightly colorful during the Warring States Period and the ensuing Qin Dynasty (221–207 B.C.E.) and Han Dynasty (202 B.C.E.–220 C.E.). Surviving paintings depict animals and mystical beasts such as dragons, usually in highly stylized forms more interesting for their symmetrical patterns than their verisimilitude.

Paintings of other sorts were common, especially on silk. By the end of the Zhou Dynasty (ca. 1045–256 B.C.E.) there were tens of thousands of silk paintings, but only one from the Zhou survives, dating to the 400s B.C.E. Housed in the Beijing Historical Museum and known as *Lady with the Phoenix*, it was discovered in Changsha and is about eight by twelve inches. In it, an elegantly robed woman in profile looks at a dragon and a phoenix.

The invention of paper in the 100s C.E. significantly affected Chinese art. Paper expanded a painter's artistic possibilities beyond silk by being cheaper and firmer. Calligraphy was regarded as a fine art and often became part of paintings, uniting into a form of storytelling that was created on paper scrolls. On a scroll a single figure or landscape could be depicted as if in motion, with the unrolling of the scroll showing someone standing and turning around or showing the passage of time in a single setting. Combined with the calligraphic art, by the 400s C.E. scrolls had become short moving pictures, telling tales about the Buddha, tales from mythology, or even tales drawn from contemporary life.

CHINESE CALLIGRAPHY

Chinese writing inscribed on bones and turtle shells that were used to foretell the future is known from as early as the Shang Dynasty. Even in the 1500s B.C.E. Chinese writing was taking the form it has today, creating a writing tradition that has been unbroken for 3,500 years. Chinese is written in ideograms, characters that represent an idea or thing. These began as small pictures representing objects such as trees or houses; then such characters were combined to suggest new ideas. During the Han Dynasty and thereafter, scholars were held in high esteem because they knew 40,000 to 50,000 individual characters.

Early in the Han Dynasty calligraphy came to be regarded as an art form. Calligraphers used brushes lightly dipped in very black ink that they mixed themselves to paint characters on silk, bamboo, and wood. Their work was taken so seriously that their brushes and bars of black pigment became works of art themselves. Pigment came in beautifully embossed sticks, and the grinding of such beauty to make ink impressed on the calligrapher the importance of his putting the destruction of the stick to good use. Calligraphers developed styles of their own and learned how to express emotions with the way they stroked their brushes—firm or careless, fine or crude, long or short. A form called *cursiv* developed, in which the calligrapher's strokes blended from one ideogram (written symbol) down to the next in a constant flow. The invention of paper revolutionized calligraphy by providing an inexpensive surface that held ink well. It allowed nearly any educated person to practice calligraphy, and some calligraphers became famous for their styles.

The artist Wang Xizhi (321–379 C.E.) was China's greatest calligrapher. His preface "Lanting Lu" for a book of poetry, *Meeting at the Orchid Pavilion*, is considered to be the pinnacle of Chinese calligraphy. It was written in flowing

semicursive characters that melded ideas and ideograms into images that its readers loved passionately. The emperor Taizong (r. 626–649 C.E.) revered this work so much that he wanted to have it with him in the next life, and he had it buried with him. Only copies remain.

CHINESE SCULPTURE

The history of Chinese stone sculpture is sketchy. There are stone carvings associated with the ancient rock paintings, and such carvings that depict people wearing masks date from about 3500 B.C.E. During the early Shang Dynasty tombs were sometimes decorated with carved stone or ceramic tiles portraying people, such as guardians to ward off enemies and entertainers to make the next life pleasant. Many tomb sculptures survive from the Han Dynasty. These were relief carvings in stone. Relief carvings have figures projecting out from a flat background. In the Han reliefs, the figures themselves are slightly flattened. These relief sculptures show scenes from everyday life and objects such as peasants and fish. There are many scenes of people and animals during hunting.

The most spectacular tomb sculpture predates the Han Dynasty by several years and was not in stone, but in ceramic. The tomb of Qin Shi Huangdi (r. 221–210 B.C.E.) in Shaanxi province has about 7,000 life-size figures of soldiers, though as yet 80 to 90 percent of the tomb remains unexplored. Although there seems to have been a set pattern underlying the sculpting of each figure, the soldiers are individualized with details such as improperly buttoned jackets and different sorts of personal jewelry. Each face and head is unique, as if every figure were modeled after a real-life person.

Monumental public sculpture began in the 400s C.E. Buddhism had been introduced to China in about 65 C.E., and by the 400s it had become a major part of Chinese culture. Sculptures of Buddha in the 400s resembled the Indian style of sculpture, with figures having Indian features and the serene grace typical of Indian depictions of human figures; the garments shifted from Indian ones to ones typically worn by the Chinese. An example of this is the great 45-foot-tall Buddha Amitabha from about 460 C.E. found in the Yungang Caves in Shanxi province. His massive stone features are still not Chinese, but he wears clothing typical of a Chinese man of the 400s.

CHINESE DECORATIVE ARTS

Elaborate decorations on the sides of pots, kettles, and chalices indicate that the decorative arts were already well advanced when people of the Shang began working with bronze, suggesting a highly developed art of wood carving, with the wooden works now being lost. The decorations on bronzes featured abstract images such as crisscrossed patterns and bumpy surfaces, but they also had images of animals and mythical creatures that were usually rendered in a symbolic style that often make them difficult for modern

observers to interpret. Eyes could be whorls, faces could be represented twice on two sides of a pot, and wings could be depicted with sharp S-shaped swirls. These images indicate that the Shang had a well-known and complex system of symbols that would be readily recognized by those who used the bronzes. The Shang bronze sculptors often combined realistic images with abstract or symbolic images; the ram's head was especially popular for decorating kettles and storage vessels.

The Shang was a warlike culture, expanding territory through conquest, and it is therefore not surprising that along with making extraordinarily beautiful household bronzes, they made decorated weapons. The most elaborate weapons tended to be sacrificial axes. The Shang practiced human sacrifice, usually by beheading. When a military or civic leader died, his servants would be ritually executed and interred with him to serve him in the next life. The axes used were specially made for the purpose and could feature molded human faces, engraved decorations, and openings for mouths or other facial parts such as ears.

The people of the Zhou Dynasty were a technologically less advanced group from the west who overthrew the Shang Dynasty in 1045 B.C.E. At first, the Zhou seemed to have employed the same bronze makers as had the Shang. Even so, there was a notable shift in style. The Zhou bronzes of the 1000s B.C.E. were often constructions of multiple castings, with images exploding into three-dimensional space. The Smithsonian Institution in Washington, D.C., has an outstanding example of a pot from the late 1000s B.C.E. with handles arcing up and out, heads thrusting out of its sides, and a chaos of images rendered on several vertical layers of castings. By the end of the 900s B.C.E. Zhou bronzes became mostly plain and utilitarian, leading some historians to believe that advanced casting techniques had been lost, perhaps with the dying off of the last generation of Shang artisans.

During the late Zhou (ca. 600–221 B.C.E.), an era of warfare, fine detail in bronzes made a comeback, possibly signaling influence from cultures to the west that reintroduced advanced bronze-casting techniques. At first, blocky vessels seem to have been preferred, with symbolic animal faces and thick, upraised lines in decorative, often leafy, patterns. By the end of the Zhou, bronzes of extraordinary complexity and beauty were again being produced, and casters were playing with three-dimensional space with the surety of masters of their craft. An outstanding example produced during the late Zhou resides in the Hubei Provincial Museum. It is a drum stand about 21.25 inches in circumference at its base; the base is a platter with an attached cylindrical post that bears the weight of the drum. Around that post and filling the platter are writhing dragons, their bodies and limbs driving out into space in myriad angles. Graceful and full of motion, it is a high point in the art of casting bronze and represents the sort of detail and skill of the best bronzes of its age.

ARTS IN OCEANIA

In Australia the native peoples have painted on exposed rocks since ancient times; their images tell creation stories and relate their history. Stone Age peoples did not survive long enough to be able to explain their art to modern historians; too often, when such civilizations have survived, modern people have not been interested in their culture. For instance, people arrived at Easter Island in the 400s C.E. and began carving small sculptures; eventually, after hundreds of years, they began erecting mammoth statues along the edges of their island. In the 1800s C.E. most of the Easter Islanders were shipped away to Peru as slaves, resulting in the deaths of those who knew what their written language and their sculptures meant.

Australia offers a special chance to learn about Neolithic art from people who still paint in the ancient ways. Thus it is known that large blocks of stylized images actually tell stories, with creation stories being common. Many rocks feature images of hands, made by placing a hand against the surface of a rock and then blowing pigment around it. In the late 20th century similar handprints were found in remote caves and rock surfaces in Borneo, suggesting a possible continuity in artistic practice from people who migrated to Borneo and then on to other islands before eventually reaching Australia. Painted with the handprints in Borneo are elongated figures of humans and large images of animals that are so detailed that they must have taken days to paint. A few of these paintings have been dated between 10,000 B.C.E. and 8000 B.C.E. In both Australia and Borneo there are animal images that, like ones found in India, depict their insides as well as their outsides.

JAPAN, KOREA, AND SOUTHERN ASIA

What survives of ancient Japanese art is pottery. On the island of Kyushu pottery shards dating to 12,000 B.C.E. have been discovered. During the Jomon Era (13,000–300 B.C.E.) the inhabitants of the Japanese islands made elaborately shaped vessels. During the Yayoi Era (300 B.C.E.–300 C.E.) the Japanese made *haniwa*, ceramic figures varying in height from about four inches to seven inches. They were usually figures of people wearing their everyday garb, sometimes holding the tools of their trade. They were set upright in the ground, surrounding graves; sometimes hundreds of them encircled a large tomb. Archaeologists think that they represented spirits that would guard graves against evil. They are notable for the way in which posture or facial expression gives each one a unique individuality.

Koreans and peoples along the southern edges of China tended to adopt Chinese styles and art forms. Most of what is presently known of ancient Korean art comes from its ceramics. The cups, plates, and serving dishes from ancient Korea show that their makers were well schooled in Chinese techniques, especially in the use of glazes. They also made ceramic figurines as burial goods and as toys.

Much of the rest of southern Asia was divided between Chinese and Indian influences. For instance, some of the

Nanyue of the Yangtze River migrated south into North Vietnam after China conquered their country in 333 B.C.E. and brought with them Chinese tastes, but the natives were related to the peoples of Indonesia and were influenced by India. The kingdom of Funan was centered on the Mekong Delta from the 100s to 500s C.E. By the 300s C.E. it included central Cambodia. The archaeological finds of Funan include temples and statues in the style of India.

ASIA PACIFIC JEWELRY

Determining what ancient Oceanic jewelry may have been like involves more speculation than hard evidence. Stone Age peoples survived not only in Australia but also in places like New Zealand and Papua New Guinea long enough to leave for study recently made jewelry. Necklaces, bracelets, and anklets made of pig or shark teeth strung together with animal sinews or string made from palm leaves were common. In Indonesia wood, seashells, and metal would be combined to create headgear, necklaces, and bracelets that were supposed to protect warriors in battle and cure sickness. Beads of glass and quartz were popular, especially in the Philippines, where beads sometimes represented supernatural powers.

In much of ancient Asia beads were valued decorative elements. In Japan they had magical powers and were important components of rituals. Still, jewelry in general was not important to the Japanese. The opposite was true in India, where beads and other decorations were highly esteemed. A single bead of glass of a rare color could be worth as much as a precious gem in India. According to Hindu tradition, jewels had divine attributes, and even the gods worshiped gems. For instance, Indra worshiped rubies and Vishnu worshiped sapphires. India had rubies, sapphires, emeralds, and diamonds in abundance; in fact, India was the world's only source of diamonds until the gem was discovered in Brazil in the early 1700s C.E. Gems were incorporated into all kinds of Indian jewelry. Turquoise, a valued mineral, was imported from the Himalayas.

Ancient Indians loved wearing jewelry. The Harappans wore toe rings and anklets of gold and silver. Neck rings were common. These were made of solid bars of gold, silver, copper, or other metals that were bent, or they were composed of wires that were tightly wound together, ropelike. During much of the period from 500 B.C.E. to 500 C.E., only members of India's two highest castes, the priests and the warriors, were allowed to wear gold and silver, but this did not discourage members of lower castes from wearing jewelry made of other metals.

During the Six Dynasties period in China (220–589 C.E.), women took to wearing silver bracelets. Rings often had settings with gems, with various stones that held mystical properties. For instance, a jade ring was said to recognize the soul of its owner, and if lost would find its way back to him or her.

EUROPE

BY KIRK H. BEETZ

EUROPE OF THE LAST GREAT ICE AGE

The earliest dated European art forms are paintings from caves in southern France. These paintings date from 32,000 to 30,000 B.C.E., during the last great ice age. Other seemingly related paintings in caves from France and Spain date as recently as 15,000 B.C.E. The world of these ancient artists was very different from the modern one. All of Scandinavia and much of northern Europe were covered by a giant glacier that was so heavy it pressed Scandinavia down below sea level. Most of Britain was covered by a glacier, and it was connected by land to the rest of Europe.

The people who lived in this environment were scattered in small groups. They were hunter-gatherers, meaning that they lived from hunting wild animals and gathering wild edible plants. Their cave paintings depict bison, deer, rhinoceroses, mammoths, and horses—the creatures they hunted. These animals are depicted in profile (from the side). This format allowed the artist to show all parts of the animal: head, body, tail, and all four legs. Throughout the era of ice age paintings, artists took pains to be sure that all parts of animals showed. Even dead animals were shown in profile, lying on the ground as if seen from directly above. The animals are depicted not only with precision but also with a vibrant sense of life, showing a mature artistic style that indicates that people began painting far earlier than the earliest paintings yet discovered.

These cave paintings are found deep underground. To get to them sometimes requires crawling around stalagmites and stalactites (spikelike mineral deposits) or large fallen stones and through narrow passages. The artists illuminated their caves with stone lamps filled with flaming animal fat, and they brought meals with them so that they could spend hours at their work. To reach high surfaces of rock walls or ceilings, they built wooden scaffolds, cutting holes high in the rock to insert branches to hold up the scaffolding. They used stones to smooth out the rock surface for their paintings, though they often tried to include the natural bumps and cracks in the rock surface in their compositions. For certain parts of their pictures, they used flint to first carve lines into the rock. For instance, the bristling hair of bison would be cut first and then filled with colored pigment. The artists mixed pigment with animal fat for painting, or they put pigment into their mouths and blew it onto the rock.

Ice age painters' practice of working very deep inside caverns has led to much speculation by archaeologists and historians. Because a great deal of art has been inspired by religious beliefs, many archaeologists believe that creating the paintings deep in the ground represented access to a supernatural world: Even tens of thousands of years later, Greeks and Romans believed that caves led from the world of the living to the world of the dead. Many ancient peoples believed

Bird bone engraved with animal heads, Late Magdalenian, dating to about 10,500 C.E., from the cave of Courbet, Penne-Tarn, France (© The Trustees of the British Museum)

that art had a transforming power—that the act of painting made whatever was depicted actually happen. Thus, paintings that show hunting are thought to have been created to make a successful hunt become reality. In some of the caves, paintings of animals show signs of having been struck repeatedly, as if by the points of spears, suggesting a ritual in which the hunt is made real by attacking the paintings.

On the other hand, the paintings may have had other purposes, and the paintings deep in caverns may have been the only ones found because they were out of the way of erosion by nature and humans. Paintings on rocks outside caves and paintings near the entrances of caves could have been destroyed by wind, rain, and vandalism. Those that have been found are fragile; even exhaled human breath damages them, so others may have existed in profusion only to be worn away over 15,000 to 30,000 years. The paintings could have served as lists of game available in a region or as part of initiation rites for young people, like many works by the San (or Bushmen) in southern Africa.

The paintings of human beings in the caves also are puzzling to archaeologists. Among the brilliantly detailed animal figures are ones of men who are graceless stick figures. On occasion they appear to be hunting; on other occasions they may be dancing. In the Lascaux Cave in France is a painting from 15,000 to 13,000 B.C.E. of an apparently wounded or dead man, placed between a rhinoceros and a disemboweled bison. He seems to be wearing a mask of a bird. The only way to know he is male is from his prominent penis. Why are the men portrayed so badly, while the animals are portrayed so beautifully? The answer is as yet unknown.

The problem becomes more complicated when the portraits of women are considered. Many small stone carvings of women from the same era as the early paintings have been found. They have been dubbed Venuses by archaeologists, in humorous reference to the Roman goddess of love and beauty. The Venus of Willendorf from Austria, dating from 28,000 to 23,000 B.C.E., is the most famous of these figures. She is

carved from limestone and is only a little more than four inches high. Her stomach, breasts, and thighs are huge, but her arms are small, with her hands resting atop her breasts. Her head is covered by a cap or elaborately curled hair, so that her face does not show. This sculpture may be a fertility symbol, with the breasts and stomach representing a woman's ability to create new life.

There are other depictions of women, and many, like the Venus of Willendorf, are artistically superior to the depictions of men. In the Musée d'Aquitaine in Bordeaux, France, is a relief carving (with the figure projecting out from a flat background) of a woman from 23,000 to 20,000 B.C.E. She is about 18 inches tall and is depicted from the front. Like the Venus of Willendorf, her face is obscured by what may be locks of hair, and her breasts, stomach, and thighs are large. Unlike the Venus of Willendorf, she has well-proportioned arms. In her right hand she holds aloft a bison's horn. She is better detailed than the depictions of men from her era. These Venuses suggest that their sculptors may have been from a matriarchal society or perhaps that women controlled the religious practices.

In addition to creating the earliest-known paintings and rock sculptures, the ice age peoples of Europe appear to have created the earliest clay sculpture. In a cave at Ariège, France, are two clay bison, modeled in relief. They each are about two feet in length and date from about 12,000 B.C.E. Like their painted counterparts, they are in profile and in the same graceful style.

MESOLITHIC: 9000–4000 B.C.E.

By about 9000 B.C.E. Europe was warming, and the glacier over Britain had disappeared; Scandinavia, however, was still under a glacier, and Britain was still attached by land to the rest of Europe. Mammoths and rhinoceroses no longer lived in Europe, and reindeer had moved northward, followed by the ancestors of the Lapps, who eventually would populate northern Finland. Some of the major cultural groups that

would figure in the later history of European art had begun to form, each belonging to two major language groups: the West Mediterraneans in the Iberian Peninsula, where Spain and Portugal are today, and the Indo-Europeans, who began somewhere north of the Black Sea or southeast of the Baltic Sea and migrated eastward and westward, occupying all of central and northern Europe as well as much of Asia.

Both the West Mediterranean peoples and the Indo-European peoples were inheritors of the artistic legacy of ice age Europe, but the direct line of development of art is easier to see in Iberia. There are not as many paintings and other art works known from 9,000 to 4,000 B.C.E. as from earlier, perhaps because a matriarchal religious system changed or perhaps because Europeans had other preoccupations, spending their energies using new tools such as stone saws and working at new technologies such as dugout canoes. With the loss of some of their largest prey, people may have had to spend more time hunting than earlier, thus diminishing the time they had to create art. Perhaps the spreading out of the European population over new lands revealed by the retreating glaciers diminished the sort of interplay among groups that would have stimulated new ideas in art. There were only about 75,000 people in all of Europe.

Still, in Spain are rock paintings that incorporate new detail in the portrayals of men. The most famous is a rock painting in Castellón, Spain, sometimes called the Marching Warriors, though they could be dancing. They have noses, lips, and beards, and the leader wears a feathered headdress. They carry spears and bows. The painting dates from 7,000 to 4,000 B.C.E. Much has been made of the resemblance between this painting and the rock paintings of the Sahara of the same era, and it is possible that some of the Saharan painters and the West Mediterraneans were part of a single cultural group.

In about 6500 B.C.E. people in the Balkans and Greece began practicing agriculture. Some historians view this event as the beginning of an invasion of Europe by people from the Near East, who eventually conquered the areas through central Europe to northern Europe, replacing the people already there. A more likely possibility is that the idea of agriculture spread through Europe. Even though they were still living primarily by hunting and gathering, Europeans were already a mostly settled people who lived in small villages. The spread of agriculture brought with it new trade routes, and with those trade routes came an exchange in artistic ideas.

For instance, in what is now Hungary, in the 5000s to 4000s B.C.E., people made ceramic stamp pendants that could emboss symbols and images in clay, an idea that probably came from Syria. The symbols, consisting of lines and curves, may have served as charms. They also sculpted ceramic human and animal figures and what may be phallic symbols. None of these sculptures is unbroken, making it hard to tell how detailed they may have been. A sign that people were adopting a more sedentary way of life, staying in one location, comes from clay models found in Bulgaria, dating from

5,000 to 2,000 B.C.E. These depict household furniture such as chairs and couches. Their purpose is unknown, but they may represent a tradition of toy making.

LATE MESOLITHIC AND NEOLITHIC: 4000–2000 B.C.E.

By 4000 B.C.E. the Indo-Europeans occupied most of central and eastern Europe, northern Europe, southern Scandinavia, and most of Britain, which was no longer attached by land to the rest of Europe. The West Mediterraneans still occupied Iberia and some of southern France. This era saw special creativity in the manufacture of household wares. For instance, a pot from the 3000s B.C.E., found in Hungary, looks like two bowls placed lip to lip and fused, with the stem of the top lid open and a face etched into it. The bowl is decorated with zigzags, straight lines, crosshatching, and other designs, perhaps representing clothing for the body of the face or perhaps simply intended to please the eye. It may have been meant for use in religious rites, but it may simply reflect the human tendency to beautify even everyday objects.

Romania has proved a rich site in sculpture from the 3000s B.C.E. Its figurines tend to be female and spare in appearance, with sharp angles. Many female figures also were produced in Ukraine during the 3000s B.C.E. Two ceramic figures of a woman and a man were found in a grave in Cernavodă, Romania. Although they are nearly abstract, they seem very human. The woman is fat in the stomach and thighs, with small, sharply angled breasts; a long neck; a circular head with impressions for eyes; a flat nose; and a pursed mouth. The man is seated on a small stool, his knees high, with his elbows pressed into his thighs and his hands pressed into his cheeks. His head is more oval than the woman's, with the same sort of eyes, nose, and mouth. They come across as ordinary people at rest, both looking a little weary. They represent a tradition of geometrical sculpture that would survive until the era of classical art.

Between 3000 and 2500 B.C.E. the Únětice culture in what is now central Poland learned to make bronze by combining tin and copper. This development did not occur until about 2300 B.C.E. in Greece and the Balkans, 1800 B.C.E. in Britain and Iberia, and 1500 B.C.E. in southern Scandinavia. Bronze would give artists an important new medium for their sculptures.

BRONZE AGE: 2000–500 B.C.E.

By about 2000 B.C.E. the Indo-Europeans had come to dominate Europe. Within Europe they had fragmented into the Celts of central Europe, the British Isles, and Iberia; the Germanic peoples, possibly from the east, occupying southern Scandinavia; the Slavs of northeastern Europe; the Italics of southern Europe; the Illyrians of the Balkans; and the Thracians of eastern Europe. Of these groups, the Celts would develop the most distinctive style of art. The most important outside influence on Indo-European art came from Mycenae, Greece, in about 2000–1200 B.C.E. Mycenaean art has been

found in northern Europe, and northern European art has been found in Mycenae. One of the most interesting paintings of the era is a mural from the Mediterranean island of Thera in the 1500s B.C.E. that depicts what appears to be a boat from Scandinavia.

Numerous rock paintings and carvings from 2000 to 500 B.C.E. were created in Scandinavia, by Germanic peoples sometimes called Nordic by anthropologists. These paintings and carvings have been found in Norway, Sweden, and Denmark, and they number in the hundreds of thousands. The artworks appear on broad rock faces. First they were carved by using an unknown tool to punch chips out of the surface. In the earliest examples a color lighter than the rock was added into the carved lines, giving the figures greater definition. In later examples ochre—a mineral with iron oxide, colored red, brown, or yellow—was added into the lines. The subject matter is varied, showing people dancing, hunting, and even making love, but pictures of ships predominate. The interest in ships is indicative of oceangoing trade, perhaps into the Mediterranean, which would help explain the Mycenaean influence in Britain and northern Europe as well as central Europe. Among the rock carvings from the first century B.C.E. are studies of chariots, depicting various kinds of harnesses, and of spoked wheels, sometimes apart from the pictures of the chariots. In European art of the period wheels with spokes often represented the sun. Chariots often indicated the presence of an elite warrior class.

By 1500 B.C.E. Mycenaean metalwork, especially in copper and gold, had spread across western Europe. A scepter buried with a British chieftain duplicates one found in Mycenae, dated at about 1600 B.C.E. Mycenaean armor was in central Europe by the 1500s B.C.E. and may have influenced the development of helmets and body armor among the Celts. Golden cups from about 1500 B.C.E. that imitate Mycenaean styles and techniques for working gold have been discovered in Britain and in far northwestern Germany. The spread of Mycenaean influence in Europe cannot be explained fully by oceangoing traders and must have included overland trade routes. The Mycenaean set up trading posts in the Balkans and perhaps farther north to Germany, and they had trading posts in Britain. When the Mycenaean culture abruptly ended in about 1200 B.C.E., their traders may have been stranded in those trading posts, and their artists may have ventured into central Europe to find employment. They brought with them their techniques for metalwork, which may help to account for the flowering of Celtic metal sculpture that followed.

The Celts loved jewelry, and Celtic sites that have not been plundered yield a rich assortment of jewelry. Beads were well loved, and even Egyptian glass beads have been found not only in central Europe but also as far as northern Germany, probably imported into Europe through trade routes established by the Mycenaean. A necklace from Britain from 1500 to 1000 B.C.E. shows the use of shale beads and faience beads. Faience is brightly colored glazed pottery. Bones and antlers also were worked, mostly for decoration. Amber was

mined in Jutland in modern Denmark and exported throughout Europe, where it was used to make beads and strung on necklaces. Eastern Europe, especially Hungary and the Czech Republic, has yielded bracelets and pendants from 1500 to 1000 B.C.E., many with designs that echo Mycenaean ones, yet some show the intricate interlacing of curves and lines as well as the three-pointed swirls, which would set apart Celtic art.

It is in metal that Celtic art from this era fully captivates the imagination. Much of the metalwork seems to have served ritual purposes, sometimes given in sacrifice to a local god. For the Celts the world was full of gods; lakes, rivers, mountains, stones, and more had their own gods. This means that rivers such as the Thames in England have yielded finely sculpted gold and bronze. Early examples that hint at what was to follow come from the Únětice culture, from what is now eastern Germany. They produced armlets (bands worn around the arm), earrings, beads, and pins of gold from 1500 to 1000 B.C.E. Their designs were simple, sometimes just a winding of strands of gold into circles of wire to form tightly wound beads. Even so, there are hints of what would come. For example a grave in Germany has yielded an armlet from about 1500 B.C.E. that has lines along its length and a twisting design between the lines, somewhat like a simple version of the twisting and looping of lines in later Celtic armbands and torques (neck rings).

Of particular interest are the many model cart sculptures of the era. The earliest ones tend to be ceramic. For instance, in the National Museum in Belgrade, Serbia, is a three-wheeled wagon pulled by what look like ducks, dating to the 1300s B.C.E. Archaeologists find this cart interesting because of the three wheels, which indicate experimentation in the design of carts; from the point of view of art, the interest is in the ducks, which are portrayed only from the breast up, and the very plain human-shaped figure, which may represent a god. The sculptor emphasized the basic shapes of his or her subjects without providing details. The theme of waterbirds pulling a cart seems to have been an important one in the Balkans. From Romania circa 800 B.C.E., but housed in Naturhistorisches Museum in Vienna, is a bronze four-wheeled cart with a cauldron in the middle. It is surrounded by abstractions of ducklike birds, facing forward and backward in continuous lines. Housed in the same museum is a bronze four-wheeled cart from the 700s B.C.E. found in Bosnia and Herzegovina. This wagon is carrying the birds instead of being pulled by them. There are two ducks, with one as a receptacle and the other riding on its back and capping the receptacle. The birds were cast in multiple pieces and then fused together by hammering, and they are more realistic than the earlier pieces.

From Denmark, from about 1300 B.C.E., comes a bronze sculpture well known to both archaeologists and art historians: the Sun Wagon. It has six wheels with spokes. At that time these could have represented the movement of the sun. On a wire chassis (the framework attached to the wheel axles) are a horse and disk. The disk is elaborately decorated with swirls and circles. Some of the gold leaf that covered its

sides remains. The horse is recognizable as a horse, but it is a flow of curves not found in real horses. Its surface was carved with lines representing a mane and harness. The sculpture was broken, probably deliberately, before it was buried; it was customary at the time to break objects before offering them as sacrifices. An even more spectacular model wagon comes from southern Austria from 650 B.C.E. It may be the pinnacle of European art of the era. On the cart stands a tall, slim woman holding on her head a shallow bowl, perhaps where incense was burned. Less than half her size are men standing and on horseback, and among them are deer with large, tall antlers. All are depicted in a fluid style that seems to be the logical descendant of the earlier carts. The depiction of carts by European sculptors would continue into the era of the Roman conquest, with the images becoming more realistic.

IRON AGE: 500–50 B.C.E. AND THE ROMAN CONQUEST

Historians often record 500 B.C.E. as the peak of Celtic European culture. The Celts dominated almost all of Europe. Their society was dominated by warriors, who believed that killing, looting, and enslaving others were honorable pursuits. They were constantly at war either against non-Celts, such as the Slavs or the Etruscans, or among themselves. Their art from this era is often bloody, reflecting a warrior's code of kill or die. The Celts loved art and were ostentatious in their displays of jewelry. The number 3 was a magical number to them, and their jewelry often features three-pointed swirls, as well as very intricate interlaced patterns of lines.

It would be a mistake to say they were not influenced by art from other cultures, but their artists absorbed the techniques of others and then worked them into their own Celtic traditions. Thus, even when their sculptures began to shift from the abstract forms found in their model carts to the realism of classical art, they continued to incorporate their own ideas of what made for natural forms. To the Celts almost everything they saw had a living vitality, and this vitality was seen in the graceful curves of plants and animals. The apparent geometric designs on pottery, full of sweeping curves and sharp angles with nothing in particular represented, were to the Celtic artist a depiction of the complexity and vitality of the natural world. What may look like three-pronged swirls to an outsider looked like the sun coursing across the sky to the Celt. Their twining together of lines that never seem to end was an expression of the eternal movement of life.

The Celts of central Europe also made representational art, either carving in the realistic manner of the Greeks and Romans or making ceramic images for use in temples and public buildings. It was customary for Celtic warriors in central Europe to cut off the heads of their enemies and display them. In Roquepertuse in southern France one such display still exists, now decayed. It is a sanctuary with tall stone pillars which have skull-shaped niches in them, in which were placed skulls, a few of which remain. In about 200 B.C.E. real heads began to be replaced by sculptures of heads. These stone

and ceramic pieces were not portraits in the sense of detailed accuracy. The sculptors emphasized the outstanding features of their subjects such as thick lips, a bushy moustache, curly hair, or a long nose. When the Romans invaded Gaul in 58 B.C.E., under the leadership of Julius Caesar, they would see these sculptures side-by-side with real severed heads in monuments built to celebrate warriors and warfare.

IRON AGE TO THE END OF THE ROMAN EMPIRE: 50 B.C.E.–476 C.E.

Although Celtic and Germanic artists learned to create works in the classical manner of the Greeks and Romans, they never lost their love of ornamentation and of the intricate, flowing lines of Celtic art. Long after they had absorbed the Roman way of life—speaking Latin and thinking of themselves as Roman people—traits of their ancestral culture lingered. For instance, they continued to wear thick-barred armlets. These became the rings that early medieval German poets described—the rings of power that would inspire the idea of magical rings in J. R. R. Tolkien's classics *The Hobbit* and *The Lord of the Rings* in the 20th century. To the Celts and Germans the giving and receiving of armlets symbolized the bond between lord and follower. In Scandinavia the elaborate swirls and intertwining of lines endured into the era of the Vikings.

In 312 C.E. Rome's Emperor Constantine I (r. 306–337 C.E.) converted to Christianity, ending centuries of persecution of Christians. In much of Europe, Christianity already had been taking hold, but Christianity did not sweep through Europe when it became the official religion of the Roman Empire. Yet it became a profound influence on European art. One form in which Christian art excelled was the illustrated manuscript. Copies dating from the Roman era are very rare, but others from the 500s and 600s C.E. survive and have been widely reprinted in the 20th and 21st centuries. They look like ancient Celtic art. The three-pointed swirls, intricate interlacing of lines, and interweaving of vines are notable in European Christian manuscripts, whether they are copies of the Bible or biographies of saints.

The Celtic cross remains a popular image. It typically consists of a Christian-style cross with a circle around the spot where the vertical and horizontal bars meet. The circle is the ancient Celtic symbol of the sun, adapted to decorate sculpture for the new religion and perhaps adding a touch of the traditionally supernatural, which would be recognized by Celtic viewers. Sculpted stone versions survive in much of Europe. On these would be carved traditional Celtic designs or figures representing a biblical passage or Christian story.

The images and subjects found in ancient European art continued to be explored by artists in later eras. From the graceful bison of cave art to abstractions of human and animal shapes, to the stylish and dynamic geometrical designs of the Celts and Germans, artists have continually reused, reinterpreted, and further developed the art forms and styles begun by ancient artists.

GREECE

BY MICHAEL J. O'NEAL

It would be difficult to overstate the influence of ancient Greek art, particularly sculpture, throughout the world. Greek art inspired the artists of the later Roman Empire, and the influence of Greek art spread, through the conquests of Alexander the Great in the third century B.C.E., to the Middle East, central Asia, Southeast Asia, and the Far East. In the West, Greek art, with its high degree of technical perfection and its interest in the human form, inspired many artists of the European Renaissance, and that influence extended into at least the 19th century.

Very little painting survives from ancient Greece for the simple reason that paintings, unless stored and cared for properly, deteriorate over time. The ancient Greeks painted primarily on wooden panels, which had fallen into a state of near total decay by the fourth century C.E. In contrast, pottery and sculpture are created with more durable materials, so art historians have many examples of ancient Greek sculpture and pottery to study. The Greeks, though, regarded painting as an important art form. The works of one painter of the fifth century B.C.E., Polygnotus of Thasos, were held in particularly high esteem for hundreds of years, but none of his paintings survive. Otherwise, the only surviving Greek painting can be found on the walls of tombs and on terra-cotta pots. Copies of a few paintings from the Roman era exist, but they tend to be of poor quality.

The history of ancient Greek art is conventionally divided into three periods: the Archaic, the Classical, and the Hellenistic. Together these three periods span about a thousand years. During the Archaic and into the Classical Periods, sculptors and potters were regarded less as artists than as craftsmen who went through apprenticeships to learn their trades. In fact, the ancient Greek word *tekhnē* is usually translated as “art,” but it is the word from which the English word *technique* comes, suggesting that these artists were at the time thought of primarily as craftsmen. Only later, during the Hellenistic Period, did sculptors and painters come to be thought of as artists, in the same category as dramatists and poets.

THE ROOTS OF ANCIENT GREEK ART

Ancient Greek art had its roots in the art of earlier Bronze Age civilizations in the region around the Aegean Sea. Little was known about these civilizations until archaeologists excavated sites at such cities as Knossos, Mycenae, and Troy, which were cultural centers during the Bronze Age. These civilizations flourished from about 3000 to 1200 B.C.E. The first, the Cycladic culture, arose during the Early Bronze Age (about 3000–2200 B.C.E.). Craftsmen during this period, working in small walled villages, produced decorated pottery, silver jewelry, and marble sculptures. These sculptures represented the human form and often were used as grave offerings. Art historians regard this sculpture as the very earliest produced by a Greek civilization.

The second Bronze Age culture was that of the Minoans, who flourished from about 2200 to about 1800 B.C.E. on the island of Crete. These people constructed buildings and palaces, and their artwork included vases and frescoes found on homes and public buildings. This artwork is noteworthy for its vivid colors, dynamic figures that seem to be in motion rather than static, and the development of more three-dimensional figures, having more of a sense of depth rather than being flat.

The third ancient culture, the Mycenaean, flowered during the Late Bronze Age, from about 1600 to 1200 B.C.E. The Mycenae occupied an area of the Greek mainland south of what would become Athens. The Mycenae produced decorative art, ceramics, and painted weapons and vases, often depicting battles and hunting scenes. Their artwork was more geometric than that of the Minoans and is considered a foreshadowing of later Greek Archaic and Classical Period art because the geometric designs resemble those of later Greek art. The Mycenae unexplainably disappeared after about 1200–1100 B.C.E.

THE ARCHAIC PERIOD

Art historians date the start of the Archaic Period of Greek art at about 1000 B.C.E. The period extended to roughly the time of the Persian Wars (480–448 B.C.E.), a series of conflicts between Persia and several Greek city-states. Most of the art that survives from this time is in the form of sculpture, pottery, gem engraving, and coin design. The number of coins from this period is small; coins were not used until about the seventh century B.C.E. and were not in common use until about the fifth century B.C.E.

The pieces that survive from the Archaic Period represent only a small percentage of the work that the early Greeks produced. In the early years of Christianity sculptures of Greek pagan gods from this period and later were burned or otherwise destroyed as a way of rooting out pagan beliefs. During the Middle Ages, Greek statues made of marble were burned in order to create lime, and bronze statues were melted down for their metal for use in such items as weapons. Many sculptures that survive were buried and later found or else went down with ships at sea as they were being transported from their original sites to countries in Europe and recovered in recent centuries.

Art historians divide the history of archaic pottery into five periods, each with a unique style. The first is called proto-geometric. During this period potters began to put abstract geometrical designs on their pots. This trend continued into the geometric period, which began roughly in 900 B.C.E. After this time geometrical designs were common features on pots, and by the late geometric period (about 750 B.C.E.) the practice was universal. During these three periods the pots had a natural light color, though they were decorated with substances that turned black when the pot was fired in a kiln. The “black figure” period began in the seventh century B.C.E., followed by the “red figure” period in about 530 B.C.E. These

terms refer to changes in the coloration of pots. During the black figure period the background of the pot was red, and the figures depicted on it were black. In the red figure period the reverse was the case: The background was black, and the figures were red.

During these two later periods potters moved away from abstract geometrical designs; as their skills developed, they began to include pictures of human figures on their pots. Many of these figures were gods and goddesses, but other pictures were of battles, hunting forays, heroic and legendary people, and horses. Much of the pottery also depicts erotic themes. Some of the pottery is signed, but art historians tend to identify particular artists by their themes (for example, “the Achilles painter,” referring to the Trojan War hero) or by where their works are currently located (such as “the Berlin Painter”).

While a good deal of pottery survives from the Archaic Period, pots are more fragile than statues, so art historians have far more statuary to study than pottery. Even so, only a small percentage of Greek sculpture survives. Like pottery, little sculpture was produced for purely decorative purposes. Most was commissioned by the state or by wealthy individuals, and most was used for offerings in temples or as memorials or grave markers.

The dominant form of sculpture was the *kouros*, a figure of a standing male nude. Less important, though still common, were *kore*, or representations of standing female nudes. The prevalence of these statues reflects the Greek belief that the human form provided an elevated subject for art, and most showed young men and women in their physical prime (even when they were used as grave markers for the elderly). Since Greek gods and goddesses had human forms, sculpture could capture an ideal of beauty, nobility, and other virtues, and a particular sculpture could represent either a god or an athletic champion. This concern with secular, or nonreligious, themes and the beauty of the individual human form laid the foundation for much of Western thought and art over the following millennia.

The *kouroi* and *korai* were carved according to a kind of formula. The body is rigid, and the figure’s hands and arms are held to the sides. Most have a mysterious smile. The pose is from the front, with the left foot slightly forward. Part of the reason for this stylized form was the chiseling techniques the artists used. They carved the statues from marble using point chisels, which made artistic innovation and subtlety of design difficult. It also concentrated the force of the sculptor’s hammer blows, crushing the stone’s crystals and giving the sculptures an opaque, or cloudy, appearance.

THE CLASSICAL PERIOD

Art historians cite the Persian Wars as the beginning of the Classical Period of Greek art, which extended to the death of Alexander the Great in 323 B.C.E. This period is known primarily for its exquisite statuary, both in stone and bronze. Statuary from this time had a wider range of uses than it did during the Archaic Period. In particular, it decorated the

Hermes with the Infant Dionysus by Praxiteles (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

interior of public buildings, such as the Parthenon in Athens. Many of these buildings had pediments, or triangular spaces at the gable ends of pitched roofs. Statues were often placed in those pediments to fill them in and give them visual appeal.

The Elgin Marbles, named after the Englishman Thomas Bruce, the seventh earl of Elgin, who transported them to his homeland, are a major artistic treasure from this time. Also called the Parthenon Marbles, they include statues from the Parthenon’s pediments and marble panels called metopes on which battle scenes were carved. (A metope is a flat panel that is part of a tryglyph; a tryglyph is a raised ornamental structure that consists of three raised vertical bands with metopes between them.) Also included are parts of a frieze—a horizontal band of carved stone, typically depicting a progression of events and figures and running along the top of a wall—from

the interior of the temple. The originals that survive include 524 feet of frieze, 92 panels, and 17 statues. While experts disagree about the meaning of the frieze, many believe that it depicts the procession that was held every four years in connection with the Panathenaic Games, which in turn were held in connection with a larger religious festival, the Panathenaia.

Classical Greek statuary is famous for its extraordinarily high degree of precision and technical perfection. During the Archaic Period, the *kouroi* and *kourai* were rigid and stylized. The sculptors seemed to have worked from a pattern so that many of the statues are similar in appearance. None of the figures were in natural poses, and none of the sculptures seem to have captured either motion or emotion.

The classical Greek sculptors took the art form to new heights. They came to celebrate the human form for its aesthetic beauty. Even when they were depicting the gods and goddesses, they gave to the figures perfectly proportioned human forms, right down to the details of the fingers and hands. The poses of their figures were more natural, and the subjects' poses in general had more variety. The statues are more fluid and realistic, and many of the figures seem to be in motion rather than held rigidly. While the statues of the Archaic Period seem almost two-dimensional, those of the Classical Period are more three-dimensional, bursting with energy and movement. On the other hand, the figures depicted by most of the Archaic Period sculptures were smiling, if only faintly. During the Classical Period most of the figures have solemn expressions. This feature reflected the Greek ideal of emphasizing reason and logic rather than emotion.

Art historians believe that the emphasis on depicting the human form reflected in art the same concerns that preoccupied Greek philosophers of the era: studying and observing the natural world in order to explain it. Historians generally believe that these developments in philosophy and art reflected the emergence of democratic institutions in Greece during this time period. The *kouroi* were the products of an aristocratic society; the sculptures of the Classical Period were the products of a society in which people were more equal. For this reason, many of the sculptures of the Classical Period depict real people. Historians believe that the statues of the heroes Aristogeiton and Harmodius in Athens, erected to celebrate the end of earlier Greek tyranny, may be the first-ever public statues of real people. Also, many cemetery statues depict the deceased rather than idealized figures.

Classical Greek sculptors are the first Greek sculptors that historians know by name, at least in some cases. One of the most prominent was Phidias (ca. 493–ca. 430 B.C.E.). After the general Pericles defeated the Persians and assumed power in 449 B.C.E., he named Phidias superintendent of public works in Athens and made him responsible for beautifying the city. Phidias also supervised the design and construction of the Parthenon. He produced two of the most famous works of the Classical Period. One was the statue of Zeus at Olympia, one of the Seven Wonders of the Ancient World. This work, considered his masterpiece, showed the god Zeus seated on a throne.

His flesh was carved in ivory, and his tunic was made of gold. The figure of Zeus himself was 42 feet high, filling the entire height of the temple. Phidias's other masterwork was his Athena Parthenos, one of three statues of the goddess Athena on the Athenian Acropolis. This statue, made of gold and ivory, was 38 feet high. Both of these sculptures are now lost. They were destroyed by fire after they were taken to Constantinople (modern-day Istanbul), though copies and descriptions exist.

Another prominent classical sculptor was Praxiteles (ca. 400–ca. 330 B.C.E.), best known for his female nudes, especially the now-lost Aphrodite of Knidos. His model for these nudes was probably a courtesan named Phryne, with whom he may have had a romantic relationship. His sculptures are famous because they were carved and polished in a way that makes the light bounce off them, giving them a shimmering, almost lifelike appearance. He was also one of the first sculptors to give his figures curly hair. Praxiteles created what artists and art historians call the "Praxitelean curve." This term refers to a sensuous, almost erotic posing of the model to create the illusion of a living, seductive figure. Later artists copied the curve, which can be seen in Hermes with the Infant Dionysus (housed at the Olympia Museum in Greece).

THE HELLENISTIC PERIOD

The Hellenistic Period of Greek art began roughly with the death of Alexander the Great in 323 B.C.E. and ended in the first century B.C.E. Alexander's death marked a key turning point, for during the years 336 to 323 B.C.E. he extended the Greek Empire through conquest. Most of these conquests were eastward, so Greek influence extended to such places as Persia; Egypt; the kingdoms that occupied modern-day Afghanistan, including most prominently the kingdom of Bactria; and India. The influence flowed in the other direction as well: Greek art was influenced by forms of artistic expression from these other countries. While formerly Greece had been a collection of relatively isolated city-states, after Alexander the entire Mediterranean region was alive with commerce, travel, and cultural exchange.

Hellenistic art can be distinguished from classical art by its greater boldness and sense of experimentation. While artists did not entirely abandon the rules from the Classical Period, they created their own conventions through art that was more dramatic and that portrayed a wider range of human emotion; a good example is the bronze Boy Jockey (now in the National Archaeological Museum of Athens), recovered from a shipwreck off the Greek coast. The statue—of a nearly life-size boy riding a horse—captures in new ways a sense of tension, energy, and movement. One of the world's most famous sculptures, housed in the Louvre Museum in Paris, is the Winged Victory at Samothrace, also called the Nike of Samothrace, an 8-foot-high statue created by Pythocritos of Rhodes in about 190 B.C.E. (*Nike* means "victory" and is the name of a Greek goddess, and Samothrace is a Greek island.) Unfortunately, the statue is missing its head and arms, but some observers believe that the damage in a strange way en-

hances the sculpture, creating a sense that the figure, with its intricately carved robes, is almost floating in space.

The sculptors of the Hellenistic Period retained the earlier interest in figures of gods and goddesses, but they also turned to more human themes, giving their figures a mysterious smile or an expression of surprise. Many of the statues from this period are erotic and sensual. Common figures included Aphrodite, the goddess of love, beauty, and sexual passion (known in Roman mythology as Venus); Pan, the half-man, half-goat god of the woods who, according to myth, had affairs with many nymphs; and various satyrs (any god of the woods noted for love of unrestrained revelry). Among this type of sculpture is the famous Venus de Milo, is an 80-inch-high marble sculpture once thought to have been created by Praxiteles but now believed to have been created by Alexander of Antioch sometime around 130–90 B.C.E. Although the statue's arms are missing, visitors to the Louvre in Paris continue to be amazed by the beauty of the figure depicted, with its perfect proportions and the Praxitelean curve.

COINS

Although coins are not typically thought of as “art,” art historians take an interest in ancient Greek coinage for two reasons. One is that a large number of coins survive from the period, so they are available for study. The other is that Greek artisans exhibited considerable skill in crafting coins, giving art historians insight into Greek craftsmanship and aesthetics—particularly because coins were made by hand one at a time.

In making a coin, a craftsman carved the image for one side in reverse into iron or stone and then carved the image for the other side into another block. After the silver or gold was heated to the melting point, it was placed between the two blocks, and the top block was struck with a hammer. (For this reason, coins are still said to be “struck” when they are manufactured.) This punched the images onto the coin. The fact that many Greek coins are technically perfect is testimony to the high degree of artisanship craftsmen brought to coin making.

Coins developed in China and India in about 600 B.C.E., but in the Greek Empire, they emerged at roughly the same time in the kingdom of Lydia (now in western Turkey). In common with other forms of Greek art, historians divide the history of Greek coinage into the archaic, the classical, and the Hellenistic. Archaic coins were relatively crude, consisting initially of lumps of gold or silver with geometric designs, though in time flat coins were developed. Later, coins became more sophisticated and included an image of a god or goddess as well as animal symbols.

By the Classical Period, Greek coinage had achieved greater technical proficiency, and the aesthetics of Greek coins were more pleasing. During this period, many of the conventions of coinage still in use today were developed. On one side of the coin were images of gods, goddesses, or heroes. On the other were symbols, such as the owl that symbolized Athens. Also, inscriptions were engraved on the coins

for the first time. During the Hellenistic Period, Greek influence spread into such areas as Egypt, Iran, Syria, and as far as India. Many of these kingdoms began producing their own coins, and in some cases the coins were mass-produced. Gold came to be used more frequently than silver. While many of these coins lacked the artistic qualities of classical coins, many also represented the highest level of the coin maker's art, and some were quite large. What distinguishes Hellenistic coinage from that of earlier periods was the inclusion of the images of living persons on coins. While this practice was frowned upon in Athens, many surviving coins from other regions in the realm, especially Syria and Egypt, contain magnificent portraits of their rulers.

JEWELRY

Ancient Greek jewelry not only reflected the love of beauty but also was connected with important moments in people's lives. Jewelry was given as gifts at birth and marriage, and much surviving jewelry was buried in tombs. Throughout a person's life, jewelry was worn in honor of the gods.

Most Greek jewelry was made with gold or silver, though some was made with semiprecious stones and cheaper materials, such as bronze or clay. Some early Greek jewelry was cast in molds, but most was made by hammering sheets of metal to the desired thickness and then soldering the pieces together. Most such pieces of jewelry had a design on the surface produced with a variety of techniques, including repoussé. This process creates a relief on the surface by hammering or pressing on the reverse side. Other techniques included granulation (using tiny granules of metal to create a decoration), engraving, and filigree (decorations created with fine wire). Wire was often used to connect the pieces of such objects as necklaces.

ROME

BY WILLIAM H. PECK

The history of Roman art is derived from two important sources: actual works of art that have been preserved by chance or rediscovered by archaeology and the writings of ancient authors. Abundant examples exist of some of the art forms practiced by Roman artists and craftsmen, but it is to the literary sources that we must turn to learn about traditions, techniques, and personalities. Of these sources Pliny the Elder (Gaius Plinius Secundus), who lived and wrote in the first century C.E., is by far the most important writer on arts and crafts. His *Natural History* contains detailed information on almost every aspect of the arts as practiced in his time.

The art of ancient Rome developed from two important roots. The first was the artistic tradition of the Etruscans, who occupied the northwestern part of the Italian peninsula and flourished from the eighth century B.C.E. to the rise of the Romans. The second major influence was the art of the Greeks, with which the Romans came into contact through the Greek colonies in southern Italy and on the Greek mainland itself.

Etruscan art provided a base that was mainly concerned with realistic representation, whereas Greek art contributed ideas of idealism and perfection. The combination of the two gave Roman art its distinct style.

Roman art went through several historic phases, which closely follow the history of Rome itself. During the Republic (509–27 B.C.E.) the arts of Rome were highly dependent on Etruscan models, attitudes, and techniques, particularly in portraiture. As the Roman Empire developed, the arts took on a distinctive character that can be recognized as an outgrowth of Etruscan art but with added characteristics derived from Greek influences. In the third period, called “Late Antique” (roughly 300–600 C.E.), art forms assumed new styles and character, reflecting the changes in the fortunes of the Empire and the addition of new attitudes and religious beliefs.

Much of Roman art was meant to be essentially propaganda, in the service of the state and the rulers. The word *propaganda* is used today mainly in the negative sense of misinformation, but in a broader definition it means information intended to convey a special point of view. This was the purpose of a great deal of the art of the Romans; it celebrated the qualities the Romans accepted, especially as demonstrated by the accomplishments of a strong emperor or a victorious military leader. As a consequence, Roman art provided a mirror and inspiration for a strong government and state.

The various art forms employed by Roman artists and craftsmen included sculpture, painting, plaster and mosaic work, pottery, metalwork, weaving, jewelry making, wood-working, and glassmaking. Of these mediums, sculpture is the best-known art for us today, partly because of the widespread use of statues for propaganda purposes but also due to the chances of preservation. Roman sculpture was made in a large variety of materials, ranging from marble and other kinds of stone to bronze, copper, and even silver and gold, as well as terra-cotta (fired clay). Wood was also used but is seldom preserved. Of all these materials, the most important works were done in bronze, an alloy of copper and tin. Bronze statues frequently were copied in marble, and it is in those versions that many famous compositions have come down to us, because the metal originals were often melted down for other purposes.

The Etruscan heritage on which Roman art was founded is particularly evident in terra-cotta, a material favored by the Etruscans. Clay images were used extensively for the decoration of temples and other buildings. The Etruscans were also very able workers in bronze and passed this tradition on as well. However, the Roman artists used techniques and materials in their own way for decoration, information, and votive purposes. Sculpture is generally divided into two major types. Sculpture “in the round” involves three-dimensional statues meant to be seen from all sides; sculpture “in relief” includes designs carved against a flat background. The first requires the artist to visualize how the work will be seen as the observer moves around it. With the second the artist must be able to suggest roundness and depth in a shallow space.

Both types were used by the Romans for appropriate purposes. Three-dimensional statues decorated public areas and private dwellings. Relief sculpture enlivened the surfaces of buildings and monuments.

PORTRAIT ART

The Roman use of realism in portraits lets us see the ancient Romans as they saw themselves, or at least as they wanted to be seen. During the time of the Republic portrait sculptors attempted to be very realistic. The portrait of the typical *paterfamilias* (male head of the household), for example, while intended to show him as a strong personality who shared with his family the Roman virtues of wisdom, strength, steadfastness, and loyalty, might convey these desirable characteristics and indicate experience and achievement by depicting him at advanced age, often bald and wrinkled. With growing influence from the arts of classical Greece came more of an attempt to create an ideal and somewhat ageless vision of the individual. A good example is the statue of the emperor Augustus created around 20 B.C.E. and found at the villa of his wife Livia at Prima Porta in Rome. In this sculpture the figure and likeness of the emperor are idealized to suggest that he is not an ordinary person but has qualities that associate him with the gods of Rome and make him more than human. (In fact the Julio-Claudian family traced their line back to the goddess Venus/Aphrodite.) A similar example is the equestrian statue of Marcus Aurelius (161–180 C.E.) that depicts the emperor as a philosopher-king rather than as a conquering military commander. This idealization in the arts was learned or copied from Greek art; even the pose of the statue of Augustus imitates a Greek original. The love of Greek customs and art was especially strong under the emperor Hadrian (117–137 C.E.), an ardent admirer of Greek culture who encouraged the imitation classical style.

The Romans continued to look to Greece, particularly Greece of the fifth century B.C.E., for inspiration and for models in the arts. They imported Greek art and even Greek artists to decorate their public buildings and homes. A favored practice was the copying of famous originals to adorn homes and gardens, much as one might have a copy of a famous painting on the wall today. This penchant resulted in numerous Roman copies that today give us our only knowledge of the lost Greek originals. One example of such a lost original is the Venus Genetrix type, an image of Aphrodite adapted by the Romans. It is known from more than 70 preserved copies or variants, suggesting that it was very famous in the Roman world.

Many portraits of famous Romans have been preserved, particularly of the emperors and their families. We can recognize the nobility of Augustus or the decadence of Nero in the images made of them because of the abilities of artists to capture such qualities in addition to surface appearances. Portraiture is probably one of the greatest art forms developed by the Romans. It also exemplifies the combination of Etruscan and Greek sources that came together to influence Roman art.

ROMAN COPIES OF GREEK ORIGINALS

In almost every museum that has a collection of Greek sculpture many of the labels will say “Roman copy after a Greek original.” As Rome grew powerful in the Mediterranean world, the ruling classes aspired to become cultured and knowledgeable about art, literature, and the other aspects of a civilized people. This cultural ambition resulted in an admiration of Greek art, particularly the art of the fifth century B.C.E., and led to the serious collecting of Greek art on a grand scale.

The Romans had several ways to satisfy the demand for sculpture to decorate the houses and villas of the well-to-do. First, actual Greek works, purchased or looted, were exported to Rome literally by the boatload. Underwater archaeologists have found countless examples in the sea as well as in the port of Athens, where the artworks were lost in the process of being shipped. Second, Greek sculptors were brought to Rome, either as slaves or as free operatives, to produce their sculpture locally. Third, copies of famous works by artists of great reputation were ordered and produced for the Roman market by the thousands.

Greek artists such as Phidias, Polyclitus, and Praxiteles were famous in their time, and individual works by them were well known throughout the Greco-Roman world. Since these works usually stood in temples or public places, it was impossible to acquire the originals, but copies were considered a good substitute.

Most of the famous pieces of sculpture were cast in bronze, and only a few have survived. Most of the copies for the Roman art trade were carved from marble. The difference in material necessitated small changes in the composition. A bronze statue could stand securely on its own legs with little chance of breaking, but stone copies needed additional support around the legs. This fact helps to explain much of the drapery, tree stumps, small animals, and other additions found in the Roman copies. Copyists took other liberties as well. If the original was considered too revealing of the female form, a more modest arrangement of the draperies might be employed. To fit in with a particular placement or arrangement, the whole composition might be reversed so that the figure gestured with the left hand instead of the right. Copies could also be made in different sizes. The Roman collector could choose the size best suited for his house or garden.

We have knowledge of many famous works of art only from the copies commissioned by Roman collectors. In some cases there are dozens of examples based on the same well-known original that was destroyed or lost long ago.

Relief carving was used to embellish the interior or exterior of buildings, the surfaces of monuments such as the triumphal arch and tombs, as well as smaller structures such as altars and sarcophagi (stone containers for the dead body). Relief sculpture could consist of compositions made up of figures and decorative devices of plants, fruit, and other symbols. The Ara Pacis (Altar of Peace, made around 13–9 B.C.E.) of the emperor Augustus is an example of the use of figural decoration while depicting a procession of members of the imperial family and servants in a stately composition. The decoration of the Arch of Titus (around 81 C.E.) uses relief to commemorate a significant historical event, the sacking of the Jewish Temple of Jerusalem and the removal of the temple treasure.

From some of the ancient authors we know that, in addition to sculpture, painting was an important art form. Paintings on canvas or on wood panels from Roman times have seldom been preserved, and this much-respected art has almost totally disappeared, so this is one instance where we must turn to the written evidence. Pliny the Elder describes paintings exhibited in the Roman Forum as well as the unusual example of a colossal 120-foot-high painting commissioned by Nero, naturally of himself. Pliny also tells us that realistic portraits attracted a great deal of interest and caused considerable discussion and comment.

Some panel paintings found in the dry climate of Egypt may give us an idea of the Roman painting tradition. When the Romans occupied Egypt, it became common to put a painted portrait, rather than a modeled mask, over the face of a mummy. In these mummy portraits, painted in wax pigments on thin wood panels in a very realistic manner, some evidence of the painting styles of the Romans during the time of the Empire has been saved for history.

WALL PAINTING

In contrast to the scarcity of original Roman portrait painting, many examples of paintings on the walls of public buildings and private houses have survived. It is important to remember that this kind of wall painting was intended as a kind of interior decoration and often followed a set formula or pattern. It generally employed the technique called *fresco*, painting on the plaster of a wall when it is still wet or “fresh.” The major advantage of this method is that the painting becomes a permanent part of the wall.

The subjects of wall painting often included views of gardens and vistas of elaborate buildings, creating the illusion that the room was open to pleasant scenery. Roman houses had few real windows, and wall images of this kind helped to lessen the feeling of confined spaces. The greater part of

fresco painting, however, was simple color and geometric shapes, intended to add variety to the rooms it decorated. In some cases it imitated varicolored stone to suggest a richer and more expensive effect. Roman wall fresco painting gives us a great deal of information about the artistic taste of the people whose houses it decorated.

The artists who specialized in wall painting were organized with a master craftsman as the lead designer and assistants to accomplish the more routine tasks. There is historical evidence that a “figure painter” was paid more than the ordinary wall painter. There is also evidence that Roman painters used pattern books for repeated decorative designs and types. The technique of fresco painting required that the plaster be applied to the walls in sections, only as much as the painters could decorate in a single day. The materials used, in addition to the lime plaster, were mainly natural pigments. These included chalk white, carbon black, and earth colors such as red and yellow ocher. Blue had to be specially produced from a copper compound. The use of natural materials has contributed to the permanence and preservation of the paintings.

From archaeological evidence we can trace the development of Roman wall painting from the second century B.C.E. to about the fourth century C.E. Styles changed with popular taste. At Pompeii, where many examples were preserved when the town was buried in 79 C.E. by the volcanic eruption of Vesuvius, it is possible to distinguish four styles. Not all scholars agree on the historical sequence, but the “four styles of Pompeian painting” form a basis for the general study of the art form. The first style consisted of a combination of paint and plaster, imitating stonework, often brightly colored. The second style kept some of the imitation stonework but added fanciful views of imaginary architecture with the intention of suggesting illusions of depth. In the third style the illusions of architecture became less important, and images on the walls were treated more like surface decoration, even when they represented landscapes. The fourth style reverted to an emphasis on fantastic architecture and illusionist spaces and became even more elaborate.

In addition to fresco painting, interior walls were often further ornamented with plaster decoration. This work often imitated relief carving in stone and served to make interiors even richer in appearance. Decorative plasterwork was a highly skilled craft, used in the embellishment of buildings as important as Nero’s palace in Rome, the *Domus Aurea* (Golden House).

MOSAIC

Mosaic was another important art form used in the decoration of architectural spaces. The Romans especially favored it because it added color and interesting compositions to floors in a much more durable material than rugs or carpets. It was not only hard wearing but also easy to keep clean. Mosaics consist of small pieces (*tesserae*) of stone, or sometimes ceramics or glass, set in a cementlike matrix. The stones were

generally of natural colors, collected from many different sources. The designs of mosaic floors might be simple geometric patterns, scenes of daily life, illustrations from Greek and Roman mythology, or special themes such as the seasons or months of the year. In some cases mosaics were made in imitation of famous paintings. Usually, the subject of figural decoration was selected to suit the purpose of the building. For example, the designs in Roman public baths were often compositions with Neptune, god of the sea, surrounded by mermaids and mythical sea animals. At Ostia, the seaport of Rome, mosaics in an area of commercial offices depict the various kinds of business and trade carried out. The subject matter of a domestic mosaic floor could suggest the cultural interest or special occupation of a householder.

Some exceptional mosaics were made as small wall decorations. Usually composed of very small pieces of stone, they approach the art of painting in their detail and realism. Some of these wall pieces are compositions of familiar objects that would today be called “still lifes.” Depicting bottles, glasses, fruit in baskets, and similar items arranged in interesting groupings, they suggest the skill of the mosaic makers as well as of the painters who probably originally designed them.

CERAMICS AND METALWORKING

Pottery or ceramics, the art of working with clay, has been a necessary and important craft in almost every civilization and culture. In the ancient world pottery took the place of many materials in use today, such as glass and plastic. Efficient ceramic manufacture was especially crucial to the Roman economy, because vital products such as olive oil and wine were shipped in clay containers. In addition to the simple containers made for cooking, eating, storage, and shipment, the Romans developed several art forms based on clay. Small statuettes or figurines made from molds were popular as decorative and religious objects. They included carefully detailed and brightly painted representations of gods and goddesses or even favorite athletes and gladiators. Useful items such as clay oil lamps were made by the hundreds of thousands, but they were often enhanced with interesting designs. Probably the most important type of ceramic ware made in Roman times was the pottery called Arretine ware, made in the region of modern Arezzo. This type took advantage of a kind of fine red clay that lent itself to the production of cups, plates, and bowls with fine designs, made in figured molds. Arretine ware was imitative of designs made in silver and may have been a substitute for the more expensive material. Often these clay vessels were stamped to designate the maker and even the individual craftsman responsible for the design, suggesting that Arretine ware was special enough for the artist-designers to take pride in their work.

Roman craftsmen were particularly skillful in making objects of metal. In part this was one of the traditions learned from the Etruscans, who had been famous as metalworkers throughout the ancient world. Roman bronze workers created objects ranging from colossal statues to simple pots and

Roman terra-cotta relief showing an Egyptian scene set on the Nile, from the first century B.C.E. (© The Trustees of the British Museum)

pans to weapons and armor. Many different household objects found in the ruins of Pompeii and nearby Herculaneum (also destroyed in the great Vesuvian eruption) evince the widespread use of bronze for such items. It is very informative to see the variety of metal objects used in everyday life: containers, serving implements such as pitchers and ladles, scales for weighing food and other materials, tools and medical instruments, and even small stoves for hot water. These may be classified as crafts objects rather than works of art, but they were often designed to be decorative as well as useful. Tables, chairs, beds, and accessories such as lamp stands were made either completely of bronze or with bronze parts or fittings. This wealth of material attests to a well-developed and resourceful metal industry.

The armies of ancient Rome, as well as the combatants in the frequent gladiatorial games, required a vast amount of arms and armor, usually made of bronze but occasionally of silver or even gold for special ceremonial uses. This military

gear ranged from swords and spears to beautifully decorated body armor and helmets. The metal craftsmen who worked in the imperial armories were highly skilled in making practical protective pieces as well as “parade” armor meant only for display. Helmets and arm guards made for the gladiators were often as thick as boiler plate and provided excellent protection in the arena.

Specialized metalworkers dealt with the luxury crafts in gold and silver. They produced splendid table services and display pieces for the aristocracy and the wealthy. Highly skilled craftsmen made matching sets of ware and utensils decorated with scenes from mythology and embellished with garlands of grapevines, olive branches, and other plant forms. These opulent sets required the ability to adapt metalworking techniques to creating a high level of careful detail.

Another specialized area of metalworking was coinage. During the sixth and fifth centuries the Greeks had developed the design and production of coins to a high degree of

art. Under the Roman Republic and Empire the specialized artistic design of coins continued. The materials were gold, silver, and bronze and other alloys. The art was in the cutting of the dies from which the coins were struck. The images were mainly of the emperor, his family, and other important persons, as well as symbols of state and representations of myth. Roman coins are not only miniature works of art but contain considerable historical information.

OTHERS ARTS AND CRAFTS

Few examples of the art of woodworking have been preserved, but from depictions in wall painting, representations in relief carvings, and a scant few remains, we know that the craft was used extensively in furniture making. Similarly, few products of the art of weaving survive. The climate of Italy and much of Europe has prevented the preservation of garments and other woven materials, so we must rely on the pictorial evidence in paintings, relief carvings, and mosaics. However, garments preserved from parts of the Roman Empire, such as Egypt, give us an idea of textile decoration. Materials used were cotton, linen, and wool. Design devices included colorful borders and appliqué, so the impression we have from sculpture of Roman attire as colorless is not completely accurate. Colorful cottons from India and silks imported from China have been found in the oasis caravan city of Palmyra in the Syrian desert, further attesting to a general interest in richly decorated dress during the time of the Roman Empire.

Roman craftsmen excelled at the art of jewelry making. In part this was one more tradition inherited from the Etruscans. Over the centuries the Etruscans had evolved a highly developed jewelry industry exhibiting great artistry and technical skill. They were especially expert in working gold. Among other techniques they developed was granulation, a method of applying tiny balls of gold in patterns on a plain surface. Roman jewelry makers continued to use methods invented by the Etruscans and took them to an even higher degree of accomplishment. In addition to working in gold and silver, they were skillful at engraving stones to be set into rings, bracelets, earrings, and necklaces. Where today these gemstones would probably be diamonds, rubies, and emeralds, the ancient jewelers used semiprecious stones such as carnelian, agate, and quartz. The designs might include images of the gods and goddesses, scenes from mythology, and the name or motto of the owner. The art of the cameo in glass or multicolored stone was also highly developed. Elaborate profile portraits were often done in this technique, which required great skill in design and execution.

Not all jewelry or objects of personal adornment were made of precious metals. One of the most characteristic objects used by Roman men and women alike was the fibula, a brooch that served to fasten a cloak or other garment. The fibula was like a large safety pin with spring action and a clasp, but it was often decorated with designs so that it became an object of art in its own right.

Some of the great achievements of Roman artists and craftsmen were in the art of glassmaking. Glass was not a new invention—it had been produced in some parts of the ancient world for centuries—but the methods of making *blown* glass did not become well known until the first century B.C.E. Roman craftsmen excelled in the manufacture of all sorts of vessels and containers in glass—jars, bottles, plates, bowls, inkwells, and even such specialized objects as baby feeders. The forms employed ranged from simple undecorated shapes to elaborate and fanciful showpieces. Glass was mainly free-blown but also blown in molds to give it designed shapes and surface decoration. Cameo glass was produced by coating one color of the material with another, then grinding away parts of the surface to make a design. Some examples of complicated glassmaking that survive are evidence of a highly developed working tradition in a material that challenged the imagination of the artisans to great heights of creativity.

The arts of Rome reflected the accomplishments and aspirations of the Roman people. The artistic traditions evolved with the development of the Roman state from its beginnings in the Republic to the height of Empire and its eventual decline. The values of republican Rome are best illustrated by the severe portraits of distinguished personalities of the time. The attitudes of the ruling elite during the greater expansion under the Empire are shown by the return to forms that imitate Greek styles and by the flourishing decorative arts. With the division of the Empire in the fourth century and the advent of Christianity, the arts, particularly sculpture, underwent changes that reflect the social situations of the time.

The Arch of Constantine (312–15 C.E.) illustrates these changes, being decorated with reliefs salvaged from previous reigns as well as work from the time of Constantine himself. The reused pieces are in the traditional styles reflecting the influences of the Greeks and Etruscans. The new compositions are in a style that can be characterized only as more schematic and less realistic. They depict the emperor and his court, but in graphic contrast to earlier representations such as that of Augustus and his entourage on the Ara Pacis, the Arch of Constantine shows the ruler and courtiers in stiff frontal views. The art of Rome had once again adjusted to the needs of its time. The interest expressed was not in realistic or ideal representation but in information conveyed in the most direct and diagrammatic fashion possible.

THE AMERICAS

BY ARDEN DECKER

ANCIENT NORTH AMERICA

The most significant cultural activity of ancient North America took place in a region now known as the American Woodlands, which extends from the Hudson Bay to the Gulf of Mexico and from the eastern Great Plains to the Atlantic coast. While evidence suggests that the creation of utilitarian objects dates back to the Paleo-Indian Period

(13,000–8000 B.C.E.), regional cultural traditions first arose in the Late Archaic Period (3000–1000 B.C.E.). From utilitarian to ceremonial objects the American Woodland cultures laid the foundation for a tradition of distinct and sophisticated art forms.

Mostly utilitarian items were created by the Early and Middle Archaic Woodland cultures (8000–3000 B.C.E.). Items such as mortars, pestles, axes, and knives were made from stone and copper. Ceremonial objects and ornaments of minimal design also began to be produced. The first significant art forms in North America—mostly portable carved stone objects—were made by the Woodland peoples of the Late Archaic. While they continued the tradition of stone tool making, they also made many ornamental objects out of highly polished precious stones, such as beads and pendants. Such ceremonial objects as simply shaped smoking pipes and flutes made from luxury materials became more prevalent.

Poverty Point (1600–1300 B.C.E.), in northeastern Louisiana, was the largest and most influential site of this period. Numerous ceremonial, burial, and ornamental objects were created there, including the first known human figures in North America. These figurines of men and women would have been hand-molded out of clay and then fired. At the Great Lakes burial site known as Glacial Kame (1500–1000 B.C.E.), a uniquely shaped object called the sandal-sole gorget (an ornamental collar named for its sandal-like shape) made its appearance. These ornaments were carved from shell and often featured small relief carvings of animals. At Glacial Kame and the nearby Red Ocher site, unique bird-shaped atlatls (throwing devices used to propel spears) with large, popping eyes have been found, which suggest the importance of imbuing functional objects with a sense of design.

By the time of the Early Woodland Period (1000 B.C.E.–100 C.E.), regional communities had made developments in agriculture, ceramic production, and the burial of the dead and had become even more sedentary. This period was marked by growth in the practice of mound building. The Adena burial sites of the central Ohio River valley are the most complex. Here mound building became more monumental and complex, as did burial caches. Fine utilitarian and ornamental objects made from luxury materials were buried with the dead. Along with these objects, some late Adena burial mounds contained stone pallets incised with highly stylized designs. Of particular note are the ceremonial smoking pipes found in association with later Adena complexes. Instead of being confined to a simple, tubular shape, these pipes incorporate zoomorphic (animal-like) and human figures as part of their design or as the whole. This advancement greatly influenced the carving practices of the later Woodland cultures.

Many of the key objects of the Middle Woodland Period (200 B.C.E.–400 C.E.) were created by the Ohio Hopewell culture. While the Ohio Hopewell culture is best known for highly sophisticated mound building (ranging from geometric or curvilinear designs to zoomorphic forms), they did engage in small-scale artistic production of particular importance.

The Ohio Hopewell began carving two-dimensional animal and human cutouts from copper, shell, and mica. They also made human figurines from fired clay. Ornamental objects like breastplates, headdresses, and cymbal-shaped earspools (circular ear ornaments that are hollow at their centers and worn by being placed within a hole in the earlobe) decorated with animal designs also were created. They developed the platform pipe, in which the traditional tubular pipe was modified to include a curved platform base with a carved bowl on top. Quite often these pipes displayed highly naturalistic renderings of bears, birds, wolves, and other animals. Many Hopewellian characteristics appear in objects created in contemporary and later Woodland sites, indicating that the Ohio Hopewell tradition played an essential role in the development of artistic production in this period.

Another significant region of artistic activity in the Middle Woodland Period arose in Alabama. The Copena complex (100–600 C.E.) developed a distinct brand of pipe design in which the entire pipe takes on the shape of an animal, bird, or other creature. Evidence of these great pipes has been uncovered as far as the Ohio River valley, again signaling a widespread exchange of cultural practices in the Middle Woodland Period.

ANCIENT MESOAMERICA

While evidence of human activity in Mesoamerica dates back to at least 8000 years B.C.E., it was not until around 1500 B.C.E. that the most significant early center of culture arose in Central America with the Olmec. This early culture set the stage by establishing the artistic production that all subsequent cultures would follow. Monumental sculpture, portraiture, images of supernatural deities, and semiprecious stone objects were the key art forms developed by the Olmec and shared by all ancient Mesoamerican cultures.

The Olmec culture developed along the Gulf Coast of Mexico around 1500 B.C.E. Sometimes referred to as the “mother culture” of Mesoamerica, the Olmec developed many of the crucial stylistic elements that become characteristic of Mesoamerican art. The earliest Olmec site is San Lorenzo, a complex, man-made center of civilization established south of what is now Veracruz, Mexico, in the Early Preclassic Period (1500–1200 B.C.E.) Significantly, the well-known monumental stone colossal heads were created here. These giant heads are entirely three-dimensional (sculpted in the round). They probably depict important Olmec rulers and provide early evidence of portraiture. While the heads share many similar features (deep-set eyes, wide nose, full lips), they are also each slightly different.

The second most significant Olmec site is La Venta, near the border of what are now the Mexican states of Tabasco and Veracruz. Founded during the Middle Preclassic Period (1200–400 B.C.E.), La Venta also produced impressive examples of monumental art. In addition to colossal heads, there are large stone altars that actually functioned as ruler thrones. These thrones depict a ruler seated in a niche con-

nected to a rope attached to captives who are carved in relief on the sides of the object. This imagery probably indicates the ruler's earthly and supernatural powers.

Also of note is the appearance of the stela form of monumental sculpture, where a large stone slab is decorated with relief carvings to commemorate an event or person. Relief carvings are created by cutting a design into stone and then removing the background to make the design stand out. Often depicting rulers, deities, or both, stelae became one of the most distinguishing art forms in Mesoamerica. Stelae functioned as records of events and have provided significant information concerning Mesoamerican history, society, and religion. The Olmec carved smaller objects in the form of supernatural beings in jade and greenstone. One example is the werejaguar, a supernatural figure marked by its almond-shaped eyes, upturned lip, pug nose, and cleft head. The features of the werejaguar reappear throughout Mesoamerican art.

Other unique artistic developments are found outside the Olmec center. Highly naturalistic male and female figurines were made at Xochipala (in modern-day Guerrero) and Tlatilco (north of Mexico City) and lifelike ceramic baby figures at Las Bocas (in central Mexico). Cave painting also began during the Middle Preclassic Period. One example found at Oxtotitlan depicts a ruler in the guise of a bird deity. While Olmec cultural production was varied, a clear emphasis was placed on rulers and supernatural beings. Despite the dominance of the Olmec for many centuries, the culture eventually collapsed sometime before 100 B.C.E. for reasons still unknown.

The Zapotec culture arose within the Oaxaca valley region during the Late Preclassic Period (400 B.C.E.–150 C.E.). A key Zapotec site, Monte Albán, features impressive examples of monumental architecture and art. Of particular importance is the Temple of the Danzantes, which is named for its numerous incised stone slabs featuring dancing figures. The dancers are male captives who bear physical evidence of their captors' power and brutality; they all have their eyes closed, symbolizing their death, and are stripped nude as a form of humiliation. Each dancer also has a scrolling motif emanating from the genital area as a sign of mutilation. Given the abundance of dancers (numbering at least 300), the Zapotec rulers clearly wished to express their dominance and power, but not all of their art production focused on such issues. The Zapotec also created ceramic and jade objects that demonstrate the influence of the Olmec. Indeed, pieces of Olmec jade have been found at Monte Albán and throughout later sites, providing further evidence of the Olmec's prestige and influence.

An entirely different artistic tradition developed in western Mexico during the Late Preclassic. Unaffected by activities taking place elsewhere in Mesoamerica, the cultures of western Mexico produced a style of ceramics unlike any other. In Colima unique ceramic vessels in the shape of hairless dogs were created. Often wearing human masks, the Colima dogs display an unusually high degree of charm and natu-

ralism. The Nayarit engaged in an entirely different form of ceramics, creating unusual scenes of human figures placed in architectural settings. From ball courts to domestic houses, the Nayarit ceramic scenes provide an unprecedented view of daily life in Mesoamerica. This area is known for their unusual, nonfunctional ceramic art works, which was their primary form of artistic production.

Many important cultural developments of the early Maya also occurred during the Late Preclassic Period—in the highlands of Chiapas, Mexico, and Guatemala; along the Caribbean coast; and in the Petén region of northern Guatemala. The highland sites of Izapa in Chiapas and Kaminaljuyú in what is now Guatemala City produced objects that bear the mark of Olmec influence, but they developed stylistic programs all their own. The importance of stelae as markers of rulers, deities, and events evolved with the development of glyphs and an iconographic, or symbolic, program. Images on early Maya stelae primarily emphasize the mythical and supernatural (such as the water god Chaak, the mythical World Tree, and the bird deity), though ruler stelae do appear at Kaminaljuyú. These stylistic developments set the stage for the Maya to become one of the most sophisticated cultures in the world.

The most important and influential center of civilization in all of ancient Mesoamerica was Teotihuacán. Located in the Valley of Mexico, it became a powerful urban center of commerce and cultural activity during the Early Classic Period (150–650 C.E.). At its height it is estimated that the city's population reached as high as 125,000 inhabitants. Teotihuacanos expanded upon the existing pantheon of Mesoamerican gods to develop a synthesized and complex visual program. This culture produced monumental art and architecture as well as ceramics, ceremonial and burial objects (like censers, adornments, and figurines), and intricate masks. Many monumental stone sculptures were created at Teotihuacán, such as a large depiction of Chalchiuhtlicue (the water goddess, also called the Great Goddess, an important deity in this culture). Not all of the sculpture produced at Teotihuacán was monumental in size. Many extraordinarily detailed figurines in various poses have been found. Also large, brightly colored ceramic urns with human and animal elements were created from mass-produced elements. Numerous beautiful death masks have been found at Teotihuacán, which demonstrate an emphasis on craftsmanship.

Caves and mountains were essential components of Teotihuacán's religion, because it was from these locations that water flowed and life was generated. This concept informed much of the art produced there, particularly with respect to the prevalence of the Great Goddess. The most unusual and striking contributions made by Teotihuacanos to the history of art were their advancements in mural painting. Brightly painted and intricate murals would have decorated the walls of Teotihuacán's buildings. Many of these murals seem instructive, in that they depict processional scenes of figures in profile carrying ceremonial implements like incense bags and maguey spines for bloodletting. The only figures that were de-

picted frontally were gods. The most well-known example of this may be seen in the murals in the Tepantitla apartment complex: The Great Goddess is portrayed amid an abundance of water and plants, which she brings to the people. From her head grow plants and insects. She is flanked by two figures in profile that make offerings to the goddess. Below the Great Goddess flows water from a mountain that carries many small figures with speech scrolls flowing from their mouths, presumably out of happiness. Clearly, the emphasis in this mural is on life and abundance.

ANCIENT SOUTH AMERICA

Social development took place throughout the South American coast and along the Andes mountain ranges, extending from modern-day Venezuela and Colombia south toward the north of Chile. The most significant cultures of the Andean region formed in modern-day Peru. With sharp contrasts in the ecological climates of these areas, from the desert coasts, fertile waters, tropical forests, and mountainous highlands, it is perhaps not surprising that much of these cultures' artistic output is marked and shaped by contact made between the irrigational coastal groups and the migrant and farming peoples of the highlands. Despite the diverse influences from the natural landscape, much of ancient Andean art centers on issues of universality, duality, the supernatural realm, or human life.

Evidence of textiles in South America dates back to the Lithic Period (10,000–3000 B.C.E.). Although these first textiles did not yet feature patterns or artistic elements, they provide us with the longest continuous historical record of textiles ever found. Along with new technical developments in textile arts, in the Preceramic Period (3000–1800 B.C.E.) the important concepts of duality, multiplicity, and transformation began to be incorporated into textiles. At the coastal Andean site of Huaca Prieta, in the Chicama Valley, the development of such fiber arts may be traced. More than 9,000 twined cotton scraps have been found there, featuring complex images and polychrome patterns. Specifically, they depict strange and fantastical images, such as double-headed birds and crabs with legs turning into snakes. Images that embody transformation and duality are central to all later Andean arts. Jewelry, feather work, mirrors, and female effigy figures also have been discovered at Preceramic Period sites.

As society grew, so did a more sedentary, agricultural lifestyle. This led to the beginnings of monumental sculpture and wall murals during the Initial Period (1800–800 B.C.E.). At the site of Moxeke in the Casma Valley, near Peru's northwest coast, colorfully painted, monumental adobe sculptures were created in association with the site's main pyramid. Once placed along the structure's platforms, there are now only several remaining fragments, including two severed torsos and one decapitated head. Painted in blue, white, and pink with heavy, black incised lines, the figures are heavily modeled. Although their identities are unknown, the figures suggest the grisly power of the Moxeke rulers.

The largest ceremonial site in all of the Americas was Sechín Alto (1800–900 B.C.E.), also in the Casma Valley. As this coastal site was near Moxeke, the art and architecture had much in common with this earlier culture, including the depiction of gruesome acts of decapitation and dismemberment. The central focus of Sechín is the walled temple complex called Cerro Sechín or Sechín Hill. The wall comprises more than 300 large granite monoliths incised with images that make up a long procession of warriors and victims. Alternating images of decapitated heads, dismembered bodies, abstract spinal columns, and victorious warriors all move toward the north entrance of the complex. The images are composed of deeply beveled (cut at a slant) lines to create the outline of the body, while the smaller interior details are created with shallow incisions. The victims are indicated by their contorted mouths, closed eyes, and unkempt hair, which all indicate their deaths and humiliation. While it is unknown if this procession represents a historical event or mythological story, the important use of art as political propaganda is evident. Like the Moxeke adobe sculptures, these monoliths suggest the awesome power of the Sechín elites and signal the arrival of conflict and conquest in Andean society.

The first major artistic development of ancient South America was the Chavín style, which emerged during the Late Initial/Early Chavín Period (900–500 B.C.E.). The Chavín arose in the north of Peru, where they united and synthesized the developments of earlier cultures into their own unique style. Chavín artistic production included monumental sculpture, ceremonial objects, textiles, gold work, and various types of portable art. All monumental stone Chavín art was done in relief carving. Major Chavín monuments focus on uniting the natural elements and on duality in relation to the totality of the universe, a central concept of Andean thought. This style is characterized by complex, obscure images that allow the viewer to perceive alternate realities. Often described as hallucinatory, artworks of this period often feature transforming deities, animals, and shamans.

The Chavín Period is most often discussed in two phases; the Early Chavín is marked by the development of the Chavín de Huántar site and the construction of the Old Temple. Chavín de Huántar probably functioned as a sacred oracle and ceremonial center where priests would consult and perform rituals. Most of the religious cult activities took place in the Old Temple, with ceremonies performed by and for the elite class and not for society at large. The specificity of place, function, and audience greatly affected the design of their art. This is readily seen in one of the key artworks from the Early Chavín period—the Lanzón or Great Lance.

The Lanzón, named for its blade shape, is a monolithic stone sculpture that featured prominently within the Old Temple's sunken court. The Lanzón originally was placed within a cruciform-shaped gallery inside the center of the temple. The gallery's shape represented the four cardinal directions and therefore marked the location as a world center.

The Lanzón acted like a supernatural channel, in that it was placed in the center of this space rooted in both the ground and the ceiling. The Great Lance is a misnomer, as the shape actually refers to digging sticks used in the highlands for farming and not to a blade. The shape of the work suggests that the Lanzón refers in some way to plentiful crops and the survival of the people. The supernatural deity stands with the right arm up and left arm down, as a sign of uniting the heavenly and the earthly. In typical Chavín style, the Lanzón is incised with round eyes, flat nose, upturned mouth with large fangs, and clawed feet. The entire deity is covered with small repeating elements that perform dual functions and may be read in two ways, thus challenging the viewer's perception. This technique of using one set of lines to create two images is called contour rivalry. For example, on the deity's belt, fanged mouth bands with eyes may be interpreted as faces in either direction.

The second phase of Chavín art, known as the Early Horizon/Late Chavín Period (500–200 B.C.E.), focused on the New Temple addition in Chavín de Huántar. Monumental stone works centering on themes of transformation and fertility continued to be produced and become more synthesized, as is exemplified by the Raimondi Stela. This monumental work carved in diorite presents a complex dual image using contour rivalry. When looking at the stela in the upright position, the viewer sees a standing agricultural deity known as the Staff God. The deity displays eyes with pendant irises, a fanged mouth, and clawed feet. In either hand, the figure holds two staffs composed of snakes, faces, and vegetation. From the deity's head grows an enormous headdress. Yet when the stela is inverted, the viewer is confronted with an entirely different image. The headdress now forms a series of supernatural animal faces growing out of one another and charging down toward the earth. This stela exemplifies the Chavín culture's extraordinary facility for expressing the concept of duality.

Portable art also made up a large portion of Late Chavín artistic output. Ceramics, cut shells, textiles, gold work, obsidian, drug paraphernalia, and weaving tools have been found in association with the site of Chavín de Huántar. Of particular note is the use of gold to create wearable art, such as pectorals (breast coverings), crowns, masks, or appliqués.

During the period from 200 B.C.E. to 600 C.E. South American art continued to evolve among the Paracas, Nazca, and Moche peoples. In what is now Peru's Ica region, located along the southern coast of the central Andes, the Paracas peoples developed some of the most sophisticated, unique aesthetic systems to date. They became nearly obsessed with the detailed process of creating their works, mostly in ceramics, textiles, and gold. Thanks to the arid, desert climate in which the Paracas lived, many examples of their work have been preserved. Paracas art demonstrates an avid interest in color, repetition, curvilinear forms, and geometric patterns and often features animals and colors indicative of the region. This obsession with process and detail became one of the key

characteristics of later Andean art, particularly among the Inca. The primary deity featured in both Paracas and Nazca art is a monkey-like figure with round eyes and a grin on his face. This deity is often engaged in the act of head-hunting, an essential component of Andean culture. It was believed that the act of decapitation allowed the captor to retain any power or energy the captive possessed. The victim's power could then be added to that of the aggressor.

The people living near the Nazca River, southeast of Ica, also made textiles and ceramics of extraordinary quality. But the Nazca are perhaps best known for their enormous earth drawings or "geoglyphs." Utilizing geometric principles and simple survey techniques, the Nazca created their lines by moving the darker top layer of earth away to reveal the lighter layer underneath. These large-scale drawings found in the desert most often depict abstract images of birds, animals, anthropomorphic (humanlike) figures, plants, and geometric designs, which may be seen in their entirety only from an aerial perspective. Many of these same designs are echoed in the painted ceramics of the Nazca. While the geoglyphs have long puzzled archaeologists and art historians, they probably served a ritual purpose, one that reinforced the Nazca's relationship to their unique landscape. Many theories on the meaning of the Nazca lines have been formulated, from astronomical associations to indications of water sources, but it is clear that the lines were intended to be viewed solely from the celestial realm.

Moche is a term used to describe the culture, people, and kingdom that developed along Peru's northern coast at this time. The Moche peoples are now best known for their ceramics, but they also created textiles and engaged in metallurgy. Their ceramic output consists primarily of portrait heads of rulers as well as ancestor figures and supernatural animal-headed deities. Moche ceramics are all stylized, though they are rendered in a naturalistic, three-dimensional style. They are typically limited to a color palette of cream and red. While their ceramics do portray supernatural beings, the Moche mostly were concerned with the human world, a unique characteristic of this culture.

► astronomy

INTRODUCTION

Astronomy was probably the first science that ancient peoples pursued. They looked heavenward and recognized that the objects they saw in the sky seemed to move with great regularity. The sun rose each morning and set each evening, and the moon appeared in predictable patterns. They also noticed that stars seemed to form groups that had particular shapes, such as the Big Dipper. From these observations, they tried to infer the cosmology (the branch of thought that deals with the origins of the universe) they lived in.

In time, ancient peoples began to understand that they could use this regularity for their own purposes. They noticed, for example, that they could predict the shortest day of the year, knowing then that the days would become longer, and lengthening days signaled the start of the growing season. They could use this information to predict, for example, when rainy and dry seasons would arrive. Since prehistoric people attributed natural phenomena to the will of the gods, they came to attach their astronomical observations to religious beliefs. Thus, the harvest at the end of the growing season, when the sun was lower in the sky, was as much a religious event as it was an agricultural one. Similarly, a momentous event such as an eclipse, the appearance of a comet, or the appearance of a supernova (making a star visible for the first time) was believed to be the manifestation of will of the gods. Such events could create great fear among people.

Astronomy served a number of purposes other than just to mark the passage of time or tell farmers when to plant. Kings and other rulers encouraged astronomers to study the regularity of the heavens. In this way they could predict events, demonstrate their divine knowledge, and retain their power. In this vein, horoscopes and zodiacs enabled shamans, priests, and others to "predict" events based on the movements of the stars, similarly giving them authority and power while at the same time making life a little less uncertain for people.

Astronomy and architecture were also strongly connected. Architects used astronomy to site the foundations of buildings, and in turn buildings, because of their orientation to the sun, moon, star constellations, the points of the equinoxes and solstices, and the like, could be used as astronomical observatories. They could also function as calendars by marking, for example, the summer solstice or the autumn equinox. It is believed that many ancient stelae, or upright

stone slabs or pillars, were also used for astronomical purposes. Modern archaeologists are often amazed at the precision with which ancient builders sited their buildings; the four sides of the Great Pyramid at Giza (Egypt), for example, are oriented precisely north, south, east, and west.

Early astronomy was not an exact science, primarily because trigonometry had not yet been discovered. The ancient Greeks developed trigonometry, which deals with the relationships between angles and distances. Only then were early astronomers able to make increasingly accurate observations of the stars and predictions of their movements. In time, early astronomers began to compile star catalogues, mapping the heavens in the same way they tried to map the earth.

AFRICA

BY TOM STREISSGUTH

The astronomical lore and knowledge of ancient Africa are still largely a mystery to archaeologists. Several sites of astronomical significance have been excavated, but their true purpose is still unknown. With no written records to consult, historians must carefully examine each site—with its alignments of standing stones and markings—and speculate on how these “observatories” may have been used.

In ancient Africa the brightest objects of the night sky were important for the purposes of navigation and time-keeping. These objects include the moon, the Milky Way, the constellation Orion, the planet Venus, the stars Sirius and Canopus, and the star cluster known as the Pleiades. Observation of the sky may have also served more utilitarian purposes. On the frontier between the Congo and Uganda, a lunar calendar dating to 6500 B.C.E. has been found in the form of the Ishango bone. The bone has a series of notches carved into it that kept track of the 28-day cycle of the moon’s phases. The Batammaliba people in Togo and Benin built their houses so that they were aligned with the course of the sun at the equinoxes—the days of spring and fall when the lengths of day and night are equal. In the kingdom of Kush, established in about 1000 B.C.E., pyramids raised near the capital of Meroë have their fronts facing the eastern rising of Sirius, a star that was also important to the astronomers of ancient Egypt.

Observatories in the form of stone megaliths (groups of enormous stones that form a structure) arranged to indicate the positions of the stars and other bright objects have been discovered in Zimbabwe, Togo, Kenya, Sudan, and Benin. The oldest such site in Africa lies in the Nabta Basin of southern Egypt. Here stone megaliths weighing up to one and a half tons were raised in a circle 12 feet in diameter. Archaeologists have dated the circle to the fifth millennium B.C.E., a date that makes it the world’s oldest astronomical observatory.

Nabta was once the site of a shallow lake and a settlement of herders who migrated through the region when it was much more temperate and fertile than it is now. On the western edge of the settlement, the inhabitants shaped and

raised the large stones, aligning two groups of stones along a north-south axis while pointing another to the rising of the sun at the summer solstice, the day on which the sun reached its northernmost point in the sky. In this arid region the solstice signified the return of annual rains and the life-giving flooding of the Nile River.

A similar group of stones known as the Namoratunga II circle was found in a remote region of northwestern Kenya. This arrangement of 19 basalt stones was used as a calendar by the Borana, a people of northern Kenya and southern Ethiopia who reckoned their days and months using seven prominent stars and their positions relative to the moon. At Great Zimbabwe, a city raised by the Karanga people, a series of pillars and other structures are enclosed within a thick, high wall. Patterns in the wall indicate the position of the sun at the solstices.

A vast system of more than 1,000 stone circles and monuments also exists in Gambia and Senegal, covering an area of 15,000 square miles. Each circle has as many as 24 stones, reaching up to seven feet in height. Archaeologists date the circles to as early as the fifth century C.E. and believe them to be burial sites. However, the careful alignment of the stones also suggests that they may have been used as astronomical observatories. Another mysterious set of more than 70 standing stones was excavated in the 1960s near Bouar, a town of the Central African Republic. These stones were raised around 500 B.C.E., according to radiocarbon dating of artifacts found nearby.

With scarce physical evidence, historians must also draw on contemporary traditions for clues to the astronomical knowledge of ancient Africa. Along the coasts of Africa, sailors and fisherman orient themselves using prominent stars, such as Sirius and the Orion constellation. The Bozo people of Mali carefully observe the Pleiades star cluster and time the season of fishing in the Niger River when the Pleiades disappear from the night sky.

Another people of Mali, the Dogon, have developed remarkable insight into Sirius, the brightest star of the sky. In Dogon lore Sirius has a companion star, known as *po tolo*, which is associated with a small white grain known as *fonio*. This companion star is small, white, and very dense, with a mass that holds all other stars of the sky in their place. *Po tolo* circles Sirius every 50 years, and the Dogon hold a regular ceremony to celebrate this event. In fact, the nature of Sirius as a binary star with a dense, “white dwarf” companion known as Sirius B, which is invisible to the naked eye, was not established by modern astronomers until the 20th century and the era of the modern telescope.

EGYPT

BY LEO DEPUYDT

The term *astronomy* implies a level of complexity that Egyptian astronomy does not exhibit. Because Egyptian astronomy was relatively unsophisticated, the designation

Inner coffin of the priest Hornedjitef, Thebes, Egypt (third century B.C.E.); the coffin lid interior is decorated with figures relating to astronomy. (© The Trustees of the British Museum)

systematic observations of the sky might be more suitable than *astronomy*. Then again, astronomy has a historical dimension. Before it became complex, it had to be simple. A full appreciation of astronomy involves a proper understanding of where the subject was at every stage of its evolution, even in its small beginnings.

One reason that Egyptian astronomy could not have been truly scientific is that trigonometry had not yet been discovered. The Greek astronomer Hipparchus discovered it in the second century B.C.E. Trigonometry relates angle and distance to each other. In observing the sky, one cannot measure the distance between the zenith (the point in the sky right above us) and a point on the horizon or between a point on the horizon and a certain star. In trigonometry it is not the distances themselves that matter but the relation between distances and angles. The numbers of trigonometry are mostly irrational, meaning that they cannot be expressed in fractions featuring whole numbers. Without such irrational numbers, a true scientific astronomy is impossible. Nowhere in hieroglyphic writing is there a trace of irrational numbers.

Ancient Egyptian texts and images are replete with references to the night sky and what happens there. Strictly speaking, these texts and images are not astronomical. Still, they, too, contribute to our understanding of how Egyptians viewed the night sky. They were understandably fascinated by the disks of light and the twinkling dots, even if they did not understand their true nature. As a result, they interpreted the movements in the sky in terms of tales populated by divine characters. Among the earliest such interpretations are the texts inscribed on the walls of the inner rooms of the pyramids dating to the third millennium B.C.E. It is no longer possible to reconstruct fully what these authors saw and why they saw it in the star sky, just as it is not clear why someone sees a certain shape in a certain cloud. This may account for the frustrating incomprehensibility of much of the so-called Pyramid texts, a collection of ancient Egyptian religious texts. A remarkable section in the Pyramid texts is the Cannibal hymn. The contents of this hymn are unique in Egyptian literature. There is mention of slaughtering firstborn children, slitting throats, eating organs, cooking body parts, using victims for kindling, and lighting fires with thighs. On the surface, there is no way of interpreting its contents charitably, yet the hymn may be nothing more than a description of how the sun dims the light of the stars—that is, eats the stars, so to speak—when it rises in the morning. In fact, much of the texts found in pyramids appear to concern an effort to interpret the movements of the stars.

The best represented type of early-period astronomical text is the so-called star clock. Star clocks, of two main types, are found in tombs. The first type appears on the insides of coffin lids dating to about 2100–1900 B.C.E. In this type, the year is subdivided into 36 intervals of 10 days, for a total of 360 days. Twelve stars are listed for every 10-day period, one each for every hour of the night. The second type of star clock

is found on the walls of subterranean rock tombs dating to the 12th century B.C.E. In this type, the year is subdivided into 24 intervals of 15 days, also for a total of 360 days. Thirteen stars are listed for every 15-day period, one for each of the 12 hours of the night plus an additional star for what is called the night's "beginning."

The first type of star clock may be called "diagonal," because stars shift exactly one position every 10 days in the table of columns and lines every 10 days. The second type is then "broken-diagonal." This type is not laid out in tables, but if one reconstructs the tables, the stars shift, on average, more than one position for every 15-day period. Star clocks, found only in tombs, have been interpreted both as calendars and as clocks, but they may well be neither. It was customary to adorn tombs with representations of what life had been like on the earth, and therefore star clocks probably do not do more than evoke the changing positions of the stars over the course of a year. They served for the deceased as a recollection of what life had been like on the earth and of what it might again be like in the afterlife.

At a later period, from about 500 B.C.E. onward, Egyptian astronomy began to exhibit the influence of Babylonian and Greek astronomy. Horoscopes and zodiacs were imported from Mesopotamia from about 100 B.C.E. onward. Among astronomical texts dating to this time is the papyrus Carlsberg 9, kept in Copenhagen. The text is written in Demotic, which is a stage in the development of the Egyptian language. Carlsberg 9 has often been called the only Egyptian mathematical-astronomical text, but the sole and simple aim of the numbers in the text seems to be to distribute 145 lunar months of 29 days and 164 lunar months of 30 days (which total 9,125 days) over 25 Egyptian years of 365 days (which also total 9,125 days) in a certain optimal pattern of alternation of 29-day and 30-day months.

It is a matter of controversy whether the Egyptian star names can be successfully matched with modern stars. Some believe they can. Others, including the present writer, believe they cannot. But everyone agrees that the star named *sopdet* in ancient Egypt refers to Sirius.

THE MIDDLE EAST

BY DAVID BROWN

Clay seals dating to the fourth millennium B.C.E. in Mesopotamia depict stars with gods. The Sumerians identified major deities of their pantheon with the brightest heavenly bodies. For example, Utu was the sun god, Nanna the moon god, and Inana the planet Venus. The cuneiform script preserves the close connection between gods and asterisms (stars or planets). The sign for "asterism" in cuneiform script consists of three *dingir* signs, where *dingir* means "god" or "divinity." The *dingir* sign itself, meanwhile, depicts a star.

In later classical Sumerian literature Jupiter and Mars are identified with the gods Šulpae and Nergal. By about 1700 B.C.E. the Mesopotamians had identified the five planets now

known as Mercury, Venus, Mars, Jupiter, and Saturn. In both the Sumerian and the Akkadian languages the term for these bodies means "wild sheep asterism," rather picturesquely designating the planets' "wandering" nature against the background stars.

The Mesopotamians did not merely identify asterisms with major gods but also treated them as agents of those gods. They believed that the behavior of the stars carried messages the gods wished to impart to humankind, and the decoding of these messages developed into an elaborate art of "astral divination." In other contexts some stars or groups of stars were thought to rain down direct influence and imbue substances or situations with special potency. This concept, too, formed an important part of the intellectual endeavor of some Mesopotamians, and we identify it as "astral magic."

Cuneiform tablet with observations of Venus, neo-Assyrian, seventh century B.C.E., Nineveh, northern Iraq (© The Trustees of the British Museum)

Astral divination involved encoding the phenomena of the heavens into omens and associating them with events on earth. Thus, eclipses were thought to signify that the king might die if appropriate magical countermeasures were not invoked. Omens of this sort are also known from about 1700 B.C.E. Given that signs in the heavens are visible to all, it is not surprising that they were thought to offer comments on the king, the land, or the state, and not on private individuals. Not until the configurations of the heavens at the moment of any individual's birth could be determined was it possible for astral divination to enter the private domain to any great extent.

From the Old Babylonian Period (2000–1600 B.C.E.) to around 700 B.C.E. no surviving sources can be classified as “astronomical,” if by this term we mean the prediction or calculation of celestial configurations at a given moment. There are, however, compositions in cuneiform that elaborate numerically on certain idealizations as to the movement of the heavens. Most famously, one of the 70 tablets of the celestial omen series known by its opening words as *Enūma Anu Ellil* (“When the gods Anu and Ellil . . .”) is devoted exclusively to the lengths of time for which the moon and sun are visible throughout the year. Nevertheless, the lengths of time are derived from assumptions as to the ideal length of the month (30 days) and of the year (360 days), the ratio of the longest to the shortest day (2:1, where the reality is closer to 3:2), and so forth. This tablet (number 14) represents a very poor model of the actual behavior of the heavens, but despite appearances its purpose was astrological, not astronomical—hence its place in the great omen series. It provided a set of ideal times against which the real behavior of the heavens could be compared and interpreted. In short, if observed reality cohered with the ideal, that boded well; otherwise, it boded ill. Compositions such as *Enūma Elishl*, the creation epic of the cult of the main god of Babylon, Marduk, further show that the ideals employed in celestial divination were those ascribed to the universe as it was believed to have been when the gods first formed it.

By around 700 B.C.E. astral divination had become a large industry, with expert scholars employed directly by the Assyrian kings and the great Marduk temple of Babylon taking detailed records of successive ominous phenomena. We are well informed about this period because large numbers of the scholars' letters to their kings were discovered in the ruins of Nineveh. It has been suggested that competition among scholars for royal favor led them to attempt to *predict* forthcoming celestial configurations ominous to the king. They did so by studying the long records of dated ominous configurations, such as eclipses or the heliacal rising (the first appearance in the east directly before sunrise) of the planets, and eliciting the intervals at which such configurations recur. There is no reason to assume that astronomy came about because of a desire to regulate the calendar or for intellectual interest, as has often been assumed in the past.

Relatively rapidly the Assyrian investigators discovered a characteristic interval between eclipses of the same type,

amounting to 223 months exactly, or 6,585 days and about 8½ hours, on average. There is some evidence of attempts to model the variation of the interval about that mean as early as the eighth century B.C.E. In the seventh century B.C.E. scholars identified intervals, expressed in years, at which the planets exhibit the same phase (such as opposition or heliacal rising) in more or less the same place on the ecliptic. For example, they found that Jupiter is in the same phase at the same place in the sky every 71 years. They also discovered the means by which the length of the month, very ominous to the Mesopotamians, could be determined. The methods derived depended on summing the intervals between sunrise and moonrise and sunset and moonset recorded some 18 or 18½ years earlier. It was only very recently that the rationale behind these methods became clear to modern scholars and revealed that the ancients must have carefully scrutinized their records of such lunisolar intervals in order to extract these periodicities. Truly, bookwork lies behind the world's oldest astronomy.

If astronomy was invented to service royal astral divination, the democratization of deriving interpretations from the sky led to its first and greatest transformation. Babylon had become the home of astral science with the demise of Assyria around 612 B.C.E., but with the arrival of the Persians in 539 B.C.E. it ceased to be a capital. It appears that the scholars who had been making astronomical predictions for their kings turned to the private market. Where celestial divination derived interpretations from visible phenomena, private astrological predictions were based on the calculated locations of all the planets, be they above or below the horizon, at a given moment (usually the moment of the subject's birth). The zodiac was probably invented around 500 B.C.E. as a way to provide a framework for those calculated locations, and it is to this time that we should date the earliest private birth astrology, though the earliest known actual birth chart or “proto-horoscope” dates to 410 B.C.E.

Calculating planetary locations at a given moment represented a new challenge for the Babylonian astronomers, one they met by interpolating between locations of the phases, determined from the database of observations and characteristic periods. In due course they derived means to calculate planetary locations and the details of eclipses without constant recourse to the database of observations. These database-independent methods constitute the high point of cuneiform astronomy and are found in tablets unearthed in Babylon and Uruk. They reached their most advanced state around 200 B.C.E. after centuries of evolution. Thereafter, these wonderful methods reappear along with zodiacal astrology in the Egyptian, Greco-Latin, Iranian, and Indian worlds.

ASIA AND THE PACIFIC

BY MICHAEL ALLEN HOLMES

Most of the advances in the scientific study of the heavens in ancient eastern Asia were achieved by the people of China, where astronomical truths were sought largely to refine the

understanding of astrology. Kings, in fact, restricted such study to scholars under royal employment, in hopes of maintaining a sure hold on power that was often secured through accurate predictions. Into medieval times ordinary citizens were punished for possessing or using objects associated with the measurement of celestial bodies or with divination based on such measurements. The importance ascribed to the study of astronomy is reflected in the fact that the Chinese recorded a number of observations before either the Greeks or the Babylonians.

In general, the ancient Chinese classified astronomical events into two categories: predictable and unpredictable. Predictable events included the shifting of the phases of the moon and the rotation of the constellations around the North Star. Unpredictable events of particular note included the wandering of the planets (whose orbits were long undetermined in geometric terms), the appearance of comets, and instances of sunspots, which were especially observable when dust storms in northern China screened the sun's glare. A great deal of attention was paid to these unpredictable events, which wise men, particularly those in the service of rulers, interpreted in order to extract cosmic meaning.

Knowledge regarding predictable events, then, was valued largely for its providing the frame of reference against which unpredictable events occurred. The origins of an imperial almanac, which served as a register of these predictable events, are so ancient as to be obscure. The almanac delineated the annual astronomical cycle, including the lengths of the months (which were based on the phases of the moon and thus varied from year to year) and the dates of the equinoxes (the two times of the year at which the sun crosses the equator and day and night are of relatively equal length) and solstices (the times of year when the sun is at the greatest distance from the equator and the day is either at its shortest or at its longest, depending on the season). The year began at the winter solstice, when the yang force—a Chinese conception associated with warmth, among other qualities—was at its nadir. Since the winter solstice often proved to be a cloudy day, its date was calculated based on that of the summer solstice, which was determined through the measurement of the shadow of an 8-foot stone pillar. The length of the year was estimated to be 366 days until the fourth century B.C.E., when the figure was revised to 365¼ days; further corrections were made continually thereafter.

According to legend, basic star charts were first compiled sometime before 1000 B.C.E. by a shaman named Xian, who identified the Big Dipper, among other constellations. The revolution and rotation of the Big Dipper around the North Star, rather than the movement of the sun, provided the basis for many Chinese astronomical computations. Records still exist of the star charts compiled in the fourth century B.C.E. by the early astronomical observers Shi Shen and Gan De—whereas charts compiled by Timocharis (ca. 320–260 B.C.E.), of Greece, have never been found. Much later, in the fifth century C.E., Qian Lezhi incorporated the findings of his

Covered jar, from the second to first century B.C.E., China; the scene is of a blue beast (the star Sirius) with bared fangs lunging at a mounted archer (the adjoining constellation, Bow). (Copyright the Metropolitan Museum of Art)

three regional predecessors into a single chart, coding their findings with the colors white, red, and black.

Comets, eclipses, and supernovae (explosions of stars) were seen as especially momentous astronomical occurrences. Records of comets are more extensive in China than in anywhere else in the ancient world, and these records provided the original basis for determining the orbit of Halley's comet, which was sighted in China first, in 240 B.C.E. Records of eclipses extend back even further in time, as inscriptions were found on oracle bones—animal bones that were used for divination—dating back to the Shang Dynasty, which ended around 1045 B.C.E. Thus, Chinese records predate Babylonian ones by some seven centuries. Starting in the third century B.C.E. eclipses were carefully registered. Supernovae, which are stellar explosions that can make distant stars visible to the naked eye for the first time, were referred to as inexplicable *new stars* or *stranger stars*.

The Chinese made a number of advances in the design of astronomical equipment. The Han Dynasty, which lasted from the second century B.C.E. to the second century C.E., witnessed the invention of a star-mapping tool called the *armillary sphere*, a fixed set of rings demarcating the sectors of the sky. The ring representing the skyward extension of the

equator, dubbed the *Gauge of the Red Road*, was particularly important, as it allowed for increased accuracy in the measurement of the paths of the sun and moon; the astronomer Geng Shouchang, who lived during the first century B.C.E., is credited with the invention of the equatorial ring. In the first century C.E. an even more important ring was added: one denoting the ecliptic, or the path taken by the earth around the sun, allowing for even greater accuracy in measurement taking and prediction making, especially with regard to eclipses; this ring was dubbed the *Gauge of the Yellow Road*. Overall, Chinese astronomical predictions never equaled those of the Greeks, whose geometry was more refined.

One of the most renowned Chinese astronomers was Zhang Heng, who lived in the second century C.E. and was also a poet. He is widely credited with the invention of the first comprehensively functional armillary sphere, featuring rings representing the equator and the ecliptic as well as a meridian, circling the earth over the poles, and a horizon. The accuracy of this sphere, which was a yard in diameter and was dubbed the *Gauge of the Enveloping Sky*, allowed a fourth-century astronomer named Yu Xi to discover the fact that the equinoxes occurred some 20 minutes earlier every year, a process called the *precession of the equinoxes*. (This process was actually first discovered by the Greek Hipparchus around 120 B.C.E.) Zhang Heng is also presumed to have built the first orrery, a smaller armillary sphere combined with representations of other bodies in the solar system, all of which moved in accordance with reality using water power. This smaller sphere was a prototype for modern clockwork.

Advances in astronomy were also achieved in ancient India, though on a less definitive scale. One known fact is that during the rule of the Guptas, in the fourth and fifth centuries C.E., the number of days in the year was calculated with accuracy exceeding that attained by the Greeks. Otherwise, generally speaking, scientific knowledge was recorded in such elaborate Sanskrit that the sharing—and further developing—of that knowledge was somewhat hindered. Other Asian and Pacific cultures, including those in Japan, Korea, Southeast Asia, and Australia, are known to have amassed knowledge of the stars, particularly of the appearances of constellations, over the millennia. However, little concrete evidence exists to demonstrate how far back into ancient times this knowledge existed.

EUROPE

BY STEPHEN M. FABIAN

Hesiod, a Greek poet-farmer of the seventh century B.C.E., provides a calendar that weds productive human activity to astronomical observations. “At the time when the Pleiades, the daughters of Atlas, are rising,” he says, “begin your harvest, and plow again when they are setting. The Pleiades are hidden for forty nights and forty days.” Recorded two centuries after he lived, Hesiod’s *Works and Days* combines astronomy with mythology, religion, the cycles of flora and

fauna, farming and sailing, and the celebration of holidays, indicative of astronomy’s integration into ancient cultures. But Hesiod’s ability to use accurate observations of celestial events, such as the heliacal rising of the Pleiades (their first appearance near sunrise after a period of invisibility due to proximity to the sun), and their timing with important tasks must be the result of years—even generations—of careful sky watching. This and other evidence suggest a long prehistoric European tradition of systematic astronomical observations that were the basis for successfully coordinating and synchronizing human activity with the perceived natural and cosmic cycles engendering life, power, and fecundity.

The roots of European astronomy run deep. The archaeologist Alexander Marshack interprets the crescent-shaped and circular carvings on an eagle’s wingbone from the Dordogne Valley, France (ca. 30,000 B.C.E.), as tallies recording the synodic—or lunar phase—cycle. While Marshack’s interpretations remain the subject of controversy, researchers have found precise astronomical alignments among many of the hundreds of megalithic (“large stone”) constructions—including mounds and passage tombs, single standing stones (menhirs), and stones in rows, circles, and other geometric patterns—of Neolithic peoples from the Mediterranean to Ireland and the North Sea built between 4500 and 2000 B.C.E.

The Scottish engineer Alexander Thom visited and made measurements at many of these sites in the middle decades of the 20th century. His main postulates include a standard megalithic unit of measure (for example, the “megalithic yard”), and he theorizes that this unit of measure allowed for the precise layout of features (such as Pythagorean triangles), that these features often incorporated astronomical alignments to the rising and setting positions of important celestial bodies, and that such layouts functioned to mark off important events and periods of time which included a standardized megalithic year and even allowed for eclipse prediction. Scholars continue to debate Thom’s specific claims, but his work and that of others make it indisputable that astronomy was significant to life in ancient Europe.

The oldest reliably dated megalithic site with a precise astronomical alignment is that of Dissignac in Brittany, France (4500 B.C.E.). Its main feature is a mound with two passage tombs, one of which is oriented so that the rising December solstice sun shines directly down the 7-meter passage to illuminate the rectangular burial chamber. Another important passage tomb is the mound and site of Newgrange (ca. 3000 B.C.E.) in Ireland. There the light of the rising December solstice sun penetrates approximately 20 meters to the burial chamber via its main passage and a “roof box” feature above it. The mound at Newgrange also is surrounded by rings of stones, many of which are engraved, and some scholars interpret astronomical relevance in the iconographic (symbolic) features of these stones, their placement, and the effects of their shadows, such as the shadow cast on the December solstice from a stone of one ring onto a three-leaved spiral design of another stone directly at the tomb’s entrance.

Some Neolithic Europeans seem to have been particularly interested in marking the extreme positions of the moon. At Callanish, in the Outer Hebrides of Scotland (third millennium B.C.E.), for example, a burial mound is ringed by a stone circle from which emanate apparent avenues to east, south, and west as well as to the north-northeast. This last avenue, in its southerly direction, is oriented to the moon's southernmost setting point (major standstill), a point to which it would return only once every 18.6 years. Thom identified the site as a "lunar observatory" based on his measurements there, and the site's lunar significance is enhanced through its association by the archaeologist Aubrey Burl with a description made by Diodorus of Sicily (first century B.C.E.) of a circular temple said to be dedicated to the moon and its divine visitation every 19 years.

Site location and orientation are no more important than at Crucuno (probably built around 3000 B.C.E.), a site in Brittany that is a rectangle of stones with sides oriented exactly to the cardinal directions with lengths of precisely 30 and 40 megalithic yards and therefore a diagonal of 50, the classic Pythagorean dimensions. The diagonals themselves align precisely to the rising and setting of the December and June solstice suns, a phenomenon possible in the Northern Hemisphere only at this latitude (47.5°N). Crucuno's stunning combination of astronomical alignments with cardinal orientation as well as its ideal geometric and numeric proportions is a strong case for ancient European sophistication in coordinating cosmic features into the cultural landscape.

The most famous megalithic site of Europe associated with astronomy is Stonehenge on England's Salisbury Plain, whose numerous features represent several major building phases between approximately 3000 and 1500 B.C.E. Stonehenge has been called an astronomical observatory and is associated with a computational device for predicting eclipses, but many claims are disputed. Its least controversial alignment is that of the main avenue in conjunction with its trilithon (two large vertical stones supporting a horizontal stone) and bluestone horseshoes, past the Heelstone, to the June solstice sunrise. The astronomer Gerald Hawkins suggests that the site's circle of 56 Aubrey holes (a ring of debris- and chalk-filled pits that encircles the stone monument portion of Stonehenge and is associated with the site's earliest building phase) functioned in an elaborate tally system for predicting eclipses, but there is little corroborating evidence to support this computational scheme.

Still, the interest of ancient Europeans in making and utilizing precise and complex astronomical observations should not be underestimated. A recently unearthed and somewhat controversial artifact from Germany known as the Nebra sky disk furthers this association. Dated to approximately 1600 B.C.E., the bronze disk is inlaid with golden symbols that have been interpreted as the sun or full moon, crescent moon, and stars, including the Pleiades. The artifact also is

associated with an enclosure atop a hill known as the Mittelberg ("Central Hill"), which is associated with astronomical observations. Since it was not excavated using proper archaeological methods, the authenticity of the sky disk has been questioned, though microscopic analysis suggests that it is genuinely ancient.

Without the confirming evidence of written records from the era, interpretations of archaeological remains of ancient Europe must remain speculative, but the mounting data indicate that ancient Europeans were interested in and skilled at observing the sun (especially solstices and equinoxes), moon (including its standstill positions), and prominent stars (notably for their heliacal rise). Even in the absence of writing—as Hesiod's orally transmitted poetry reveals—astronomical observations are recorded in hand-worked devices, such as the Nebra disk, and alignments of cultural features to orient people in time and space, to organize their productive and ritual activities, and to integrate and synchronize them within the flow of natural and cosmic forces.

GREECE

BY TOM STREISSGUTH

The mythology of gods and heroes accounted for what the ancient Greeks observed in the heavens until the advent of geometry. The Greek astronomers replaced the ancient legends with a system of mathematical logic created not by remote gods but by philosophers. In this way the natural world, including the sun, moon, and the mysterious lights of the night sky, could be understood as a consistent, harmonious system rather than as arbitrary chaos or the whim of a deity.

The earliest Greek astronomer of renown was Thales of Miletus (ca. 625–ca. 547 B.C.E.), who lived in a colony of Ionia on the eastern shores of the Aegean Sea. According to tradition, Thales predicted a solar eclipse of May 28, 585 B.C.E., and, in this way, helped the warring Medes and Lydians reach a cease-fire. He used a mathematical system of predicting eclipses from Babylonia, which relied on the saros (eclipse) cycle of every 18.6 years.

While written records and observations of Babylonia formed an important foundation for Greek astronomy, the Greeks went further to create more complex blueprints for the structure of the universe. Anaximander of Miletus (ca. 610–ca. 545 B.C.E.) held the sun as the highest and farthest body in the heavens, followed by the moon, the stars in their fixed positions, and the planets. Like nearly all the Greek astronomers who followed him, Anaximander was a geocentrist: He believed that the earth lay fixed, at the center of the universe.

Pythagoras, a philosopher of about 500 B.C.E., created concepts and theorems that could be applied universally to observations of the natural world. He recognized that the earth is a sphere—the perfect geometrical shape—and determined that the orbit of the moon was inclined, or tilted,

to the plane of the earth's equator. The Pythagorean sect of southern Italy saw in nature a symmetrical structure, with all things having an underlying unity of form, based on numbers, ratios, and proportions.

Observed nature is not always symmetrical, however, and later Greek thinkers had to account for many strange anomalies. For the astronomer, the most serious was retrograde motion: The earth's orbit relative to that of the planets occasionally makes it appear that the planets are moving in reverse. Eudoxus of Cnidus (ca. 400–ca. 347 B.C.E.) tackled this problem while proposing a geometrical model for the motion of the heavenly bodies. He believed in simple circular motion, as did the Pythagoreans, but added two spheres that were concentric—sharing the same center point—and nested within each other. The planets moved along the edges of these spheres, which rotated in opposite motion. The smaller, planetary sphere was inclined to the larger sphere, which lay on a different axis. This arrangement explained the apparent motion of the planet backward and forward in the sky.

Aristotle (384–322 B.C.E.) refined the system of Eudoxus, proposing that the motion of each of the heavenly spheres has an effect on the others. Aristotle confirmed the belief in a spherical earth by observing that earth's shadow on the moon during lunar eclipses is curved. Of all the Greek philosophers, Aristotle had the strongest influence on medieval astronomers, who imitated his elaborate schema to explain all observable phenomena—including the earth and stars, planets, sun and moon, and the four basic elements of water, air, fire, and earth.

The varying distances of the stars, planets, sun, and moon—shown by their changing brightness—could not be explained by spheres and perfect circular motion. More sophisticated geometric models of the universe were required. Using the Pythagorean theorem and the geometry of Euclid (fl. ca. 300 B.C.E.), Aristarchus (ca. 310–230 B.C.E.) measured the ratio of distances to the moon and sun, showing that the sun was farther from the earth than was the moon. He also proposed a heliocentric, or sun-centered, universe, an idea counter to the prevailing wisdom that placed the earth at the center of the universe. Aristarchus explained the apparently fixed position of the stars as a result of their great distance from the earth. The planets in his system moved around the earth in an eccentric orbit, with the earth located off the orbit's center. This arrangement accounted for the varying speeds and brightness of the planets.

By comparing the length of shadows at two distant locations in Egypt, Eratosthenes (276–194 B.C.E.) of Alexandria came up with a fairly accurate measure of the earth's circumference. He also calculated the distance of the sun and the moon and the 23.5-degree tilt of the earth toward the plane of its orbit around the sun. Apollonius of Perga (ca. 262 B.C.E.–ca. 190 B.C.E.) introduced a theory of epicycles. The planets moved on a circle, or epicycle, whose center moved

about a greater circle known as the deferent. In his book *The Sand Reckoner*, the mathematician Archimedes of Syracuse (287–212 B.C.E.) calculated the diameter of earth's orbit and that of the sun and used this ratio to determine the diameter of the universe.

Hipparchus (ca. 190 B.C.E.–ca. 120 B.C.E.) was an astronomer and mathematician of Nicaea, in Asia Minor. He proposed mathematical theorems for the motion of the sun and moon; created a system of brightness magnitudes for the stars; compiled a star catalogue; built a celestial globe; and discovered precession, the movement of the axis of a rotating body. Hipparchus was the first to divide the circle into 360 degrees, which allows astronomers to map the heavens and geographers the earth. Many consider Hipparchus to be the greatest of all the Greek astronomers, but only one of his books survives. By contrast, Claudius Ptolemaeus (Ptolemy) of Alexandria (ca. 90–ca. 168 C.E.) earned the highest renown of all Greek astronomers. Ptolemy wrote an important work of observations, theories, and calculations known in Greek as *Mathematike Syntaxis* and more familiarly by the Arabic-derived name *Almagest* (The Great Book). This 13-book treatise drew on Greek and Babylonian astronomy as well as observations that Ptolemy himself made over a span of 40 years.

The *Almagest* was first translated into Latin in the 12th century by Gerard of Cremona. The book gives a mathematical theory of the motion of the sun, moon, and planets. The sphere theory propounded by Aristotle was used by Ptolemy as the basis for his description of the epicycles of the spheres. Ptolemy compares observations of the solar equinoxes and solstices with those of Meton and Hipparchus and gives a precise measurement of the length of the seasons. Ptolemy postulated a spherical universe, at the center of which lay the spherical, fixed, and unmoving earth. The planetary spheres contained, in ascending order from the earth, the moon, Mercury, Venus, the sun, Mars, Jupiter, Saturn, and the stars.

Ptolemy's *Almagest* also contains a star catalogue updated from that of Hipparchus and listing 1,022 stars and 48 constellations. The star-mapping techniques described the stars as points on a grid, a system that he later extended to earthly locations in other books. Ptolemy's system of a 360-degree globe, further divided into minutes and seconds, could also be applied to earthly locations—what is known at present as latitude and longitude. This system of location was later used in his book *Geographia*. The *Almagest* was the standard scholarly text on astronomy until the 16th century in Europe. Ptolemy's geocentric universe was accepted by European and Arab astronomers for more than 1,000 years after his death, until it was replaced by the heliocentric system devised by Copernicus.

Alexandria remained the center of Greek astronomy, philosophy, and mathematics after the time of Ptolemy. Writers created commentaries on the works of past astronomers and helped preserve their theories. Theon of Alexandria (ca.

335–ca. 405 C.E.) wrote commentaries on Ptolemy's *Almagest* and was the father of Hypatia, the first well-known female mathematician. Marinus of Neapolis (ca. 450–ca. 500 C.E.) speculated on the nature of the Milky Way, arguing that it could not be a collection of very faint stars, a theory that dated back to the fifth century B.C.E.

ROME

BY JOHN M. McMAHON

Scientific astronomy did not occupy as important a position in Rome as it held in Greece, but knowledge of the heavens remained a major factor in the intellectual, social, cultural, and political life of the Roman world. Early contact with Etruscan civilization in Italy and later with Hellenistic Greek civilization in the Mediterranean influenced attitudes toward astronomy throughout the Roman period. The Romans' own practical nature, which favored applied knowledge over theoretical science, largely determined the role astronomy played. Roman writers often included astronomical subject matter in literary works, and by recording the discoveries of the Greeks, Roman technical writers ensured that scientific astronomical knowledge reached both Roman readers and those of later ages.

During their earliest history the Romans incorporated the monthly lunar cycle into a formal calendar, a concept that may have originated with the Etruscans. Made up of 10 months (March through December), it had an unnamed period of time during the winter. King Numa Pompilius (ca. 715–ca. 672 B.C.E.) added two additional months, January and February, to fill the gap. Since the annual solar cycle is not compatible with a purely lunar calendar, numerous adjustments to the Roman civil calendar were made over the centuries. Finally, in 46 B.C.E. Julius Caesar (100–44 B.C.E.), advised by the Greek astronomer Sosigenes, refashioned the Roman calendar by basing it on the sun's apparent yearly motion.

Roman farmers incorporated knowledge of the heavens into agricultural activities and relied on recurring seasonal events in the sky to indicate appropriate times for plowing, sowing, and harvesting. These times were marked by the observable annual rising or setting of specific stars and constellations, which were noted on a *parapegma*, or "star calendar." Cato the Elder (234–149 B.C.E.) refers to such information in his *De agri cultura* (*On Agriculture*). The writings of later authors on farming practices, such as Varro (ca. 40 B.C.E.) and Columella (ca. 60 C.E.), reveal the transition from the use of astronomical information to the Julian civil calendar.

In the Roman world at large other practical applications of astronomical information were common. Seafaring and navigation, a major component of trade and commerce, necessarily depended on astronomical principles and a familiarity with the starry sky. Among a variety of astronomically oriented instruments developed by Greek science during

the Roman period, such as the astrolabe (a two-dimensional working model of the heavens) and the celestial globe, sundials were by far the most commonly used. These instruments came in a wide range of sizes and applications, both public and private. Surviving examples of the latter indicate that some were even designed for use as portable personal timepieces. Public sundials were also set up, the most famous being the enormous Horologium Augusti of the emperor Augustus in Rome's Campus Martius, which served as a political as well as calendrical monument.

During a period of close cultural assimilation in the seventh and sixth centuries B.C.E. the Romans adopted from the Etruscans the practice of observing the heavens to ascertain the will of the divinities, to interpret past events, and to predict future ones. In accordance with carefully prescribed rules, the visible sky was divided into specific regions to determine what celestial occurrences might mean for human affairs. Such traditional practices became an essential part of Roman religious and civic custom. The tendency to recognize in the movements of the heavenly bodies an influence on people's lives became common in the Roman world with the spread from the East of the pseudoscience of astrology. Manilius (early first century C.E.) composed an entire didactic poem (a poem meant to instruct the reader) on astrology called *Astronomica* (*Astronomical Matters*), and many leading figures were believers in the efficacy of astrology.

From the third through first centuries B.C.E. the Romans were increasingly exposed to a more purely scientific approach to astronomy through their expansion into the Greek cultural sphere. This contact occurred first in southern Italy and Sicily and subsequently on mainland Greece and in Asia Minor, long the home of thriving centers of learning. An important Roman from this period was Sulpicius Gallus, who wrote a work on astronomy based on Greek sources. His scientific knowledge of mathematical astronomy was such that, as an officer in the Roman army in 168 B.C.E., he predicted a lunar eclipse before the battle of Pydna.

Intercultural contact with the Greek world also introduced to the growing Roman intellectual class those philosophical and literary elements associated with knowledge of the heavens. The foremost example of this process was the *Phaenomena* (*Appearances*) by Aratus (ca. 315–240 B.C.E.), a lengthy didactic poem based on the earlier work of the astronomer Eudoxus (ca. 400–ca. 350 B.C.E.). Combining astronomical subject matter with Stoic philosophy, Aratus proposed that the orderliness of the heavens was evidence of divine intent in the universe. The *Phaenomena* became very popular throughout antiquity and greatly influenced a number of Roman authors, including Cicero (106–43 B.C.E.) and Ovid (43 B.C.E.–17 C.E.), both of whom wrote Latin versions of the poem. On the other hand, the Roman poet Lucretius (ca. 94–55 B.C.E.) enlisted astronomy in support of Epicurean philosophy, which he expounded in his work *De rerum natura* (*On the Nature of Things*).

The Latin literary tradition also includes astronomical material, with Roman writers adapting it to their own cultural and social contexts. The poet Virgil (70–19 B.C.E.) bases parts of his *Georgics* on the Greek agricultural poem *Works and Days* of Hesiod (late eighth century B.C.E.), a major source for early Greek observational astronomy. Political elements appear in the *Georgics* as well. For example, Virgil suggests that the origin of the constellation Libra derives from cosmic support for the emperor Augustus. Ovid, too, incorporates into his epic *Metamorphoses* elements from the account of the beginnings of the universe in Hesiod's *Theogony*. A number of tales in Ovid's works also recount instances of catasterism, the transformation of a mortal into a star, constellation, or other celestial object. This concept was not restricted to myths, for at the very end of the *Metamorphoses*, Ovid describes the ascent of Julius Caesar's spirit as a comet, known as the Sidus Iulium ("Julian Star"). Ovid also wrote in praise of astronomers in his *Fasti* (Festivals), a poem explaining the myths associated with the traditional Roman calendar.

Popular handbooks of astronomy appear during the Roman period. While many were in Greek, such as that of Geminus (ca. 110–40 B.C.E.), the *De astronomia* (Concerning Astronomy) of Hyginus (early first century C.E.) was an important Latin work. In addition to outlining the basics of astronomy, the author retells from Greek sources the myths related to the constellations. Vitruvius (late first century B.C.E.) includes an account of the heavens in his work on architecture. Another important figure was Pliny the Elder (24–79 C.E.), whose second book of the *Naturalis historia* (*Natural History*), preserved for later ages valuable information about the scientific astronomy of the day.

THE AMERICAS

BY J. J. GEORGE

Most ancient American cultures paid attention to what was happening in the sky. The periodic cycles of the sun, moon, stars, and planets, being reliable and predictable, allowed for the development of the calendar. Broadly speaking, astronomy was one area that contributed to a greater Mesoamerican cosmology, and subsequent uses helped define and order such areas as agriculture, site orientation, astrology, myth, shamanism, divination, and even warfare. Our best astronomical data come from successful early agricultural cultures in Mesoamerica—the Olmec of the Gulf Coast of Mexico (1500–400 B.C.E.), the Zapotec of the Valley of Oaxaca at Monte Albán (600 B.C.E.–900 C.E.), and the inhabitants just outside the Basin of Mexico at Teotihuacán (1 B.C.E.–650 C.E.). The Classic Period Maya (200–900 C.E.), building upon earlier Mesoamerican thought, established the clearest astronomical record. Astronomy in the ancient period focused on horizon and zenith events of the rising and setting sun, moon, planet Venus, and star cluster Pleiades and on the sacred four cardinal directions.

The beginnings of the Mesoamerican calendar signified the first concrete astronomical achievement. A carved stela, or upright stone, from La Mojarra on Mexico's Gulf Coast (150 C.E.), exhibits in hieroglyphic form the beginnings of a solar 365-day calendar. When used in tandem with a unique 260-day sacred calendar (called the Tzolkin), like a system of interlocking cogwheels, this stela established everything in the Mesoamerican world, from agricultural rites to ritual and religious ceremonies to feasts and the inauguration of New Year. This stela also records a hieroglyph for Venus as well as a date that correlates with a visible solar eclipse. The Mayans later developed an extraordinarily accurate Venus table as well as an eclipse table that accurately predicted the occurrence of those celestial events.

Mesoamerican site orientation, the layout of a particular ritual site or city across the landscape, often had astronomical significance. For example, a structure referred to as Building J at Monte Albán strongly suggests an astronomical relationship. Building J is unique in that it is roughly pentagonal (with a "pointer" side and a stairway side) and set considerably askew (nearly 45 degrees) from the general site orientation. Recent research suggests that Building J aligns with another building (Building P) to form a sightline that extends to the horizon point where the rising star Capella announces the solar zenith passage.

Similarly, Building J aligns with a neighboring site, Caballito Blanco, which has a similar skewed building. A straight line between the two coincides with the sunset position on the horizon on the day of the solar zenith passage, when at local noon the sun is directly overhead and casts no shadow of perfectly vertical structures. In the opposite direction the line marks the sunrise azimuth on the morning after the antizenith (nadir) passage, when the sun is directly below at local midnight. It has been suggested that Building J was a calendar temple, a structure that embodied numerology and astronomy and permitted Mesoamericans to create their interlocking calendars.

By 550 C.E. Teotihuacán, northeast of modern-day Mexico City, was the sixth-largest city on the planet, with an estimated population between 125,000 and 250,000. The Aztecs later called Teotihuacán the place where time began and centered their origin myths there. Astronomical alignments were used at Teotihuacán for overall site orientation and to orient more specific dates related to agriculture and the sacred calendar. The overall orientation of its grid pattern falls within what is often referred to as the 17-degree family of orientations, a group of orientations widely distributed throughout Mesoamerican sites with axes typically 15 to 18 degrees clockwise from the cardinal directions.

Punctuating the grid of Teotihuacán is a large, flat-topped pyramid called the Pyramid of the Sun (a second pyramid on the site is called the Pyramid of the Moon; both names are attributed to the later Aztec) and a ceremonial structure called the Ciudadela, both skewed approximately 15.5 degrees and

16.5 degrees clockwise from the cardinal directions, lining up with certain mountain peaks that could have been used as natural markers of sunrises and sunsets on significant dates. These dates were necessary for predicting important seasonal changes and for efficiently scheduling corresponding agricultural activity. For example, in the first century C.E. these alignments would have recorded sunrises on February 11 and October 29 and sunsets on April 30 and August 13. The intervals from February 11 to October 29 and from August 13

to April 30 are exactly 260 days, again coinciding with the 260-day sacred calendar. The 260-day period is also tied to the human gestation period, the time from the first missed menstrual flow to birth, thereby connecting the functional aspect of the calendar to the birth cycle as well as to agriculture, ritual, and urban planning.

The astronomical record for North and South America in the ancient period suffers from a lack of hard data. Data for later periods are much more convincing. Some evidence does suggest, however, that ancient North American mound builders used the star group Pleiades as a celestial template for particular clusters of conical mounds in the Midwest, such as burial mounds and earthworks at Poverty Point, Louisiana (1600–1300 B.C.E.); Adena burial mounds in Ohio, Kentucky, and West Virginia (1000 B.C.E.–200 C.E.); and Hopewell mounds in southern Ohio (200 B.C.E.–400 C.E.). The Pleiades were important, especially in northeastern North American latitudes, because their horizon cycle corresponds to the limits of the frost-free zone and thus helped define the growing season once agriculture became common.

The medicine wheels left by the nomadic Indians of the Great Plains are thought to have astronomical significance, though the exact use is unclear. Medicine wheels are enigmatic large patterns of linear stone alignments, many of which have the appearance of a spoked wheel. Often the spokes, or rays, point to the horizon and mark points of the summer solstice sunrise, the winter solstice sunrise, or the rise of the star Sirius. Various examined sites, such as those at Majorville in Alberta, Canada, and Moose Mountain in Saskatchewan, show evidence of use dating back to 2500 B.C. Many of the medicine wheels are thought to exist from later periods.

In South America a clearer data record exists for the Inca (1438–1534 C.E.) than it does for earlier cultures, such as those at Chavín de Huántar (900–200 B.C.E.), Paracas (600–175 B.C.E.), and Nazca (1–700 C.E.). The most suggestive early astronomical possibility comes from the Nazca culture, which created the Nazca Lines with some possible astronomical significance in mind. Shaman imagery on textiles from the Paracas culture suggests at least an affinity for connecting the earth and the heavens through visual iconography, or symbolism. Architectural remains at Chavín de Huántar show a solar east-west axis that conflates architecture, human ritual, and cosmological associations. A corresponding north-south axis is suspected, thereby symbolizing all four cardinal directions. More research needs to be undertaken to establish a clearer record for the relationship of astronomy to these sites.

THE NAZCA LINES

First located in the 1920s from aerial reconnaissance, the Nazca Lines have prompted debate, speculation, and confusion over what exactly they represent. Created by the Nazca culture (1–700 C.E.) across a 130-square-mile swath of desert tableland on the central Peruvian coast, the lines are made by displacing dark stones from atop lighter ones. Created over many hundreds of years, the more than 1,000 miles of lines consist of overlapping, radiating lines and trapezoids and immense figures of animals, humans, plants, and objects (including a monkey, a dog, a killer whale, lizards, birds, a tuber, geometric figures, and even a fantastic figure often referred to as the Martian). The span of a hummingbird image is greater than the length of five jumbo jets. One line goes perfectly straight for 13 miles.

Theories have linked the lines to pilgrimages, water rituals, astronomical alignment, ceremonial walkways, and religious activity tied to ensuring a good harvest. Modeling the lines with the aid of computerized mapping in reference to celestial positioning has shown that twice as many astronomical alignments show up than would be expected from pure chance. Furthermore, prominent archaeoastronomists (scholars who combine astronomy and archaeology to study ancient civilizations) have used computer analysis to show that many lines point to the sun's position on the horizon during the time of year when the rains begin.

The immensity of the lines prevents them from being viewable on the ground, automatically orienting them to the celestial world above, where a shaman, or holy man, in bird form might have been the intended audience. Although their overall meaning is still debated, most theories involve the idea of repeated ritual action. Where some of the rituals are tied to water and thus to agriculture and seasons, simply by raising one's head one connects the lines at one's feet to the horizon and eventually to the rising sun and stars.

The Middle East

~ “*The Reports of the Magicians and Astrologers of
 Nineveh and Babylon,*” excerpts, ca. 2500–670 B.C.E. ~

II. Omens from the Horns of the Moon

When the Moon’s horns face equally, there will be a secure dwelling for the land. When at the Moon’s appearance [its horns] are pointed, the king, wherever his face is set, will rule the land (or) wherever he presses on will overcome. From Irasshi-ilu, the king’s servant, the greater.

When at the Moon’s appearance its right horn is long and its left horn is short, the king’s hand will conquer a land other than this. When the Moon at its appearance is very large, an eclipse will take place. When the Moon at its appearance is very bright, the crops of the land will prosper. When the day is long according to its calculation, there will be a long reign. The thirtieth day completed the month. In Elul an eclipse of Elam. From Nergal-etir. . . .

V. Various Omens from the Moon

When the Moon disappears, evil will befall the land. When the Moon disappears out of its reckoning, an eclipse will take place. (The Moon disappeared on the twenty-fourth day.) When a halo surrounds the Sun on the day of the Moon’s disappearance, an eclipse of the left side of the Moon will take place.

In Kislev a watch was kept for the eclipse, the halo surrounding the Sun and the disappearance of the Moon (being the causes of the watch for an eclipse in Kislev) having been observed. May the king, my lord, know, and may he rest happy! From Irasshi-ilu, the king’s servant (the greater).

VI. Omens from Halos

Last night a halo surrounded the Moon, and Jupiter and Scorpio stood within it. When a halo surrounds the Moon and Jupiter stands within it, the King of Akkad will be besieged. When a halo surrounds the Moon and Jupiter stands within it, there will be a slaughter of cattle and beasts of the field. (Marduk is Umunpaudu at its appearance; when it has risen for two (or four?) hours it becomes Sagmigar; when it stands in the meridian it becomes Nibiru.) When a halo surrounds the Moon and Scorpio stands in it, it will cause men to marry princesses (or) lions will die, and the traffic of the land will be hindered. From Nabu-mushesi.

When a halo surrounds the Moon, and Regulus stands within it, women will bear male children. From Nergal-etir. . . .

When the greater halo surrounds the Moon, that land will be enlarged, destructions will surround men. When it surrounds and Cancer stands within it, the King of Akkad will prolong life. When Regulus stands within it, women will bear male children. When the greater halo surrounds the moon and is thin, there will be a giving of years to the king. (A great halo has surrounded it and has remained for many nights and is uninterrupted.) From Shapiku, of Borsippa. . . .

IX. Omens from Stars

. . . . Venus is appearing at sunset in the Tropic of Cancer: this is its interpretation. When Venus appears in Sivar, there will be a slaughter of the enemy. When Venus appears in the Tropic of Cancer, the King of Akkad will have no rival. Five or Six days ago it reached Cancer. This is its interpretation. When Venus approaches Cancer there will be obedience and welfare in the land: the gods will have mercy on the land. . . . The crops of the land will prosper; the sick in the land will recover. Pregnant women will perfect their offspring. The great gods will show favor to the sanctuaries of the land, the houses of the great gods will be renewed. From Shumai. . . .

Mercury is visible with Mars at sunset; it is ascending to Shugi. There will be rains and floods. When Jupiter appears at the beginning of the year, in that year its crops will prosper. From Nadinu.

XV. Omens from Eclipses

On the fourteenth an eclipse will take place. It is evil for Elam and Aharru, lucky for the king, my lord; let the king, my lord, rest happy. It will be seen without Venus; to the king, my lord, I say, “There will be an eclipse.” From Irasshi-ilu, the servant of the king (the greater).

To the king of countries, my lord, thy servant, Bel-usur. May Bel, Nabu, and Shamash be gracious to the king, my lord! An eclipse has happened, but it was not visible in Asshur; this eclipse passed the city

(continued)

(continues)

Asshur, wherein the king is dwelling; now there are clouds everywhere, so that whether it did or did not happen we do not know. Let the lord of kings send to Asshur, to all cities, to Babylon, Nippur, Erech, and Borsippa; whatever has been seen in those cities the king will hear for certain. . . . The omen for an eclipse happened in Adar and Nisan; I send all to the king, my lord, and they shall make . . . ceremony for the eclipse. Without fail let not the king omit to act rightly. The great gods in the city wherein the king

dwells have obscured the heaven and will not show the eclipse; so let the king know that this eclipse is not directed against the king, my lord, or his country. Let the king rejoice!

Greece

~ Ptolemy: *Tetrabiblos*, excerpt, second century C.E. ~

Book I**4. Of the Power of the Planets**

The active power of the sun’s essential nature is found to be heating and, to a certain degree, drying. This is made more easily perceptible in the case of the sun than any other heavenly body by its size and by the obviousness of its seasonal changes, for the closer it approaches to the zenith, the more it affects us in this way. Most of the moon’s power consists of humidifying, clearly because it is close to the earth and because of the moist exhalations therefrom. Its action therefore is precisely this, to soften and cause putrefaction in bodies for the most part, but it shares moderately also in heating power because of the light which it receives from the sun.

It is Saturn’s quality chiefly to cool and, moderately, to dry, probably because he is furthest removed both from the sun’s heat and the moist exhalations about the earth. Both in Saturn’s case and in that of the other planets there are powers, too, which arise through the observation of their aspects to the sun and moon, for some of them appear to modify conditions in the ambient in one way, some in another, by increase or by decrease.

The nature of Mars is chiefly to dry and to burn, in conformity with his fiery color and by reason of his nearness to the sun, for the sun’s sphere lies just below him.

Jupiter has a temperate active force because his movement takes place between the cooling influence of

Saturn and the burning power of Mars. He both heats and humidifies; and because his heating power is the greater by reason of the underlying spheres, he produces fertilizing winds.

Venus has the same powers and tempered nature as Jupiter, but acts in the opposite way; for she warms moderately because of her nearness to the sun, but chiefly humidifies, like the moon, because of the amount of her own light and because she appropriates the exhalations from the moist atmosphere surrounding the earth.

Mercury in general is found at certain times alike to be drying and absorptive of moisture, because he never is far removed in longitude from the heat of the sun; and again humidifying, because he is next above the sphere of the moon, which is closest to the earth; and to change quickly from one to the other, inspired as it were by the speed of his motion in the neighborhood of the sun itself. . . .

8. Of the Power of the Aspects to the Sun

Now, mark you, likewise, according to their aspects to the sun, the moon and three of the planets experience increase and decrease in their own powers. For in its waxing from new moon to first quarter, the moon is more productive of moisture; in its passage from first quarter to full, of heat; from full to last quarter, of dryness; and from last quarter to occultation, of cold. The planets, in oriental aspects only, are more productive of moisture from rising to their first station, of heat from first station to evening

rising, of dryness from evening rising to the second station, of cold from second station to setting; it is clear that when they are associated with one another they produce very many variations of quality in our ambient, the proper force of each one for the most part

persisting but being changed in quantity by the force of the stars that share the configuration.

From: Ptolemy, *Tetrabiblos*, translated by Frank Egleston Robbins (Boston: Harvard University Press, 1940).

Rome

≈ Petronius: “*The Banquet of Trimalchio*,”
extract from *The Satyricon*, 60 C.E. ≈

Our applause was interrupted by the second course, which did not by any means come up to our expectations. Still, the oddity of the thing drew the eyes of all. An immense circular tray bore the twelve signs of the zodiac displayed round the circumference, on each of which the Maniple, or Arranger, had placed a dish of suitable and appropriate viands: on the Ram ram’s-head peas, on the Bull a piece of beef, on the Twins fried testicles and kidneys, on the Crab simply a crown, on the Lion African figs, on a Virgin a sow’s haslet, on Libra a balance with a tart in one scale and a cheesecake in the other, on Scorpio a small sea-fish, on Sagittarius an eye-seeker, on Capricornus a lobster, on Aquarius a wild goose, on Pisces two mullets. In the middle was a sod of green turf, cut to shape and supporting a honeycomb. Meanwhile an Egyptian slave was carrying bread around in a miniature oven of silver, crooning to himself in a horrible voice a song on wine and laserpitium. . . . Seeing us look rather blank at the idea of attacking such common fare, Trimalchio cried, “I pray you gentlemen, begin; the best of your dinner is before you.” . . .

The second course had now been removed, and the company being merry with wine began to engage in general conversation. Our host then, lying back on his elbow and addressing the company, said, “I hope you will all do justice to this wine; you must make the fish swim again. Come, come, do you suppose I was going to rest content with the dinner you saw boxed up under the cover of the tray just now? ‘Is Ulysses no better known?’ Well, well! even at table we mustn’t forget our scholarship. Peace to my worthy patron’s bones, who was pleased to make me a man amongst men. For truly there is nothing can be set before me that will nonplus me by its novelty. For instance the meaning of that tray just now can be easily enough explained. This heaven in which dwell the twelve gods resolves itself into twelve different

configurations, and presently becomes the Ram. So whosoever is born under this sign has many flocks and herds and much wool, a hard head into the bargain, a shameless brow and a sharp horn. Most of your schoolmen and pettifoggers are born under this sign.”

We recommended the learned expounder’s graceful erudition, and he went on to add: “Next the whole sky becomes Bull; then are born obstinate fellows and neatherds and such as think of nothing but filling their own bellies. Under the Twins are born horses in a pair, oxen in a yoke, men blessed with a sturdy brace of testicles, all who manage to keep in with both sides. I was born under the Crab myself. Wherefore I stand on many feet and have many possessions both by sea and land, for the Crab is equally adapted to either element. And this is why I never put anything on that sign, so as not to eclipse my horoscope. Under the Lion are born great eaters and wasters, and all who love to domineer; under the Virgin, women and runaways and jailbirds; under the Scales, butchers and perfumers and all retail traders; under the Scorpion, poisoners and cutthroats; under the Archer, squint-eyed folks, who look at the greens and whip off with the bacon; under Capricorn, the ‘horny-handed sons of toil’; under Aquarius or the Waterman, innkeepers and pumpkin-heads; under Pisces, or the Fishes, fine cooks and fine talkers. Thus the world goes round like a mill, and is for ever at some mischief, whether making men or marring them. But about the sod of turf you see in the middle, and the honeycomb a-top of it, I have a good reason to show too. Our mother Earth is in the middle, round-about like an egg, and has all good things in her inside, like a honeycomb!”

From: Petronius, *The Satyricon*, translated by Alfred R. Allinson (New York: Panurge Press, 1930).

► borders and frontiers

INTRODUCTION

At first, people may have had no concept of borders anywhere in the world. The world's human population was so small and the available land so big that peoples of different cultures could settle among each other with so much space between them that they did not care that the others were there. Even when cities began and central governments formed, it was possible that people would know they were no longer on their native land only when they bumped into settlements of people belonging to another culture.

As human populations expanded, controlling food supplies became important. It is possible that the first borders were just boundaries between farms, perhaps marked by stones. With the beginning of large public works projects, such as irrigation canals, groups of people formed a mutual interest in protecting what they built and the lands on which they all worked. Territory that remained wild became frontiers between communities but lacked defined borders.

Perhaps the first borders formed around trade routes. That trade routes could define a frontier was common in the ancient world. Control of trade routes could bring in wealth in the form of tariffs charged to traders and could stimulate a local economy through trade with other peoples. Building forts on trade routes and ignoring much of the rest of the land was also common in ancient times. The fortifications on borders suggest that the borders were intended to keep people out; this, in turn, suggests that borders originally were reactions to warfare and invasion.

Probably more than any other ancient culture, the Romans were concerned about borders. In most of the world people defended towns or cities, but the Romans developed the idea of defending borders that were far from cities and trade routes. In so doing, they could hope to prevent enemies from reaching their cities. The emperor Augustus (r. 27 B.C.E.–14 C.E.) tried to establish clear borders that cartographers could map, using natural barriers such as rivers.

Many cultures used natural barriers such as rivers, mountain ranges, and deserts for borders. These were not perfect, because enemies could cross rivers, scale mountains, and endure thirst, but a river crossing could be defended, and mountains and deserts could kill would-be invaders. Even so, these natural barriers required watching, and people crossing them would be considered outsiders and potential threats. Sometimes natural barriers were unavailable or there were not enough to mark clearly defined, defensible borders. Thus, marking borders with fortresses was often done. For example, the Great Wall of China was a long fortification that defined China's northern border and helped protect the Silk Road, a major trade route.

Much of the world still had ill-defined borders when the Western Roman Empire fell. In much of Africa the idea of borders took root only when Europeans arrived during the Renaissance era. In China the northern border was defined by the Great Wall and a vast desert, but the southern border was vague, because of dense forests and native populations that resisted China's rule. In the ancient Americas territory between the frontiers of cities was often claimed by no one. Thus, creating borders was not a universal desire among ancient peoples. Instead, borders may have developed out of a

desire to protect territory where natural resources were too scarce to be shared, to protect trade routes, or to protect a nation's wealth and population from raiders.

AFRICA

BY JUSTIN CORFIELD

The borders and frontiers of many of the civilizations in Africa were ill defined until the colonial period, and even then discrepancies between treaties often occurred. In terms of North Africa, the Egyptians, the Numidians, the Carthaginians, and subsequently the Romans were able to establish frontiers to their lands largely with small garrisons in isolated oases astride trade routes. Tariffs were generally collected on entry into a particular city rather than across any given frontier. Some writers of the ancient world speak of a borderless world—"one world"—especially in relation to the period of Alexander the Great (336–323 B.C.E.) and again for the Roman Empire.

Until the emergence of larger kingdoms, most of society was organized into states centered on cities or towns, with their surrounding hinterland supplying produce to them. Most of these larger settlements were located in rich, arable areas. A few others appear to be located on land trade routes. Certainly two of the routes across the Sahara appear to terminate in the ports of Lixus (modern-day Larache, Morocco) and Oea (modern-day Tripoli, Libya). The former is set in good agricultural land, but the latter had little arable hinterland, though even this might have been enough for Carthaginian farmers, using slave labor, to construct aqueducts.

During the ancient period the dual system of land tenure arose, which existed in much of North Africa until the establishment of the European colonial empires in the 19th century. Essentially the boundaries of cities were clearly defined, often by walls or fortifications, and land within them was available for purchase or rent with a system of land tenure not too different from that operating in many of those countries today. However, in the countryside, even though the land occupied by an individual farm might be defined, with no accurate cadastral service, that is, a register of ownership of land, the fullest extent of any kingdom or empire tended to be defined in terms of the presence of army garrisons placed in particular far-flung small settlements to ensure the easy collection of taxes and the maintenance of law and order. As a result, the areas that paid taxes to a particular ruler were within his borders, often leaving the southern boundaries of Carthage, Numidia, and Roman North Africa ill defined.

Gradually, the Egyptian Empire and the empires of Carthage and subsequently Rome tended to fix boundaries of provinces and install provincial governors who were in charge of dispensing justice as well as collecting taxes within their area of authority. To achieve this objective, provinces, and hence borders, had to be more clearly defined than they had hitherto been. Most literature exists for the Romans, who

certainly built forts in the desert in Tripolitania (modern-day western Libya). In addition, there also seem to have been large numbers of fortified farmhouses, probably occupied by *limitanei* (soldier-farmers).

Although the Romans originally took over and absorbed the lands of the Carthaginians, maintaining Mauretania as a client state, in 42 C.E. they annexed Mauretania, and within two years it was divided into the two provinces Mauretania Tingitana and Mauretania Caesariensis. During the first century there was significant Italian migration to Mauretania, leading to more lands being opened to agriculture and the borders of the existing chieftains being more closely delineated. In the 210s, during the reign of Septimus Severus, the only African-born emperor of Rome, there was a reduction in trade throughout the whole Roman Empire and consequently an economic slump in North Africa, which saw the reduction of Roman influence over the more distant Saharan outposts. However, during the later periods of the Roman Empire maps tended to show more details connected with the East African coast, including coverage as far south as Cape Delgado, south of Zanzibar, possibly on account of traders returning with new information.

The descriptions of the different tribes in North Africa noted by the fifth century B.C.E. Greek historian Herodotus show that society was organized by clan groups following different customs but that there was clearly no physical barrier from one community to another. Indeed, rather than groups being divided by rivers, many tribes were located astride them. The problem was further exacerbated by the nomadic tribes that operated in the Sahara and in parts of central and southern Africa. Because the area was very sparsely populated, for the most part the borders of one area were to remain undefined until recent times, when primarily European cartographers took an interest in Africa.

However, in some areas the frontiers of particular groups can be clearly ascertained. Work by the anthropologist Patrick Munson in Sudan has shown that farmers in the Tichit-Walata part of the Sudan from 1000 B.C.E. had tended to congregate in fortified cliff-top villages, clearly showing that protection from attack was more important than access to fertile arable land. The settlement of Tin Hinan in the Hoggar, nearly 1,000 miles south of Algiers, excavated in 1926 and again seven years later, showed the importance of fortifications there to protect the local people from marauders during the first century B.C.E.

On the east coast of Africa, at Port Durnford (in modern-day South Africa), in 1912 a fortress was discovered that enclosed five acres, obviously showing the need of the people there to be able to withstand a substantial siege. Inland, even before the massive stone buildings of Great Zimbabwe were constructed in the ninth century C.E., there were smaller efforts to centralize power. These kingdoms were probably defined by the areas from where tax revenue, often the form of cattle, was raised and where men were available for conscription.

At Jenne-jeno, in what was then known as Ghana but is now modern-day Mali, remains of a large settlement (covering 60 acres by 450 C.E.) has been excavated. Houses made from mud sustained a large town on ground slightly higher than the plains that surround the site. The thin walls show that there seems to have been little danger of internal conflict. However, the entire site is surrounded by a wall that measures about 10 feet wide at the base and runs for slightly more than one mile. Although two Roman or Greek beads have been found there, it seems likely that any trade would have been through intermediaries.

EGYPT

BY MARIE PASSANANTE

The borders of ancient Egypt remained remarkably stable for such a long-lived civilization, largely because Egypt was a country defined by natural borders. It occupies the long section of fertile land lining the Nile Valley that stretches from the Mediterranean Sea in the north down to Elephantine, near modern Aswān, in the south. On the east and west the Nile Valley is adjoined by harsh deserts. The greatest fluctuations to the Egyptian borders occurred during the three Intermediate Periods, times of political upheaval that took place after the Old Kingdom (2575–2134 B.C.E.), Middle Kingdom (2040–1640 B.C.E.), and New Kingdom (1550–1070 B.C.E.). During and after these periods, Egypt was divided internally among rival Egyptian dynasties (First Intermediate Period, 2134–2040 B.C.E.), among Egyptian dynasties and a

group of foreigners called the Hyksos (Second Intermediate Period, 1640–1550 B.C.E.), and among Egyptian dynasties and Libyan tribes as well as invaders from Kush in the south (Third Intermediate Period, 1070–712 B.C.E.).

The Egyptians used several terms when referring to their borders. The term *tash* was applied to a physical, politically defined border, such as the border between Egypt and Nubia in the south. *Wepet-ta* literally means “the horns of the Earth.” It was applied to limits of Egyptian domination in the south. The term *khent-hen-nefer*, translating to “the frontier region of the last fortification,” also referred to the southern border. It was used with reference to the region bordering Egyptian territory. This region was not officially part of Egypt but was still under Egyptian control.

The Mediterranean Sea borders Egypt on the north. Few nations attempted sea travel before 1500 B.C.E.; their ships were designed mostly for river travel and were not sturdy enough for the sea. The northern border of Egypt was relatively secure and did not need to be as heavily fortified as the south and the edges of the delta. South of Elephantine was the land of Nubia. As well as being a major source of gold and the only source of goods from Africa, Nubia was home to a potentially dangerous people who could—and did—threaten the security of the Egyptian state. From the Old Kingdom to the New Kingdom, Egypt engaged in extensive military activity directed against Nubia in order to retain control of this important area. The southern border of Egypt was set at the first cataract of the Nile, the mythical source of the Nile. Elephantine was established here as a frontier town and as a base for trading with

The Semna dispatches, administrative documents from an Egyptian outpost, from Thebes, Egypt, Twelfth Dynasty (© The Trustees of the British Museum)

Nubia in the Old Kingdom. Several settlements were established south of Elephantine to control the frontier, including the town at Buhen at the second cataract.

In the Middle Kingdom, two series of fortresses were built along the Nile to protect Egyptian interests in the south. The first series of forts was built to the north of the second cataract and includes the fortress at Buhen. These forts were completed by the end of the reign of Sesostris I (r. 1971–1926 B.C.E.). The second set of forts—at Semna, Kumma, Uronarti, Shelfak, and Askut—was built south of the second cataract by Sesostris III (r. 1878–1841 B.C.E.). Between Semna and Uronarti there is also a fortified brick wall almost three miles long. Sesostris III left inscriptions declaring Semna to be the border of Egyptian control. The inscriptions announced that no Nubian was allowed to pass Semna either by land or by water, with the exception of Nubian traders and envoys; Nubian traders were allowed to travel as far as Iken, just south of the second cataract. The control of the region between Elephantine and Semna was entrusted to the governor of Elephantine, who held the titles Great Controller of Nubia and Overseer of all Foreign Lands.

The kings of the New Kingdom increased the zone of influence and built forts from Semna to the fourth cataract. South of the fourth cataract, Thutmose III (r. 1479–1425 B.C.E.) built a fort at Napata and left an inscription delineating the boundary of the Egyptian Empire. The length of the Nile from Edfu, north of Elephantine, down to Karoy, the region beyond the fourth cataract, was entrusted to the leadership of the viceroy of Kush. The viceroy acted on the king's behalf in Nubia, protecting the trade routes and leading the Egyptian army against Nubian rebellions when necessary.

In the east, along the length of the Nile Valley, the desert was uninhabitable by a sedentary civilization. However, the eastern desert was populated by the nomadic Medjay, whose numbers were insufficient for a major invasion of Egypt, yet they were independent enough to be considered a minor threat. Beyond the eastern desert lies the Red Sea and the Arabian Peninsula, which is largely uninhabited. The only point in the east where Egypt was vulnerable to attack was the eastern edge of the delta, where a frontier region was recognized from the Mediterranean to the Gulf of Suez. The Middle Kingdom pharaoh Amenemhet I (r. 1991–1962 B.C.E.) built a fortress there called the Walls of the Ruler as a base for trading and mining expeditions into Sinai. The eastern delta was a heavily trafficked area, as it was the entrance point for the caravan route to Palestine. The road from Egypt to Palestine was called the Ways of Horus and was protected by a series of fortresses. In the New Kingdom, Avaris, the former capital of the Hyksos, was transformed into a military stronghold.

As in the east, the greater part of the western border was protected by an extensive desert. Also as in the east, the most vulnerable spot was at the western edge of the delta. New Kingdom Egypt saw an increase in attacks from the west. As a result, a line of fortresses was built along the edge of the delta, most likely by Ramses II (r. 1290–1224 B.C.E.). The fort

marking the westernmost point of Egyptian occupation was called “The Fortress of the West.”

THE MIDDLE EAST

BY KIRK H. BEETZ

During the 7000s B.C.E. nomadic peoples gradually settled in Mesopotamia and domesticated crops such as wheat and barley. Their territory was defined by two great, meandering rivers that flowed across the Near East and into the Persian Gulf, the Tigris and the Euphrates. At first the settlements were small, and there was little concept of *borders*. As settlements grew during a population boom enabled by secure farming techniques, some became city-states.

The settlements dug irrigation ditches to draw water from the rivers into farmlands; rain was rare, however, and without rain to leech out salts left from the irrigation water, lands became ever less fertile, requiring that more and more land be farmed to feed the growing population. This meant that during the Uruk Period of roughly 4300–3100 B.C.E., farmlands of different Sumerian cities began bumping into each other. By then the notion of land ownership was well established, with property owners identifying their boundaries with large stones. However, ownership of territory by a city's people was hard to establish, because there were no defensible frontiers. Further complicating the situation were nomadic tribes that would loot the food and wealth of a city or would move into a region of land and settle, creating pressure on nearby cities by competing for natural resources.

During the Early Dynastic Period of the Sumerian culture (2900–2334 B.C.E.) competition for land frequently resulted in warfare. City administrations had been run by a chief administrator, who could be overruled on city policy by a council of civic leaders that in turn could be overruled by a vote of the people. Success in war required strong leaders, and chief administrators who were notably successful gradually became kings, though their power was still tempered by the will of the voters. Cities came to define their territory as having at their core an urban land area; during the 2000s B.C.E., walls were built around these central urban areas. Around the walled city would be homes and intensively cultivated land, the outer limits of which constantly expanded. Then there was a sphere of influence that included villages protected by the central city and a frontier that was disputed by other cities.

In 2334 B.C.E. Sargon I became king of the city-state Kish, and he may have been the ruler who began the doctrine of constant territorial expansion in order to protect territory already held. Without defensible frontiers, any territory was open to invasion. To many rulers in the ancient Near East the best way to secure territory was to push the frontier out as far as possible; this created a perpetual state of conquest, because protection of newly won lands meant conquering the neighbors of those lands. To help hold together his ever-expanding kingdom, Sargon I created a cult of personality, in which he became synonymous with the city-state and claimed to be the

lover of the goddess Ishtar. The kingdom he created was called Akkad, after the name for Agade, its now-lost capital city. The territory of the empire was defined primarily by trade routes, along which the Akkadian government would build fortresses to protect travelers, and it was primarily along trade routes that Akkad directed its aggression. Sargon I and his successors extended the Akkadian Empire into Anatolia and Iran, but eventually it became too big to protect, and nomads invaded along its breadth, causing the empire to collapse in 2193 B.C.E. Still, Sargon left as a legacy the concept of a nation composed of many cities.

Another big step in thinking about borders and frontiers came with the Hittite Empire of about 1650–1205 B.C.E. The Hittites settled in Anatolia in about 2000 B.C.E. and established Hatti, a nation that, like others in the Near East, had a nebulous territory determined more by cultural influence than by well-defined borders. In 1344 B.C.E. King Suppiluliuma I established discipline in its government and ordered the government's policies. In 1335 B.C.E. Egypt's pharaoh Akhenaten died, and Egypt's politics became muddled, giving Suppiluliuma the opportunity to seize lands held by Egypt in the Levant.

In 1285 B.C.E. Egypt's Ramses II tried to recover the lost Egyptian territory, and he and the Hittite ruler Muwattali II met in battle at Kadesh in Syria; both sides claimed victory, but Ramses II nearly lost his life, and the Hittites actually extended their territory southward. After that, Egypt slowly regained territory until the two sides ended their conflict in 1258 B.C.E. with a peace treaty that was recorded and copies of which still exist. In it, the nations carefully defined a border that demarcated the frontiers of each country. Although some portions of national borders were still vague as late as the Persian Empire of 559–330 B.C.E., the trend was toward defined borders and treaties that recognized where they were.

With the completion of the invasion of the Greeks under Alexander the Great in 326 B.C.E., some portions of national borders were still vague, and the creation of clearly defined borders in the Near East became a must. At Alexander's death the Near East fragmented into small states ruled by Alexander's generals. One of these generals, Seleucus I, succeeded in uniting most of the Asiatic territories Alexander had conquered into the Seleucid Kingdom (ca. 312–ca. 174 B.C.E.). One of his achievements was to create clearly defined borders among the states and between the Seleucid Kingdom and its neighbors. In about 174 B.C.E. Mithridates I of the Parthian Empire, originating in Iran, conquered most of the Seleucid Kingdom.

The Parthian Empire endured attacks on both its western and eastern frontiers, and the fighting in the east was so persistent that a clear border was difficult to maintain. In the west former Greek states had clearly defined borders left from the Seleucid Kingdom. In 100 B.C.E., western Parthia shared borders with Armenia, Edessa, and the remnant of the Seleucid Kingdom in Syria as well as smaller states, each with a well-established territory and clearly defined borders. Rome

Babylonian boundary marker from about 978-943 B.C.E., Sippar, southern Iraq (© The Trustees of the British Museum)

was able to pick off these states one at a time and absorb them into the empire, beginning in 101 B.C.E. with the takeover of small Cilicia in Anatolia.

The structure of well-defined borders served Rome well. Borders enabled Rome to seize individual provinces within the Parthian Empire on the pretense that it was extending itself only to the next border to the east and no farther. Parthia played this game as well, and states in northern Mesopotamia and Syria shifted back and forth between the two countries until 273 C.E., by which time Rome had reorganized its eastern holdings into new provinces that included a chunk of the Parthian Empire north of the Euphrates River. In about 300 C.E. Constantine created the Eastern Roman Empire, known as the Byzantine Empire (ca. 300–1453 C.E.), and established its Near Eastern border with a new province called Oriens. When the western empire ended in 476 C.E., the border established by Constantine I for the eastern empire remained intact.

ASIA AND THE PACIFIC

BY MICHAEL ALLEN HOLMES

Nations and states as defined in modern terms, with explicit boundaries often demarcated by lines of latitude and longitude, did not exist in Asia and the Pacific region in ancient times. Also nonexistent was the means for making maps that could have recorded boundaries. While cartography using parallel lines running north to south and east to west was developed as early as the third century, standardized, widely distributed maps would not have been available to the masses in ancient times. In turn, borders were not necessarily viewed as fixed, and from India through Southeast Asia to China the extents of city-states and kingdoms were ever in flux.

The most immediate ancient borders, then, were fortifications surrounding towns and cities, which in northern China appeared as early as Neolithic times, over 4,000 years before the Common Era, when simple ramparts were constructed with compacted earth. Over the centuries, these walls grew higher and more expansive, indicating communities' needs to defend themselves from invaders. Within the larger states that developed, as often coinciding with geographic regions, a fief ruled locally was known as a *feng*, literally referring to its earthen boundaries. Meanwhile, stone walls were also being constructed, particularly to the north, to prevent incursions from the nomadic horsemen-warriors who were the forefathers of the Mongols and other peoples.

Modern eastern-central China, excluding Tibet, the northwest, and southern expanses, was unified in 221 B.C.E. with the rise to power of the Qin Dynasty. Accordingly, the Qin emperor Prince Zheng, who became known as Shi Huangdi, or "First Emperor," is said to have overseen construction that connected many of the northern walls to produce the Great Wall. Some historians doubt, however, that the Qin walls were seamlessly interconnected and that it makes sense to speak of a single "Great Wall" in Qin times. These walls were supplemented and rebuilt sporadically over the centuries and, including all of its various branches, came to span some 4,500 miles by the Ming Dynasty, beginning in the 14th century C.E. Its utility ultimately proved marginal, as successful invasions were eventually conducted by the northern warriors.

Aside from the historically spectacular Great Wall, borders in the ancient world were largely defined by geographical formations that more naturally provided defense and limited the transportation of both peoples and their belongings. In the region of China the Gobi Desert, consisting of formidable swaths of both sand and rock, impeded travel to the north, especially on foot, beyond the Great Wall. Similarly, the Tarim Basin, consisting largely of the Taklamakan Desert, and surrounding marshlands, restricted travel to the northwest, while to the west, the Tibetan Plateau naturally isolated its own inhabitants. Through the Qin Dynasty and into the Han Dynasty, which lasted from 206 B.C.E. to 220 C.E., armies undertook incursions into the southern forest-

land and jungle beyond, much of which was subject to violent monsoons, nominally extending the Chinese border to the daunting waters of the South China Sea. Since the land and its peoples were difficult to conquer, the Chinese state incorporated the region only in that the emperor declared this intention; many borders would have been defined thus in ancient times.

The only other ancient Asian kingdom rivaling China in size was India, with the two great regions separated by Tibet and the extremely high and vast Himalayas. The Himalayas extend some 200 miles from north to south and, like the Great Wall at its inception, 1,500 miles from west to east. Meanwhile, the Kirthar and Sulaiman ranges to the northwest, which merge into the Hindu Kush to the north, effectively sealed India off from mass incursions from the Middle East and Central Asia. To the south, the Western and Eastern Ghats prevented unhindered maritime access by way of either the Arabian Sea or the Bay of Bengal.

Whatever borders existed within the Indian subcontinent in ancient times are little known, inasmuch as few historical records survive from antiquity. Throughout India, apart from the mountainous margins, the countryside is mostly flat, and the majority of rivers are narrow enough to make crossings manageable. Thus, prehistoric kingdoms were established and reestablished constantly, with no specific landmarks serving as permanent borders. The disparate kingdoms centered on the Indus and Ganges river valleys were united for the first time in 324 B.C.E. by Chandragupta Maurya, who was perhaps inspired by the failed attempt at conquest of the region by Alexander the Great in 326 B.C.E. When the Maurya Dynasty ended in 185 B.C.E., borders within India returned to a state of flux for some 500 years. While Greco-Bactrian, Persian, Scythian, and various barbarian invaders breached India's natural borders throughout this period, they were typically absorbed into Indian culture and life, essentially leaving the region's outer borders intact. Northern India was again unified with the advent of the Gupta Empire in 320 C.E.

Other regional kingdoms in ancient times were smaller in scale and even more geographically isolated; consequently both the definition and defense of their borders were generally of little concern. One entity found in the third century C.E. in Southeast Asia, covering modern Cambodia and southern Vietnam, left no historical records of its own but was referred to as Funan by the Chinese; it may have been either a state or simply a collective of ports, as the thickly forested terrain would have made regional unification impractical. Southeast Asia was populated by several bronze-using civilizations, including the Khmer and Cham; other complex cultures have been discovered archaeologically and are not known to us by name. Similarly, while people are known to have used advanced sailing techniques to reach and occupy islands throughout the Pacific for millennia, the isolation of individual islands meant that significant states did not come into existence until much later in history. On

the islands of modern Japan as well, while people long inhabited the more arable valleys, the abundant mountains served to inhibit interaction and cooperation among tribes. By the third century C.E. small states had come into existence, but even the largest occupied only a loosely defined portion of the southernmost Japanese island, Kyushu. The first significant Japanese court did not appear until the sixth century C.E.

EUROPE

BY KIRK H. BEETZ

Most of the territory of ancient Europe consisted of unsettled wild lands. The practice of agriculture probably came to Europe from the Near East, passing through Anatolia in modern Turkey, the Balkans, and then north and west throughout Europe, ending in southern Sweden, with all the people farther to the north remaining hunter-gatherers. By 4000 B.C.E. almost all of Europe had adopted agricultural ways. It was a period in which different cultures could mix with only rare conflicts. Thus people could move among settlements in Europe with little hindrance. This would continue to be the case until about 2500 B.C.E., but by then what is now called the megalithic culture had begun to change how Europeans regarded territory.

The culture that built the megaliths was probably the first to establish anything recognizable as a single group's territory. The word *megalith* means "large stone," and the megalithic people built huge stone monuments such as Stonehenge in England. In about 3000 B.C.E. Europeans north and west of the Alps and all the way south through Portugal began building burial chambers constructed of stones that were often 13 feet in height. These impressive burial chambers could have been built by large families or clans as ways to let other people know that they claimed the nearby territory and were showing their claim by burying their dead in a tomb that could be seen for miles.

By about 2000 B.C.E. burial chambers for only one person were being built, indicating that a tomb was honoring a leader, perhaps a chief or a priest. Other megalithic structures such as Stonehenge were being erected not only to mark burials but also for worship. These building projects involved transporting stones weighing several tons for many miles, probably by boat along the Atlantic coast of the Continent and the west coast of Britain and both coasts of Ireland. Planning and building such huge projects required the cooperation of hundreds of people over long periods and probably involved the cooperation of several villages, all part of a chiefdom that ruled over hundreds of square miles of land. Such interaction suggests recognition that one group of people could own territories consisting of many villages.

In southern and eastern Spain ca. 2340 B.C.E. people began building fortresses. Tin was mined in southern and eastern Spain, and tin was one of the two metals required for making bronze, the other being copper. Of the two met-

als, tin was the harder to find, and merchants from the Near East would sail all the way to Spain to trade for it. To protect their tin mines and themselves, the peoples of the region built walls and towers of stone. These structures meant that they were claiming territories for themselves.

In the 600s B.C.E. Carthage, a city on the coast of North Africa southwest of the island of Sicily, began conquering the southern coast of modern Spain. By 264 B.C.E. the Carthaginians controlled almost all of Spain's trade in tin. From 237 to 218 B.C.E. they conquered the land north, beyond the Guadalquivir River in southern Spain and along Spain's east coast to the Ebro River, displacing Celtic tribes. On the east coast in 218 B.C.E. they conquered the town of Saguntum, an ally of Rome, and this conquest started the Second Punic War (218–201 B.C.E.) between Carthage and Rome. When Rome invaded Spain, the Romans found two kinds of Celtic peoples: one still in the process of shifting from nomadic lives to living in towns and cities and the other living settled urban lives in Carthaginian territory. At the end of the war, Rome made its newly won Spanish territory into the province Hispania, using the Pyrenees mountain range as its northern border.

North of that border was Gaul, which was populated by Celts. *Celt* is the name given to the majority of Europeans by the Greeks; the Romans called them Gauls. Anyone speaking one of the Celtic languages is called a Celt (pronounced "Kelt"). The Celts originated in either central Asia or central Europe. They were a violent people ruled by warriors. Individual Celtic tribes often held ill-defined territories in which farmers worked to serve the warriors. Other tribes packed everything they owned onto large carts pulled by horses and traveled across the land. They routinely waged war against each other and raided territories for loot and slaves. In 390 B.C.E. Celts raided Italy and sacked the city of Rome. When Julius Caesar (100–44 B.C.E.) set out to conquer Gaul in 58 B.C.E., Rome already controlled portions of the region in modern-day southern France and northern Italy, with borders through the Alps and along the headwaters of several southern rivers.

In central France, Caesar found many Celts living in towns and cities made of wood, and there were some small kingdoms with ill-defined frontiers. To defy Rome, in 52 B.C.E. some of these kingdoms united under one of the kings, Vercingetorix—perhaps the first time they had thought of themselves as one people; however, they were defeated at the town of Alesia. In the north, near the Rhine River, Celtic tribes still tended to be nomadic, organizing themselves around the carts that carried their possessions when they traveled. To Caesar, the Rhine was a natural border. To the north of the river lived another ethnic group of people, the Germans. Caesar believed that the Germans were migrating into northern Europe from Asia. Some historians contend that the Germanic peoples developed within Europe, perhaps in modern-day Poland, but in general they have much in common with ancient central Asian tribes. They were territorial, and they had small realms

that they called kingdoms. During Caesar's time they took control of southern Scandinavia, forming many small kingdoms. It was Caesar and Rome who introduced the concept of fixed borders to central and northern Europe.

The Germanic tribes that lived outside the Roman Empire were constantly at war with each other, and they sometimes banded together in small kingdoms for self-defense. Along the southern coast of the Baltic Sea there were several kingdoms that became fairly stable in the 500s C.E., but in the modern Ukraine they had difficulty establishing stable borders because of attacks from nomads such as the Scythians and from displaced peoples such as the Huns, who had been forced out of central Asia by the Chinese. Some Germanic tribes wanted to settle in Roman territory because behind Roman defenses they would be protected from invaders from Asia, but within the empire's borders Germanic tribes swept through Europe, looting and killing. By 395 C.E. borders in Roman Europe had lost most of their meaning and the new Germanic overlords struggled to establish clearly defined national borders. Much of the history of Europe after 476 C.E. involves almost unending wars to create and protect national frontiers.

GREECE

BY JEFFREY S. CARNES

Until the time of Alexander the Great (356–323 B.C.E.), ancient Greece was not a single political entity but was instead composed of a large number of individual city-states (poleis)—well over one thousand of them, according to the best modern estimates. As such, Greece may have had more borders than any other known civilization. These borders may be classified broadly as internal (with other Greek-speaking poleis) and external (with non-Greek civilizations).

Borders between Greek poleis were typically defined by the natural features of the landscape: rivers, mountains, and coastlines. (In addition to the numerous poleis on islands, cities in mainland Greece were often on the coast, as were virtually all of the numerous Greek colonies spread throughout the Mediterranean.) Borders between cities could also change in accord with political developments. For instance, as Athens took over the surrounding smaller communities in its region of Attica (including Piraeus, which became Athens's seaport, and the village of Marathon, site of a famous battle against the Persians in 490 B.C.E.), they were incorporated as political divisions known as *demes* rather than as independent cities, usually maintaining their former boundaries.

When it was necessary to mark borders, boundary stones known as *horoi* were used. Some still exist and are similar in size and form to the boundary markers used to delineate the space of a public place, such as the agora (marketplace) or temple precincts. As with many aspects of Greek life, boundaries had a minor religious significance: Boundary stones were under the protection of Zeus Horios, or Zeus of the Boundaries. (Such epithets were common for

the major Greek gods; hence, Zeus Xenios, responsible for protecting *xenoi*, or strangers.) Given the general competitiveness of Greek culture, border disputes must have been fairly common, but little direct evidence of them remains. On some occasions disputes were serious enough to require the appointment of neutral commissioners, known as *horistai*, to settle them.

Borders were not normally guarded except in times of war: The ancient world lacked the elaborate system of routine border controls found in modern nations. Since war, however, was a more or less constant threat during certain periods, fortresses might be established at certain key points to control access to one's territory. Warfare was often directed at depriving one's enemies of the materials necessary to conduct a war, so cross-border raids were extremely common. During the Peloponnesian War (431–404 B.C.E.), Spartan incursions forced the Athenians from outlying districts to retreat behind

Dedication by Alexander the Great to Athena Polias, around 330 B.C.E., from Priene, Asia Minor; this was one of several dedications Alexander made in the course of his travels while extending the boundaries of the Greek world. (© The Trustees of the British Museum)

their city walls, which were designed to guard only Athens and its port of Piraeus. In addition, one of the key incidents of the later part of the war was the Spartans' seizure of Decelea, at the northern edge of Athenian territory, and their construction of a fortress there, in effect giving them partial control of their enemy's borders. Border controls could be tight enough to cut off the flow of goods in case of wartime embargo: Characters in Aristophanes' *Lysistrata* complain that the war has deprived them of access to such luxuries as eels from nearby Boiotia.

As for external borders, population pressures, political upheaval, and the generally poor quality of soil in mainland Greece led to the frequent founding of colonies, starting in approximately 750 B.C.E. and continuing for more than two centuries. As a result, Greek frontiers were constantly shifting, and Greek speakers shared borders with virtually all the peoples of the Mediterranean: Lydians, Medes, and Persians (among many others) in Asia Minor; Scythians along the Black Sea; Etruscans and various Latin peoples (including Romans) in Italy; Carthaginians and Sicels in Sicily; and Gauls in the south of France. Alexander's conquests expanded the Greek world still further, bringing Greeks into contact with lands as distant as Afghanistan and India.

Frontiers had a strong hold on the Greek popular imagination. Border areas and hinterlands were where the norms of human culture were subject to reversal and where the "otherness" of strangers could extend to the barbaric and the monstrous. Various cities, including Crete and Sparta, had rituals that involved sending young men out to the frontiers of the polis to take part in rites of passage, which could involve behaviors (thieving, deception, ritualized pederasty) that were normally excluded from the city itself.

The best-known example of the strange fascination of frontier regions is the array of odd and semihuman peoples encountered by Odysseus during his wanderings, ranging from the relatively normal (but socially inept) Phaeacians to the monstrous and cannibalistic Cyclops Polyphemus. Yet peoples less fantastic than these were widely believed to exist just beyond the frontiers of the known world. Among these were the Amazons, an all-female tribe who were everything that Greek women were not supposed to be: independent, nomadic, sexually and militarily aggressive. Always located on the very edge of the known Greek world, the Amazons were an embodiment of the notion that the edge of this world was the edge of civilization itself. In fact, the supposed location of the Amazons moved eastward, starting from Asia Minor and winding up in the Caucasus Mountains: As the border of the known world moved, the Amazons moved with it.

ROME

BY TOM STREISSGUTH

The Roman Empire, the largest realm of ancient history, began as a village spread across the hills near the Tiber River in central Italy. The Romans established a republic after

deposing their last king, Tarquin, around 509 B.C.E. Upon turning back an invasion from the north by the Celts in 390 B.C.E., the Romans began the conquest of the Italian peninsula. They expanded their control north to the Po River and south to the Greek colonies along the Mediterranean. The Roman frontiers, as well as private estates and city limits, were marked by boundary stones sacred to the god Terminus. An elaborate ceremony accompanied the placement of these stones. During the annual festival of Terminalia, at the end of the Roman year on February 23, the stones were cleaned, and the blood of sacrifices poured on them to renew their protective powers.

During the third and second centuries B.C.E., the growing republic clashed with Carthage, a North African empire, in the Punic Wars. After the last of these conflicts ended in 146 B.C.E., the Romans established their first overseas colonies in Sicily, Spain, Sardinia, Corsica, and Numidia (modern Tunisia). Roman armies then subdued Macedonia, southern Greece, Asia Minor, and the rest of North Africa, the province of Asia (Syria), and Gaul (France) in the first century C.E.

With the conquest of Gaul by Julius Caesar, at the Battle of Alesia in 52 B.C.E., Rome's frontier extended to the English Channel and the Rhine River, which served as natural barriers against the Germanic tribes to the east and north. The Roman provincial governors allowed local commerce and culture to continue without interference, using these territories as sources of revenue and buffers against the barbarian tribes beyond. To encourage cooperation in the frontier territories, Rome held out the promise of citizenship to all outsiders who served in the Roman armies.

Under the first Roman emperor, Augustus, who reigned from 27 B.C.E. to 14 C.E., Rome expanded to the Sahara in North Africa, the forests of Germany, the Atlantic coast of Gaul and Hispania (Spain), the Danube River in the northeast, and the Red and Black seas in the east. The defeat of a Roman legion in Germany's Teutoburg Forest in 9 C.E. persuaded Augustus to end any further expansion of the empire and station his legions behind these natural frontiers.

Rome reached its greatest extent during the second century C.E., when the emperor Trajan conquered Dacia, pushing the northern frontier of Rome beyond the Danube. Trajan's successor Hadrian strengthened the frontiers with forts, walls, and earthen ramparts in Britain and along the Rhine. A network of roads, originally built to carry the legions into enemy territory, extended to the empire's farthest limits. The vast network of roads—more than 50,000 miles—symbolized a superior civilization, highly skilled in engineering and capable of mustering armies of laborers to meet its needs. Local subjects were taxed to maintain the roads and levied to build them when the legions first arrived. The roads allowed the fast movement of armies as well as trading caravans, messengers, and private mail carried between the capital and the major cities out to the frontiers.

Roman fortifications were strategically placed along the frontiers. They were laid out in a quadrilateral, with

a ditch surrounding the perimeter and earth thrown up behind it to form a rampart. On top of the rampart was a palisade of timber or stone. The camps were divided into three main areas, centering on the *praetorium*, the tent of the commander, where the symbolic banners were kept safe. In front of this structure was the *praetentura*, where the elite troops camped closest to the entrance; at the rear was the *retentura* for the common troops and cavalry. A principal gate cut into the rampart faced the enemy, with secondary gates sometimes built at the rear and sides. The largest forts covered as much as 50 acres, included quarters for civilians and slaves, and housed an entire legion of about 5,200 soldiers. Smaller outposts, signaling stations, watchtowers, and temporary camps protected laborers, travelers, and smaller campaigning forces, who would abandon these quarters at the end of the fighting season.

Where the threat of attack was constant, Roman engineers raised continuous physical barriers. Hadrian's Wall and the Antonine Wall in northern Britain protected Roman colonies against the troublesome Picts, who attacked from their homeland in what is now Scotland. In Germany the Roman *limes*, running nearly 400 miles, was raised in the first century, after the Roman defeat in the Teutoburg Forest. It was a rampart of earth and stone, which was more a boundary marker than a defensive structure, since not even Rome could raise a wall strong and long enough to guard the entire Rhine frontier. Watchtowers and small forts were placed at regular intervals along the *limes* but were not always manned.

Tribes living outside the border stones and walls found Roman territory, with its wealthy towns and farming estates, a most inviting target. The long frontier could not be guarded at every point, so Rome began hiring *auxilia* (mercenaries) from the local population to beef up the army. In the second century, however, Germanic tribes overran the Danube frontier—a preview of the full-scale invasions to follow as the empire weakened over the next three centuries. In the third century civil unrest in Rome prompted the emperors to pull back from the Rhine-Danube frontiers, leaving the northern frontiers exposed. As Goths, Vandals, Franks, Burgundians, and Huns raided Roman territory in northern Europe, fortifications were abandoned, and hundreds of Roman towns were raided and pillaged.

In 293 the emperor Diocletian divided the empire in half. The western half continued to be ruled from Rome, with Maximian as emperor. The eastern half had its capital at Nicomedia, where Diocletian ruled. In 324 the emperor Constantine shifted the capital to Byzantium. This former Greek town, on the narrow straits between the Aegean Sea and the Sea of Marmara, thrived as the western empire weakened and Rome's European provinces suffered increasing violence and administrative chaos. In 410, the Vandals stormed down the Italian peninsula and sacked Rome itself. In 476 the Germanic chieftain Odoacer deposed the last western Roman emperor in his palace at Ravenna, Italy. Historians traditionally have marked this event as the fall of the western empire.

THE AMERICAS

BY J. J. GEORGE

Maps and timelines of the ancient Americas that outline spatial and temporal borders are becoming more defined through research and exploration. Culture area borders as clearly defined as the contemporary border between the United States and Canada or Mexico were unknown. The sweeping arcs and circles that most maps use to delimit the ancient cultures of the Americas are largely arbitrary, but nonetheless instructive. For the people who lived within them, defining these areas and then defending them proved to be a subtle political or economic maneuver, though defensive architecture, battles, and skirmishes often added clarity and definition.

A frontier generally designates a physical margin, fringe, or outer boundary—more of a zone than a line—dividing peoples. It is also the division between settled and uninhabited parts of one nation, state, or culture area. Since the North American landscape during much of the ancient period comprised vast swaths of variable terrain traversed by hunter-gatherer bands and some semisedentary groups, it can be said that much of the land was frontier. Similarly, in Mesoamerica and South America, early settled agrarian culture areas were small in comparison to the total landmass, and often a substantial frontier existed between contemporaneous cultures. When those cultures came into contact, the notion of borders became relevant.

Borders symbolize aspects of nationhood and identity construction and are linked to state building. Factors that ultimately define borders include natural topographic limiters or barriers (mountains, rivers, or forests, for example); competition for space, resources, or power; the relationship of a dependent periphery to a central core; trade; tribute; migration; warring; and, on a broad scale, climate change. New technologies allowed for expansion into previously uninhabitable areas. Any combination of these factors contributed to the classification and continuous redefinition of borders throughout the Americas.

By 300 C.E. the Inuit of the far arctic north had settled at Birnirk, in what is today Barrow, Alaska, where they maintained a subsistence pattern based primarily on maritime resources such as whale and seal. Scarce resources and a changing climatic environment necessitated group cohesion for survival. Later, having mastered the technology necessary for surviving the harsh climate, a period of expansion ensued. This time of ferment meant that new groups were coming into contact. War and trade, instead of subsistence, became the focus of innovation, sometimes expressed aggressively across informal borders in order to procure goods meant for survival. Farther south the frontier between Inuit and Aleut populations on the Alaska Peninsula was relatively resource-poor and acted as a buffer zone between two relatively richer zones. The boundary remained stable over a long period of time until the Thule culture—because of environmental change, increased tech-

nological efficiency, or population pressures—was finally able to penetrate the boundary.

Along the Northwest Coast raiding and warfare were the primary forms of interaction. Three-thousand-year-old remains of human skeletons excavated in Prince Rupert Harbour, British Columbia, show a high rate of injury among males. Numerous fortified sites have been found, some of which are thought to be true villages, indicating at least that some understanding of borders was coming into existence. Since borders are intrinsically tied to notions of ownership, possession, and power, it is not unusual to find fortified sites adjacent to areas of resources. Notably, along the Northwest Coast the earliest sites that suggest a more sustained sedentary or non-nomadic lifestyle, with a greater commitment to principles of defense, are found beside rivers with rich salmon runs, a primary food staple for the area.

Between 200 B.C.E. and 400 C.E. some Hopewell Indian complexes as far east from their Illinois and Ohio “centers” as eastern Pennsylvania and New York are thought to have been assumed into a Hopewellian culture, representing daughter communities or colonies derived from one or the other center. The exact nature of the relationship is unclear. Gathering disparate villages under an umbrella classification to define the spatial aspects of a culture does not necessarily establish or define a border, though it does indicate broader spheres of influence or interest that are suggestive of transparent borders and frontiers with a limited political, economic, and territorial association.

Between 1500 B.C.E. and 300 B.C.E. the early Mesoamerican Gulf Coast settlements attributed to the Olmec civilization acquired the marks of town planning, with regular site orientations and large-scale constructions. An emerging nobility, established channels of commerce and communications, the construction of monumental architecture, and a significant population in the thousands supported by a large area of peripheral settlements all imply a form of political economy and integrated local and distant polities. These are conditions that precipitate the establishment and control of border areas. The monumental carved heads of the Olmec, sculpted from basalt rock gathered from the Tuxtla Mountains, are further evidence of established relations and regional economies that transcend defined borders.

Farther south, in Mexico’s Valley of Oaxaca, three converging valleys and their surrounding alpine environment defined the generic borders of the earliest sustained villages. Around 1400 B.C.E. a regional network of small villages with a total population suspected to be around 500 defined the early settlement. By the period referred to as Monte Albán I (500–300 B.C.E.), a population thought to be about 17,000 clustered at the hilltop civic-ceremonial center of the same name, with as many as 50,000 at the surrounding sites. The increased proportion of populations living on the far periphery may have been related to defensive concerns and border control. Through the periods of Monte Albán II and Monte Albán III, by about 450 C.E., more sites were built in defen-

sible positions, and several of these sites still have evidence of standing fortified walls. They may have been located there simply as administration centers or as centers for traffic monitoring, though they strongly suggest a mechanism for frontier maintenance in their aggressive, forward placement and defensive architecture.

The topography of Andean South America provides some of the most extreme physical markers for natural borders and frontiers. The landscape moves rapidly upward from a coastal desert cut through by rivers to the high alpine environments. These natural obstacles to easy migration provided obvious borders and frontiers and helped define areas of settlement. By 4000 B.C.E. settlements based on the rich maritime environment along the coast had been established. Between 1 and 700 B.C.E. the Recuay culture, a highland culture composed of a large number of independent polities, shared its borders with the Moche culture, a lowland coastal entity, and the two were known to have expansionist tendencies. In response to intensive competition with Moche neighbors, Recuay settlements were founded along ridgetops, which served as defenses, and were sometimes fortified with moats, restricted access, perimeter walls, and parapets. On its side, Moche pottery testifies to warfare, with its common themes of warriors, weapons, and trophy heads. Despite natural geographic buffers, the Moche and the Recuay fought over and defended their borders while continually trying to expand them.

► building techniques and materials

INTRODUCTION

In a modern city a common sight is that of towering cranes that reach high into the sky to lift building materials to the tops of huge, multistoried buildings under construction. In cities, small towns, and rural areas, the sound of tractors, bulldozers, and backhoes, along with electric saws and drills, pneumatic hammers, and the engines of massive trucks, accompanies the construction of roads, bridges, houses, public buildings, and the like.

In a world in which these labor-saving tools are so common, even indispensable, it seems almost impossible to understand how ancient people built many of the structures that define their civilization for modern-day historians and archaeologists. Yet build them they did, using whatever materials were available to them and working out construction techniques that enabled them to erect some of the most magnificent structures the world has ever seen. Lacking the tools and materials so common in the 21st century, they had to rely on their ingenuity as well as on massive teams of laborers (often slaves), to muscle local materials into usable and permanent structures.

Prehistoric peoples relied on whatever materials were at hand. In some regions it was common to build structures such as houses out of reeds, grasses, thatch, clay, mud, bark, bamboo, stones, or wooden poles and beams. A common

early building technique is called wattle and daub. *Wattle* refers to a lattice wall constructed with small, flexible tree branches woven together. Once the wall was complete, a daub made of mud, perhaps strengthened with ground-up straw, was smeared over it, like plaster. Also common among early peoples were earth mounds, typically used as burial sites.

As people began to gather in cities and as civilization became more complex and advanced, early builders began to use a wider variety of materials and to devise building techniques that allowed them to create more elaborate structures. As it is today, wood was a common building material in forested regions, but wood is nondurable and especially vulnerable to moisture, so modern scholars have very few examples of wooden structures to study. Further, when some regions of the world became deforested as populations grew, builders had to turn to other types of building materials, particularly stone. In many cases, this stone was joined with cement and covered with a layer of adobe, limestone plaster, or some other substance.

Stone is heavy, making it hard to transport, so builders typically relied on the type of stone that was locally available. In some regions it was sandstone and in others marble, granite, or some other stone. Using primitive hand-held cutting tools, miners quarried the stone, dressed it (that is, cut into shape, trimmed, and smoothed), and then transported it to the building site. Where possible, as in ancient Egypt, builders used water power to transport the stone.

At a building site builders relied on a number of tools to ensure that their buildings were level and square and that walls were perpendicular to the ground. These included such tools as plumb bobs and various other contrivances that gave them level, perpendicular lines. Water troughs were also commonly used to find a level line. Levers, pulleys, and ropes, along with a good deal of manpower and the work of horses or oxen, were used to lift materials into place. In some cases, such as the pyramids of ancient Egypt, large ramps were constructed to raise the materials; sometimes these ramps were almost as much of a construction project as the building itself.

AFRICA

BY KIRK H. BEETZ

Most ancient Africans used clay, rushes (a type of plant), wicker, grass, bamboo, or tree bark when building. Stone was used for construction primarily in the northeast and east of Africa. Elsewhere in Africa stone was rarely used for anything but altars in shrines, and then it tended to be used as it was found and left uncut.

The majority of Africans lived in huts. These were usually windowless, with the only opening being a doorway. As a result, interiors were smoky from the open cooking fires or clay ovens. Huts were most often circular but could be oval. Their walls were made of clay that had probably been dug up and transported by women. These clay walls were built up in circular layers, first a bottom one of perhaps eight inches high,

with an opening for the doorway. The next layer would then be spread on top of the first.

In northwestern, sub-Saharan Africa, the walls curved inward, layer by layer, giving the finished structure a dome-shaped roof. Elsewhere in Africa the houses were topped by thatch. These thatched roofs were usually conical, with the thatch hanging over the top edge of the clay wall. In some areas the roof might be made of wood, but again forming a cone.

Sometimes walls had frameworks of wattle, or poles intertwined with branches. The wattle would be covered inside and out with clay. In areas where clay was hard to find, walls were made of tree bark or woven rushes. Such walls seem to have been most often constructed in grassy areas that were drier than Africa's rain forests. The herdsman culture of the Sahara grasslands of 5095–2780 B.C.E. built huts of wicker with grass roofs.

Many materials used in ancient African building were not durable. Buildings disappeared quickly if they were not maintained. For instance, wood decayed rapidly in the moist regions of Africa, and in the drier regions voracious termites ate it away. Even clay bricks eroded from wind and rain. Such

erosion left many ancient buildings little more than melted heaps. One building material that does manage to endure is stone, although even it is subject to erosion. Cultures that used stone are likely to have had some building remains survive. Most use of stone in southern and western Africa dates from the Middle Ages and later, but in northeast Africa at least two cultures from the ancient era built in stone. One was the kingdom of Kush, and the other was Axum.

Kush was a Nubian kingdom, to the south of ancient Egypt. Its principal building materials were reeds, wood, clay, and stone. Most Kushites lived in houses made of reeds, probably laid over a wooden framework. Their homes tended to look like rounded cones, with the reeds of the walls gathered together at the top. Even now, ceramic finials are popular in Africa, and these reed houses seem to have had ceramic finials shaped like pots on their peaks. (A finial is a decorative object placed on the peak or corner of a roof.)

In Kushite cities and towns, houses were made of durable sun-dried brick or fired brick that was less durable and would erode quickly in rain. The houses consisted of complexes of huts that served as rooms. There would be an outer wall with only one door in it, and along the inside wall were about five

Wattle framework being filled with red mud, a construction technique used in ancient times, from Zambia (© Board of Regents of the University of Wisconsin System)

brick huts. Each hut, or room, opened onto a central courtyard where most of the home's activities took place. Kush was founded around 900 B.C.E., and for some two hundred years, brick was the favored building material for palaces, temples, and other important buildings.

The Kushites were heavily influenced by the Egyptians, and one Egyptian building device in particular facilitated a shift to using stone for major construction. This device was the *shadoof*, a long, wooden pole that pivoted on a post near its middle. Heavy stone blocks would be placed in a basket that hung from ropes at one end, and a counterweight was placed on the other end to swing the basket upward. The *shadoof* had its limits: It could not lift stones that weighed several tons, like those found in monumental Egyptian structures, but it could lift stones weighing hundreds of pounds. It is still in use in eastern Africa.

Sandstone was favored in Kushite buildings. The Kushites were skilled rock carvers. They imitated Egyptian techniques using wooden mallets and metal chisels to carve pillars and decorations on walls. They hollowed out impressive cisterns, tanks cut out of rock to hold water. The most famous structures in Kush are the pyramids where kings and members of the royal family were buried. While they are not as large as many Egyptian pyramids, they do sometimes top one hundred feet in height. To achieve this height, ramps made of piled rubble were built perpendicular to one side of a pyramid, and rectangular stones were dragged up to within several feet of where they were to be set and then hauled the rest of the way by a *shadoof*. It is not clear whether the stones were fully dressed before or after they were set in place, but given the evenness of the slopes of the sides of these pyramids, the dressing was probably completed afterward. Although special care was taken in the building of tombs for royalty, good workmanship was shown in the graves of ordinary people also. These graves were lined with bricks, and a shelf was built within the graves on which the corpses were placed.

The Kushites took great pains in the making of their doors. Ancient visitors described wooden doors that were carved with images of gods, kings, and their people. Palace doors were made of ebony inlaid with ivory. Gold foil was applied by hammering it onto images on the doors. Gold was also used for images on walls and pillars, making the walk along a corridor to the palace doors one of constant glitter.

For over a thousand years, the people of Kush built impressive structures, but sometime before 350 C.E. their government collapsed, probably from a combination of overgrazing the land, loss of trade contacts with Europe and the Near East, relentless raiding by desert nomads, and pressure from Axum, a city in northern Ethiopia that had developed into a kingdom. Axum was influenced by African, Near Eastern, and Indian cultures, because it was a focus of trade between Africa and Asia. The Axumites lived in communities built of brick and stone. Their houses were blends of influences, often featuring columns like those found in southern India.

When using stone, they built their walls with uncut rock with dressed and smoothed rocks for doorways.

EGYPT

BY KIRK H. BEETZ

The earliest Egyptians were probably subsistence farmers who were squeezed into the region of the Nile River as the surrounding deserts expanded during a long period of climate change. Their homes were probably huts made of dried mud. By the end of the Predynastic Period in about 3000 B.C.E., geography and climate had left Egypt with four abundant building materials: mud, reeds, straw, and stone. It is likely that Egyptians also built structures of wood, but these seem to have been primarily temporary buildings set up for special events and then taken down. For most of its history Egypt needed to import wood for large construction projects from Nubia and farther south as well as from the Levant.

The manufacture of mud bricks is described in the book of Exodus in the Bible, and the process changed little during ancient Egypt's long history: Mud was tamped into rectangular molds and left out in the sun to dry. To make the bricks more cohesive, chopped straw was often added. The result was a building block that could be made in large quantities quickly. Its disadvantage was that it wore out quickly; rains and winds could destroy a building of mud brick in a couple of decades. More durable than sun-dried bricks were fired bricks. At first the bricks were roasted in open fires, but this made for uneven baking. Tougher, more enduring building blocks were produced when eventually kilns were built for firing them. Until the era of Djoser, king from about 2630 to about 2610 B.C.E., mud bricks were Egypt's primary building material whether for small homes or massive public works; even obelisks were originally stout piles of mud bricks. As late as the New Kingdom of 1550–1070 B.C.E., mud bricks were still used for building the tombs of most commoners.

The first Egyptian stone construction known is a floor of granite for a tomb at Abydos, about 100 miles north of Thebes, probably for a king of the Second Dynasty (2770–2649 B.C.E.). Even though there were supplies of limestone nearby, the granite had been shipped down the Nile for the purpose. The stone blocks were not well dressed, only roughly squared, and they were poorly fitted together. A revolution in building with stone began with Djoser's tomb at Saqqara. At first it was going to be a typical mastaba, or underground tomb carved down into rock and topped with a square masonry platform. Sometime during its building, Djoser or his chief architect, Imhotep, decided to expand the structure above the ground. First a step that was lower than the walls of the mastaba was built around it, and then smaller mastabas were built on top of one another, forming steps that may have represented a ladder for ascending to heaven. These were built with local limestone, roughly dressed and coated with finely smoothed limestone blocks from Tura, an ancient site for quarrying thought to have had the finest stone. The stones were not the

massive sort used in the Great Pyramid but were smaller than a human being; the Egyptians were experimenting with the stones as they built, seeing what they could do. Now known as the Step Pyramid, it was surrounded by a temple complex of stone and mud brick.

Not only tombs but also temples became signs of the power of Egyptian rulers, who built them even in the far reaches of the empire. But spreading out big building projects across the landscape created logistical and labor problems for the builders. Most ancient Egyptian public works projects were carried out by volunteers. Typically, they would donate their labor for part of the year to work on such structures as giant pyramids. Only a small group of people would work on construction projects all year round, among them, architects, foremen, engineers, specialized artisans, and those who served them, such as physicians who repaired their injuries and bakers who supplied them with bread. A small town built for full-time workers on the Great Pyramid of Khufu has been uncovered near the pyramid. It has individual homes, places for eating, supply areas, and shops, mostly built out of mud bricks. The main avenue that bisected the town was probably covered.

In the outer reaches of the empire, it may have been hard at times to find enough volunteers or local people to conscript for the building of monuments. For instance, the famous Great Temple of Ramses II at Abu Simbel, with the colossal statues on its facade (ca. 1270 B.C.E.), has within it depictions of Nubian slaves working to build it. Even so, later accounts of the use of tens of thousands of slaves to build the Great Pyramid of Khufu, from about 2551 to about 2528 B.C.E., are erroneous; most of the public construction was done by volunteers, by people paying their taxes with their labor, or by conscripts who were paid for their labor.

The Nile may have looked like a highway filled with giant stones during and after the era of Khufu. Granite or limestone blocks would be quarried at sites along the river. Workers would hack at rock, forming a narrow trench into which wooden stakes would be pressed; the stakes would be soaked and, as they expanded, would crack the rock. This technique was used for stones ranging from 200 pounds to 60 tons, for stones intended for bearing weight to long, tapering ornamental obelisks. The stone would be placed on sleds made of wood and reeds; the ground in front of the runners would be wetted down, making the ground slippery, while teams of men hauled at ropes, pulling the stones to the river. The blocks would be slid onto reed boats built specifically for ferrying stone. Special docks were built near the individual sites of construction, and the stones would be hauled by sled to the building site. At some sites, such as the Giza Plateau, basic limestone could be quarried nearby, but special stones such as granite or the Tura limestone used for outer facings had to come via the river.

Ramps for raising stones have been found at the Medūm pyramid built by Snefru (r. 2613–2589 B.C.E.) and beside an unfinished pylon at the temple at Karnak (on which construc-

tion began in the 16th century B.C.E. and proceeded through the reigns of 30 pharaohs). Exactly how the ramps were structured is not known, but they were used to haul even huge stones up and into place. Egyptian masons would then coat the top of a row of stones with mortar, not to hold them together but to act as a lubricant to ease the sliding of the next row of stones onto them. Once in place, the stones would be fully dressed by carvers so that they would fit together tightly.

HOW TO BUILD A PYRAMID WHEN ONE HAS NOT BEEN BUILT BEFORE

When King Djoser ruled Egypt, the tombs of kings were mastabas. These tombs were mostly underground, carved into solid rock, and had a couple of long stairways, with chapels, storage rooms, and a place for the sarcophagus. Aboveground would be a rectangular or square area composed of sloping walls filled in with mud brick. Perhaps the inspiration to make the mastaba of Djoser more impressive came from the ancient tradition that said that a deceased king would climb a stairway into the afterlife. The ancient Egyptians gave credit to Djoser's chief administrative officer, Imhotep, for what happened.

First he had the outer wall of the mastaba surrounded by another, lower wall and had the space between the two walls filled in. It made the original mastaba look more impressive and may have served to brace the first mastaba's walls for what came next. A platform was erected atop the mastaba, and another smaller platform was built on top, giving the tomb four steps and making it a step pyramid.

Imhotep decided to make the pyramid higher, but its base was probably not going to tolerate more weight being placed on it. Instead of adding another level onto the top, Imhotep shifted construction to the side of the pyramid. He built outward about half again the length of one side of the bottom step. Then stone was leaned against the side of the pyramid and built outward to form steps that were level with the original steps. Each level was now much wider than it had been. When this new construction was even with the fourth level of the original pyramid, the top level had as much surface area as had the original plain mastaba and could now bear more weight.

With more weight possible, two more levels could be added atop the original top step. The visible levels were faced with white limestone and polished. The smooth, white limestone walls shone in the sunlight. At 200 feet high and with a base of 393 by 467 feet, the Step Pyramid of Djoser dominated the land for miles around.

Wooden scaffolding would eventually be built to give sculptors and painters access to the outer walls. In the case of the pyramids at Giza, granite stones were set on the outsides of the pyramids, carved until they formed smooth slopes to the tops of the pyramids, and then polished so that they shone brightly in sunlight, while displaying carved images and glyphs.

THE MIDDLE EAST

BY JAMES A. CORRICK

The building materials used in Mesopotamia, Persia, and the rest of the ancient Near East were reeds, wood, stone, and mud bricks. Reeds, harvested along the banks of the Tigris, Euphrates, and other rivers, were commonly used because houses could be built quickly and cheaply from them. A reed house began with a circle of holes for a round structure or two parallel lines of holes for a rectangular one. The builder then pushed bundles of tightly tied tall reeds into each hole and pulled together the bundles opposite each other, tying them at the top to form the roof that was then covered with a mat woven of reeds. More mats were hung in the openings left for doorways.

Unlike reeds, trees were scarce in much of the Near East, particularly in Mesopotamia, and wood was not generally used to construct houses or any other buildings. Instead it was reserved for door frames, doors, roofs, supports for roofs, and paneling. Mesopotamia used stone, as did the rest of the Near East, but more rarely because it had few sources of the large stones needed for construction. Stone was used to make city walls, building foundations, and floor paving. It was less often used for the walls of buildings. The Persians, who had a readier source of stone, used it to make stairs, doorways, window frames, and columns, many of which stood 65 feet high. They sometimes carved whole building elements out of a single stone block, as they did with the great stone staircase in Persepolis.

Even the Persians did not use stone for building walls, however—not even for their palaces. Like the Mesopotamians and other ancient Near Easterners, they constructed building walls from brick. Indeed, of all the building materials of the ancient Near East the most common was brick formed from mud. Mud brick was quick and easy to make as well as to use. In the heat of Near Eastern summers, bricks had the added advantage of absorbing and radiating that heat very slowly. Thus brick buildings, particularly those with thick walls, remained relatively cool. Mud bricks were made from river mud or clay that was mixed with either sand or finely chopped straw to give added strength. At first individual bricks were shaped by hand. These handmade bricks were either cigar shaped or bun shaped. Although shaping bricks by hand would continue, after 2700 B.C.E. many Mesopotamians began to use rectangular molds, which formed bricks that were twice as long as they were wide.

The brick makers either pressed the mold down into a mass of prepared mud or filled the mold up with mud. Be-

Clay foundation peg, the first Dynasty of Lagash, around 2400 B.C.E. from Bad-tibira, southern Iraq (© The Trustees of the British Museum)

ginning around 2700 B.C.E. Mesopotamians began manufacturing plano-convex bricks. A mold would give a brick a flat bottom and flat sides (planes). The top, however, bulged or curved out, forming a convex surface. It was this convex surface that faced out and became the exterior wall of a structure. The plano-convex brick was confined to Mesopotamia, and even there this shape was mostly abandoned after 2400 B.C.E. Mesopotamian brick makers after that time scraped off any excess mud, making every surface a flat plane. This technique would be used by all other Near Eastern brick makers, including the Persians.

Once shaped, a brick was removed from the mold to dry and harden. The hardest mud bricks were those baked in ovens. However, it was easier to let bricks dry in the sun, the trade-off being that sun-dried bricks were not as strong as oven-baked ones. Once dried, by whatever method, the brick was ready for use, primarily in building walls. Brick walls were built up one horizontal layer, or course, at a time. Each course had to be cemented to the course under and over it, using any one of a number of methods. Workers could simply press wet bricks together and let them harden in place. More commonly they used mortar, a moist substance that adhered the courses to one another when it dried. The most usual mortar in the Near East was clay or mud mixed with straw or grit. In Mesopotamia another common mortar was bitumen, a black, sticky petroleum material that seeped up from the area's underground oil deposits. Bitumen and other mortars were also used as plaster coverings for brick constructions. Mud bricks, even baked ones, needed protection from sun, wind, and rain. Plastering them once a year protected them from disintegrating over time.

Walls made of stone were also built in courses and were often cemented together with mortar. One form much favored by the Phoenicians did not use mortar but rather stones shaped into equivalently sized rectangles that fitted tightly together. Then the blocks were laid in courses in which groups of three or four stones had their ends facing out of the wall while other groups had their long sides exposed. This alternation of the ends and sides of wall stones increased the wall's stability and helped prevent its collapse. Another method of stabilizing both stone and brick walls was to add buttresses that kept heavy walls from collapsing under their own weight. Although buttresses take a variety of shapes, in the ancient Near East they were flat pillars of brick or stone that projected out from a wall. The buttress transferred the outward force that the wall's weight exerted down into the ground.

Walls could also crumble under the weight of a building's roof. However, by resting the rafters that supported the roof on buttresses, builders could partially relieve the wall of carrying the load. Walls could also be weakened by being pierced with openings for doors and windows. The absence in Mesopotamia and other parts of the Near East of wood or stone to reinforce window frames and doorjambes also meant the absence of full support for the wall above. Consequently,

windows were often kept small and narrow, a single brick's width, for instance. By carving windows out of single blocks of stone, the Persians were able to increase the size of these window openings for their public buildings. The stone frame provided the necessary strength to hold up the brick wall above it.

Doors also were made as small as possible. Some early Near Eastern houses even had doors so low and set so narrowly that people crawled through them to reach the interior. Larger doors became possible through reinforcement. Builders placed two upright posts, or jambs, on either side of the opening and then laid a beam of wood or a stone, known as the lintel, across the top of the jambs. The lintel transferred the weight of the wall above the door down to the jambs. An exceptionally large doorway or the gateway in a city wall would have buttresses against either side as added bracing. Lintels were not sufficiently strong to bear the weight of large expanses of wall. They would break under such weight. Thus for entryways in large walls, Near Eastern builders used the arch, which was invented in Mesopotamia by the Sumerians in the fourth millennium B.C.E.

The most common type of arch in the ancient Near East was the corbeled arch. A corbel is a brick or block of stone that sticks out of a wall and on which another building element, a rafter or a beam for example, rests for support. In a brick corbeled arch—most made of brick—the object being supported was another brick. This second brick would itself stick out over the end of the first brick. On top of the second brick a third brick was laid, also projecting beyond its support. As one overlapping brick was added to another, gradually the side of the arch rose, looking much like a series of brick steps. From the other side of the entryway, another brick staircase rose to meet its counterpart, forming the apex of a triangle.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Little is known about what ancient peoples of Oceania built. Many lived in caves even into the modern age, and others probably lived in huts made of branches and sticks. On Easter Island, where people arrived around 400 C.E., there is evidence of such huts, but most of the people lived in caves they dug in the slopes of the island. For much of eastern Asia, little has been uncovered for Neolithic structures, probably because they were either temporary or built from perishable materials, principally wood.

In the prehistoric era the peoples of the Indian subcontinent and Southeast Asia built domed homes of mud, and their tombs for local leaders were typically large mud domes called *stupas*. When the Buddha died in 483 B.C.E., his cremated remains were divided among eight stupas, but in 260 B.C.E., King Asoka opened seven of these stupas and divided the remains among 84,000 stupas throughout most of India. One of these is the Great Stupa in Sanchi in central India,

which still stands. Its mud dome was eventually blanketed by bricks without the use of mortar.

Although it is known that Indians used wood for building many structures, superseding the use of mud in the north early in recorded history, little is known about the ancient wooden structures because they did not survive long enough. Heavy rains and humidity made wood rot quickly. Still, a little is known about early wooden buildings from surviving temples carved in stone. In about 150 B.C.E., in the Western Ghats mountain range along the west coast of India, rock carvers expanded caves that initially had been homes for religious ascetics, creating spectacular temples and monasteries. The ceilings of some of these temples are arched, and representations of wooden beams have been carved into them. The carvings show many small wooden beams fitted together to form arches, resembling a technique used in ancient China at that time. Iron axes with flat edges were used for the initial dressing of the stone, and fine tools of iron and stone were used for carving images.

The Indians used the post-and-crossbeam technique, in which two or more posts are set in the ground in a row and beams are laid across their tops to bear the weight of a roof or higher floor while leaving openings that could be filled by walls or doors. When building with bricks or small stone blocks, they used the corbeling technique to create openings in free-standing stone structures, such as towers. A corbeled opening is an arch shaped like an upside down V of steps, in which blocks are set with one end projecting outward and the other end held in place by the weight of blocks piled on it. Because they have no mortar to hold them together, the blocks are prone to shifting from the effect of earthquakes or erosion of their foundations, sometimes causing the structures to collapse. When building tall stone structures such as gateways, Indians first constructed an outer framework of bamboo that crisscrossed to make squares up which workers could climb.

Corbeling without mortar created problems for ancient builders that they did not fully solve. Most of Indochina and Indonesia imitated Indian building techniques. In the region of modern Cambodia, the Funan kingdom of the first through sixth centuries C.E. imitated Indian construction techniques, but their tall brick buildings would fall down. Later Funan and Angkor (802–1432 C.E.) builders in the region of modern-day Cambodia used sand to even out the foundations of their buildings, but water would wash away the sand, and towers would tilt and eventually crumble. They tried to solve that problem by hollowing out stones at the bases of buildings and inserting timbers buried in the ground to stabilize tall structures, but in the wet climate the timbers would rot, and the walls and towers would fall. These ancient builders and those in Java tried using dowels of iron for holding stones in place, but they required maintenance; iron would rust and fall apart and then so would walls.

In China, around 4000 B.C.E., the Yellow River culture built homes that were circular, with timber walls shored up on the outside by mounds of dirt and conical thatched roofs

that peaked in the middle. This basic structure spread to much of eastern Asia, and circular houses were still being built on the island of Honshu in the 200s C.E. As the Yellow River culture encountered cultures from the south and north, building protective structures became as important as building homes. During the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) towns were surrounded by walls of tamped dirt. On the northern frontiers, during the Zhou Dynasty (ca. 1045–256 B.C.E.), some small feudal provinces built long walls to deter nomadic northern tribes from invading. In 214 B.C.E. the emperor Shi Huangdi began to have these various walls connected into the Great Wall. The inner part of the wall was filled with debris, while stones were laid for the outer parts of the wall. This technique became common for building fortifications in China.

Even though the Great Wall is justifiably renowned, the great genius of Chinese architecture came not in the building of the wall but rather in creating techniques of construction that could be applied to monumental structures and to tiny homes and that were versatile enough to be adapted to different building materials according to availability. Thus, in northern China golden loess from desert areas was used for bricks, which were combined with wood to build structures; in central China stone would be combined with wood; and in southern China stone would be combined with bamboo as well as wood. All builders followed basic practices developed by the time of the emperor Shi Huangdi: Foundations would be excavated and filled with unhewn stone, bamboo or timber frameworks would be created for workers to climb, posts would be set in the foundation to bear most of the weight of the structure, and walls would bear little or no weight.

The posts would often have to bear immense weight, especially from roofs tiled with earthenware. On the top of a post, Chinese workers would place struts, usually of wood, that spread out upward like upturned legs; on their ends would be laid crossbeams or more struts spreading out, and the pattern would be continued as high as needed to reach the bottom of the floor above or the roof; the effect was to draw the weight of a building into the posts. This method resulted in buildings that had posts throughout their interiors, often set close together; provided the posts were sturdy, builders could place almost anything they wished onto a structure, which resulted in majestic pagodas, imposing palaces, shops, and houses for rich and poor.

The ancient Chinese used corbeling for their arches. This resulted in sometimes awkward public works, especially bridges, which tended to have tall, steep arcs that were very hard for people and carts to traverse while burdened. Even as the Great Wall was being built, Chinese engineers were borrowing from the technique of post and crossbeam to lay sturdy stone bridges. The stone beams were as long as 70 feet and weighed as much as 200 tons; these beams were smoothed with iron axes, dragged to riversides, lashed across several boats abreast, and floated into place during

flooding season inland or the annual high tide near the sea. Even during the late Shang Dynasty, builders used primarily stone tools, with bronze being reserved for weapons and household goods such as pots. By the end of the Zhou Dynasty iron was commonly used for axes and picks as well as for woodworking tools.

Chinese building techniques were imitated in Japan and the region of modern Thailand, and they spread to the west and southwest as the Chinese Empire grew. The homes of most Japanese were made of wooden walls and thatched roofs and were round or oval. In Korea and northern Vietnam, Chinese building techniques arrived with the migration of Chinese beginning during the Zhou Dynasty, with Koreans becoming masters of the craft of building by the 200s C.E. and carrying their skills first to the Japanese island of Kyushu in the 300s and Honshu in the 400s.

EUROPE

BY JUDITH A. RASSON

People throughout prehistory used locally available building materials that were assembled in different ways with little alteration beyond basic shaping. They did not use building materials that required many steps in preparation, such as roof tiles, which had to be fired before they could be used. The people of the Paleolithic cultural period (in the Pleistocene geological period, which ended about 8000 B.C.E.) were nomadic hunters, relying only on wild animals and plants for food. To find food, they moved from place to place several times during the year. Conveniently located caves provided campsites, but elsewhere they built shelters. The structures they built did not require a great deal of investment in labor or materials.

Archaeologists think that they used animal skins to make tents or sometimes piled pieces of shrubs against a framework of saplings to make shelters. Examples of temporary dwellings have been found in France and Ukraine, among other places. What they have in common is stones or other heavy objects encircling the floor, probably used to hold the walls in place, and poles supporting a roof. The covering of the roofs is not known for sure; it may have been branches or skins. In France (at Terra Amata, dating to about 36,000 B.C.E.) stones outlined the tent or hut and poles around the edges and in the center supported a roof of some kind. At the Paleolithic site of Mezhirich in Ukraine (dating to 13,000 B.C.E.) lower jaws of mammoths were nested together to form the floor and tusks held up the roof.

Later, after climatic changes at the end of the Pleistocene, people began to control the breeding of plants and animals for food instead of relying only on wild foods. Domesticated plants and animals characterized the economy of the Neolithic and the subsequent Bronze and Iron Ages (broadly, 7000 B.C.E.–500 C.E.). Relying on domesticated food resources meant that people settled in villages, where they lived all year round. They needed to construct buildings that were more

substantial and usually larger than earlier buildings and would last longer than a tent or brush shelter.

The main building materials of the Neolithic, Bronze Age, and Iron Age were wood and shrubs (brush, slender branches, planks, and posts), stone, clay, plant materials such as chaff and straw, and sod (in some areas). The way raw materials were used and the shapes and sizes of structures varied across Europe. All the raw materials were used without further processing other than shaping. People throughout Europe took advantage of local resources to construct a wide range of buildings.

Stone was not generally used for walls unless wood was scarce, as in the area around the Neolithic settlement of Skara Brae in Scotland (dating to 3100–2500 B.C.E.), which was wind swept and mostly treeless. Stone was the main building material; even the furniture was made of stone. Houses were dug into the ground and had an inner and outer wall of dry-laid sandstone slabs with earth packed between them. Earth also covered the roofs; the beams may have been made of driftwood. On Dartmoor in England granite was abundant, and during the Bronze Age natural slabs were set upright in circles to form walls. The roofs were probably made of wild shrubs like heather or straw or perhaps pieces of sod. During the Iron Age in Ireland underground chambers (called *souterrains*) lined with stone were built below wooden structures. Even when stone was used, it was dry-laid; mortar, which starts with a chemical reaction, was not used until Roman times.

Wood in many forms was a common building material in prehistory. Hard, durable tree trunks of oak or ash often served as the main posts of the structural framework. Smaller withes, or slender branches, of flexible wood such as hazel filled in the walls, often as wattle. Clay mixed with chaff or other fine-textured vegetal material was used as daub, or plaster, for the walls. The added organic materials left tiny openings in the clay so it would dry and also reduced the weight a bit. The walls were built directly on the ground surface or in foundation ditches. There were no separate foundations, so eventually the posts and walls decayed, leaving only the post holes and ditches. Much of the information archaeologists have about prehistoric building materials was preserved when the buildings burned down, preserving impressions of wood and other plant material in the remaining mud plaster.

In Central and Eastern Europe during the Neolithic and Bronze Age, wooden posts dug into the ground formed the framework of structures. The walls were made of wattle thickly plastered with daub, most often made from clay mixed with chaff. Straw was used to thatch the roofs. Houses built in this way are known from numerous sites: in Germany (the Neolithic site of Köln-Lindenthal), Poland (the Neolithic settlements of Brześć Kujawski and Olszanica), Hungary (Neolithic site of Herpaly), Serbia (Neolithic settlements of Vinča, Divostin, and Selevac), and elsewhere. Similar construction techniques continued in use during the Bronze Age

(at settlements such as Százhalombatta Földvár in Hungary) and elsewhere throughout the region.

Wonderful preservation of building materials is found in hundreds of so-called lake-dwelling settlements occupied from 4000 to 500 B.C.E. (the Neolithic, Bronze, and Iron Ages) scattered on both sides of the Alps from France to Greece (most famously in Switzerland). Because the sites are waterlogged, wood and other perishable materials are well preserved and show a range of uses. Wooden posts were driven into the ground to support the house. Covered with saplings and branches, this became a foundation for a wooden floor; the structure's framework was also of wood. The walls were made of wattle and the roof was probably of reeds or straw. Similar materials were used in Ireland during the late Bronze Age and Iron Age to construct artificial islands called crannogs. Tree trunks were driven into the mud of a lakebed to create a stable base, which was then covered with stones and peat. Dwellings and other structures were then built on this platform.

Besides being used for plaster, the earth itself could be part of structures. Large ditches were sometimes dug around settlements throughout Europe during the Bronze and Iron ages, usually interpreted as defensive and defining the territory of the settlement, and perhaps also serving to confine domestic animals. The earth dug out of the ditch was usually piled up next to the ditch in a bank or berm or rampart. This made the ditch seem even deeper.

It was mainly during the Iron Age that sod or turf was used to build structures by cutting it into slabs like bricks and stacking them up to form walls. Turf slabs could also be used to make roofs if they were laid over a strong wooden framework; this was done because they became heavy after soaking up water when it rained. This building material was used extensively in Scandinavia during the Iron Age, but it is also known from the United Kingdom. Elsewhere in Europe during the Iron Age wood, wattle, and daub continued to be the main building materials.

GREECE

BY CHRISTOPHER BLACKWELL

Archaeological excavations in Crete, beginning with those of Sir Arthur Evans in the late 19th century, have revealed the earliest buildings in the Greek world. The lowest excavated levels at the Cretan palace of Knossos, dating to around 7000 B.C.E., suggest structures with stone foundations and walls of mud bricks that had been sun-dried but not baked in an oven or furnace. On top of these ruins the monumental palaces of the Bronze Age (second millennium B.C.E.) were built. These structures combine finely worked walls, built of limestone and gypsum blocks shaped by masons who would "sign" blocks using unique marks, with rubble walls built of unevenly shaped stones, which were often the leftover remains of earlier structures that had been destroyed in this earthquake-prone area.

These walls were frequently plastered over and covered with frescoes. The walls defined rooms—often kept small so as to survive earthquakes—and served as retaining structures, creating terraces that allowed the palaces to sprawl over large, hilly areas. Wooden columns supplemented the stone walls in supporting ceilings that covered rooms and open-air colonnades. There is evidence of wooden beams inserted horizontally in the fabric of stone walls; these may have served as shock absorbers to protect the otherwise brittle walls during earthquakes.

During the latter third of the second millennium B.C.E., the Mycenaean Greeks of the Peloponnese favored large, strongly fortified settlements. These are notable for their megalithic constructions—immense blocks of stone, roughly shaped and stacked without mortar or with only a thin layer of clay. Some of the blocks in the walls of the palace at Mycenae measure 26.25 feet in every dimension. The ancient Greeks of centuries later believed that the mythical giants called Cyclopes must have built them, and this style of construction is still called Cyclopean. These immense stones lie in regular courses, forming so-called ashlar walls. Inside their corridors, the upper levels of stone project inward, each slightly farther, until the two walls meet and lean into each other; this technique, also used to create large domed chambers, is called corbel vaulting.

The period after the collapse of the Bronze Age civilizations until the reemergence of literacy in the eighth or seventh centuries B.C.E. is known as the Greek dark ages. Construction from this period is much more modest, with sites such as Lefkandi in Euboea (the long island along the eastern coast of Greece) and Smyrna (modern İzmir, Turkey) yielding the remains of simple mud-brick structures. These show evidence of thatched roofs supported by wooden poles. Even the Temple of Apollo Daphnephoros ("Laurel-bringing Apollo") in Eretria was, during the mid-eighth century, a small building (26.25 feet by 19.6 feet) of wood and brush.

By the Archaic Period (seventh to sixth centuries B.C.E.) and the Classical Period (fifth to fourth centuries B.C.E.), deforestation had made wood scarce in Greece, so much so that wooden structures were remarkable. A character in Plato's *Critias* says of Greece in the early fourth century, "There are some mountains that now have nothing but food for bees, but they had trees not very long time ago, and the rafters from those felled there to roof the largest buildings are still sound."

The monumental architecture of the Classical Period, therefore, was constructed mainly of limestone, trachite (a kind of sandstone), and marble. For economic reasons, buildings in any area would tend to use local stone. The ancient travel writer Pausanias notes this when he describes the temples and public buildings of Athens as being built mainly from Pentelic marble that had been brought from Mount Pentelicon just to the east of Athens. Stone blocks were fitted and joined with wooden or metal clamps, and important buildings had roofs of terra-cotta tiles.

The buildings of the Athenian Acropolis are the most famous representatives of Classical Greek architecture. They suggest an aesthetic of gleaming white marble, but this idealized vision is a mistaken one resulting from an accident: In antiquity, these buildings were painted in bright colors that have wholly worn away with time. Large buildings were invariably built using post-and-lintel construction, with upright columns supporting horizontal blocks of stone. The strength of stone lies in its capacity to withstand compression, not in its capacity to flex; when the horizontal beams (the “lintels”) had to extend across a wide gap, the weight of the roof or upper floor would cause them to crack because they could not flex. So any large building would need many internal columns to support the roof. In many Classical Period Greek buildings, the internal elements, less visible from the outside, would be made of common limestone, with more costly marble used only for external elements.

The masons used bronze and iron tools, with wooden mallets to shape the stone. Very rough shaping could be done by driving wooden wedges into cracks. When these wedges

were soaked with water, they would expand and break off pieces of stone. Transporting large blocks of stone was laborious. Because the rigid chest-reinforcing harness for horses was not to be invented until well into the second millennium C.E., only oxen had the chest strength needed to drag heavy loads unaided, and their speed was limited to barely more than one mile per hour. Transportation by sea involved more risks, but it was cheaper and faster. The only famous exporter of marble was an island, Paros, the source for Parian marble.

The blocks for these marble buildings were roughly shaped in the quarry and finely shaped, or dressed, at the building site. Columns were constructed by stacking many drums of stone on top of one another. Each drum had a hole through its center; these holes would be lined up in the finished columns and then filled with molten metal to provide rigidity. Fluting, which consisted of vertical grooves, was cut into the columns after they had been entirely assembled.

Stones were lifted using the simple but sound principles of leverage, which were famously identified and described by the Greek mathematician Archimedes during the third

Dolphin fresco in the queen's megaron (reception hall) at Knossos, the capital of Minoan Crete (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

century B.C.E. but had been well known long before then. Workers would raise blocks slightly with wooden levers, place wooden supports underneath, and repeat until the stone was high enough to move into place by sliding it over wooden rollers.

There were variations and innovations in the basic techniques of post-and-lintel structures in stone. Most notably, the historian Thucydides reports that the Temple of Athena Chalkioikos in Sparta was lined in bronze (*chalkioikos* means “bronze-house”); the bronze was melted down from weapons the Spartans captured during a battle at Aphidna.

In the Hellenistic Period (323–31 B.C.E.) building techniques did not change fundamentally, with the main innovations being aesthetic flourishes (often combined with cost-saving measures), such as the use of colored stone, marble veneers over cheaper limestone construction, or bricks covered with plaster painted to look like marble.

ROME

BY TOM STREISSGUTH

The craft and science of architecture made important advances in Roman times. Roman leaders considered public buildings as personal monuments to themselves, legacies of their power and benevolence. For this reason, many imposing structures were raised in the Roman cities, and Roman architects enjoyed wide renown and lucrative patronage. The early Roman builders borrowed their construction techniques from the Greeks and from the Etruscans of northern Italy. The Etruscan arch, adopted by the Romans in the third century B.C.E., marked an important advance over the post-and-beam construction traditional to the Greeks. The first arches were corbeled—made up of horizontal courses of stone, overlaid slightly as the courses rose higher and extended across a limited space. Later arches were true arches, made of stone that was cut and fitted to produce a regular semicircle.

The Roman discovery of *caementum* (cement), in approximately the second century B.C.E., made possible not only the longevity but also the more grandiose scale of Roman buildings. *Caementum* was made of three parts sand and one part burnt lime, mixed with a volcanic ash known as *pozzolana*. The ash helped the mixture dry quickly and evenly into concrete and also made it waterproof. Builders often added a rubble of small stones and broken brick to the mix to strengthen it. Concrete was impervious to fire and weather, and it bore more weight than stone. It was also more abundant and easier to handle than stone, which had to be laboriously cut, transported, raised into place, and fitted. Concrete allowed walls to support heavier loads and gave builders more flexibility in designing interior spaces.

Simple leveling devices, including the *chorobates* and the *groma*, ensured precise alignment of foundations, walls, and piers. The *chorobates* was a long, narrow wooden bench, with plumb lines hanging near both ends. The plumb lines were

Iron window grill, Roman Britain, late third or fourth century C.E. © The Trustees of the British Museum

precisely matched to a vertical line marked on the bench supports. To ensure the measure, the surveyor checked a small trough of water or oil on top of the *chorobates*; if the water line was straight, the device lay horizontal. The surveyor then sighted along the top of the device to a distant ranging pole to mark position and height. To align vertical surfaces, Roman builders used the *groma*, a wooden crosspiece suspended from a pole. Plumb lines hung from the four ends of the crosspiece. The surveyor verified that the lines hung a matching distance off the ground and then sighted along the plumb lines to ensure that a distant wall or pier (vertical support) was at a perfect right angle to the ground.

Once a site was surveyed and marked out, builders raised wooden frames to begin construction. *Caementum* could be poured into frames of nearly any size and shape. The drying concrete was faced with stones of tufa, a soft and porous volcanic rock. Different facing patterns went in and out of style over the course of Roman history. The earliest style was the *incertum* wall, in which tufa stones were placed randomly into the concrete. Reticulum walls had regularly shaped blocks, a technique begun at the end of the first century B.C.E. Dressed stones, commonly of tufa or travertine (limestone), were joined to the concrete in the *quadratum* wall. In later years, marble, porphyry, and alabaster were also used to face Roman buildings.

Finished stone walls were given a film of stucco, which could be decorated with painted signage or simple geometric designs. Interior spaces in both private homes and pub-

lic buildings, displayed fresco paintings of mythological or pastoral scenes or of more utilitarian pictures, giving visitors a hint at the profession or business at hand. Floor mosaics, employing colored tiles placed into concrete floors, grew popular after their introduction from Greece in the first century B.C.E. In the early empire, brick facing was a fairly uncommon technique, as the sun-dried (unfired) brick cracked easily from weather and stress. Later, kiln-drying techniques made bricks harder and stronger. Vast brickyards on the outskirts of Rome provided the basic facing material that endured until the Western Roman Empire's decline and fall in the fifth century C.E.

During the empire, cement mixed with a lighter ash known as scoria allowed the Romans to construct larger and loftier interior spaces. For their public baths and consecrated temples, such as the Pantheon, the Romans designed slender arches over entrances and raised domes and half-domes over interior spaces. A series of regularly spaced arches over a rectangular hall provided the frame for a barrel vault, while intersecting arches framed the groin vault. Stronger concrete walls could also be pierced with large window spaces, which, in this era before sheet glass, were commonly filled with wooden latticework.

The expanding empire raised a great variety of large public buildings, including markets, baths, temples, meeting halls, palaces, and such outdoor structures as hillside terraces, aqueducts, racecourses, amphitheaters, watchtowers, and speaking platforms. The arch and vault, along with concrete, gave architects great flexibility in the design of these structures and in the floor plans of large homes and *insulae*, or apartment blocks. Thousands of these massive Roman structures have endured more than two millennia, while modern concrete buildings, which are raised on skeletons of steel beams and slender iron bars, begin wearing out in a few decades.

Under the emperor Augustus, the first great public baths and theaters as well as multistory *insulae* were built in the city of Rome. In 64 C.E., however, a massive fire destroyed entire neighborhoods, and thousands of buildings had to be demolished. The emperor Nero passed new building regulations to prevent another such disaster. Building height was limited to seven stories, and all buildings were required to have porticoes (a colonnade, or row of columns, supporting a roof) for easier access to upper stories. Private homes had to keep fire buckets and equipment handy, and no common walls were allowed—all new Roman buildings had to be freestanding.

The gradual decline of the later empire degraded Roman construction and architecture. Late-empire architects replaced scoria and pozzolana with pumice, a weaker bonding material. There were few design innovations, and builders had to rely on inexpensive materials. Without the resources to maintain and repair buildings or to replace those lost to fire, war, or earthquake, Roman cities grew more chaotic and public buildings smaller and plainer. The great public structures, such as the Colosseum and the Pantheon, be-

came public meeting halls, storage yards, useful stone quarries, and finally empty monuments to Rome's past glory and engineering genius.

THE AMERICAS

BY ARDEN DECKER

Much of what is known of early building practices centers around the movement and shaping of the natural landscape. Everyday buildings were usually created from perishable materials, so it is architecture of a more monumental nature that has provided archaeologists with much of what they understand about building techniques and materials in ancient times. Adobe bricks, mud, clay, stone, and perishable materials made up the majority of building materials for all ancient American cultures.

In ancient Mesoamerica the wattle-and-daub building technique was one of the simplest and most prevalent methods used. A wood latticework (wattle) was covered in a mixture of clay, mud, and straw (daub) to create a structure. Posts were added for houses that would have been covered with thatched roofs and sometimes with plaster. During the Late Preclassic period (400 B.C.E.–150 C.E.) the simple wattle-and-daub style of housing became larger, incorporating cut stone and plaster. The development of columns during this period allowed for the construction of larger enclosed rooms.

More monumental structures, such as platforms and temple pyramids, were also made using this method. Platforms from the Early Preclassic period (1800–1200 B.C.E.) have been found at San José Mogote, in the Oaxaca Valley of Mexico, which were made using wattle and daub and then faced with bun-shaped adobe brick. Such platforms would have served as bases for large-scale public buildings. However, adobe brick was used less often as the working of stone became more and more sophisticated. At the early Mayan site of Nabké, in the Petén (present-day Guatemala), this sophistication was carried forward with the development of apron moldings (joint stones that slightly hang over the bottom stonework of a wall), which allowed cut stones to be secured to walls that were growing ever higher and steeper, which would be exploited by later Mayan centers.

The Early Preclassic site of San Lorenzo (dating to around 1700–1200 B.C.E.), located on the Gulf Coast of Mexico, was built on a large, man-made platform constructed from excavated, existing earth as well as imported filler materials. Measuring 3,937 feet by 1,969 feet and standing 164 feet high, this is the first example of large-scale construction in Mesoamerica. Such a structure would have required large forces of organized labor. The platform pyramid style of construction would reach mammoth scale at Teotihuacán, Mexico (around 100 C.E.). For the Pyramid of the Sun, the first major structure built here, nearly 30 million baskets of dirt and rubble were hauled to the site. The final structure was finished off with a layer of mud and volcanic gravel that was then covered with a

layer of plaster and faced with stone. Teotihuacán apartment complexes, built on top of raised platforms, were constructed out of adobe and stone and then covered with plaster.

As in Mesoamerica, building materials used by the ancient Andeans ranged from simple structures made from perishable materials to monumental structures built from stone and adobe. During the period from around 3500–2000 B.C.E. more permanent domestic and ceremonial structures began to be created out of stone and clay or stone and adobe.

At the Chavín site called Cerro Sechín, in northern Peru (ca. 800 B.C.E.), a style of temple construction developed. After a platform had been created from excavated earth, the temple itself was built using a series of cone-shaped adobe bricks that were arranged in rectangular form and then filled in with mortar. The cones were laid out point to point so that their round circular bases would form a roundel pattern on the wall. This created a flat, smooth wall surface. The structure was then covered by a wood or straw roof. Some structures were also faced with stone. This building technique would be continued after the Chavín culture declined.

Ancient Andean burial mounds and other monumental structures were built primarily of adobe brick. The large burial tombs of such north-coast cultures as the Moche (ca. 300 C.E.) consisted of low platforms as well as large adobe mounds. In the Moche site Huaca del Sol, near the northern coast of Peru, more than 143 million molded adobe bricks were laid in columns to create a burial mound. On the south coast the burial mounds and temples were smaller but still utilized adobe.

The earliest North Americans, like the Mesoamericans, built structures primarily from ephemeral materials, but there is evidence that they used more permanent building techniques. Pit houses were the earliest style of building in North America; they began to be built about 4300 B.C.E. Round or oval-shaped pits would be dug into the earth, providing at least one wall of the structure, and mud-covered vertical poles supplied the framework. The roof was made of perishable materials supported by a single crossbeam or by posts. Variations on the pit house were created in numerous periods throughout ancient North America.

Perishable structures would have been built above ground as well. Some were round and contained internal hearths for winter use, while in the summer, rectangular structures without hearths would have been occupied. On

the Northwest coast the construction of large, rectangular, wooden plank houses dates back to around 1100 B.C.E. These structures would have required a great deal of communal labor to build and were most likely reused throughout many generations.

The North Americans also built monumental structures out of the existing landscape. Impressive mounds were constructed over burial and ceremonial sites and would have required carrying massive amounts of soil to the site with the aid of baskets and simple tools. One of the earliest great examples of mound building is found at “Poverty Point” in modern day Louisiana (dating to ca. 1500 B.C.E.) Here, six semicircular ridges, divided into segments measuring 9.8 feet high and 131 feet wide, were constructed from excavated earth to form a horseshoe shape. Mound sites would become larger and more elaborate in later cultures, taking on more complex geometric and curvilinear shapes. These ceremonial structures demonstrate the North American people’s propensity for building on a monumental scale.

► calendars and clocks

INTRODUCTION

An old proverb defines the difference between ancient and modern life by saying that early people had time but no watches and busy modern people have watches but no time. As the proverb pertains to ancient peoples, it is only partly true. While ancient peoples did not have tools for measuring time that rival the modern atomic clock, they were vitally interested in the passage of time and developed numerous ways of measuring it. In doing so, they became the world's first astronomers, using the movements of the heavenly bodies to keep track of time.

Prehistoric peoples tended to rely on the moon and stars rather than the sun to mark the passage of the seasons and to define the year. In ancient Africa, for example, early peoples devised a calendar based on the movements of various star groups in conjunction with the phases of the moon. These types of calendrical systems are called lunar calendars (as opposed to solar calendars). Throughout the world, people observed the phases of the moon and used them to define months and seasons. In some cases, such as ancient Rome, the agricultural seasons were used to structure the calendar, giving rise in Rome to a calendar of ten months. Only later were calendars devised that relied on the movement of the sun. In some cultures both lunar and solar calendars were used, often making the calendrical system complex and hard to understand. Solar calendars were used principally for civil purposes, while lunar calendars were used mainly for religious and ritual purposes. It was the ancient Egyptians who worked out the fact that the year is $365\frac{1}{4}$ days long.

Ancient peoples were concerned with the passage of the seasons, for the seasons determined when crops needed to be planted or when people could expect the arrival of a rainy or dry season. Historians believe that many public monuments, including burial pyramids, were positioned to mark the arrival of the summer or winter solstice or the spring or autumn equinox. A passageway, for example, might have been constructed in a pyramid in such a way that the sun's rays are focused straight into the passage at the time of the spring solstice.

Most ancient peoples were not interested in accurate timekeeping throughout the day. It was enough to have a rough idea of what time it was by observing the passage of the sun throughout the sky. Most ancient cultures used primitive sundials, often consisting of nothing more than a stick placed in the ground. The shadow cast by the stick marked the passage of time. Later, more formal sundials were built, and the ancient Greeks spread the use of sundials and water clocks throughout the Mediterranean region. Some public monuments may have served as sundials as well. These include obelisks, or tall, tapered structures capped with a pyramid (similar to the Washington Monument in the U.S. capital). The stela, or a stone slab or monument positioned vertically, may also have served as a public sundial.

AFRICA

BY MICHAEL J. O'NEAL

While ancient Africans in general had little interest in measuring the hours and minutes of the day, they needed to mark the passage of the seasons. To that end, they developed an

View of the royal tombs at Meroë, ancient city of northeastern Africa in present-day Sudan; the entrances face east, toward the rising star Sirius, a positioning that suggests that they served as a type of calendar. (Courtesy of the Oriental Institute of the University of Chicago)

expertise in astronomy, for the progression of days, months, seasons, and years represents the movement and rotation of the earth in relation to the sun and moon. Archaeologists who study these matters refer to their field of inquiry as archaeoastronomy. These scholars are interested in archaeological evidence of astronomical observations that ancient societies made to keep track of time.

One of their major findings was the discovery of a calendar system used by the Borana of southern Ethiopia and northwest Kenya. The Borana, ignoring the sun, developed a calendar regulated by seven stars and star groups observed in conjunction with the phases of the moon. In 1978 archaeologists discovered at a site near Lake Turkana in Kenya a cluster of 19 stone pillars. The name of the site is Namoratunga, meaning “stone people.” Writing carved on the stones provides evidence that the pillars date to 300 B.C.E.

The Borana measured time using a 354-day lunar year with 12 months; they did not keep track of weeks. Every three years a leap month was added so that the lunar years remained consistent with the 365-day solar year. The Borana relied on seven stars or star groups: Their modern names are Triangulum, Pleiades, Aldebaran, Bellatrix, Orion’s Belt, Saiph, and Sirius. The new year began when a new moon was observed in conjunction with Triangulum; the next month began when the new moon was seen in conjunction with the Pleiades, and so on. The Borana had names for only 27 days of the month, even though the month could be as long as 30 days; when they arrived at the end of the list after 27 days, they started over with the name at the beginning of the list.

Astronomers and archaeologists, though, have struggled with how the Borana knew that the specific star systems were near the moon, because some of these stars cannot be seen when they are too close to a new moon. Some researchers believe that the 19 Namoratunga pillars were intended to mark the positions of these stars, allowing the stars’ placement in the sky to be known even when the stars themselves could not be seen clearly. Using statistical analyses, archaeologists have determined that the possibility is less than a half a percentage point that the pillars could have marked the stars’ locations by chance. For them, this is strong evidence that the cluster of pillars was an astronomical observatory and hence a calendar.

Structures that function like calendars have also been found in other parts of ancient Africa. In central Sudan the kingdom of Kush flourished from about 1000 to 100 B.C.E. The area features numerous pyramids, similar to the pyramids found in ancient Egypt. The entrances to these pyramids face east, directly at the rising star Sirius. This positioning suggests that they served as a type of calendar. In numerous places in Tanzania archaeologists have discovered cave drawings of precisely drawn circles. The circles are concentric and exactly spaced. The number of circles ranges from one to 29 or 30—numbers that suggest some connection with the lunar cycle.

Little is known about timekeeping in ancient Africa. Like most cultures throughout the world, the ancient Africans probably kept track of time throughout the day with some sort of basic sundial. A sundial can consist of little more than a

stick placed in the ground. When the sun rises, the stick casts a shadow that points toward the west. As the sun rises higher in the sky, the shadow becomes progressively shorter until noon, after which the shadow begins to lengthen and point toward the east. In fact, a stick is not even necessary. A tree or any other vertical object would serve the same purpose.

One of the earliest forms of the sundial was the obelisk, a tall, tapered, four-sided monument with a pyramid at the top. (In the United States, the Washington Monument in the nation's capital is an obelisk.) The ancient Egyptians built the continent's first obelisks in about 3500 B.C.E. While these monuments served various purposes, they also helped the community keep time by functioning as massive sundials. Over the following centuries, similar obelisks were built in other parts of Africa.

One of the most famous of these obelisks was in the kingdom of Axum in northern Ethiopia. The precursors of this kingdom were established as early as 500 B.C.E., and the region quickly emerged as a major trading center, a gateway between east and west. Axum's influence spread throughout much of northeast and east Africa and the Arabian Peninsula. Prior to the Christian era in Ethiopia, a number of towering obelisks were constructed, including one that is 78 feet tall and weighs over 100 tons. The obelisk was in the news in the early 2000s because it had been looted and taken to Italy by the Italian dictator Benito Mussolini when Italy occupied Ethiopia in the 1930s. In April 2005 the Italian government returned the obelisk to its home.

Other types of timekeeping devices were developed and spread throughout North Africa during the centuries when the region was under Greek control, beginning in the fourth century B.C.E. In such countries as Syria, smaller sundials had a plate that marked the hours and a gnomon, or "shadow maker," that cast a shadow that moved with the passage of the sun. Under the influence of the Greeks, water clocks, which measure time by the regulated flow of water, became common in North Africa starting in about the fourth century B.C.E.

EGYPT

BY LEO DEPUYDT

In 45 B.C.E. Julius Caesar instituted the Julian calendar that we still use in modern times. Pope Gregory XIII slightly modified it by decree in 1582 C.E., and it is therefore now known as the Julian-Gregorian calendar. This calendar offers a kind of continuity from 45 B.C.E. down to the present time that makes the study of calendars of little concern to historians of the Middle Ages or the French Revolution. Calendrics demands a much higher degree of attention and energy from historians concerned with the time before the birth of Christ than it does from later historians.

In the history of humanity the ancient Egyptians were the first to notice that the year is close to 365 days long and also to put that number into calendrical practice. What is more, they were ahead of everyone else in this respect by

2,000 to 3,000 years. The Babylonians, the Greeks, the Hebrews, and others all regulated daily life by the moon. So did the Romans until the fifth century B.C.E., when they switched to a complex calendar that exhibits peculiar vestiges of lunar time-reckoning. The sole division of 365 days that is positively recognizable in ancient sources is a year of 12 months of 30 days plus five added days. This structure was known in antiquity as the "civil" calendar. This continuous cycle is often praised for its simplicity, as if it is a work of genius. One wonders about the historical circumstances in which this simple structure was created, presumably in the early third millennium B.C.E. Not a shred of evidence has survived about these circumstances. It is not known, for example, how the number 365 was obtained.

The civil calendar is pseudo-lunar, because the length of its months is close to, but not quite the same as, the average length of real lunar months, which is a little more than 29.5 days. The civil calendar is pseudo-solar, because the length of its year is close to, but not quite the same as, the average length of the solar year, or the year of the seasons, which is about 365.2422 days long. Because the civil year, at 365 days, is about a quarter day shorter than the solar year, the Egyptian calendar shifts in relation to the seasons. It falls behind in relation to the solar year and the seasons by about one day every four years. This means that a given day, for example, the Egyptian New Year's Day, which at a given time fell in summer, would slowly recede into spring, then winter, fall, and again to summer, returning to the original point after about 1,460 years. This motion in relation to the solar year is commonly described as wandering, hence the term *wandering year* for the Egyptian 365-day year.

All this does not mean that there was no lunar time-reckoning at all in ancient Egypt. Lunar time-reckoning was used marginally in religious life, for instance, in order to regulate services in the temple. Lunar calendars cannot differ from one another in many ways. One way is the position of the first month of the lunar year inside the solar year. In that respect, no evidence contradicts the following hypothetical scenario. Earlier on, the first lunar month began in the summer around the time in July when the star Sirius rose again early in the morning after it had been invisible for about two months. The rising of Sirius was the lunar calendar's anchor. As the civil year wandered, the rising of Sirius came to coincide with the civil new year in about 1300 B.C.E. At that point, the lunar calendar switched anchors from the rising of Sirius to the civil new year. Civil calendar and month names were henceforth attached to one another by a naming procedure in a kind of double-helix calendar, winding its way through time. A civil month was given the same name as its lunar twin, that is, the lunar month beginning in it. This double civil-lunar calendar system therefore exists purely by virtue of specific assignments of names. Ancient Egypt thus knew two calendars, the dominant 365-day calendar, usually called the civil calendar, and the somewhat marginal lunar calendar. By contrast, past

research on ancient Egyptian timekeeping is characterized by a proliferation of postulated calendars. Then again, there is no conclusive evidence for the existence of more than two calendars at any one time in Egyptian history.

Much discussion on calendars has revolved over the decades around the two problems of the month names. Egypt had both a nonlunar calendar—that is, the civil one—and a lunar calendar. It comes as no surprise that the two problems of the month names have everything to do with the relationship between these two calendars. The first problem is that the last month can be named as if it were the first, namely, *opener of the year* or *birth of Re*, which are also names for New Year's Day, the quintessential beginning. The second problem is that a feast could sometimes be celebrated on the civil day 1 following the civil month with the same name, as if a feast called January were celebrated on February 1.

The two problems of the month names came about as the result of two actions by ancient calendar makers. First, calendar makers transferred month names from the lunar calendar to the civil calendar. As a result, the name of the first lunar month—the month inside which the civil new year fell—was rolled backward in time onto the 12th and last civil month, resulting in the awkward circumstance that the last civil month was named as if it were the first civil month. Second, calendar makers transferred the names of feast days from the middle of lunar month X, that is, from the full moon, to day 1 of the civil month, because that civil day 1 fell inside lunar month X. The name of the feast day at full moon was the same as the name of the entire lunar month X. As a result of the first action, the name of lunar month X was rolled back onto the civil month preceding the civil day 1 that had received the same name owing to the second action. Consequently, it was indeed as if a feast called January was celebrated on February 1.

Clocks were not in any kind of regular use in ancient Egypt, even if a small number of water clocks, sundials, and related devices have been preserved. The rise of mechanical clocks dates to the Middle Ages, in the 13th and 14th century C.E. Before mechanical clocks, people's lives were not normally guided by numbered subdivisions of the day. The daily course of the sun, the yearly succession of the seasons, and the agricultural cycle sufficed as markers of time. For most people most of the time, there was no need to count the days or to watch clocks. Life was much simpler then.

THE MIDDLE EAST

BY DAVID BROWN

Some mythological texts composed in ancient Mesopotamia describe great lengths of time in terms of a round number of years, but what was a year to a scribe? Years were counted from one seasonally or sidereally recurring event to another, and there is no evidence in cuneiform sources that the small difference between a seasonal (or equinoctial) and a sidereal (or stellar) year was remarked upon. An equinoctial year is

the period between one spring equinox, when day and night are of equal length, and the next. A stellar year marks one 360-degree rotation of the sun. The two lengths are slightly different. Nevertheless, around 150 B.C.E. cuneiform scholars determined lengths of the year that are close to both. The Greek astronomer Hipparchus at about the same time was seemingly the first to note and quantify that difference.

More generally, though, years were defined in terms of lunations, the intervals from new moon to new moon. One year was defined as either 12 or 13 lunations. The seasonal names given to the months of the calendars used during the course of the third millennium B.C.E. indicate that from the earliest times the year was characterized by its seasons. An attempt was made to insert an extra month into the calendar about every three years to ensure that the beginning of the first month of the year coincided roughly with the vernal equinox, the date in spring when day and night are of equal length. A lunation lasts either 29 or 30 days, with slightly more than half lasting 30. Because 12 lunations fall some 11 days short of the length of a year, without the addition (known as intercalation) of an extra month, the start of each month would fall ever earlier in the year, and the agricultural activities described by their names would soon occur within inappropriately named months.

A rule-of-thumb intercalation of one extra month every three years was employed in most areas of Mesopotamia and periods of history. During the course of the second millennium B.C.E. the names assigned to the months by the people of

Fragment of a basalt water clock, from Tell el-Yahudiya, Egypt, Macedonian Dynasty, around 320 B.C.E. (© The Trustees of the British Museum)

Nippur came to be those most commonly used. The astrological Mul.Apin tablets, which date to this period, refer to the intercalation and to rules used to determine when it should take place. They also associate the equinoxes and solstices with the heliacal rising of certain stars—that is, their first appearance after a period of absence from the sky in the east directly before sunrise—thereby equating the sidereal year with the equinoctial. One reference in a classical Sumerian composition known as *The Farmer's Instructions* states: “When the constellations in the sky are right, do not be reluctant to take the oxen force to the field many times.” This suggests that the stars had long been used to determine the time of the year.

Not until the seventh century B.C.E., however, is there any evidence that the months and years were put into any form of systematic arrangement, leading to what is termed a regulated calendar. This regulation was connected with the rise of astronomical prediction. The most accurate of the schemes devised by Mesopotamian scholars for regulating the numbers of months and years was also the longest lasting. During the first half of the first millennium B.C.E. it was noted that 19 years last almost exactly as long as 235 lunations. Multiplying 19 by 12 yields 228, which is 7 less than 235. Therefore, this scheme implies that 7 of those 235 months are intercalary. The Mesopotamians distributed those intercalations in a particular manner throughout the 19 years while adhering to the age-old tradition of inserting them after either month 12 or 6. Before long, people other than astronomers were making use of this relationship, including the governmental authorities (who used it in dating contracts and the like.) The scheme was adopted in 503 B.C.E. by the Persians and in the late fifth century B.C.E. by the Athenians, who used an identical formula attributed to a scholar named Meton. The scheme is often referred to today as the Metonic cycle. The Macedonians reconciled their calendar with the Babylonian 19-year scheme before 323 B.C.E., and the Parthians continued to use it when they acquired hegemony over Babylonia. The 19-year scheme appears in Indian sources of the second or third centuries C.E. It perhaps arrived with zodiacal astrology from Roman Egypt, Parthian Iran, or China, where a 19-year scheme had been in use for some centuries.

From the third millennium B.C.E. the year is sometimes said to comprise 12 months of 30 days each, or 360 days. This is an idealization, useful both in administration and divination. It simplified calculations and provided the basis for a series of further idealizations as to the behavior of the heavenly bodies, against which their real behavior could be compared and interpreted. Thus the span of 360 days is not an estimate of the length of the year, for providing such information was not the aim of the texts in question. The Mul.Apin tablets give a length of 364 days for the year. Again, this probably does not represent the level of accuracy prevalent at that time. A year of 364 days is used in West Semitic circles in the first millennium B.C.E. because it amounts to 52 weeks of seven days and therefore fit with cosmological ideas common to this area. In Mesopotamia increasingly accurate values of the

length of the year in terms of days and smaller units are found in the astronomical texts beginning around 700 B.C.E.

Days were measured from sunset to sunset. In the astronomical texts a further “day,” defined as 1/30th of a mean lunation, was employed to facilitate calculations. Lengths of time shorter than a day were measured in both seasonal and nonseasonal units. Watches (such as that used by a village to guard against intruders)—three at night and three during the day—varied in length depending on the time of the year. There is some evidence of the use of seasonal time units in compositions found in Nineveh and in the “proto-horoscopes” found in Babylonia.

Far more common, though, was the use of units that did not vary with the time of year. Prime among these was the UŠ, defined as 1/360th of a day. Its origin lies in the observation of the similarity of the sun's daily and annual motions, for the UŠ is to the day as the day is to the (ideal) year. Given the sun's daily revolution, 1 UŠ amounts to 1/360th of a revolution and is the ancestor of the modern degree. The UŠ is used as a unit of time and celestial displacement in Mul.Apin. From early in the first millennium B.C.E. the intervals between the culminations of the members of a certain group of stars—meaning the point at which the stars appear directly overhead—were given in terms of their mutual displacement. That these displacements were understood as time intervals is confirmed by their direct equation with weights of water collected from a constant-head water clock, where the water flows out without emptying the clock, since enough other water flows in to keep the head constant. No examples of Sumerian water clocks still exist, but descriptions of them appear in mathematical texts of the early second millennium B.C.E.

Herodotus, in the fifth century B.C.E., wrote that the Greeks adopted the gnomon (a vertical stick that casts shadows and is thus used to tell time) from the Mesopotamians. The Mul.Apin tablets do describe some form of time measure involving shadows, though there is no direct evidence for the use of sundials in ancient Mesopotamia. Time intervals were most commonly measured with the water clock, supplemented by the use of culminating stars at night. In India are examples of the sinking water clock, a bowl with a hole in the base. The bowl sits on the surface of a reservoir and gradually fills until it sinks. A possible example of a sinking water clock from Nimrud, dating to the eighth century B.C.E., is in the British Museum in London.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Ancient Asians constructed elaborate calendar systems based on the cycles of the sun and moon. The people of China and India both created calendars that kept track of solar cycles, the moon's movement around the earth, and the movements of the stars, especially the stars corresponding to the 12 zodiac signs. These calendars probably started as a means of tracking the seasons so that farmers would know when to

plant and harvest their crops. Both the Chinese and Hindu calendars are still used today.

The Chinese calendar was supposedly invented by the first legendary ruler of China, Huang Di, who is said to have reigned from 2698 to 2599 B.C.E. Although various calendars were in use over the centuries, Chinese tradition says that the first year of the first calendar cycle was either 2637 B.C.E. or 2697 B.C.E. under the Gregorian calendar system (the system used in the United States today). The Chinese calendar runs in cycles, or epochs, of 60 years. Chinese years are numbered from one to 60; after 60 years, a new epoch begins and the count starts over. If the calendar began in 2637, the current cycle is the 78th 60-year cycle; if the calendar began in 2697, the current cycle is the 79th.

The most ancient Chinese dates are impossible to verify because the first few centuries of calendar keeping were somewhat flexible. The year had 12 months based on the movements of the moon and the sun, but people constantly had to adjust the calendar to keep up with the seasons, adding one or even two months as needed. The first generally accepted specific date is in 841 B.C.E. (The Chinese kept dates before then, but we do not know what they were.) The first month started around the time of the winter solstice; if an extra month was needed to put the seasons back in sync with the calendar, it was added at some point during the year. Instead of calling years by their numbers, the Chinese typically marked dates by the year of the current ruler's reign.

In 484 B.C.E. the Chinese invented a more precise calendar with $365\frac{1}{4}$ days. The Qin Dynasty instituted the use of this calendar throughout China in 256 B.C.E. It still needed an extra month from time to time in order to keep the months stable. In 104 B.C.E. Emperor Wu of the Western Han Dynasty established new rules to govern the calendar; these rules are still used today. Under these rules the solstice generally occurs in the 11th month. The first day of a new month begins at midnight on the day of the new moon. Each year has 12 months, and every third year has an extra month that can fall after any month; the extra month shares the number of the month that precedes it. Each month corresponds with one of the 12 signs of the zodiac. According to the Gregorian calendar, the Chinese New Year occurs at a different time every year.

The Chinese zodiac added another layer of complication to the calendar. The 12 zodiac signs are rat, ox, tiger, rabbit, dragon, snake, horse, sheep, monkey, rooster, dog, and pig. Every Chinese year is assigned one zodiac sign; for example, 2006 was the year of the dog. The cycle repeats itself every 12 years. Each day is divided into 12 hours, each of which corresponds to two Western hours. Each of the 12 hours is labeled with one of the zodiac signs. The Chinese also divide the day into 100 equal parts, each of which roughly corresponds to 15 Western minutes. For the most part, people in ancient days told time by the position of the sun and the shadows it cast on the ground. Accurate mechanical clocks were not invented during the ancient period, but people did use sundials made

of bamboo or other materials. These could be very accurate at determining the days of the winter or summer solstice; the sundial's shadow would be shortest at the winter solstice and longest at the summer solstice.

Many Asian nations adopted the Chinese calendar system. In Japan, for example, the emperor Kōtoku decided in 645 C.E. that the nation would begin the practice of naming periods of time for the current emperor. The Korean calendar was taken directly from the Chinese calendar and recognized the Chinese New Year. According to tradition, the calendar began counting with the year 2333 B.C.E., the year in which Korea was supposedly founded. Most Asian cultures adopted the Chinese zodiac system, occasionally substituting animals that seemed more appropriate to them; for example, Vietnam and Thailand placed a cat in the fourth position, and Japan inserted a wild boar in place of the pig.

The Hindu calendar of India was invented in Vedic times, between 1300 and 1500 B.C.E. The Vedas, the main scripture of Hinduism, describe the cycle of the calendar. The Vedic calendar began with the spring equinox, the day at the end of winter when night and day are of the same length. The year is based on the length of time it takes the earth to circle the sun. The calendar is both a solar calendar, based on the earth's movement relative to the sun, and a lunar calendar, based on the moon's movement around the earth. The solar calendar has 12 months, each corresponding to a sign of the zodiac. Each month has between 29 and 32 days, determined by the length of time the constellation of stars associated with a particular zodiac sign remains in the path of the sun across the heavens. The 12 months are also defined by the portion of the earth's orbit around the sun, called the *rashi*. The calendar also has lunar months, based on the cycle of the moon. When the lunar calendar falls out of sync with the *rashi*, or solar months, an extra month is added to the lunar calendar. The combination of lunar and solar months is known as a lunisolar calendar. The first day of the first year of the Hindu calendar is said to be January 23, 3102 B.C.E. The calendar runs in 60-year cycles, or epochs. Each year has a name, and the names start over when a new epoch begins.

The Vedic calendar has a very complicated approach to daily timekeeping. Each day is a *tithi*, or lunar day, but because a day is measured by the length of time it takes the angle between the sun and the moon to increase a specified amount, a day can range from 19 to 26 hours in length. Each Hindu month is divided into 30 *tithi*, which are further divided into two groups of 15 days. These divisions are meant to keep the month in step with the phases of the moon.

Most ancient people did not have clocks, instead noting the positions of the sun, moon, or stars to furnish a rough idea of the time. The earliest clocks were water clocks, containers made of stone or metal. Water was set to drip at a constant rate into such a container and gradually filled it; markings in the container indicated how much time had passed by the time the water level reached them. Other water clocks were bowls with small holes in the bottoms;

people put them in larger containers of water and they gradually filled and sank.

One of the earliest water clocks discovered in Asia was bronze basin water clock dating to the Han Dynasty (202 B.C.E.–220 C.E.). It contained several wooden arrows carved with lines; as water flowed out of the basin, the arrows sank, allowing the viewer to tell how much time had passed by markings on the arrows. Starting around 300 C.E. Chinese artisans began making more elaborate and accurate water clocks, using multiple basins to hold water and floating arrows. Some of these clocks could ring bells to mark the hours. Others were attached to astronomical devices that showed the positions of the stars and planets.

EUROPE

BY AMY HACKNEY BLACKWELL

The earliest European systems of keeping time were based on the movements of the sun and the moon. Stone Age people as early as 30,000 years ago appear to have kept track of days by making notches in bones. Rituals were timed according to the phases of the moon, and the new moon was a common time for celebrations. People observed the natural changes that happened to plants and animals at particular times and remembered them from year to year. Some ancient people probably named the times of the year according to events that took place in particular seasons, such as “deer time,” or “bird-migration time.”

In prehistoric times people built megalithic, or large stone, structures in western and northern Europe, some of which may have functioned as primitive solar calendars. One of the most famous such sites is Newgrange in Ireland, a tomb that was built in about 3200 B.C.E. Newgrange consists of a passageway leading to a subterranean burial chamber containing several side chambers. The entrance to the tomb is constructed so that every year at the winter solstice the rising sun shines through a slit over the entrance and illuminates the main burial chamber for 17 minutes. When Newgrange was built, the light would have fallen directly onto a spiral design on the far wall.

Other Stone Age sites in Ireland were also designed to catch the sun on particular days of the year. The tomb at Dowth catches the light of the setting sun at the winter solstice. The tomb at Knowth has an eastern-facing passage that catches the light of the rising sun on the spring and autumn equinoxes, the two days each year when day and night are of equal length. Knowth’s western-facing passage catches the light of the setting sun on the same days. Stonehenge, a circle of giant stones built in England between 2700 and 1500 B.C.E., also appears to have been constructed to catch sunlight on specific days. Sunlight shines on the center of the monument on the day of the summer solstice, and similar phenomena happen at the equinoxes.

Ancient people kept track of the seasons for various reasons but mostly to know when to plant or harvest their crops.

The Celtic and Germanic people who lived in Europe in ancient times also used calendars to help them plant and reap, but they appear to have been more interested in keeping track of days for ritual purposes. Holidays fell on the winter and summer solstices and the spring and autumn equinoxes, and ancient European calendars were designed to identify these days. Druids, the priests of the Celtic world, used calendars to plan festivals—one in each quarter of the year. Because each festival fell on either an equinox or a solstice, they needed to know when these days would occur. Some scholars believe that Celts began using calendars as early as 800 B.C.E. The most famous Celtic calendar is the first century C.E. Coligny calendar, found in France in 1897 and dated to the first century C.E. The calendar’s letters and numbers were carved in Latin letters on a bronze tablet. The tablet depicts a five-year cycle that contains exactly 62 months.

The Coligny calendar, a similar calendar found nearby at Villard d’Heria, and the writings of the Romans Julius Caesar and Pliny the Elder have provided historians with the means of reconstructing the Celtic calendar system. The Celtic calendar was lunisolar, which means that it tracked the movements of both the earth around the sun and the moon around the earth. Julius Caesar (100–44 B.C.E.) noted that the Gauls kept track of time by counting nights, not days. The Celtic calendar based its months on the cycles of the moon, though no one knows whether months began at the new moon or the full moon. Each month was divided into two halves, or fortnights; the first half was 15 days, and the second half was 14 or 15 days, alternating by month. The 30-day months were considered lucky, and the 29-day months were thought to be unlucky. The lunar year was 354 or 355 days long. To keep the year in sync with the earth’s orbit around the sun, or the solar year, Celts added a 13th month every two and a half years. Scholars believe that each new year began on the autumn equinox.

As the Romans gained power, they spread their calendars through Europe. Before 46 B.C.E., people in Spain and other parts of Europe under Roman domination used the old Roman calendar. This calendar had 12 lunar months, adding up to 355 days in a year; the Roman priests would periodically insert an extra month between February and March to put the calendar back in line with the seasons. The decision of whether to add the extra month was entirely up to the discretion of the priest in charge, and some priests did not bother to add the month for several years in a row. The calendar became quite confusing, especially for people who lived some distance from Rome, and most people using the system never knew what date it was.

The Gauls and Germans gradually adopted the Julian system created by Julius Caesar in 46 B.C.E. Under this calendar, a year was 365 days long, with an extra day added to February every four years. The year was divided into 12 months, and each week consisted of seven days, with both months and days named after gods. The Julian system was virtually identical to the modern Gregorian calendar. The Germans and

SEVEN OR EIGHT DAYS A WEEK?

Ancient Romans did not use weeks. They marked points in the month by naming specific days (calends, ides, nones) after phases of the moon. They also counted market intervals, but market days were eight days apart, not seven. Europeans north of the Mediterranean did not count weeks either, instead letting the moon guide them from night to night. These systems worked well for centuries, so why did people switch to a seven-day week?

The answer comes from a combination of astrology and Christianity. Ancient Babylonians invented a seven-day week in 700 B.C.E. They chose the number seven because they knew of seven planets (five modern planets plus the sun and moon) and believed that each day was controlled by one of these heavenly bodies. They named each day after a planet. By the fourth century C.E. many Romans had adopted this seven-day system, substituting the names of their own gods for the Babylonian ones. These names are still visible in three English day names: “Sun” day, “Moon” day, and “Saturn” day.

When the Roman emperor Constantine converted the Roman Empire to Christianity in 313 C.E., he had to decide when to celebrate the Sabbath. In 321 he issued an edict declaring an official seven-day week, with the Sabbath on Sunday. Everyone then knew when they were supposed to rest and worship.

The seven-day week gradually spread through the empire over the next couple of generations. Europeans beyond the reach of the empire took longer, but even they eventually adopted the seven-day week as the primary unit of time. By the fifth century even Anglo-Saxons in Britain were using the week, but they renamed four days after their own gods. The day that the Romans had named for the war god Mars became “Tuesday,” named for the heroic Germanic god Tiw. The day the Romans had named for Mercury became “Wednesday,” after the god Wodin. The following day, named for Jupiter by the Romans, became “Thursday,” for the god Thor. The day the Romans had named for Venus became Friday, for the goddess Frigga.

Gauls adapted the system to their own uses, but they renamed the months and the days of the week after their own gods.

Ancient Europeans did not spend much time worrying about the time of day. They might use sundials to give themselves a rough idea of the time, but they had no mechanical clocks, and, like most ancient peoples, they saw no need for minute-to-minute precision in timekeeping. As the Romans infiltrated the continent, Gauls and Germans adopted Greek and Roman technologies, such as the sundial and the water clock. A sundial was a flat disc with an upright piece oriented in such a way that the sun’s light created a regular pattern of shadow over the course of a day. Romans brought sundials with them to Gaul and Britain, installing them in their home gardens. After the Romans left, the Europeans kept their timepieces; early medieval monastery gardens often contained sundials installed according to the Roman practice.

The water clock was a device that allowed people to keep track of time by measuring the regular flow of water into a stone or metal vessel. The water dripped at a constant rate and gradually filled the container; markings in the container indicated how much time had passed when the water level reached them. This was especially useful for timing the hours of the night, when the sun was not available to provide visual clues. Water clocks could at best provide only a rough estimate of the time, and they had to be refilled constantly with water in order to work at all. Still, they could provide more information about time than mere astronomical observation. For example, when Julius Caesar visited Britain in 55 B.C.E.,

he used a water clock to determine that the nights there were longer than those on the Continent. Water clocks were valuable objects in ancient times; often a town would acquire a single water clock for the entire community.

GREECE

BY TOM STREISSGUTH

An accurate measure of the year was important for ancient societies concerned with the best times for planting and harvesting, for observing annual religious festivals, and for recording their own history. Early methods for counting the days, however, were not precise enough to match the true solar year, meaning that calendars gradually went out of phase with the seasons. The Greek writer Hesiod (ca. 700 B.C.E.), in his poem *Works and Days*, advises tillers of the soil to reckon planting and harvest times by the first appearance of stars in the night sky. After Hesiod’s time the Greeks developed a more artificial system, a lunar calendar of 12 months with an “intercalary” 13th month inserted when needed to make up days missing from the lunar year. Calendars changed somewhat from one Greek city to the next; each had its own method of figuring the precise length of the year and the time to impose the extra month.

Athens, the dominant city of ancient Greece, left behind the calendar most familiar to historians. The months of Athens had 29 or 30 days, alternating from one month to the next. Each month was divided into three shorter periods. The first 10 days were those of the “waxing moon.” The second

period was simply named by the consecutive numbers, from the 11th to the 19th, and the final 9 or 10 days were counted in reverse order from tenth to the first—the days of the “waning moon.” The final day of a 29-day month, for example, was the “second waning moon,” while that of a 30-day month was the “first waning moon.”

The first month of the year, Hekatombion, arrived with the summer solstice (other city-states began the year at different times). Hekatombion was followed by Metageitnion, Boedromion, Pyanepsion, Maimakterion, Poseidon, Gamelion, Anthesterion, Elaphebolion, Munychion, Thargelion, and Skirophorion. The intercalary month was known as “second Poseidon” and came after the month of Poseidon. This calendar results in a year of 354 days, plus the intercalary month. The Athenians figured their calendars in eight-year cycles, with the extra month added in the second, fifth, and eighth years. This system was further corrected in 432 B.C.E. by the astronomer Meton (fl. fifth century B.C.E.), who noted that every 19 years the phase cycles of the moon match the cycles of the solar years. Meton proposed a 19-year calendar cycle in which there were 235 months; 125 of them were “complete” 30-day months, and 110 of them were “deficient” 29-day months. The month containing every 64th day became a deficient month, and that day was omitted; there were nine intercalary months.

As Greek measurement of the heavens and the sun grew more precise, astronomers came up with lengthier calendar cycles. In the fourth century B.C.E. Calippus (ca. 370–ca. 300 B.C.E.) suggested a change to a 76-year cycle, which would have been a total of one day shorter than the Metonic cycle. The astronomer Hipparchus (ca. 190–ca. 120 B.C.E.) proposed a 304-year cycle of 3,760 months. These refinements were never publicly adopted; they would have meant complex record keeping and would have made little practical difference to everyday citizens. A second “conciliar” calendar divided the year into ten *prytaneis*, marking the term of office of the *prytany*, or council chairman, elected from each *phylai*, or tribe. (Until 307 B.C.E. there were ten *phylai* in Athens.)

The Athenians and other Greeks named their years according to the leader in power (the designation “B.C.E.” not being in use before the time of Christ). Starting with the Alexandrian writers of the third century B.C.E. historians adopted the four-year cycle of Olympiads to date events. They cited the number of the Olympiad, counting from the first (in the year we know as 776 B.C.E.), followed by the Olympiad year—first, second, third, or fourth (“zero” was unknown in the ancient world). The Greeks counted Olympiads to be 49 or 50 months apart, as different city-states inserted intercalary months at different times.

The confusions of the lunar calendar and the intercalary months prompted Julius Caesar, a leader of Rome, to appeal to the Alexandrian Sosigenes to come up with an accurate solar year. Sosigenes, who is mentioned only in the book *Natural History* of the Roman writer Pliny the Elder, devised the Julian calendar, with a year of 12 months and a leap year

including an extra day every four years. This calendar has survived with a slight modification made in 1582 under Pope Gregory XIII, who suspended the leap day every 400 years to put the calendar more precisely in line with the solar year of approximately 365.25 solar days.

The ancient Greeks first measured time with the sundial, which the historian Herodotus (484–ca. 425 B.C.E.) claimed had originated in Babylonia. A Greek sundial held a vertical gnomon (indicator), which cast the sun’s shadow on a flat surface. Later sundials used the inside of a bowl or a circular depression made in stone or earth. Eleven lines marked out the hours, with the first hour beginning with the sunrise and the last ending at sunset. Sundials grew more complex and precise as different hour lines were marked for different seasons of the year.

According to the biographer Diogenes Laertius, writing in the third century C.E., the sundial gnomon was the creation of Anaximander of Miletus (ca. 611–ca. 546 B.C.E.). Anaximander also fit the indicator into a simple and portable wooden instrument made of two pieces of wood set at right angles. By casting the sun’s shadow on its vertical piece, the gnomon marked the passage of the sun and the progress of the day. The instrument also held markings showing compass directions and could predict solstices and equinoxes.

Another instrument used to measure time was the clepsydra (literally “water thief”), a spherical or cylindrical vessel made of stone or clay. An aperture at the bottom of the vessel allowed water to escape at a slow, constant rate and fill a receiving vessel positioned underneath. As the water level rose in the receiving vessel, the passing hours were indicated by a series of horizontal lines on its inner surface. Unlike sundials, clepsydras could be used day or night and on sunny or cloudy days. The best-known example of a Greek water clock is the Horologion of Andronicus, or Tower of the Winds, built in the marketplace of Athens in the first century B.C.E. Water from the nearby Acropolis supplied the Horologion, which had a 24-hour time indicator as well as sundials to show the time of day and the seasons of the year.

ROME

BY DAVID KELLY

The original Roman calendar system, developed in the seventh or early sixth century B.C.E., was based on an agricultural cycle, not on the lunar cycle; as a result, it had 10 months, for a total of 304 days. Each new calendar year began in March, at the vernal equinox. It had 10 months, six with 30 days each and four with 31 days. This is why the Latin names of the months of our calendar do not correspond to their positions. The ninth month is called September, even though that word means “seventh” in Latin. In the same way our 10th month is called October, which to the Romans meant “eighth”; “November,” the 11th month, translates to “ninth”; and December, our 12th month, comes from the Roman word for “tenth.” After December the 61 days remaining in the earth’s

revolution around the sun were not counted, since the calendar was based on the agricultural cycle, the Romans had no need to measure the winter months.

Early Roman calendars kept pace with the sun by periodically adding a month of 27 days after February, at the discretion of the *pontifex maximus*, a priest who was appointed by the emperor and often wielded his control over the calendar for political reasons. By the sixth century B.C.E. the Romans changed to the 12-month calendar, with a total of 355 days per year. This still was not in accordance with the earth's revolution around the sun, which was later measured as taking 365.25 days per year, but it was close. By the time of Julius Caesar (100–44 B.C.E.), the calendar was about three months ahead of the earth's natural revolution around the sun.

The Julian calendar, instituted in 46 B.C.E., revised the calendar into what has become the standard for Western civilization. Starting in January of 45 B.C.E. the year was established at 365 days, with an extra day added every fourth year. The Julian calendar was out of sync with the earth's revolution by only about 11 minutes each year. Since Caesar's time, the only significant change has been the Gregorian calendar, commissioned by Pope Gregory XIII in 1582: It removed 10 days that year and included provisions to keep extra days from building up in the future by removing three days every 400 years. This was accomplished by skipping leap year in years that are divisible by 100 (but not by 400), so that February of 1700, 1800, and 1900 did not have the extra leap-year day added, while February of 2000 did. The Julian calendar was so influential, though, that it was still followed in Britain until 1751.

Romans did not count the days continuously through the month until it ended. Instead, they broke the month into three separate sections. The first day of each month was Kalends; the Nones, originally the day on which the moon reached its first quarter phase, was the designation for the seventh day of some months (March, May, July, and October) and the fifth day of the rest; and the Ides, based on the time of the full moon, was the 15th day of those same months and the 13th of the others. Days were measured counting up to the next demarcation. The third of March, for instance, would be "5 before Nones March" (*V ante diem Non. Mar.*): the Romans counted inclusively, so their tally would include the number they were counting toward. The 10th of March would be "6 before Ides March" (*VI a.d. Ides Mar.*), and the 20th of March would be "12 before Kalends April" (*XII a.d. Kal. Apr.*).

Ancient Romans were quite familiar with many of the methods we use today to measure time, even though they did not feel the need to be as precise about time as we are in the modern world. The Romans did not divide the day into 24 equal hours but instead divided it into two halves, with 12 night hours and 12 day hours. The duration of these hours varied as the year changed, except at the two equinoxes, when day and night are the same length. In winter, when the days

are shorter, a daytime hour could be as short as 45 minutes, while in the middle of the summer, when daylight lasted longest, a daytime hour could be as long as one and a half of our hours. In addition to being affected by the seasons, the lengths of sunlight hours also varied across the Roman Empire according to one's longitudinal position.

In the Roman day "first hour" was the hour following sunrise. "Midday" was the sixth hour after sunrise, "12th hour" the hour before sunset, and midnight the sixth hour of the night. Hours were marked with sundials or, in wealthy households, with water clocks. Anything occurring before midday was referred to as *ante meridiem*, which is used today by its common abbreviation "A.M."; anything after midday was called *post meridiem*, or "P.M." While this system of dividing the day was consistent across the empire, the Romans were far less skillful at measuring units of time within an hour. At first there was no attempt to measure time in shorter increments than the hour. In 263 B.C.E. the first sundial was brought to Rome from Sicily, as part of the treasure gained in the first Punic War (264–241 B.C.E.). It was not calibrated for the Roman sun and was therefore unreliable. Eventually someone realized that the problem was not just with the Sicilian sundial, constructed for a different latitude, but indeed with all sundials, which could not be adjusted for accuracy as the earth changed its position relative to the sun during the year.

In 159 B.C.E. the water clock was imported from Greece. This clock measured time according to how much water dripped through a narrowed opening in a measured span. Because it did not rely on the sun, a water clock's measurement could remain constant throughout the year. This benefit, however, was also a weakness: without any universal source such as the sun for reference, it was very unlikely that the time measurements of any two water clocks were consistent with each other. Ancient Rome was instrumental in devising a calendar that could follow the earth's revolution around the sun, but the Romans were never very accurate about measuring units of time within the days.

THE AMERICAS

BY ANGELA HERREN

Many inhabitants of the ancient Americas developed sophisticated methods of marking time based on careful observation of natural and astronomical phenomena. While the archaeological record in North America provides no evidence of calendar and clock use, simple farming began around 100 B.C.E., suggesting a basic knowledge of seasonal cycles. In Mesoamerica and South America the alignment and orientation of many pre-Hispanic buildings and archaeological sites acknowledge the rotation and movements of the sun, moon, and stars. Painting, sculpture, and portable arts often reflected ritual activities designed to promote success in seasonal agriculture. In ancient Mesoamerica the Maya and their predecessors developed sophisticated 260-day and

365-day calendar counts. Integral to daily life, these complementary calendar systems spread throughout Mesoamerica and dictated agricultural, ritual, and social activities until the arrival of the Spaniards in the 16th century C.E.

The first inhabitants of the Americas who crossed the Bering Strait land bridge approximately 10,000 to 12,000 years ago, after the last ice age, surely possessed a basic understanding of the movements of the sun. However, the region's first farmers, around 2000 B.C.E., necessarily developed a more acute interest in seasonal climate changes as they cultivated important staple crops like maize, beans, squash, and tomatoes. Early settlers created ritual centers oriented to the cardinal directions, and several early Mesoamerican structures mark the summer and winter solstices.

For example, the Old Temple at the highland Andean site of Chavín de Huántar dates to the late Initial Period (ca. 900–500 B.C.E.) and forms part of a cardinally oriented ceremonial center. A U-shaped structure typical of coastal Andean sites, the Old Temple turned away from the other buildings at the settlement and faced the rising sun in the east. Archaeologists discovered that darker stones set within the patio floor emphasized the east-west trajectory of the sun and the processional movement of participants in temple rituals. This patio also contained a sunken circular court.

Relief carvings of shamans in human and jaguar forms line the walls of this court, echoing human movement through the space. The entrance to the Old Temple on the east side of the building led to a dark, windowless, and labyrinthine interior. Set within a cruciform space at the center of this structure, a 15-foot-high monolithic stone sculpture of a Chavín deity marked the intersection of the four cardinal directions and a fifth vertical dimension, making it an axis mundi, or center of the world. As the Andean scholar Rebecca Stone-Miller notes, the wedge shape of the sculpture probably references the shape of the local highland foot plow. Obeisance to this supernatural deity ensured successful planting.

The Nasca Lines, created by the Nasca people who inhabited the Ica and Nasca Valleys of the Andean coast around 1–700 C.E., may also mark astronomical and seasonal events. Created by brushing away darker, oxidized stone to reveal the lighter earth beneath, the Nasca Lines create trapezoids, radial lines, and outlines of the forms of humans, plants, animals, and other objects. Comprehensible only from an aerial view, the Nasca Lines cut straight lines across mountains and valleys, revealing forms on an immense scale. Archaeological remains indicate ritualized use of the lines. Studies suggest that the Nasca Lines point to the sun's position on the horizon at the start of the rainy season and that the lines may run parallel to streams that traverse the plain.

In Mesoamerica, buildings that mark astronomical phenomena and a complex calendrical system developed in the Late Formative and Proto Classic periods (400 B.C.E.–250 C.E.). Mound J at Monte Albán, a small observatory that points to

bright stars during the zenith passage of the sun, is one of the oldest chronographic markers and may contain some of the earliest recorded dates in Mesoamerica.

Early inhabitants of Mesoamerica in Guatemala and the Mexican regions of Veracruz and Chiapas devised several methods of keeping time. The oldest, a 260-day calendar, marked the intersection of a continuous and repeating cycle of 20 day names and 13 numbers. As the day signs and numbers meshed together, it took 260 days to arrive back at the original configuration. Painter-scribes recorded this information in almanacs, and diviners used the calendar to interpret the future. Each day name carried positive or negative associations with a supernatural entity. Diviners called in after the birth of a child assessed the nature of his or her birth date, renaming the child on a more auspicious day as necessary. The 260-day calendar probably derived from the nine-month human gestation period.

A 365-day solar calendar came into use shortly thereafter. This calendar consisted of 18 periods of 20 days. Each period had a name and associated number. Ancient Americans considered the five days remaining at the end of this count unlucky and dangerous. People avoided activity during this time and viewed them as unfortunate birth dates. Known as the Vague Year, the solar year calendar lacked leap days and eventually wandered through the seasons, necessitating moveable feasts or periodic adjustments of the associated festivals. Mesoamericans used the 260-day and 365-day calendars concurrently and kept track of the intermeshing of these two cycles. Every 52 years the two calendar counts completed a full cycle, or calendar round.

While the calendar round completed every 52 years and then started over, the development of the Long Count or Initial Series allowed records of a much longer span. The Long Count posited a starting point, or zero date, equivalent to the European date of 2 August 3114 B.C.E. Units of time measured the amount of time elapsed since that point. According to the Maya system, time was recorded in units of 400 years, 20 years, single years, 20 days, and single days. These five numbers appeared on monuments and architecture in a specific order, with the largest numbers first. The Maya used a vigesimal system, or a system based on units of 20, the number of fingers and toes on a person. In the Long Count system, all years equaled 360 days. These dates appear carved on stone monuments and portable objects, and painter-scribes may have recorded the calendar counts in native paper manuscripts like those in use in the 16th century.

No clocks from the ancient period of the Americas exist, but early inhabitants may have noted the position of the sun in the sky and the movement of shadows around the everyday objects that surrounded them.

► ceramics and pottery

INTRODUCTION

The making of ceramics arose independently in several different parts of the world. It seems that for every culture that learned to make ceramics, the first ceramics were functional: They were vessels for carrying liquids or grain, containers for storage, pots for cooking, pitchers for pouring, cups for drinking, or utensils used in cooking or eating. It is a sign of a universal desire to have beauty in one's life that pottery that was both decorative and functional came to predominate in the world's ancient cultures. The earliest designs on pottery

seem to have had no other purpose than to beautify. Potters employed whatever materials they had at hand to color their pottery, using red, yellow, brown, and black probably because those colors could be made out of minerals or, in the case of black, out of charcoal.

Ancient ceramics were of three kinds: unfired, partially fired, and fired. Firing involves baking a clay object in high heat to dry and solidify it. Unfired pottery was usually dried in sunlight, which had significant limitations. One was that pottery making had to be seasonal, because wet weather would destroy wet pottery and cloudy skies would prevent sunlight from drying the clay. Another limitation was that sun-dried clay did not hold together well. The clay would crumble and fall apart with use.

Partially fired pottery is usually of clay that was fired literally in an open fire. How ancient potters discovered the technique of firing is not known, though it is often guessed at. It is possible that early potters learned about firing after accidentally dropping clay into a fire; alternatively, they may have used pots for boiling water or cooking stews and discovered that the bottom parts of the pots hardened, kept their shapes better than the bottoms of unfired pots, and were more durable than unfired bottoms. Examples of partially fired pottery are found in almost every ancient pottery-making society.

Fired pottery was the most desirable kind of ceramics. It held its shape better than unfired or partially fired pottery, which invited potters to experiment with the shapes of their products. Thus, with fired pottery come works of art such as human, animal, and plant figures. The earliest attempts at complete firing probably involved covering pottery completely with fiery wood and ash in an open fire. Sometime during the 3000s B.C.E. the vertical kiln was invented. It was heated at the bottom, and heat rose up out of the top; pottery was placed in a chamber over the heat. Temperatures between 850 and 1300 degrees Fahrenheit could be reached, but the flow of heat meant that the pottery would be unevenly baked. Another important development in the third millennium B.C.E. was the invention of the potter's wheel, which allowed potters to work faster and to shape wet clay as it spun. The Romans invented a horizontal kiln, and such a kiln was in use in China by 200 B.C.E., achieving temperatures over 2100 degrees Fahrenheit. This advance allowed for the development of porcelain in the 700s C.E.

AFRICA

BY KIRK H. BEETZ

The skills for making ceramic objects were not developed equally in ancient Africa. In northeastern Africa, where the potter's wheel was imported from the Near East, the manufacture of pottery became as sophisticated as anywhere in the world. Nearly all the rest of Africa, however, knew nothing of the potter's wheel until Arabs or Europeans introduced it during the Middle Ages. Without the

potter's wheel, pottery was made by molding with the hands or by laying ropes or slabs of clay on top of each other. Very often, the results were coarse and rough, but several African cultures developed techniques for creating polished, beautiful work.

Exactly who did the work is hard to determine. In most modern African societies working with clay falls almost entirely to women. Women dig the clay from quarries, transport it, and then shape and fire it. Usually, they do this at home as just one of several chores performed during a day. In some places it is known that women gathered together to create manufacturing centers, which they managed like businesses, selling their wares not only among their own people but to outsiders as well. It is likely that most ancient African ceramics were made by women.

Also difficult to determine is the cultural origin of ancient African ceramics. It is fairly safe to assume that pottery found in Nubia was made by one of the cultures that existed there, but throughout most of Africa ancient pottery often has no cultural context. For instance, the Nok culture (500–300 B.C.E.) in Nigeria is known almost entirely by its ceramics, pieces of which were washed into gullies, where they were found by miners. These fragments are magnificent, but because floods carried them to where they were found, it is not known either who made them or where they were made. (They are called “Nok” because their pottery was first collected at a mine near a village named Nok.)

Many ethnic groups that lived south of Egypt were called Nubian. Dating their earliest pottery has been difficult, but a

clay sculpture of a female found just south of Egypt has been dated to 4000 B.C.E. Animal figures found farther south are nearly as old. Vessels found near Khartoum may date to 2950 B.C.E., which would mean that Nubians developed some skills for making ceramics before they were influenced by Egyptians. Until 2600 B.C.E. Nubian ceramics manufacturing seems to have remained independent of Egyptian influence. The vessels made from 3000 to 2600 B.C.E. are painted with red geometric patterns on their outsides. Inside they are black. This black was probably achieved by mixing graphite with tree resin, a formula used elsewhere in Africa. The vessels are polished smooth, probably by being rubbed with a stone, a technique that was also used farther south, in eastern Africa.

There is a gap in the archaeological record for Nubia from 2600 to 1900 B.C.E. Some archaeologists once thought this meant that a different culture moved into Nubia in 2600 B.C.E., but most now believe that the culture continued without break to 1550 B.C.E. and that the relics for the missing years have not been found as yet. From 1900 to 1550 B.C.E. come not only vessels but also numerous human figures, often abstract, portraying both young people and adults. Usually no more than five inches tall, these figures had designs etched into them, after which they were fired and polished smooth.

The most interesting ceramics in the Nubian kingdom probably belong to Kush, which existed from about 900 B.C.E. to 350 B.C.E. and actually ruled Egypt from about 780 to 664 B.C.E. The artisans of Kush were proud of their association with Egypt and used Egyptian images and styles in their work. In 590 B.C.E. the Kush kings moved their capital south to Meroë, in southern Nubia, and ceramics from here are often called Meroitic. From the 100s to 300s C.E. there seem to have been several schools of Meroitic ceramics, including pottery made with and without the use of wheels. Some art historians think they can even identify individual artists, one of whom is the Antelope Painter, known for vivid paintings of antelopes on vases.

Southeast of Nubia was the city of Axum, which built a kingdom that lasted from the first century to the ninth century C.E., based on trade with the Near East and Far East. Its people were both African and Sabeian; the Sabeians were from the southern Arabian kingdom of Sheba, where Yemen is today. They made both plain ceramic vessels and vessels with complex designs that were abstract or depicted plants and animals, using primarily the colors black and red. They also made small animal and human figures.

Nubian ceramic manufacturing techniques seem to have spread west and south in Africa. It is possible that Nubians fleeing war may have made their way as far west as Nigeria, where they may have influenced the Nok potters. Their pottery making flourished from about 500 B.C.E. to about 200 C.E. They made human figures, now existing only in fragments because they were broken long ago in floods.

The heads of their figures were sometimes spherical and sometimes elongated and were made in the manner of pots, to which features such as ears, noses, and lips were added

WHAT CERAMICS CAN TELL US ABOUT ANCIENT AFRICA

In many parts of Africa ceramics are all that remain to tell us about ancient cultures, but what they can tell us has limits. For example, the pottery of the Nok culture of about 500 B.C.E. to 200 C.E. reveals a sophisticated artistic sensibility without telling us why the Nok created these beautiful portraits of people and animals. We know that they probably liked to wear jewelry, because their figures wear necklaces, earrings, and bracelets. The features on these figures are similar to those of people native to modern Nigeria, so it is likely that they were not descended from North Africans, such as Carthaginians or from Greeks, Romans, or Egyptians. Still, this does not exclude them from being of mixed ethnic ancestry, as were the people of Axum.

The Nok ceramics inspire speculation, such as the notion that the figures belonged to shrines that were washed away in floods, since Nok pottery was deposited in gullies by flowing water; without more information, this remains no more than an educated guess. The men and women depicted in the figures are sometimes so well portrayed that the figures seem to be portraits of real people: The figures could be representations of kings and queens or even portraits of ordinary people who paid artisans to make the pottery.

Sometimes a simple piece of pottery can tell much about its culture. In the Aegyptisches Museum in Leipzig there is a small sculpture of a cow from Nubia (ca. 1990–1550 B.C.E.). It resembles the rock paintings of cattle found in the Tibesti Massif in northern Chad, dating from 5095 to 2780 B.C.E. This resemblance indicates to archaeologists that the cattle in Nubia may have been descended from the cattle herded by the lost peoples belonging to the era when the Sahara was grassland, rather than desert. This, in turn, suggests that ancient Nubian culture was influenced by or was descended from the culture of ancient Saharan herders.

before firing. Hair, head, torso, and other body parts were made separately and then fitted together using “keys,” or grooves cut into the clay into which a projection fits, with a V-shape fitting into a V-shape groove. The surfaces of the figures were polished. To the northwest of Nigeria, in Mali, ceramic figures from 2010 to 1670 B.C.E. have been found with pottery intended for daily household use. The artifacts are associated with the western Sudan culture that may have been related to the Saharan grassland cultures. The pottery was incised with lines and dots. Little is known about these artifacts.

Much of central and southern Africa is now inhabited by the Bantu-speaking culture that began spreading through Africa in the last couple of centuries B.C.E. Some of these people settled in an area beside Lake Victoria stretching westward. Their pottery is called Urewe ware, named for the region in which it was discovered, and it was made from about 200 to 500 C.E. The bases of Urewe vessels had indentations, perhaps so they could be carried on the head. The potters added designs that look like bumps, and they etched in lines, usually horizontal. The lips of the vessels tend to bend outward and then turn under and in on themselves.

EGYPT

BY ERIN FAIRBURN

Pottery in ancient Egypt first appears in the archaeological record throughout the Nile River valley in the Predynastic Period (around 3800 B.C.E.). Pottery is the predominant artifact from that point on. Two types of clay were used to make pottery in the ancient Nile River valley, marl and Nile

silt. Nile silt was formed from sediments deposited during the annual flooding of the Nile and would have been relatively easy to obtain, especially following the inundation, when deposits would settle on the surface. Marl clay appears in proximity to the limestone and shale formations near the Nile, stretching from the area of modern Cairo south. Marl is very dense and stonelike and has to be mined in underground works.

The preparation methods for the two types of clay would probably have varied very little. The first step might have been to purify the clay. Then the clay would be soaked in a pit of water to soften it. The softened clay would next be mixed by trampling. Humans trampled silt clays, but animals were probably used for marls. The person treading the clay would remove any bits of impurities found underfoot. Next, the trampled clay would be taken from the pit and placed on the floor, where workers would wedge it, a process of stamping on it that removed air pockets and any remaining impurities. An optional final step was tempering the clay to improve consistency and strength by adding foreign substances such as sand, hair, ash, chopped straw, or ground-up quantities of old pottery.

After the clay had undergone this preparation, it was finally ready to be formed into pottery. Vessels could be created by modeling, coil building, molding, and throwing. Handmade pottery was the most common, and the earliest Egyptian pottery was made by the hand techniques of modeling or coil building. Modeling was achieved by working a lump of prepared clay with the hands, using tools to build up the sides, usually a paddle of wood and an anvil, a stone,

or a round piece of clay. The technique was to hold the anvil inside the vessel and beat the outside with the paddle. Coil-built pottery is made by laying rolled lengths of clay, formed into rings, on top of each other. The sides could be smoothed out with a paddle and anvil. The best-known coil-built pottery from ancient Egypt is the black-topped red ware from the Predynastic Period. A molded vessel is created by pressing clay into a hollow mold or by pressing it over a form, which was the most common method for creating molded pottery in ancient Egypt. It was used to create bread molds employed to bake specially formed loaves. Molds were also used to create lids for canopic jars (jars that held the entrails of mummies) and certain New Kingdom (1550–1070 B.C.E.) pottery forms, including popular vessels depicting the god Bes, protector of women in childbirth.

Pottery could be produced on a turning wheel, which was a rotating stand that gave easier access to all sides of the vessel placed on it. It was turned by hand and probably could not achieve sufficient speed to throw a vessel. Thrown vessels were created on a stand either with a flywheel that was turned with a baton or a kick wheel that the potter kicked. The rate of speed it achieved allowed the potter to build up a vessel's walls purely by hand, which made for a more regular shape. Throwing was the predominant method used in vessel formation in ancient Egypt, although several techniques were often used on a single vessel.

After a vessel was formed, it had to dry. When it had turned to a so-called leather-hard, or semidry, state, various decorations could be applied. When the vessel had dried com-

pletely and after any decoration had been applied, it was fired. As there is little evidence for open firing in ancient Egypt, it can be assumed that kiln firing was the predominant method used by ancient potters, especially since a number of kilns are known. Updraft kilns, with a lower chamber for fuel and an upper chamber with a chimney-like feature for stacking vessels, could produce a high, constant temperature, reducing the risk of incomplete firings. When stacked upside down on a vented floor above the heat source, the vessels would bake simultaneously from inside and outside. These kilns could reach temperatures of 1650 to 1830 degrees Fahrenheit; 1110 degrees was sufficient for firing Nile silt vessels, but 1290 degrees was needed for marl vessels.

How pottery was used is often very difficult to determine. Labels listing contents, scientific analysis of residues left inside vessels, and charring or other visible post-firing processes help determine their function. Pottery can generally be divided into two classes, domestic and nondomestic. Domestic vessels were used in the preparation and consumption of food. They were generally made of coarse-tempered clays and bore little or no decoration. Nondomestic vessels, often used for funerary, ritual, or decorative purposes, were frequently made of finer textured clays and were more likely to be decorated.

Several types of decoration were used on ceramics in ancient Egypt, often more than one on a single vessel. Burnishing (rubbing smooth) and applying slips (thin clay used for coatings) were common techniques for domestic and nondomestic vessels; dry vessels were treated in these ways before firing.

Painted pottery group of cattle, from el-Amra, Egypt, about 3500 B.C.E. (© The Trustees of the British Museum)

These techniques were utilized on many forms throughout the history of Egyptian ceramic production. Modeling of the vessel wall was frequently done in Egypt. The clay of the wall would be manipulated by hand, often to create human or animal forms out of either the entire vessel or portions of the wall. Sometimes modeled elements, often depicting animals, were attached to the rim or shoulder of a vessel. Incision and fenestration were decorative techniques employed on leather-hard vessels and were more likely to be used for nondomestic wares. Using the former technique, designs would be cut into the clay with a reed or knife; with the latter, sections of the vessel would be cut out in various patterns.

Throughout the history of pottery production in Egypt, painting was a major method of decoration. Paint commonly had ochre (red and yellow), charcoal (black), manganese (black), or cobalt (blue) bases. Paint was applied with fingers or with reed brushes either before or after firing. Painted vessels became most popular during the New Kingdom, when “blue-painted” and polychrome decorations began to appear on nondomestic wares. Ships were common images on Predynastic and Protodynastic pottery of the late fourth millennium B.C.E. Flora and fauna were popular motifs all through the era of Egyptian pottery production. Human figures were popular on early painted vessels, and returned to fashion beginning in the New Kingdom.

THE MIDDLE EAST

BY TOM STREISSGUTH

In Mesopotamia, the “land between” the Tigris and Euphrates rivers, the abundant red clay could be shaped by hand or on a potter’s wheel, hardened over a flame, glazed, and painted. This earthenware pottery was used for preserving and storing food, such as grain, oil, beer, water, and wine, and for drinking vessels, plates, statuary, writing tablets, and seals. As one of the most durable objects of antiquity, pottery also serves as a valuable tool for modern archaeologists. The distinctive styles and colors used in different eras allow historians to date surrounding homes and streets found at the same level with remnants. The shape and size of pottery also give strong clues as to how it was made and used; its thickness testifies to its method of transport. (Thin-walled storage pottery, for example, traveled by boat, and thus reveals a civilization in contact via overseas trade with foreign lands and cultures.)

The earliest Mesopotamian pottery, from the site of Hassuna and dating to 7000 B.C.E., was hand-shaped, lightly fired, unglazed, and simply decorated with lines incised into the surface. Later designs included painted geometric forms, such as rectangular lozenges and zigzag lines. Halaf pottery (5900–5300 B.C.E.) from northern Mesopotamia is sometimes dubbed “fineware” because of the smooth surfaces that allowed potters to apply white slip (thin, watery paint) as a ground for red or black paint, mixed from oxidized ores, on the finished product. Charcoal was used to produce black paint; ground gypsum produced white paint.

Ceramic bowl with abstract decoration, from Tall-i-Bakun in modern-day Iran (Courtesy of the Oriental Institute of the University of Chicago)

Halaf pottery carried a wide variety of geometric motifs; animal forms, such as birds, leopards, deer, and rams’ heads; and depictions of feasting, ceremonial processions, and other human activities. Artisans of the Halaf Period also produced ceramic figurines that may have been used in religious ceremonies or as votive objects in the home. These statues display exaggerated female features with clothes and adornments painted on their surfaces.

The pottery of the Ubaid culture (5300–4000 B.C.E.) originated in southern Mesopotamia and gradually spread to the north as well as to Persia (modern-day Iran) and the Arabian Peninsula. Ubaid objects—drinking cups, storage jars, bowls, and plates—were made of darker clay, and they often had a brown or green tint. Simple household pots were roughly shaped and undecorated and were provided with small lugs or knobs on their sides, which allowed them to be easily carried. A distinctive feature of higher-quality Ubaid vessels is a wide rim that flares out from the vessel’s mouth. Some Ubaid ceramics were the first to be produced on potter’s wheels, which allowed the making of larger and more symmetrical forms that could be turned out at a much faster rate. Clay figurines from this period are much slimmer than those of the Halaf era and have more elaborate clothing and adornments.

The Uruk culture of the fourth millennium B.C.E. was the first to mass-produce pottery on a wheel. The production of pottery moved from the household into the hands of professional artisans, who turned out storage vessels by the thousands for the use of traders and merchants. Most of these industrial pieces went unpainted, but ceramic artists had developed cedar oil as a painting medium. Cobalt was ground

down and mixed in the medium to produce a blue pigment, copper could be added for green, and antimony produced yellow. In the city of Uruk clay was also used to manufacture writing tablets. To keep records, pictographs (figures used in a kind of picture writing) were pressed into the still-wet clay with a cylinder seal or a pointed stick.

Pottery of the Jemdet Nasr era originated around 3200 B.C.E. Jemdet Nasr jars are thick and painted in black or dark red. During this period clay seals also came into use throughout Mesopotamia (though archaeologists have discovered seal impressions from as early as the Halaf Period). Seals are small, engraved, cylindrical objects, one to two inches in length; they were also made of silver, bone, ivory, or semiprecious stone. The seals had a variety of designs and were rolled over tablets or bricks while the clay was still wet. They left a permanent, rectangular image in the clay. Engraved with images of the gods, symbols of office, or simple geometric designs, they served to authenticate records, agreements, and official documents. Later cylinder seals became items of jewelry, acting as talismans and amulets that provided the wearers with protection and good luck.

At this time clay tablets came into widespread usage for cuneiform writing, a wedge-shaped script. The tablets were incised with a reed or stick (*cuneus* in Latin) while still wet and then baked and used to keep records for trade or government functions related to the storage and movement of grain, weapons, and money. During the Uruk Period the need for record keeping arose as cities were built and people gathered under a central authority. Pictographic symbols represented commodities, while simpler designs indicated numbers.

In the second millennium B.C.E. ceramic art developed further in the Mesopotamian kingdoms. Drinking vessels were delicately shaped into abstract and animal forms that were provided with shiny glazes in a variety of colors. Painted pottery and ceramic animal figurines were everyday objects in the home. Bulls symbolized masculinity; rams and stags were given elaborate sets of horns. Female figures showed wide and rounded hips and hands held to the breasts, a symbol of fertility. Statuettes of gods and spirits were also shaped from clay and used as votive figures, guardians of the hearth and home.

By the time of the Assyrian Empire (1813–609 B.C.E.), pottery was a large-scale industry throughout Mesopotamia. Potters set up large workshops, fired their wares in massive stone kilns, and incised their work with distinctive marks and stamps. There was a wide variety of standard shapes for bowls, jugs, beakers, and plates; a distinctive blue glaze was applied that became the hallmark of Assyrian ceramics.

The fall of Nineveh, the capital of Assyria, in 612 B.C.E., brought the rise of the Achaemenid Persian Empire in Mesopotamia. Under the Achaemenids and the later Parthian and Sassanid empires, pottery artisans achieved a very high level of skill in shaping and painting clay. Vessels appeared in all manner of abstract, animal, and human forms, some very complex and others downright whimsical. As models,

the ancient Persian artisans favored horned mountain goats and deer, domestic livestock such as cattle and sheep, camels (symbolizing wealth), and horses (symbolizing speed and power). Graceful handles appeared on drinking cups and jugs; spouts emerged from unlikely places, often along the side or even at the base. Historians speculate that the many twin-spouted drinking vessels found in ancient Persian cities may have been used in wedding ceremonies or in rituals that sealed treaties and agreements by drinking from a common vessel. Ceramic workshops also produced sarcophagi and funerary urns in which to bury the dead and, for the living, monumental sculptures designed for the walls of palaces and religious shrines.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The oldest-known ceramics in Asia are found on the island of Kyushu in Japan, where pottery discovered in a cave has been carbon-dated to 12,000 B.C.E., an era in the grip of an ice age that lowered sea levels enough to connect Kyushu by dry land to Korea. The era from 13,000 to 300 B.C.E. is the Jomon Period, during which the primary way to make ceramic vessels, whether small cups or burial urns large enough for a human corpse, was to wind ropes of clay in a circle, one atop another. The ancient ceramics were elaborately decorated with designs impressed into the clay or created by adding ridges of clay to the side of the pottery, making images of trees, animals, and supernatural figures as well as abstract designs. Painting pots and other ceramic objects probably did not begin until late in the Jomon Period, when potters depicted images of everyday life on their creations.

During the Yayoi Period (300 B.C.E.–300 C.E.) numerous *haniwa* figures were made. *Haniwa* were representations of people and animals that surrounded graves and burial mounds, warding off evil spirits who might disturb the dead. Some of these figures may have been used as toys. Although they were quickly made, with sometimes hundreds being used for one burial, they nevertheless tended to be expressive, with the human figures showing emotions such as anger or happiness. It was also during the Yayoi Period that the potter's wheel was introduced to Japan. During the 400s C.E. many Korean artisans moved to the islands of Kyūshū and Honshū, bringing with them new skills. Korean potters introduced a kiln to Japan that became very popular, sometimes scores of them covering whole mountainsides. The kiln was erected on a slope, a long, brick tube pointing upward; pots were placed in it and a fire lit at the bottom end, while the heated air flowed up through the kiln's tube. Potters learned the special quirks of individual kilns and just where to place a particular ceramic object to fire it the way they wanted it to be fired.

Ceramics appeared in the Harappan culture in the Indus River region in the northwest of the Indian subcontinent about 2300 B.C.E. Harappans used potter's wheels to produce large jars that they painted with elaborate designs of animals

and plants. They also made bowls and other dishes, including goblets with pointed bottoms that would be stuck into the ground to hold them upright. Harrapans created many small figures, some of which seem to be gods but others of which may have been toys.

In the Hindu culture that followed the Harappans, the story was told of how the god Shiva wanted to marry Sati but lacked a pot for the ceremony, so he created the first man and woman, potters, to make him one. Yet there is a long gap in information about Indian arts from 1500 to about 500 B.C.E. Pottery was certainly made, but it is mostly pieces of plain housewares that remain. Indian potters made items for burials and for religious occasions. They had an exceptional period of creativity in the 200s to 400s C.E., during which they created terra-cotta sculptures that rivaled stone sculptures for both gracefulness and delicacy of facial expression.

The earliest Chinese ceramics have proved difficult to date, but they may predate 5000 B.C.E. The earliest ceramic pots were black, with clay twisted to look like rope pressed

on the outside as decoration before firing. Cultures such as the Banpos of 4865 to 4290 B.C.E. on the Yellow River painted their vessels, usually in black over a red surface. The images were sometimes inspired by nature, resulting in stylized depictions of people and plants. Alternatively, they could be intended just to please the eye; these images consisted of crisscross patterns or loops and would often feature the interplay of black and red in which the eye could be fooled into perceiving the red as the outer color. In about 2500 B.C.E. the Longshan culture, which existed in modern Henan, Shandong, and Shaanxi provinces from 3200 to 1800 B.C.E., revolutionized the making of earthenware in the Asian Pacific region by introducing the potter's wheel, probably imported from the Near East, thereby freeing both hands to shape clay. As early as 2400 B.C.E. various cultures living in central and eastern China were making toys out of clay as well as small images of people and deities to be included in burials.

The Shang Dynasty (1500–1045 B.C.E.) brought forth the invention of stoneware, which was hard and waterproof, and that came about when Shang potters learned how to mix clay that could be fired at about 2100 degrees Fahrenheit. They also learned to glaze ceramics. A glaze is a glasslike coating that seals the surface of a ceramic object and decorates it. During the Zhou Dynasty (1045–256 B.C.E.) potters made ceramic tiles for roofs, consisting of half-cylinders perhaps patterned after the shape of split bamboo. Some Zhou potters applied tinfoil to their creations, while others applied lacquer. During the Han Dynasty (202 B.C.E.–220 C.E.), lead glazing was introduced, probably from the Near East. This glazing melted at relatively low temperatures, making it cheaper to produce than other glazes. During the period of the Six Dynasties (220–589 C.E.), Chinese potters experimented with glazes and clays, laying the basis for the development of porcelain.

When China established the colony city of Lolang in Korea in 108 B.C.E., Chinese technology filtered through the Korean peninsula. Korean ceramic vessels tended to have three legs, which made them less likely to tip over than four-legged pots with uneven legs, and they were glazed green similar to those of the Han Chinese. From about 18 B.C.E. until unification of Korea in 676 C.E., potters made black or dark gray, finely decorated pots, and figurines of people and animals for burial goods and toys. When the Han potters of China began making white ceramics, Korea started producing extraordinarily beautiful decorated white ceramics that would develop into porcelain, establishing Korea as an important center of porcelain manufacture from the Middle Ages to the present.

Little is known about the ceramics of ancient Indochina. Cambodians began making pottery with brown glazes around 500 C.E., but in the region of Thailand, pottery making may not have begun until the 1200s C.E. The potter's wheel was not to be found in ancient Oceania, although pottery was introduced to Samoa and other islands before the first century B.C.E. The Philippines appear to have followed Chinese patterns of manufacturing pottery by about the first

Pottery jar with dragon handles, from China (fourth to third century B.C.E.), made to imitate a more expensive bronze vessel (© The Trustees of the British Museum)

century B.C.E., but the peoples of Indonesia seem mostly to have imported pottery from China and Korea rather than manufacture it.

EUROPE

BY ALISON SHERIDAN

Ceramic pyrotechnology—the transformation of a flexible raw material (clay) into a rigid, if fragile end product—first appeared in Europe around 24,000 B.C.E. in the form of figurines found at the cave of Dolní Věstonice in the Czech Republic and a few other sites in central and eastern Europe. However, this seems to have been an isolated phenomenon and not the beginning of an unbroken tradition. Its next appearance was not until the early to mid-seventh millennium B.C.E. in early farming communities in the eastern Mediterranean and southeast Europe. By 4000 B.C.E. it had spread across almost all of Europe.

The spread of this technology related closely to wider changes in people's lifestyles, especially the shift to using domesticated plants and animals for food instead of relying on wild resources. In most areas these changes involved the emergence of permanent or semipermanent settlements—a way of life suited to the use of fragile ceramics. However, pottery was not exclusive to farming communities: Along the northern fringe of Europe during the sixth millennium B.C.E. fisher-gatherer-hunter groups learned from their farming neighbors to the south how to make pottery. They used this knowledge to create items suited to their lifestyle, including shallow dishes that acted as lamps for burning the oil from seals and whales and pointed-based pots for cooking. Traces of fish stew have been found in one such pot from a submerged settlement at Tybrind Vig in Denmark.

The flexibility and versatility of clay gave it uses in almost every aspect of life in prehistoric Europe. Its main usage was as vessels and utensils for preparing, serving, and consuming food and drink, but it was also formed into other kinds of containers, including urns and graves for the dead and vessels for transporting trade goods. Various manufacturing processes used ceramics (for example, as molds and crucibles for metalworking), and ceramic ovens are known from several parts of Europe, including the Orkney Islands off Scotland. Fired clay served as a building material in the warmest and driest parts of prehistoric Europe. The many other uses of ceramics in prehistoric Europe include jewelry, items connected with belief systems (such as figurines, models, and cult objects), toys, writing tablets and seals, and musical instruments such as whistles and even drums.

The methods of preparing, working, and firing clay varied greatly, as did the organization of ceramic production. At the most basic level, nonspecialist (but often highly skilled) individuals hand-built pottery, firing it rapidly in a bonfire or firing pit, for use by the family or residential group. This was the norm for much of the period in question. Potting skills

Bucchero ware water jug, Etruscan, about 550–500 B.C.E., from Chiusi, Tuscany, Italy (© The Trustees of the British Museum)

were handed down through the generations. At the other end of the spectrum was the factory-based, wheel-thrown, kiln-fired commercial mass production of pottery as seen in various parts of the Roman Empire. Every variant between these extremes is found in prehistoric Europe.

There are many examples of small-scale, specialist pottery production for elite use as prestige items. These include some of the Bell Beakers of Copper Age Europe (around 2800–2300 B.C.E.), the Early Bronze Age high-status pottery of the Argaric culture in southeast Spain (early second millennium B.C.E.), and the Late Bronze Age graphite-coated and tin-inlaid pottery of south-central Europe (ninth and eighth centuries B.C.E.).

Specialist production on a larger scale is seen from around the mid-second millennium B.C.E. in the eastern Mediterranean, for example in Minoan Crete, Mycenaean Greece, and Cyprus. Such production was not only for local elite use but also for exchange or trade: sophisticated networks of contacts linked the east Mediterranean with other parts of the Mediterranean and with the Near East, ensuring the flow of many kinds of goods. Techniques of pot building included the use of the potter's wheel, often in conjunction with coil building or other methods. In coil building, rolled lengths of clay are formed into rings, one atop the other.

The trend toward large-scale, specialist production reached its peak during the first millennium B.C.E. in the form of Etruscan, Greek, and Roman pottery. Trade and other mechanisms took Greek and Roman pottery far from its places of manufacture, including into the hands of the elite in other parts of Europe. Local potters then emulated the sophisticated techniques used to make these imported pieces. This was how the technique of "throwing" pottery on a wheel spread across parts of Europe around 500 B.C.E.

Modern analytical techniques reveal much about the manufacturing methods, function, origin, and significance of prehistoric European pottery. Advances in the study of pot contents have allowed archaeologists to detect invisible traces of dairy products, meat, fish, resins, oils, and even the remains of cabbage or related plants. This technique is shedding important new light on the diet and methods of food preparation of ancient Europeans. In Britain it has revealed the use of "secondary" products such as milk around 3900–3500 B.C.E., much earlier than previously suspected. It has also shown that in England and Wales around 3000–2500 B.C.E. certain kinds of pots seem to have been preferred for cooking pork, while others were used for cooking beef.

Analytical techniques can also provide details about decoration and other surface treatments, ranging from what fibers made up the cords that were impressed into the surface of a pot to detailing methods of coating used to produce a specific surface color or texture. Analysis of the stone fragments employed as filler to stop rapid-fired vessels from exploding during firing can reveal whether pottery production was locally based or not. This technique has shown that the particularly good clays of the Lizard Peninsula in southwest England were used to make pottery that then traveled long distances during the Neolithic and Bronze Ages. We can also gain insights into prehistoric European belief systems by considering the kinds of objects made (for example, figurines) and the methods of manufacture (such as the use of recycled ancestral vessels as filler in new pots).

GREECE

BY SPYROS SIROPOULOS

Pottery surpassed its practical uses and became an art in Greece in the Bronze Age (1500–1050 B.C.E.), but there are signs that clay was worked five thousand years earlier. Ar-

chaeological excavations have come up with artifacts that indicate experimentation with clay as early as the Neolithic Period, between 6800 and 6500 B.C.E., though the general use of clay is in dispute.

Extensive manufacture and use of clay vessels characterize the Neolithic Period from 7000 to 5800 B.C.E. Decoration is very simple, mostly consisting of geometric forms in red (lines and triangles) incised on the surface of the pots, which often mimic objects such as reed baskets and leather sacks. Techniques and patterns varied greatly in different areas of Greece. In Thessaly and western Macedonia pots were decorated with human forms. On mainland Greece pots with incisions of white material were discovered. Monochrome ceramics prevailed in the Peloponnese, and decoration was not important. In Crete ceramics with incised and dotted decorations were found, while in western Greece there are indications of a connection with the Adriatic thanks to the presence of impressed ceramics, decorated with a kind of stamp. Stamping was done by using nails, seashells, or other objects to imprint a design on the surface of the pot, which was of very simple shape.

By 3000 B.C.E. bronze began to be used in Greece. Two great civilizations developed, one on the island of Crete, called the Minoan (after the mythical king Minos), and the

Terra-cotta statuette of a lady in a swing, from Agia Triada, Herakleion (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

other one in Mycenae, in the Peloponnese. The Bronze Age there ended in about 1200 B.C.E. Despite the introduction of bronze, clay was still used to produce a number of household goods, an example of which is a beautiful *hestia* (cooking stove), now kept at the Museum of Nauplia (Peloponnese, Greece), dating to 2600–2300 B.C.E. Clay objects were also made to accompany the dead in their tombs. Discoveries of numerous clay idols dating from 1380 to 1100 B.C.E. hint at the fact that clay sculpture might have been used almost exclusively for worship.

In the 1900s archaeological excavations on Crete brought to light some 3,000 clay tablets inscribed with two scripts, called Linear A and Linear B, respectively. Linear A was used by the Minoans around 1750 B.C.E., but this early form of writing has not been deciphered yet. Minoans also added inked Linear A inscriptions to stone and terra-cotta vessels. At the site of Phaestus archaeologists came across a most peculiar object: a clay disk decorated with imprints (stamps made with seal stones on wet clay) on both sides. The meaning of the 45 symbols puzzles scientists still.

Linear B tablets were found on Crete and also at Pylos and Mycenae on the Greek mainland. Most of them date to 1400–1150 B.C.E. Linear B was deciphered in 1952 by the British architect and cryptographer Michael Ventris. These clay tablets are the earliest evidence of the use of written language in the history of Greece.

During the Archaic Period (600–480 B.C.E.) the two main pottery-making techniques were the black-figure technique (invented in Corinth but perfected in Athens) and the red-figure technique. In black-figure vase painting a black coating was applied on lighter, reddish-orange clay. This coating was not color but rather a refined essence of the same clay. The details were incised with a sharp object that drew away the black coating from the surface before the vessels were fired. Sometimes white or reddish color was added later. The most celebrated artifact of this period is the so-called Amphora of Nessos (dating to 610 B.C.E. and now kept at the Archaeological Museum of Athens). This vessel marks the beginning of a series of black-figure-style works by great Athenian potters, some of whom are known by nicknames and others by conventional names (for example, Painter of the Gorgons, from a vessel of 600–590 B.C.E.). Cleitias and Ergotimos are perhaps the two most famous representatives of the early Attic black-figure style, and then Nearchus, an artist from the second quarter of the sixth century B.C.E. The names that prevail in the third quarter of the sixth century B.C.E. are those of Lydos, the Amasis Painter, and Exekias.

Around 525 B.C.E. the so-called Andokides Painter, named after the potter he worked with in Athens, used the red-figure technique for the first time. Figures maintained the reddish color of clay, while the background of the scene was painted black, as were all the details of the faces and every decorative detail of the vessels. This technique adds more volume to forms, and details are more distinctively depict-

ed through the use of various size brushes. Red-figure vase painting begins to approximate painting.

During the 30 years of Pericles' leadership of Athens (450–420 B.C.E.), a new style developed, called *totally free* or *beautiful rhythm*. The compositions are freer, sometimes figures appear in three-quarter profile, and coatings are used for indicating depth or shadows. The Achilles Painter, the Cleophon Painter, the Eretria Painter, and Polygnotos are some of the most famous artists of this time. At the same time, a new technique appeared: painting of vessels with dull red and black paint on a white ground. This technique was gradually limited to the *lekythos*, a vessel used to store olive oil for the anointing of the dead in preparation for burial or as a burial offering. A freer style developed later (420–390 B.C.E.), with scenes from daily life and domestic or ritual activities.

Ceramics of the Hellenistic Period (323–31 B.C.E.) do not have the aesthetic quality of the red-figure style of the Classical Period. The most characteristic Hellenistic vessels are certain *skyphoi* from Megara, an ancient city in Attica. These deep, two-handled cups feature embossed decoration, usually mimicking plants. Other styles appear, such as the so-called Western Klitys style (vessels with simple linear or plant decoration, in white and yellowish coloring on a dark glazed surface), the Gnathia style (with female heads, cupids, birds, musical instruments, and discs on the surface), and the Hadra style (with black tinning on a yellowish coating and multicolored painting on white coating).

ROME

BY MELISSA MOORE MORISON

Pottery is the most common artifact found on ancient Roman archaeological sites—hardly an accident, since ceramic objects played an important role in every aspect of Roman life. The Romans cooked and served their food in ceramic vessels, used lamps made of clay to illuminate their houses at night, constructed their homes and temples with brick and ceramic roof tiles, and often used ceramic urns to preserve the ashes of the deceased. Sturdier than objects made of glass, wood, or metal, ceramic artifacts like these easily survived over time and thus provide archaeologists and historians with important information about the daily lives of the Roman people. Specialists divide Roman ceramics into categories based on function. The primary categories include vessels related to food transport, cooking, and table service; lamps; bricks and tile; and ritual objects, such as incense burners and cinerary urns (used to hold the ashes of the dead).

Amphorae were large clay containers (3 to 5 feet long) used for shipment of important commodities such as olive oil, wine, condiments, and grain. Amphorae were produced in several regions of the Roman Empire, including Spain, North Africa, France, Italy, Greece, Turkey, and the Levant. Each region produced amphorae of characteristic colors, sizes, and styles. However, all amphorae shared a characteristic shape

Amphora from Pompeii, Italy (© The Trustees of the British Museum)

directly related to their function as transport containers. In order to function effectively as containers for food, amphorae also needed to be watertight, thick, strong enough to withstand the stresses of maritime shipping, and large enough to contain between 5 and 10 gallons of liquid. It was also necessary to produce amphorae in standardized sizes and shapes, so that large numbers of them (often up to 3,000) could be loaded efficiently into the cargo holds of ships.

The production of amphorae therefore presented a significant technological challenge. For this reason, amphorae were usually made in specialist workshops located near the harbors from which trade goods were shipped. Potters in each region developed specific clay “recipes” based on their understanding of the relative strengths of different clays and mineral additives. Assembly-line techniques were also employed, with one craftsman producing the top half of a vessel, another producing the lower half, and another joining the halves and adding handles and so on. Amphorae are very important indicators of trade patterns and other economic structures. The presence of a Spanish olive oil container on a small farmstead in Jordan, for example, or the discovery of a North African wine jar in a fortress in Britain says a great deal about the

extent of trade, the movement of goods, and the consumption of food within disparate provincial populations.

The Romans employed several specialized ceramic vessels for cooking. Roman cooks, like modern chefs, could choose from a wide variety of pots and pans designed to optimize the success of different cooking techniques. Herbs, vegetables, and soft cheeses were ground and mixed in the *mortarium*, a heavy bowl with sharp stone fragments embedded in its interior surface. The *olla* (or *aula*) was a deep, round-bottomed vessel used for boiling stews or porridge. One could fry or sauté fish in a shallow-angled pan with a nonstick surface (*patera* or *patina*) whereas the *patella*, a deep, straight-sided pan, was most suitable for baking casseroles (which were much-loved and characteristically Roman dishes). Grills for cooking meat were also regularly made from clay, as was the *clibanus*, a portable oven for bread baking. These vessels, in various sizes, made up a standard “set” found in most Roman households across the empire.

Beyond the standard cookware repertoire, cooks throughout Italy and the provinces also owned other vessels that reflected regional preferences in food preparation. Archaeological analysis of how cookware sets vary provides important information about Roman food preferences across the empire. Casseroles, for example, are found in relatively small quantities in provinces without a strong Roman colonial presence, as the dish is used for a specialized form of cooking most popular in Italy itself that only rather slowly became popular in other parts of the Mediterranean. Most cookware was produced in local workshops, and only a small number of ceramic cooking vessels were exported beyond regional markets. While metal versions of these objects were available, they were more expensive than the standard ceramic vessels and are less commonly found.

Tableware includes all vessels intended for food service and dining, from pitchers and platters to small cups and plates. Many Roman tableware vessels were decorated with bright red slip and intricate designs in raised relief. These designs consisted of simple geometric patterns; images of fish, birds, and plants; early Christian iconography, or symbols and images; elaborate mythological scenes; and workshop trademarks. Vessels decorated in this style are often referred to as *terra sigillata*.

Terra sigillata vessels were first produced in Italy in the first century B.C.E. Unlike amphorae and cookware, which were thrown by hand on a potter’s wheel, *terra sigillata* objects were made in molds in large factories. Clay molds were created in the desired shape, and decorative patterns were cut into the interior of the molds. When the molds were complete, they could be used to make hundreds of standardized cups, bowls, plates, and platters very rapidly. Soft, wet clay was pressed firmly into a mold and smoothed so that the exterior of the finished vessel would exhibit the desired pattern in raised relief. Once the clay was dry, the vessel was removed from the mold, coated with red slip, and finished with a decorative base and handle while the mold was immediately used

to create another vessel. Thousands of such vessels were fired at once in massive kilns shared by several related workshops. Most of the potters at the large *terra sigillata* factories in Italy (and, later, in France) were slaves.

By the first century C.E. Italian *terra sigillata* was widely exported to the large urban centers of the Roman provinces as well as the military garrisons on the frontiers, where standard table services, including cups, bowls, and plates, were issued to army units. *Terra sigillata* vessels were so popular that they were widely emulated in other regions of the empire. In the course of the second and third centuries C.E. production centers in Turkey, Syria, the Levant, and North Africa produced vessels of such beauty and high quality that they rapidly superseded the Italian products in popularity. Less elaborately decorated or plain tableware was also widely produced for local markets; each province of the Roman Empire had its own distinctive tableware suite reflecting local taste.

THE AMERICAS

BY RONALD YOUNG AND MICHAEL J. O'NEAL

Ceramics and pottery played an important role throughout the ancient American world. While all major civilizations in the Western Hemisphere produced ceramics in some form, the most advanced examples technically and artistically were produced by the great civilizations of Mesoamerica and the Andean region. Two principal characteristics marked ceramics and pottery throughout the hemisphere. First, American cultures built ceramic works by hand, for the potter's wheel was unknown in the Americas. Second, all ancient Americans decorated their ceramics with pigment or with slip, or clay thinned with water to a liquid consistency and used as a coating to produce a finer finish.

In North America, Native American groups in what is now the eastern United States produced ceramics extensively. Historians refer to these tribes collectively as the Eastern Woodlands, or sometimes just Woodlands, tribes. Included among them are such well-known tribes as the Iroquois and the Chippewa, along with a large number of smaller tribes that lived sedentary lives in the forested regions east of the Mississippi River. Some of the earliest pottery in North America may have been produced in the region around modern-day Georgia and South Carolina beginning in about 2500 B.C.E. From there it spread to the north, west, and south, so that by about 1200 B.C.E., the Woodlands tribes throughout the southeastern United States were making storage and cooking vessels out of fired clay.

The development of fired vessels and pottery was a major innovation, often referred to by historians as the "container revolution." Until the development of clay pottery, Native Americans had stored seeds, grains, and other food products in woven baskets and gourds, where they remained susceptible to spoilage by moisture. Such pottery as the people were able to produce, usually made from soapstone, was easily broken during transportation. But with the development of stur-

dier, more durable fired pottery that was glazed and therefore waterproof, people were able to store materials much more efficiently over longer periods of time. They could store not only agricultural products but also such foodstuffs as shallow-water seafood, giving their diets much greater variety. Further, the ability to store seeds contributed to the development of horticulture, which in turn gave rise to crop manipulation. All of these developments played a major role in the transition from earlier hunting and gathering to a more settled agricultural way of life.

Pottery was used for purposes other than cooking and food storage. The Hopewell culture, referring to the peoples who lived along the Mississippi and Illinois rivers (200 B.C.E.–400 C.E.), also used fired pottery for burial purposes. The pottery of the Hopewell peoples was elaborately decorated and made use of the so-called coiled pottery technique. In making a coiled pot, the potter rolled and squeezed wet clay into coils, or long segments roughly the thickness of a pencil. The clay was then wound into circles and the coils stacked one atop the other and pressed into a smooth container on the inside.

Feline-head ceramic bottle from Peru, ninth to fifth century B.C.E.
(Copyright the Metropolitan Museum of Art)

The people of ancient Mesoamerica—modern-day Mexico and Central America—produced excellent pottery. During the Formative Period (1800 B.C.E.–150 C.E.) most of the basic pottery shapes could be found in ancient Mexico, including bowls, neckless jars, long-necked bottles, and spouted trays. People of the Formative Period often decorated their ceramics by covering them in black, brown, red, or white slip and sometimes polished them by rubbing with a smooth pebble. Some ceramics were plain, while others were decorated with simple geometric patterns. People of ancient Mexico also used “negative” painting, in which they painted a design with hot wax and then dipped the pot in a colored pigment. In the firing process the wax melted away, leaving the design in the original color.

During the Classic Period (150–650 C.E.) Mexico saw the growth of urban centers with large pyramids and temples. Ceramics were used frequently in the rituals carried out in these temples. Chief among the cities was Teotihuacán. While the people of Teotihuacán produced technically advanced ceramics, their early works were aesthetically dull. They later developed a polychrome style of decoration, covering pots in a brown or black slip, which was then scraped away to show a dark body, itself sometimes painted in with cinnabar. Teotihuacán also developed a stucco technique in which artists covered pots with plaster, carved a design, and filled in the design with colored clay. This type of ceramic was fragile and impractical, but it was highly regarded at the time.

The ceramics of Teotihuacán influenced the early work of the Classic Maya (250–650 C.E.). After about 600 C.E. the Maya developed a decorative technique that used brilliantly colored pigments, and they fired their ceramics at lower temperatures. These ceramics were aesthetically pleasing but less durable than those made by the older methods. The Maya decorated their ceramics with hieroglyphs, animal images, and ceremonial scenes.

In South America the most developed civilization emerged in the Andes on the western side of the continent. The Chavíns were among the earliest of the Andean peoples, flourishing from about 900 to 200 B.C.E. They produced gourd-shaped pots in white or beige, sometimes decorated with a red inlay and topped with a stirrup handle that allowed for easy carrying, drinking, and pouring. Such stirrup handles would become a trait of later Andean people, particularly the Moche peoples. The Chavíns often covered their ceramics with a resinous paint to make them waterproof. They also used “negative” painting and incised decoration.

Later, the Moches, who flourished from about 100 to 600 C.E., created sophisticated works of art, especially mold-made pottery known for its highly naturalistic forms. Moche potters used a molding technique to produce stirrup-spout bottles, handle bottles, whistling bottles, jars, and many other forms. Moche vessels, such as fine-quality water jars with stirrup spouts, bear portrait heads of individuals, animals, plants, buildings, and supernatural beings. The unique forms

and representations of Moche ceramics have made them one of the most widely recognizable forms of pre-Hispanic art in South America. Although clay was the predominant medium of the Moches, copper, silver, and gold also were important in Moche art.

Painted lively scenes on Moche pottery provide visual descriptions of their complex rituals and daily activities. For example, Moche ceramics depict humans, animals, and deities in highly detailed, realistic activities such as hunting, fishing, burials, sacrifices, healing rites, the presentation of goblets between high-ranking individuals, combat, and other ceremonies.

► children

INTRODUCTION

The life of a child was extremely uncertain and difficult in the ancient world. First, a child had to be born alive. But in the absence of the knowledge and technologies of modern medicine, large numbers of children were stillborn or died shortly after birth. Then the child had to survive. Historians estimate that 25 percent of newborns the world over did not survive their first year, dying from respiratory problems, diarrhea (and the dehydration it caused), infectious diseases, and starvation. Even if children survived their first year, dangers still lay in wait, and larger numbers failed to survive to age 10. Meanwhile, life expectancy for adults was low, and many women died during childbirth, so a child faced the danger of losing one or both parents, making the chances of the child's survival slim.

The child had to be reasonably healthy and well formed to grow to adulthood. In most ancient cultures people did not have the resources to care for sick people who could not fend for themselves when necessary. A common practice was for sick or deformed infants to be left to die, often in forests or deserts. The word *foundling*, referring to a baby who is "found" and raised by another, attests to the prevalence of this practice.

Few children went to anything that resembled a school, though in some ancient cultures, such as Greece and Rome, young boys were often taken away at an early age for training in the responsibilities of citizenship, including military training; in ancient Sparta boys were regarded as the property of the state from the age of seven. For the most part, though, children stayed at home with their parents. Toys were few, though some archaeological evidence for toys has been found. Few parents attached much sentimental value to their children. Children were a resource, and from an early age they were taught the skills they needed to help them and other members of their clan or tribe survive, including hunting, herding,

and farming. Boys worked out of doors at these tasks, and it was expected that a boy would follow his father's occupation. Girls were taught domestic chores such as cooking.

In modern life children are thought to be the sole responsibility of their parents, though parental authority can be delegated to teachers in schools. In many ancient cultures, in contrast, children were thought of as the responsibility of the entire community. Early peoples lived in extended clans, not only with parents but also with grandparents, uncles, aunts, and cousins. Often these cultures were matrilineal, meaning that descent was traced through the female rather than the male line. In this type of culture, the responsibility for training children in the values of the community belonged to the community as a whole.

If children survived all these hardships, they were ready for initiation into adulthood. Usually at around the age of puberty boys—and somewhat less often girls—were subjected to initiation rites that identified them as adult members of the society. Often these rites involved some sort of arduous task; typically, the child was segregated from the rest of the community during the initiation. The child who successfully completed the initiation became a full-fledged member of the adult community.

AFRICA

BY MICHAEL J. O'NEAL

Generalizations about children and child rearing in ancient Africa are difficult to make. The continent of Africa is and was home to hundreds of ethnic groups, each with its own customs and traditions. Thus, to talk about "African" children and child rearing is misleading. Further, the lack of written records from ancient Africa makes it difficult for historians and archaeologists to make with confidence precise statements about children and child rearing. They know, however, that in modern times African communities continue to follow many of the same customs and to practice many of the same rituals they did many centuries ago.

The history of children and child rearing in Africa begins millions of years ago. Research by archaeologists and geneticists strongly suggests that the human species originated in Africa. The earliest "hominids," the *Australopithecines*, emerged in Africa some four to six million years ago. Among the earliest archaeological evidence are the "*Australopithecine* footprints" found near Laetoli, Tanzania. The footprints are those of an adult and child, made about 3.5 million years ago.

The concept of "childhood" as it is understood today was probably unknown in ancient Africa. Thousands of years ago human behavior was in large measure dictated by the simple goal of survival. Mates tried to produce as many offspring as possible during the woman's childbearing years, with the hope that some would survive to adulthood (when they could reproduce). Beyond mere survival the purpose of child rearing was to teach youngsters how to be human—that is, how to

function with one another in a social group in order to hunt, forage, grow crops, and perform other functions necessary to survival. In particular, children early on were taught the value of collecting food, taking it back to the community, and sharing it with other family members.

Because of the importance of food gathering, mothers learned to fashion slings so that they could carry their infants while foraging. Indeed, the child's ability to survive depended heavily on a mother's ability to carry the child long distances until he could walk as well as on her ability to provide food. Further, her survival and that of her offspring depended on spacing the birth of children, in some instances as much as four or five years apart. Otherwise, the mother would be tied down with nursing infants and unable to look for food. It was also important for the mother to maintain ties with her own brothers and sisters and those of her mate. Doing so provided her and her children with protection and a community that taught children the skills they needed to survive. Most ancient African cultures were probably matrilineal, meaning that descent was traced through the mother's ancestors rather than the father's. The father often gave the child a name, but

the matrilineal clan name remained an important part of the child's identity.

The concept of community in child rearing was important to ancient Africans. Every adult in the community shared in the task of raising children and teaching them not only physical skills (hunting, foraging, growing crops, tool making, cattle herding, and the like, depending on the economy of the particular community) but also social skills, leadership, conflict resolution, and the like. A common modern proverb that expresses this concept is "It takes a village to raise a child." This proverb, though, has many different variations from throughout Africa: "A child does not grow up only in a single home," "A child belongs not to one parent or home," and others. Skills tended not to be specialized, for specialization would have made the tribe—typically 30 to 100 people—dependent on the skills of one person at a period of time when life was precarious. Thus, children were early on taught the arts of cooperation. They often learned these lessons through community storytellers, who preserved and transmitted tales that promoted the values of the group over the individual. Children—and

Boys kept in seclusion in an initiation camp in Angola, southern Africa; such rites date back to ancient times. (© Board of Regents of the University of Wisconsin System)

adults—spent a great deal of time with their “age sets,” or people who were roughly the same age. At an early age children were responsible for labor. Boys as young as six or seven would, for example, help with herding or other farming activities; girls were responsible for fetching water, caring for younger children and the sick, cleaning, helping their mothers in the fields, and food preparation.

A key development for the ancient African was initiation into adulthood. Initiation rituals can be found in cultures throughout the world. They mark the passage of males or females from childhood to the duties and responsibilities of adulthood. An example is the traditional initiation ritual for boys among the Xhosa, a Bantu-speaking people in modern-day South Africa, whose ancestors arrived there some 1,500 years ago. Boys were isolated in a special hut built for the purpose of keeping them away from the community. Elders provided them instruction, and they lived frugally for a period of weeks or months. Perhaps the harshest part of the initiation was the *abakweta* ceremony, during which the boy was circumcised. Boys used white clay to whiten their bodies and wore a white blanket. The color white protected them from evil. They also wore traditional masks, hats, and reed skirts. All of these items, along with the hut, were burned on the completion of the process, to signify that the boys had cast off the past. The elders then herded the boys to the river, often beating them along the way. The boys plunged into the river to wash off the clay and emerged on the opposite riverbank as men. They were then painted with red ochre, and their fathers gave them new clothes or new blankets. These types of ceremonies were not limited to boys. When they reached puberty, girls, too, often underwent similar practices, as happened in the Sande society among the Mende people of West Africa. While the girls lived in huts, older women would instruct them in the duties and responsibilities of marital life. When they emerged from the hut, the community would hold a celebration.

EGYPT

BY KELLY-ANNE DIAMOND REED

At birth an Egyptian child was given his or her name; according to Egyptian religious belief, a person could not exist without a name. The name was as integral to the individual as his or her body or soul. Usually the mother named the child, and the name could be associated with physical attributes or the family's occupation or ethnic origin; it might also derive from an ancestor. Some names also reflected wishes or exclamations, for example, the name Mersure, which means “May the god Re love him.”

There was a high rate of infant mortality in ancient Egypt. Families that had five surviving children might easily have lost three others. It is thought that 20 percent of pregnancies were not carried to term, another 20 percent of newborns died within the first year, and 30 percent of children did not make it to their sixth year of life. Support for these figures derives from the abundance of children's graves dating to

ancient Egyptian times. Numerous spells were employed to aid in childbirth and keep the newborn safe. That the well-being of their children was of great importance to most parents is evident in the countless magical objects and amulets for the protection of children that have been found.

Newborns were always breast-fed, since there was no substitute for breast milk. Normally, the mother would be the one to nurse, but a wet nurse might be employed if there was a problem with the mother's milk supply. In the New Kingdom (ca. 1550–1070 B.C.E.) it was common for women of high rank to act as wet nurses for the royal family and to be paid well for their services. Nursing often continued until the child reached the age of three. It was the women who were responsible for rearing children, sometimes with the help of female servants.

Information about childhood and about children in general derives mainly from Egyptian tomb scenes, statuary and figurines, and text sources. In Egyptian art children are depicted as smaller than their adult counterparts, but they are not properly proportioned, nor are they always anatomically correct. Children are frequently shown wearing the “sidelock of youth,” possibly a marker of a child who had not yet reached puberty. Children often had their heads shaved, except for this thick lock of hair on the side of the head, gathered with a tie. In the Old Kingdom (ca. 2575–2134 B.C.E.), children were generally depicted nude until the age of puberty. In the Middle Kingdom (ca. 2040–1640 B.C.E.), they were more commonly illustrated with clothes, similar in style to that of their parents. In the New Kingdom children were illustrated both clothed and unclothed.

It is difficult to confirm whether Egyptian children had toys. Archaeologists have encountered many items that have the character of toys; however, the Egyptians also had many small models of boats, houses, people, animals and the like, usually carrying religious significance and often buried with the dead for their use in the afterlife. Such miniature magical and religious paraphernalia could be confused with toys. When found in settlement areas (as opposed to sacred sites and burial locations), these artifacts are assumed to be toys. It is also possible that the two functions overlapped—children might have played with religious items. Games were especially popular among Egyptians. They played a board game called Senet, an ancestor to our game of backgammon, and another, similar one called Twenty Squares. Tomb scenes confirm that children enjoyed wrestling, ball games, racing, swimming, and dancing.

The Greek historian Herodotus (ca. 484–420 B.C.E.) states that the Egyptians used circumcision for hygiene purposes; however, it may also have had a religious association. This act was not performed at birth or shortly thereafter but instead near a boy's 14th year, marking the transition to puberty. From the Late Period (ca. 712–332 B.C.E.) onward, priests were circumcised as a purification rite. This would seem to indicate that the practice was not universal and that not all boys were circumcised. A scene from the Sixth Dynasty (ca. 2323–

Game of Senet from New Kingdom (© The Trustees of the British Museum)

2150 B.C.E) tomb of Ankhmahor at Sakkara, the necropolis at Memphis, may show a priest circumcising a boy with a curved flint knife, though this scene may instead depict a ritual shaving. Egyptian mummies show evidence of circumcision. The Greek historian Strabo (ca. 63 B.C.E.–21 C.E), who wrote in Roman times, claims that the Egyptians also practiced female circumcision, but this has not yet been confirmed through examination of surviving female mummies.

The main education of Egyptian boys came in the form of an apprenticeship under their fathers. Boys belonging to the elite class were sent to scribal school. Scribal students often copied literary works, which has led to the preservation of numerous documents of “wisdom literature,” or texts of an instructional or philosophical nature. Because wisdom literature was set up as guidance from father to son on how to behave and how to live one’s life, it has been assumed that the majority, if not all, official scribal students were boys. Boys belonging to the upper echelons of society received a broader training, often involving the study of mathematics. It is not known whether girls received any sort of formal education. Letters dating to the New Kingdom are considered by some scholars to be evidence that at least some women were literate. Not surprisingly, young girls learned from their mothers how to take care of household duties. Theban tomb scenes also show girls serving food and drink at banquets.

Children of the poorer classes had to work from an early age. Around the mortuary complex and tomb of Khasekhemwy, the last king of the Second Dynasty (2770–2649 B.C.E.), children’s footprints were found in the mud plaster, indicating that they, too, worked on its construction. Fathers were anxious for their sons to take over their jobs, and the boys

learned their father’s trade as apprentices. Likewise boys and girls would have worked alongside their parents in the fields. For the children of the poorest class, a childhood as we know it did not exist.

Children looked after their parents later in life. Evidence from Deir el-Medina, a village near Thebes that was home to craftsmen who worked on the tombs in the Valley of the Kings and the Valley of the Queens, indicates that an aging father would give his post to his son and, in turn, the son would provide for his father. Children were not forced to look after their aging parents, but if they did not, they could be prevented from receiving their inheritance.

THE MIDDLE EAST

BY KAREN RADNER

The purpose of a marriage in the ancient Near East, including Mesopotamia and Persia, was to produce children. For Mesopotamia specifically, children were a necessity for any family, as the continuation of the bloodline guaranteed survival for all ancestors. Children were expected not only to provide for their parents in old age but also to perform memorial service to commemorate the dead of the family, thereby keeping their essence alive. Not to have children was therefore extremely awkward, and if the situation could not be helped with the assistance of prayer, magic, and medicine, a couple had the option to adopt a child or to use a surrogate mother to produce an heir. With high mortality rates among pregnant women and babies, the birth and the survival of a child were always considered a divine blessing; many people bore names that reflected their parents’ joy in having had them, often refer-

ring to dead siblings whom they had replaced. For example, the meaning of the name of the Assyrian king Sennacherib (r. 704–681 B.C.E.), the Old Testament's rendering of Sin-ahheriba, means "The god Sin has replaced the (dead) brothers."

As the French historian Philippe Ariès first recognized in 1960, the idea of childhood as a distinct phase of human life is a modern Western concept, developed as late as in the 17th century. It is therefore not surprising to find it a concept alien to the cultures of the ancient Near East, including Mesopotamia and Persia. There is no specific term for "children," from birth to adolescence, and this fact is best reflected in Near Eastern art, where children are simply depicted as miniature adults, without any evidence for a special dress code or hairstyle and without any attempt to emphasize a childlike physique, other than simply showing them to be of small size. Good examples of this can be found in the reliefs from Sumerian temples of the mid-third millennium B.C.E. as well as from Assyrian royal palaces of the ninth to seventh centuries B.C.E.

Only young children, up to the age of four years, were perceived as different from the rest of humankind: In art they are shown as bald and naked and usually in closest proximity to their mothers. While there is no general word for *child*, there are specific terms referring to babies and toddlers. Babies were called "he of the milk" or "she of the breast," referring to the fact that they were breast-fed; the available sources as well as ethnographic comparisons, derived from the study of contemporary cultures in Africa and Asia, suggest that babies were weaned relatively late, at the age of two years or even later. The word used for *toddlers* refers to the termination of breast-feeding and means literally "separated one," indicating that they were no longer physically inseparable from their mother. Babies and toddlers were normally never parted from their mothers: Slave sale contracts, for example, show that mothers were sold together with their young offspring, and administrative lists, enumerating the workforce of large institutions such as temples and palaces, list mothers with their small children; both text types date to ca. 2200 to 100 B.C.E.

A group of texts that were used to calm down a crying baby shows that this was thought to be as great a challenge to Mesopotamian parents as to modern ones. One such text that was found in a library in the city of Assur, the capital of ancient Assyria, begins like this: "He who lived in darkness, where it is not bright, came out and saw the light of the sun. Why is he weeping so that his mother cries, so that the goddess Antu sheds her tears in heaven?" While the texts are called magical incantations, invoking the help of the gods, they may well have worked also as simple lullabies, as they were chanted rather than just spoken.

A female demon called Lamashtu, mentioned in Assyrian and Babylonian ritual texts of the second and first millennium B.C.E., was thought to prey on pregnant women, young mothers, and babies, and amulets depicting this monstrous creature were used to ward her off. When a baby's mother died, a wet nurse had to be found quickly to provide milk for

Terra-cotta figurine of a woman with a child, Cyprus (1450-1200 B.C.E.) (© The Trustees of the British Museum)

the child. With the mother alive, wet-nursing seems to have been less common, though the fact that some wet-nursing contracts survive is clear evidence that the practice was well established. Moreover, in Mesopotamian prayers and temple inscriptions from the third to the first millennium B.C.E., the bond between a goddess and her adorant is often likened to that of a wet nurse and her charge: The comparison is meaningful only in a society accustomed to this intimate and nurturing relationship between a woman and a child that is not her own.

Once toddlers reached an age when they could be instructed to perform simple tasks without the need for ongoing supervision (typically at the age of four years), they were treated as adults. This is best demonstrated by the fact that we find them listed as individuals in rosters of temple dependents and similar administrative texts; the crucial factor was not a person's age in years but his or her physical ability. Hence, a boy of 10 who was small for his age could find himself at work with children several years his junior, while his physically more developed contemporary would work alongside grownup men. If concessions were made to the working conditions of children, it was not because as children they would automatically enjoy privileged treatment but because anybody with a weaker physique, including the aged or disabled, was eligible for adjustment.

Most children were educated at home, and it is important to note that education and work went hand in hand. Girls learned from their mothers all the many skills expected to be mastered by women, such as spinning, weaving, sewing, laundering, cooking, and baking, while boys were usually instructed in their father's trade: Hence, a smith would teach his son how to refine and work metal, a stonemason would train his son in the different stone-working techniques, and a scribe would instruct his son how to read and write the cuneiform script and also how to prepare writing materials. In this way, specialized knowledge and skills were passed through the generations within family networks.

There was no compulsory school attendance in the ancient Near East. Still, the ability to read and write was an advantage for the sons and, to a far lesser extent, also the daughters of the urban elite, who were typically predestined to follow the family tradition and take on a role in government and administration. A number of satirical compositions shed light on the schooldays of these students and mock their often strained relationship with their teachers, who are referred to as "master" or "father." Many, if not most, kings received formal schooling; some, such as Shulgi of Ur (ca. 2000 B.C.E.) and Ashurbanipal of Assyria (r. 668–ca. 630 B.C.E.), even proudly referenced their high level of education in the inscriptions that celebrated their accomplishments, by recording them for posterity on public monuments. As shown by a scolding letter of the crown prince Ashurbanipal's sister Sherua-etirat to his young wife, at the time in her teens, a good school performance was considered essential also for a future queen: "Why don't you write your paper [literally, "clay tablet"] and

do your homework? For if you don't, people will say: Is this really the sister of the royal princess Sherua-etirat? You are, after all, married to the crown prince of Assyria."

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

In Asia and the Pacific during ancient times, most children lived harsh lives. In some cultures—among the aborigines of Australia, for example—children appear to have had more free time than in other societies. Elsewhere in the region, however, children had to work hard beginning at a young age to help their families survive. Early in the Stone Age, about 6000 B.C.E., some peoples in central and northern Asia began following herds of game such as reindeer, linking their survival to the welfare of the herd animals; certain groups of people continued that way of life throughout ancient times. Children in these families were expected to learn to care for the animals, and as soon as they could walk they would begin participating in the work of their nomadic existence.

In societies based on pastoral nomadism children were expected to care for horses and domesticated cattle, sheep, and goats. With the development of horseback riding both girls and boys learned to ride early, and their initiation rites at puberty usually required them to display feats of horsemanship by participating in races, by capturing or herding domesticated animals, by hunting, or by displaying fighting skills.

By the second millennium B.C.E., throughout China and India, agricultural societies were settling near rivers and floodplains. Nearly all these societies practiced human sacrifice, often using children. Throughout southern Asia, east of India, children were bought to be ritually murdered in sacrifice to a goddess of fertility so that crops, especially rice, would grow abundantly. This practice continued in Burma into the 20th century.

In the early agricultural communities children were expected to learn the skills of their parents, nearly every task needed for survival. A child would learn to gather wood, make ovens, craft pottery, tan animal hides, sew, and develop any other necessary skill. As communities grew more settled, people began to specialize. The future life of children was generally determined by what their parents did: Peasant children were to be peasants, potter children were to be potters, and noble children were to be nobles. Most were peasants. From 1500 to 500 B.C.E. children of the rich and powerful had beautiful clothes, were taught by tutors, and played with finely crafted toys. From the Harappan civilization of the Indus valley of 2300 B.C.E. in India and in China from before 1500 B.C.E., small objects have been found that may have been toys: little clay animals such as horses with thick, stubby legs from ancient India and clay tigers from Asia. These items suggest that even poor children had time to play. However, throughout most of Asia children were most often victims: In India they were war trophies to be sold into slavery; in China they

were frequently slaughtered by the thousands by victorious armies; in India and southern Asia poor families often sold their children into slavery.

Lives for children in China, at least, began to change significantly for the better in 415 B.C.E., when one Confucian Chinese governor introduced a moral code to govern social behavior. At the beginning of the Han Dynasty in 202 B.C.E. Confucianism became official state policy, and in 145 B.C.E. Governor Wen Weng of Shu, where modern Sichuan is, set up schools for boys from throughout the province; so effective were his graduates that the Han government established an educational system that encouraged the most able boys to attend school and better their lives by competing for government jobs.

As another way for children to escape the grinding poverty of peasant life, beginning in the first century C.E. girls and boys could be given to Buddhist monasteries or convents at about five to eight years of age. They would be given simple robes and have their heads shaved, symbolizing their renunciation of worldly desires. Such children would have worked hard, but they probably ate regularly and, in many cases, were taught to read; as adults, they could even gain community influence and help their families.

In India religious and secular education were combined. When boys were initiated into manhood, a symbolic rebirth of the spirit, they would be sent to gurus, or spiritual teachers, to study sacred Hindu texts, mathematics, and medicine and other sciences. This would happen at age eight for boys born into the priestly caste, at age 11 for those born into the ruler and warrior caste, and at age 12 for those of the worker and farmer caste. However, those of the laboring caste and the untouchables were excluded. Some boys were sent to schools at Buddhist monasteries; these were so popular during the Gupta Dynasty of 240–550 C.E. in what is now India that one in Nalanda had more than 10,000 students. Girls were taught at home, usually by tutors and mostly in arts such as painting, singing, and literature as well as in home economic skills, including weaving and supervising servants. Girls were usually married by age 16, but boys did not finish their studies until age 18 and typically married later.

EUROPE

BY AMY HACKNEY BLACKWELL

Not much is known about childhood in ancient Europe aside from what was recorded by Greek and Roman authors. Child-birth was dangerous; many women died giving birth, and many infants died during or soon after birth. A newborn who survived birth but whose mother died stood a fair chance of dying as well from lack of a mother's care. Even if baby and mother both survived the birth, the baby's parents might not keep her. Parents frequently abandoned unwanted infants, leaving them in the countryside to die; they were especially likely to abandon illegitimate children, deformed children, and girls.

ENTERTAINMENT, EUROPEAN STYLE

In ancient Europe most children were illiterate. For entertainment they listened to stories. On long winter nights everyone in a community would gather around a fire in the woods or in a lodge and listen to a poet creating scenes from history and myth. These stories were about the things that interested European peoples: the gods who controlled the weather and human events, heroes fighting battles, dwarfs and dragons, kings and lovers. The stories gave people a sense of identity and continuity. The plots and characters were usually familiar, but the actual words varied from telling to telling, as the poet chose episodes to embellish in the moment. Poets worked entirely from memory. No one wrote down European folktales and poems until the eighth century C.E. at the earliest, and even then stories appeared in many different versions, making it impossible to identify "definitive" tales.

Many of these stories still exist today, some as a result of an oral tradition that continued through the medieval and modern period and some because they were written down by medieval monks. The *Tain Bo Cuailnge* (pronounced "toyn bo cooley"), or "Cattle Raid of Cooley," is an Irish epic telling of the rivalry between a king and queen based in part on the size and quality of their respective herds of cattle. This story introduces the fearsome Irish hero Cúchulainn (pronounced "coo-hoo-lin"). The people of Germany told stories of their gods, such as the fierce war god, Thor, and the wise father of gods, Wodin. The Gauls' stories also featured a large cast of deities, some of them borrowed from their Roman neighbors. Like the ancient Greeks, other Europeans also honored poets who could tell long tales of adventure, heroism, and love. Poets could visit any community with impunity; though many Europeans were warlike and violent, they welcomed those who offered them entertainment.

Most mothers breast-fed their infants. Women who could afford to do so, such as the nobility, would sometimes hire wet nurses to feed their babies. Women in ancient times typically nursed babies for about two years, a practice that had the effect of spacing births because nursing can decrease fertility. Rates of infant mortality were high. Children less than two years of age were vulnerable to numerous sicknesses, and ancient Europeans had no reliable remedies for them. Many babies died of diarrhea or respiratory ailments. Scholars estimate that more than one-quarter of all babies died before they were a year old. Of those children who

survived infancy, another third died by the age of 10. This was true throughout Europe.

European children lived with their extended families; households often included a husband, wife, children, grandparents, and aunts, uncles, and cousins. Children wore smaller versions of the clothes their parents wore, mainly long tunics and wool cloaks. They lived in houses made of stone or timber and mud with thatched roofs. They spent their evenings listening to folktales and participated with the adults in frequent feasts and festivals. Children did not have their own rooms or even their own beds. They slept on the mud floor wrapped in animal skins, huddled with their parents and siblings for warmth.

Most European societies of the time had no schools or other institutions for children, so children would have spent most of their time at home, playing and learning home skills or assisting their families with work around the house or farm. Farming families tried to have as many children as possible, because their labor would be needed for cultivation and keeping livestock and because those who did not survive to adulthood needed to be replaced. Most Europeans worked on their farms raising grain, cattle, pigs, sheep, hens, and geese. These tasks included sowing wheat, harvesting grain, and preparing fields for the next season; milking cows, goats, and sheep; making milk into butter and cheese; spinning wool into thread, dyeing it bright colors, and weaving it into cloth; and hunting in the forests. Girls would have concentrated on homebound tasks that other women performed, learning to cook, grind grain, bake bread, and weave. Boys would have helped their fathers and uncles with their daily work, such as plowing, hunting, and occasionally building houses. When boys were old enough, they might learn a craft such as metalwork. Boys also would have learned how to fight with swords and other weapons. If they were wealthy, they learned to ride horses.

Many noble Celtic families sent their children to live with other noble families as foster children. The most common arrangement was for a child to live with the family of his mother's brother. A child would spend several years living with his foster family and usually formed very strong bonds with his foster parents and siblings. These ties were valuable in a warlike society where allies could mean the difference between victory and defeat in battle.

Childhood was harsh and dangerous for ancient European children. Cold, hunger, and illness were constant threats, and wild animals could snatch them away. A child's parents sometimes died—the father in war or the mother in childbirth or both of them from disease. Unless someone else, such as a relative, took in the child, his fate was uncertain. There was always the chance that a child's parents would abandon her even after infancy if times were hard and food supplies were low; fairy tales of foundlings have their root in ancient stories of parents leaving children alone in the woods to meet whatever fate awaited them. The ancient Celts and Germans lived a rough existence and had no resources to waste on the

weak or sickly. They often traveled through the wilderness, wandering from one place to another without a permanent home, and they could not afford to carry useless people with them. The Romans observed that when the Gauls were on the march, they would kill their old people and anyone who could not care for himself, which included children.

Ancient European children also faced the risk of kidnap or capture in war. Slavery was a common practice in ancient Europe. Saint Patrick of Ireland (386–493 C.E.) spent seven years of his youth as a shepherd slave after being kidnapped from his wealthy family's home in Britain around 400 C.E. Many of the slaves who worked in Greece and Rome came from central and northern Europe. When Romans defeated a tribe in battle, they typically sold all the surviving women and children into slavery; in this way many European children found themselves in Rome, performing menial labor for Roman families. For some children this proved a wonderful opportunity; Roman masters and mistresses sometimes educated their slaves and treated them as family members. In other cases slavery was a dreadful existence of starvation, rape, beatings, and sometimes death at the hands of a cruel master.

GREECE

BY AMY HACKNEY BLACKWELL

The Greeks wanted children. Children were legally bound to take care of parents when the parents grew old; in the absence of any other provision for old-age care, children were essential. Many infants did not survive birth, however, and many women died during or after childbirth from bleeding, exhaustion, or infection. An infant who survived birth without a mother was in danger of dying from lack of maternal care unless another woman took him in and raised him. When a baby was born, the midwife would announce the sex and then examine the baby to see if he was healthy. If the parents decided to keep their child, they celebrated the baby's birth on the fifth day of life, publicly acknowledging the child as a family member and naming the baby in a ceremony called the *amphidromia*.

Parents did not always choose to raise the children they produced. Resources were limited, and parents who lacked food, money, or opportunities could not always afford to keep all their children. If a baby seemed sickly and unlikely to survive or if the baby was not the desired sex, usually male, the parents might decide to abandon the infant, leaving it out in the countryside to die. In most of Greece the father could decide whether to keep the child regardless of what the mother thought. In Sparta the city's elders chose which infants would be raised to adulthood. Historians do not know the percentage of Greek babies that were abandoned, but the ones most susceptible to this practice were girls, illegitimate infants, deformed infants, and the babies of slaves. Occasionally strangers would keep and raise foundling children, but usually the infants died. Greek literature sometimes mentions the

exposure of infants; the most famous infant to be saved from this fate was Oedipus, the hero of Sophocles' trilogy of plays that includes *Oedipus the King*.

The natural way to nourish infants was for their mothers to breast-feed them, a practice that was encouraged in the belief that a mother's own milk was the best food for her child. Still, nursing was considered tiring, and mothers were supposed to refrain from sexual intercourse while they were nursing a baby, a prohibition that made the practice unappealing to many parents. In reality, then, many mothers who could afford the expense hired wet nurses to breast-feed their babies. Wet nurses were women who had recently given birth themselves, were producing milk, and breast-fed babies other than their own. Some of these women were slaves who lived with the family, but others did it purely for economic reasons, receiving wages for the service.

Mortality rates were high among infants and children. Perhaps one-quarter of babies died before the age of one. Another third of children died between the ages of one and 10. Doctors had no effective remedies for diarrhea, respiratory

infections, and other common sicknesses, which killed many children. Children also died from accidents, fires, and attacks by wild animals.

Young children of both sexes stayed home with their mothers until they were about six years old. Most Greek adults seem to have liked their children and enjoyed seeing them grow up. Plato describes the play of children in his *Laws* and praises it as an excellent means of forming personality. Scholars know that Greek children had toys because they have found pictures of playthings on Greek vases and actual toys in Greek graves. These included rattles for infants, rolling carts, balls, hoops, toy animals, swings, and seesaws. Girls had dolls and dollhouses complete with miniature furniture. Children also played games; ancient authors have described blindman's buff, catch, dice, and prisoner's base. Many of these games were accompanied by traditional songs, similar to modern children's games such as London Bridge.

Both boys and girls dressed in simple tunics. Many children wore good-luck charms around their necks; bells were especially popular because they could amuse the child and were believed to ward off the evil eye, or bad luck. In literature many abandoned infants are identified by the unique charms they wear.

Around the age of six or seven boys began their educations. In Athens they were enrolled in hereditary organizations called phratries when they were still quite young. These organizations served as an extension of the family, handling community affairs and resolving disputes among members. Every Athenian citizen had to belong to one, and participating in the activities of phratries gave Athenian boys important early training in the affairs of the city. In addition to engaging in their civic duties, Athenian boys attended elementary schools, where they learned reading, writing, arithmetic, music, poetry, dance, gymnastics, and general physical education. Parents paid for school; there was no public education. Discipline was strict and corporal punishment common. Students competed in periodic public contests to show what they had learned.

In Sparta children were considered the property of the state from the age of seven. Young boys left home and moved into public schools called *agoge*, which were primarily concerned with training soldiers. Spartan schools were hard on their young pupils; boys were given only a cloak to wear, winter or summer, and were encouraged to become tough and violent. Spartan girls trained with boys in athletic feats such as running or gymnastics; this was considered essential preparation for their future duties as mothers of Spartan soldiers.

Girls in most of Greece spent their childhoods at home, in the company of their mothers and other women. They learned the skills they would need as adults, such as spinning and weaving. Girls as well as boys attended school, though they did not necessarily study the same subjects. When boys reached their late teens, various ceremonies marked their entry into manhood. Before they became adults, many boys became the lovers of men; this was considered entirely proper and good

Profile of a Greek boy (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

training for young boys. Girls married in their teens and were considered adults at that point. Many girls conducted rituals on the day before their weddings to mark this change in their status, but there were no specific public ceremonies to commemorate their transformation into women.

ROME

BY AMY HACKNEY BLACKWELL

In ancient Rome children were valued as the best means of supporting their parents in their old age and the only means of carrying on the family name. Childbirth was very dangerous to mothers and babies. Ancient midwives and physicians did not understand the mechanisms of birth very well and had few useful treatments to offer mothers. Many infants died during or after birth, and any women died during or after childbirth from bleeding, exhaustion, or infection. If a baby's mother died in childbirth, the father or other caretaker would have to find a wet nurse to feed the child, or the baby would be at risk of dying as well.

When a baby was born, the midwife would determine the sex and then examine the baby to see if it was healthy. If the parents kept the child, they celebrated its birth on the eighth day of life in a purification ceremony called the *lustratio*. If the baby was sickly or deformed or if it was a girl, the parents might decide to abandon it in the countryside to die. An ancient law attributed to Rome's legendary founder Romulus directed parents to keep all male offspring and the first born of their girls, but most people disregarded these old laws and did not abandon their female children.

Mothers were encouraged to breast-feed their infants. The physician Soranus of Ephesus (fl. second century C.E.) recommended that mothers breast-feed their own children because this provided the best food for the baby and strengthened the bond between mother and child. In practice, many mothers with the resources to do so hired wet nurses to nurse their babies. Soranus provided detailed advice on selecting a wet nurse, suggesting that the nurse not drink wine and that she live with the family. He advised breast-feeding a baby exclusively for six months and then gradually introducing foods until the child was weaned at about two years of age.

A high percentage of Roman babies and children died. Scholars believe that about 25 percent of infants died before their first birthdays. Of those children who survived the first two years of life, another third died before the age of 10. Respiratory illnesses, gastrointestinal diseases, accidents, fires, and violence killed large numbers of children.

Children of both sexes were under the authority of their fathers or other male relatives. The father, or *paterfamilias*, technically had the power of life or death over his children, though in the days of the Republic (509 B.C.E.–ca. 27 B.C.E.) and Empire (ca. 27 B.C.E.–476 B.C.E.) almost no father exercised this right. Both boys and girls spent their early childhoods in the home nursery in the care of women. Mothers sometimes

Roman rag doll made of linen, rags, and papyrus and dating to the first to fifth century C.E. (© The Trustees of the British Museum)

raised the children themselves, but many mothers employed slaves as caretakers for their young children. Corporal punishment was a common means of enforcing discipline.

Boys learned what they would need to know as men—the sons of craftsmen were taught their fathers' crafts, and the sons of farmers learned farming and animal husbandry. Sons of nobility went to school or studied at home with tutors called pedagogues, who were usually slaves owned by the family. Schools were informal by modern standards; many teachers simply set up portable desks on street corners or in town squares and taught their students amid the hubbub of the marketplace. Boys studied grammar, mathematics, geography, history, and law as well as Greek, the language of educated people in the ancient world. All boys had to learn the basics of warfare, such as swordplay, in preparation for their military service. On festive occasions boys dressed in a special toga called the *toga praetexta*, bordered in red or purple to mark the boy's juvenile status. All boys wore a necklace

called a *bulla*, a chain with a pouch containing protective amulets. Boys became adults in a ceremony conducted at the age of 16, at which point they exchanged the *toga praetexta* for a simple white toga called the *toga virilis*.

Girls spent much of their time at home, learning female skills such as weaving and sewing. They also went to school or studied with pedagogues, though female education was not considered as important as male education. Girls, like boys, wore the *bulla* necklace; they stopped wearing it when they married. They also wore the *toga praetexta* on special occasions. Girls did not undergo a ceremony inducting them into adulthood. They married at about the age of 18; younger girls certainly married, but it was often considered improper.

Both boys and girls played roles in Roman religion. Children could hold priesthoods and were in fact desired for these positions because of their purity. The young Julius Caesar (100 B.C.E.–44 B.C.E.) was appointed *flamen dialis*, chief priest of Jupiter, when he was about 13 years old. Because the *flamen dialis* had to be married, Julius Caesar wed a young girl when he took office; she served as his female counterpart, the *flaminia dialis*. Vestal virgins, the priestesses who cared for the sacred flame of the hearth goddess, Vesta, entered service at the age of seven or eight and spent the next 20 years or so performing their duties.

The Roman nobility especially valued their children, both boys and girls, as necessary players in maintaining the family's status. Boys were raised to uphold family honor. Girls were taught from an early age that their duty was to marry whomever their fathers selected as husbands for them, with the understanding that this choice would be dictated by financial and political needs and not by romantic inclination. Despite this apparently callous attitude toward offspring, there is ample evidence that Roman parents loved their children and wanted them to enjoy their childhoods. Ancient vases depict toys, and ancient writers wrote about children's games. Funeral inscriptions often mention children, and parents who lost children sometimes held elaborate funerals for them.

THE AMERICAS

BY ANGELA HERREN

Little information exists on the role of children in the ancient Americas. In the past archaeological studies focused on adult roles in society; however, some recent scholarship addresses the social experience of children in the ancient period. These studies rely on archaeological evidence and early forms of artwork that may represent infants and children. Some scholars caution that the concept of childhood is a social construct. Like their descendents, ancient Americans probably welcomed children into the world, training them early to perform tasks appropriate to their gender, but did not conceive of childhood as a distinct period in one's life. Rather, children gradually assumed the responsibilities of adulthood, probably marrying a few years after the on-

set of puberty. While men generally engaged in agricultural production, hunting, and other activities, women typically cared for children, prepared food, maintained the home, wove textiles, and in some cultures were responsible for ceramic production.

In South America the Paracas (ca. 700 B.C.E.–200 C.E.) and Nazca (ca. 1–700 C.E.) cultures interred many children in their burial grounds on the southern coast of Peru. Twentieth-century excavations along the sandy desert coastline found the remains of children among the hundreds of mummy bundles buried in shallow shaft tombs. The bodies, placed in a fetal position within a basket and wrapped in layer upon layer of cloth, generally show that the children experienced malnutrition or died from childhood diseases. The children wore textiles sized to fit their small bodies, and some burials included figurines or toys in the layers of their bundle. Archaeological evidence indicates that early cultures experienced a much higher infant mortality rate than is true today, and the average life expectancy for adults was 37 or 38 years old.

While few clues exist about childhood experience in North America, skeletal remains and artwork from Mesoamerica and South America indicate that many cultures practiced cranial deformation, compressing and shaping the skull of a newborn infant with boards or mats to achieve an aesthetically pleasing

Olmec figure of a baby (ceramic, cinnabar, and red ochre) 12th to ninth century B.C.E., Mexico (Copyright the Metropolitan Museum of Art)

profile. There is such evidence in the region of the Andes. The distinctive results of skull compression could signal the beauty, status, or ethnic group of the individual and may have had religious or ritual purposes as well. Neonatal head shaping did not seem to result in neurological damage.

Some evidence suggests that child sacrifice, a documented practice in the later Inca Period (ca. 1400–1500 C.E.), also occurred in ancient South American cultures. At times, ancient societies offered children in sacrifice to deities believed to control natural phenomena; adults considered children the most precious and pure gift they could present to the gods. In 1995 the archaeologist Steve Bourget discovered the bones of 42 male adolescents of the Moche culture (ca. 1–700 C.E.) embedded in a sacrificial plaza near a ceremonial structure called the Huaca de la Luna on the northern coast of Peru. This excavation marked the first discovery of large-scale sacrifice at a Moche site. The skeletal remains showed many healed fractures, indicating that the boys participated in combat activities in the years before their deaths.

Archaeological studies indicate that ancient Mesoamericans also practiced both cranial deformation and occasional child sacrifice. Practitioners of child sacrifice in Mesoamerica probably sought to venerate water deities to ensure adequate seasonal rains for farming or to appease deities in times of drought or famine. Some studies suggest that children chosen for sacrifice suffered from illness; ancient Mesoamericans may have viewed them as chosen by the gods for this honor. Skeletal studies indicate that some sacrificed children suffered from infection due to dental caries.

The Olmec, a culture that began to establish ceremonial centers along the Gulf Coast of Mexico around 1500 B.C.E., often represented infants or figures with infantile aspects in their artwork. Hollow ceramic figures depict the splayed legs and chubby limbs of infants. Flattening at the back of the head on these and other figures documents cranial deformation also found on skeletal remains. In addition, many ceramic baby figures have crossed eyes. The Olmec and later Maya cultures interpreted crossed eyes as a sign of beauty and

elegance and induced the effect by hanging a bead in front of the child's eyes.

Many sculptural forms combine corpulent infantile bodies and crying Olmec “baby faces” with supernatural or jaguar attributes. The resulting figure, referred to as a *werejaguar*, probably functioned as a representation of a deity. Some scholars argue that this association derives from Olmec belief that young children were closer to the supernatural world in their early years, before they learned to speak.

The Olmec also took a special interest in representing birth anomalies in sculptures. One finds numerous figurines representing dwarfs, hunchbacks, and club-footed or pigeon-toed individuals. The Olmec believed that people who were born with unusual physical traits possessed supernatural abilities. The Olmec infant cults surely viewed the small stature of dwarfs as a link to the world of their deities.

Like their descendents, the ancient Maya welcomed children and may have turned to Ix Chel, goddess of childbirth, to promote fertility. Soon after birth the infant's parents applied a pair of flat boards to the back of the head and the forehead. Left in place for several days, the device created a permanently flattened forehead, signaling beauty and status. Like the Olmec, the Maya admired and induced crossed eyes. Just as some families today pierce the ears of female children, the Maya pierced the ears, lips, and nasal septum of boys and girls to hold ornaments. Mothers cared for male and female children until the age of four; by four or five years of age male children began to train with their fathers.

The Middle East

~ The Advice of an Akkadian Father to His Son, ca. 2200 B.C.E. ~

Do not set out to stand around in the assembly. Do not loiter where there is a dispute, for in the dispute they will have you as an observer. Then you will be made a witness for them, and they will involve you in a lawsuit to affirm something that does not concern you. In case of a dispute, get away from it, disregard it! If a dispute involving you should flare up, calm it down. A dispute is a covered pit, a wall which can cover over its foes; it brings to mind what one has forgotten and makes an

accusation against a man. Do not return evil to your adversary; requite with kindness the one who does evil to you, maintain justice for your enemy, be friendly to your enemy.

Give food to eat, beer to drink, grant what is requested, provide for and treat with honor. At this one's god takes pleasure. It is pleasing to Shamash, who will repay him with favor. Do good things; be kind all your days. . . .

My son, if it be the wish of a ruler that you belong to him, if you are entrusted with his closely guarded seal, open his treasure house and enter it, for no one but you may do it. Uncounted wealth you will find inside, but do not covet any of that, nor set your mind on a secret crime, for afterwards the matter will be investigated and the secret crime which you committed will be exposed.

Do not speak ill, speak only good. Do not say evil things, speak well of people. He who speaks ill and says evil—people will waylay him because of his debt to Shamash. Do not talk too freely; watch what you say.

Do not express your innermost thoughts even when you are alone. What you say in haste you may regret later. Exert yourself to restrain your speech.

Worship your god every day. Sacrifice and pious utterance are the proper accompaniment of incense. Have a freewill offering for your god, for this is proper toward a god. Prayer, supplication, and prostration offer him daily, then your prayer will be granted, and you will be in harmony with god.

Confucius: Analects, excerpt, ca. 479–221 B.C.E.

... Mang I asked what filial piety was. The Master said, "It is not being disobedient."

Soon after, as Fan Ch'ih was driving him, the Master told him, saying, "Mang-sun asked me what filial piety was, and I answered him, 'not being disobedient.'"

Fan Ch'ih said, "What did you mean?" The Master replied, "That parents, when alive, be served according to propriety; that, when dead, they should be buried according to propriety; and that they should be sacrificed to according to propriety."

Mang Wu asked what filial piety was. The Master said, "Parents are anxious lest their children should be sick."

Tsze-yu asked what filial piety was. The Master said, "The filial piety nowadays means the support of one's parents. But dogs and horses likewise are able to do something in the way of support; without reverence, what is there to distinguish the one support given from the other?"

Tsze-hsia asked what filial piety was. The Master said, "The difficulty is with the countenance. If, when their elders have any troublesome affairs, the young take the toil of them, and if, when the young have wine and food, they set them before their elders, is THIS to be considered filial piety?"

Clarendon Press, 1893).

Greece

Herondas (Herodas): The Third Mime excerpt, ca. third century B.C.E.

[A mother, Metrotimé, brings her truant son Cottalos to his schoolmaster, Lampriscos, to receive a flogging.]

Metrotimé. Flog him Lampriscos, across the shoulders, till his wicked soul is all but out of him. He's spent my all in playing odd and even; knucklebones are nothing to him. Why, he hardly knows the door of the Letter School. And yet the thirtieth comes round and I must pay—tears no excuse.

His writing tablet, which I take the trouble to wax anew each month, lies unregarded in the corner. If by chance he deigns to touch it, he scowls like Hades and then puts nothing right but smears it out and out. He doesn't know a letter till you scream it twenty times. The other day his father made him spell "Maron"; the rascal made it "Simon": dolt I thought myself to send him to a school! Ass-tending is his trade!—Another

(continued)

(continues)

time we set him to recite some childish piece; he sifts it out like water through a crack, “Apollo”—pause,—then “hunter!”

[The poor mother goes on to say that it is useless to scold the boy; for, if she does, he promptly runs away from home, to sponge upon his grandmother, or sits upon the roof out of the way like an ape, breaking the tiles, which is expensive for his parents.]

Yet he knows the seventh and the twentieth of the month, whole holidays, as if he reads the stars; he lies awake o’ nights dreaming of them. But, so may yonder Muses prosper you, give him in stripes no less than—

Lampriscos [briskly]. Right you are, here, Euthias, Cocalos, and Phillos hoist him upon your backs. I like your goings on, my boy! I’ll teach you manners! Where’s my strap, with the stinging cow’s tail?

Cottalos [in terror]. By the Muses, sir,—not with the stinger?

Lampriscos. Then you shouldn’t be so naughty.

Cottalos. O, how many will you give me!

Lampriscos. Your mother fixes that.

Cottalos. How many, mother?

Metrotimé. As many as your wicked hide can bear.

[They proceed with the flogging]

Cottalos. Stop!—That’s enough!— Stop! Lampriscos. You should stop your ways.

Cottalos. I’ll never do it more, I promise you.

Lampriscos. Don’t talk so much, or else I’ll bring a gag.

Cottalos. I won’t talk,—only do not kill me,—please!

Lampriscos [at length relenting]. Let him down, boys.

Metrotimé. No—eather him till sunset.

Lampriscos. Why, he’s as mottled as a water snake.

Metrotimé. Well, when he’s done his reading, good or bad, give him a trifle more, say twenty strokes.

Cottalos [in agony]. Yah!

Metrotimé. [turning away]. I’ll go home and get a pair of fetters. Our Lady Muses, whom he scorned, shall see their scorners hobble here with shackled feet.

Rome

~ Plutarch: “*The Training of Children*,” ca. 110 C.E. ~

Children ought to be made to abstain from speaking filthily, seeing, as Democritus said, words are but the shadows of actions. They are, moreover, to be instructed to be affable and courteous in discourse. For as churlish manners are always detestable, so children may be kept from being odious in conversation, if they will not be pertinaciously bent to maintain all they say in dispute. For it is of use to a man to understand not only how to overcome, but also how to give ground when to conquer would turn to his disadvantage. . . .

Add we now to these things some others of which children ought to have no less, yes, rather greater care; to-wit, that they avoid luxurious living, bridle their tongues, subdue anger, and refrain their hands. . . . To begin with the last: some men there have been, who, by opening their hands to take what they ought not, have lost all the honor they got in the former part of their

lives. So Gylippus the Lacedaemonian, for unsewing the public money-bags, was condemned to banishment from Sparta. And to be able also to subdue anger is the part of a wise man. Such a one was Socrates; for when a hectoring and debauched young man rudely kicked him, so that those in his company, being sorely offended, were ready to run after him and call him to account for it, *What*, said he to them, *if an ass had kicked me, would you think it handsomely done to kick him again?* And yet the young man himself escaped not unpunished; for when all persons reproached him for so unworthy an act, and gave him the nickname of *Laktistes*, or the kicker, he hanged himself. The same Socrates—when Aristophanes, publishing his play which he called *The Clouds*, therein threw all sorts of the foulest reproaches upon him, and a friend of his, who was present at the acting of it, repeated to him what was there said in the same comical manner, asking him withal, *Does not this*

offend you, Socrates?—replied: *Not at all, for I can as well bear with a fool in a play as at a great feast. . . .*

These things, you will perhaps say, are very difficult to be imitated. I confess it; but yet we must endeavor to the utmost of our power, by setting such examples before us, to repress the extravagancy of our immoderate, furious anger. For neither are we able to rival the experience or virtue of such men in many other matters; but we do, nevertheless, as sacred interpreters of divine mysteries and priests of wisdom, strive to follow these examples, and, as it were, to enrich ourselves with what we can nibble from them.

And as to the bridling of the tongue, . . . if any man think it a small matter or of mean concernment, he is much mistaken. For it is a point of wisdom to be silent when occasion requires, and better than to speak, though never so well. And, in my judgment, for this reason the ancients instituted mystical rites of initiation in religion, that, being in them accustomed to silence, we might thence transfer the fear we have of the gods to the fidelity required in human secrets. Yes, indeed, experience shows that no man ever repented of having kept silence; but many that they have not done so. And a man may, when he will, easily utter what he has by silence concealed; but it is impossible for him to recall what he has once spoken. And, moreover, I can remember infinite examples that have been told

me of those that have procured great damages to themselves by intemperance of the tongue. . . . When Ptolemy Philadelphus had taken his sister Arsinöe to wife, Sotades for breaking an obscene jest upon him lay languishing in prison a great while; a punishment which he deserved for his unseasonable babbling, whereby to provoke laughter in others he purchased a long time of mourning to himself. Much after the same rate, or rather still worse, did Theocritus the Sophist both talk and suffer. For when Alexander commanded the Greeks to provide him a purple robe, wherein, upon his return from the wars, he meant to sacrifice to the Gods in gratitude for his victorious success against the barbarians, and the various states were bringing in the sums assessed upon them, Theocritus said: *I now see clearly that this is what Homer calls purple death, which I never understood before.* By which speech he made the king his enemy from that time forwards. . . .

Besides all these things, we are to accustom children to speak the truth, and to account it, as indeed it is, a matter of religion for them to do so. For lying is a servile quality, deserving the hatred of all mankind; yes, a fault for which we ought not to forgive our meanest servants.

► cities

INTRODUCTION

One of the basic problems in the study of ancient cities is defining what makes a settlement a true city and not a town or village. Some archaeologists use population to make this determination, with 40,000 to 50,000 inhabitants making for a true city. By that definition, the Mesopotamian settlement of Uruk, when it was ruled by Gilgamesh in about 2700 B.C.E., would have been a city because it had about 50,000 residents. Yet the requirement that a city have that many people would exclude most other Mesopotamian settlements that are called “cities.” Elsewhere, the Indus River valley settlements of Harappa and Mohenjo Daro,

the biggest settlements in their part of the world, might not qualify as cities. The large communities of the Maya (600 B.C.E.–1521 C.E.), and those of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) of China in the might not meet the criterion either.

Another approach to defining the nature of a city is by the settlement's social organization. Are the people living lives apart from one another, organizing themselves more like a cluster of villages than a unified community? Such a settlement might not be a city. On the other hand, if the city has the equivalent of a public works department, would it be a city? If there were public employees who repaired streets, lighted lamps at night, or kept the sewers clear, would that imply a civic government and therefore a city? Still, a settlement of 1,500 people might well have people in charge of lighting lamps at night and maintaining irrigation ditches or sewers. Is such a settlement a village with public employees, the beginning of a city, or a true city? Perhaps public maintenance of common ground sets a city apart from other settlements.

Another way of defining what makes a true city is by its construction. When archaeologists discuss Mohenjo Daro, they almost inevitably note that it was designed to be a city. Its streets were laid out in a grid. Its sections were defined by brick walls. It had sewers with manholes for people to enter in order maintain them. Perhaps its construction of public streets and buildings made it a city. The ancient Romans believed that to be true. When the Romans designed a city from the ground up, they made sure that it had public buildings. To the Romans, the city of Rome had become a city when King Tarquinius Priscus (r. 616–578 B.C.E.) built the first Roman Forum. That public structure made Rome a city. In ancient Mesopotamia a wall around a city served the same purpose. To Mesopotamians, that wall defined the sacred grounds of their city.

In addition to the question of what makes a settlement a city, archaeologists have long debated why cities arise in the first place. At present, the most common explanation is that ancient people banded together for agricultural reasons. This explanation has logic. In the 7000s B.C.E. people settled in the land surrounding the Tigris and Euphrates rivers to farm wheat and barley, but most of the region had too little rain to raise crops, so they dug channels out of the rivers to irrigate their fields. To dig irrigation canals required that many people work together, which may have necessitated a central government to organize them and direct their work. It also may have been more convenient for people to live in close proximity rather than scattered in villages, so that they could easily gather together for their work and share in its benefits.

There are alternatives to the view that agriculture prompted the beginning a cities. One alternative is presented by Eridu in Mesopotamia. At present, Eridu is the earliest-known city. Archaeologists have found at the very lowest level of Eridu, beneath which is only sand, a small

shrine. If archaeologists are correct that the first structure at Eridu was a small shrine, then it would appear that people gathered into a community at Eridu not to farm but to live on sacred ground. This would suggest that they gathered together first and then found a way to irrigate their land near their sacred place. The motivation for creating the city would therefore be spiritual, not agricultural. Given that the Mesopotamians regarded their cities as sacred, perhaps many of their cities began as spiritual places. Thousands of years later Romans took pains to make sure their cities were on sacred land, which suggests the spiritual motivation was important for many centuries.

Another possible reason for creating a city would be mutual protection. Sometime between 10,000 and 8000 B.C.E. people built high and thick stone walls and an intimidating stone tower at Jericho. Even that early some people needed defenses to protect themselves, their property, their harvests, or their sources of water. Jericho's ancient walls required the efforts of many people working together to build them. Did people gather together in large communities to better protect themselves from other people? Walls protecting cities were almost universal in the ancient Near East, were common in the region of China, and eventually show up as wooden palisades in northern European settlements before 700 B.C.E.

Yet another motivation for creating cities may have been trade. It seems that everywhere in the world people began trading resources before they made cities. A city might arise on a trade route where people gathered together to share the benefits of foreign goods. The city of Rome arose at the best place for travelers to cross the Tiber River in Italy. Romans had to build defensive walls because many people wanted to take that crossing from them by force. In North Africa cities arose to take advantage of the trade in salt and copper; the sites of the cities sometimes corresponded with the only place for travelers to get fresh water for many miles in the surrounding desert.

All this suggests that as one reads about the ancient cities of the world, one delves into one of the greatest mysteries of human nature. Why do we gather in cities? How do we know when we have a true city? Is there even such a thing as a "true" city? Just asking such questions while studying ancient cities may give one greater insight into one's place in the world and the part one plays in one of the greatest dramas of human history, the building of cities.

AFRICA

BY JAMES E. MEIER

Cities emerged at very early dates in some regions of Africa, especially in the Nile River valley and along the North African coast. However, in general terms the development of cities lagged significantly in Africa, particularly in sub-Saharan Africa. Irrespective of their date of establishment, cities in ancient Africa invariably arose in those areas with especially

favorable agricultural conditions or where opportunities for exploiting local, regional, and international trade networks existed at the crossroads of traditional overland routes or along major river networks or coastlines. Cities also tended to be located in zones with high levels of rainfall and fertile soils and sometimes close to abundant deposits of precious and semiprecious minerals.

Despite some notable instances of the early formation of cities, relatively few important African cities arose before approximately the 10th and 11th centuries C.E. At about that time, as highly centralized states with advanced degrees of economic specialization began to take root, many cities were established. Yet most African cities that are occupied today were established only in the late 19th and early 20th centuries, during the period of European colonial conquest. As the overwhelming majority of Africans retained their ties to the land, cultivating crops, fishing, hunting, and raising domesticated animals, urban populations remained low well into the 20th century. Africa's relatively poor soils, harsh climates, and lethal disease environments meant that most of the continent's inhabitants historically dedicated the greater share of their energies to subsistence in the context of a rural setting.

CONCEPTUALIZING CITIES AND URBANIZATION IN AFRICA

The study of cities and the process of urbanization in Africa has long been complicated by a lack of agreement about definitions. Specifically there is no universally accepted set of criteria for what constitutes a city proper, as opposed to a town, village, kingdom, or other type of political and social entity. In part, consensus has proved elusive owing to the misapplication of a Western model of what warrants the designation of city. Scholars of many different disciplines have often been guilty of seeking out those characteristics that commonly appeared among cities in the West or among the great metropolises of the ancient world outside Africa. However, many indigenous African cities developed differently and displayed features unlike those found elsewhere in the world, owing to the contingencies of culture, social organization, systems of livelihood, ecology, and climate.

The lively debate about African urbanization has been fraught with a strong European ethnocentric bias. Owing to the close association that is often made linking cities to high civilizations and vice versa, many Western scholars, believing that Africans were backward peoples incapable of high civilization without the benefit of outside influence, have been reluctant to confer the status of civilization upon early African societies, even those boasting complex and highly urbanized structures. Since many scholars have approached the study of Africans and their societies with preconceived, stereotypical, and possibly racist views, they assumed a skeptical position in crediting the creation of cities, most notably those of pharaonic Egypt and the medieval site of Great Zimbabwe, to Africans. Typically, they attributed the construction of cities

and massive engineering feats to the contributions of Arabs, Asians, and Europeans.

Overall, Western scholars have underestimated the degree of urbanism present in ancient Africa. The limited number of ancient cities that archaeologists have uncovered may partly reflect the general failure to unearth African cities of the distant past in areas outside archaeological zones of high visibility and where the building materials were primarily mud and thatch. The siting of archaeological research in Africa, which has concentrated mainly in the Nile Valley, the Ethiopian plateau, the Swahili coast, the West African savanna, and Great Zimbabwe, has been unevenly applied. Many cities and states remained undisturbed, most notably in Central Africa.

The Western conceptualization of what cities are and what they are not has typically hinged upon certain criteria, foremost among them the development of a system of writing and the erection of monumental architecture. Monumental structures might include stone or mud walls, timber stockades, palace complexes, burial mounds, or obelisks (an extremely large tapering pillar that ends in a pyramid). Seemingly, the study of ancient cities in Mesopotamia and Mesoamerica validated this approach. Although there were cities in the Nile River valley that fulfilled these criteria, great cities of venerable origins in other regions of Africa, where knowledge was retained and transferred to successive generations through oral, not written, methods, would be unfairly disqualified, as would cities that erected impermanent structures owing to the unavailability of or lack of necessity for permanent materials. Clearly, definitions of the kind widely accepted by Western archaeologists, geographers, political scientists, and historians did more to obscure than to elucidate the nature and dynamics of African cities.

Despite the problematical nature of employing broad universal criteria in discerning which population centers are cities and which towns, several useful markers and features were generally present in African cities. Most basically, African cities were the loci of dense concentrations of population, with a large percentage of residents relying upon an economic pursuit other than farming as their principal means of livelihood. Normally, political, commercial, and religious elites were centered in cities and constituted a centralized authority that exerted adequate power to control the community's agricultural surplus and to command labor for public works projects. As elsewhere in the world, African cities served as centers of far-flung trade networks and as political capitals (of provinces, kingdoms, and empires) and often evolved into centers of learning, scholarship, and religious worship. Additionally, they were characterized by social stratification and craft specialization. In Africa cities did not exist in isolation; they were intimately tied into their immediate hinterlands, in large part through their markets, which provided opportunities for farmers, pastoralists, artisans, and market traders and stimulated agricultural production in the surrounding countryside.

NOTABLE EARLY AFRICAN CITIES

Ancient African cities are often difficult to locate by modern archaeologists, given the propensity of Africans historically to use organic building materials that suffer rapid decomposition. This factor, combined with a long-standing bias toward focusing their studies on architectural remains constructed of stone, has meant that archaeologists still know little of those cities where stone-built structures were not erected. That Africans constructed few cities of stone ought not to be cause for surprise. The relative absence of catastrophic storms and the warm or temperate climates of most African environments do not warrant using materials of an especially durable or well-insulated nature. Palm fronds, thatch, mud, and adobe served admirably as the standard materials of construction.

The modest number of ancient African cities that archaeologists have discovered to date has contributed to the facile assumption of Western scholars that Africa trailed behind Asia, the Middle East, and Europe in terms of its degree of civilization. It might therefore be instructive to examine some of the most noteworthy examples of cities that were established at early dates in Africa.

Africa's earliest cities developed in the Nile River valley. Around 5000 B.C.E., at about the same time that Africans succeeded in domesticating plants and animals, permanent settlements began to appear along the Nile. Egyptian cities emerged as early as 4000 B.C.E. as centers for provincial administration, religious worship, defense, and organization of the redistribution of food in times of drought. Egypt's neighbors to the south also benefitted from the Nile River. Owing to the rich soils along the banks of the Middle Nile and its role as a natural conduit for transportation and communication, some of the earliest cities beyond Egypt's borders sprang up here as early as 2500 B.C.E. When the Egyptian state nearly collapsed during the First Intermediate Period (2134–2040 B.C.E.), the city of Kerma, in Upper Nubia just south of the third cataract of the Nile, capitalized on this weakness and emerged as an important center for the exchange of goods between the Lower Nile Valley and inland Africa. It achieved its greatest height in the period 1785–1552 B.C.E., when the Hyksos, an ethnically mixed group of possibly Asiatic peoples, conquered Egypt. By 1500 B.C.E. a resurgent Egypt extended power over Nubia but again withdrew with the collapse of the New Kingdom (1070 B.C.E.). The independent Kingdom of Kush took root, ruled by locals and centered at the capital city of Napata.

Napata may have been occupied by as early as the 15th century B.C.E. and became a religious center of great importance both for Egypt and Kush from the ninth century B.C.E. Kush came to dominate much of the Nile Valley from the first cataract into the central Sudan, with Napata functioning as its political and economic capital. Napata's first temples may have already been built in the eighth century B.C.E., and even after the seat of political power for the Kingdom of Kush was transferred to Meroë farther south, Napata remained

the kingdom's religious capital, where kings were crowned. Napata was sacked by Egyptian forces in 593 B.C.E. and again by the Roman army in 23 B.C.E.

The Kushites retreated south to Meroë, which can be reached by a direct route across the desert from Napata. Evidence of Meroë's occupation dates to the 10th century B.C.E. As the capital of Kush from the sixth century B.C.E. to the fourth century C.E., Meroë became a vital center of ironworking and trade, particularly during the first two centuries C.E., when it flourished. Situated 160 miles north of the confluence of the Blue and White Nile, Meroë became the leading trade center spanning the Red Sea and the Mediterranean world. It exported ivory, gold, copper, ebony, slaves, animal skins, and feathers. It also had ample access to iron ore and hardwood timber, which proved vital in its rise as one of ancient Africa's great sites of iron production. Meroë was also in a tropical rainfall region, and its hinterland was a rich agricultural zone capable of feeding a large urban population. It had more available land than Napata, where the Nile was narrower and the floodplain less expansive, providing insufficient agricultural land to support a large urban population.

The remains of temples, tombs, cemeteries, and monumental statuary found in both Napata and Meroë provide suggestive evidence that both cities had populations of great size and were sophisticated capitals. Meroë developed its own unique cursive script, which has not yet been deciphered. Even employing the flawed criteria of Western archaeologists, Meroë was undoubtedly a notable African city. Although Rome invaded Nubia in 23 B.C. and conquered Napata, Meroë eluded the same fate, and its prosperity was quickly restored. The Kingdom of Meroë began to decline by 300 C.E., and the city was probably invaded by Axum in 350 C.E., during the reign of the great Axumite king Ezana, who ruled from 330 to 356 C.E. and was instrumental in spreading Christianity throughout the region.

Axum's role in delivering the coup de grâce to Meroë was the culmination of a long-standing commercial rivalry between the two states. Axum had been founded in the sixth century B.C.E. by migrants from the Saba region of southern Arabia. It grew and prospered from the first century C.E. until its gradual decline in the seventh century. It became the dominant power in northern Ethiopia owing to its proximity to the Red Sea and the Gulf of Arabia and its successful exploitation of the trade between the Indian Ocean and the Mediterranean. In particular, trade ties with the eastern Roman Empire provided an important stimulus for Axum's economy. Its exports included ivory, jewelry, frankincense, myrrh, rhinoceros horn, animal hides, gold dust, tortoiseshell, and slaves. Axum's population reached upwards of 10,000, and the city could boast not only brisk international trade but also a written language and monumental structures in stone. Axum's gigantic granite funerary stelae, which were built as early as 300 C.E., have attracted intense scholarly scrutiny. The tallest stelae (inscribed stone pillars), measuring 108 feet high and weighing between 550 and 700 tons, were the world's largest

such monuments built with dry stone. In addition to their tremendous size and craftsmanship, they represent a remarkable engineering feat, not least because they were erected without the benefit of mortar.

The Swahili Coast is located along the east coast of Africa, from Mogadishu (in Somalia) down to northern Mozambique. Swahili culture was the product of a unique blend of African traditions mixed with Arab and Islamic influences. In *The Periplus of the Erythraean*, a sailor's handbook written by an Egyptian Greek in the first century C.E., the author describes how East Africa traded with other nations in Arabia, the Persian Gulf, and Asia. In time these coastal cities drew visitors and migrants from those same regions. The Swahili population was concentrated in the cities that dotted the Swahili Coast and the offshore islands. Trade with the Indian Ocean world was well established probably no later than 600 C.E., long before Islam made inroads among the coastal peoples.

West African cities of size existed even before the opening up of the trans-Saharan trade on a significant scale and the penetration of Islam. The site of Jenne-jeno (in present-day Mali) on a floodplain of the Niger River provides clear evidence of an urban center before the Christian era. The city was founded in approximately 250 B.C.E. and flourished between the second century B.C.E. and the 15th century C.E. Already by 200 C.E. it probably had a population of 4,000, which was later to swell to between 10,000 and 25,000. Its prosperity was the result of the active trade its merchants plied as they capitalized on the movement of goods along the Niger. It was close to large deposits of gold and copper and enjoyed the added advantage of being protected by marshes largely impenetrable to outside invaders. Fishing and intensive agriculture on the fertile floodplain contributed to its thriving population.

Other West African cities were founded at an early date but assumed the status of great cities only later. In the savanna and forest lands of Nigeria, the Yoruba and Edo peoples built large urban centers surrounded by earthen walls and earthworks. Most notably, the Yoruba city of Ile Ife was probably established as early as the fourth century B.C.E. in southwestern Nigeria, but it emerged as a large and powerful city only in the 10th century C.E.

The Hausa city-states of Kano, Zaria, Katsina, and Gobir in northern Nigeria were founded possibly as early as the fifth century C.E. Tapping into the lucrative caravan trade that linked neighbors to the west (the West African states of Mali and Songhay) and east (Kanem-Bornu) with Mediterranean ports on the coast of North Africa, they acquired great wealth and grew dramatically in size, but scholars know little of these city-states before the 16th century.

Carthage, a port city founded by the Phoenicians ca. 800 B.C.E., developed into a unique civilization that was variously Semitic, Mediterranean, and African in its origins. By the sixth century B.C.E. it dominated the entire North African coast. Two centuries later it controlled much of the western Mediterranean world and extended its influence even beyond

the Strait of Gibraltar, reaching Britain in the north and sailing down the coast of West Africa. Its immense wealth and power eventually brought it into conflict with the Roman Republic. Three costly conflicts with Rome between 264 and 146 B.C.E., known as the Punic Wars, ultimately resulted in the Roman conquest and destruction of Carthage. Of its population, which may have exceeded 700,000, only 50,000 inhabitants remained alive by the end of the Third Punic War.

After it was destroyed and razed, Carthage was resurrected in 122 B.C.E. by the Romans and renamed Colonia Junonia. This city too was destroyed, but in 29 B.C.E. Caesar Augustus rebuilt it, naming it Colonia Julia Carthago. Carthage declined after the third century C.E. All told, Rome built an impressive urban society along the North African coast, with as many as 500 cities and a population of nearly two million inhabitants. Roman rule ended in North Africa with the invasion in 429 C.E. of the Vandals, who were conquered in turn by the Byzantine Empire in 534 C.E.

EGYPT

BY DAVID PETECHUK

Egypt was once believed to be a “civilization without cities,” but archaeological explorations over the past several decades have shown otherwise. Settlement excavations in Egypt have revealed that towns and cities date back at least to 3500 B.C.E. The cities were essentially regional capitals connected to smaller towns that made up various administrative districts. It would be many centuries, however, before Egypt would develop cities as they are thought of today.

Although it was home to one of the most ancient civilizations in the world, Egypt has kept the secrets of its ancient settlements and cities relatively hidden. Part of the reason is that people generally lived along the fertile riverbeds, especially along the Nile River. As a result, they also lived near shifting floodplains. Because houses and most other buildings—other than the stone temples and tombs—were built of mud brick, recurring floods and the changing course of the Nile in ancient times have destroyed the bulk of these dwellings. Furthermore, the Egyptians usually built directly on top of previous buildings and settlements because of the scarcity of good building sites. Consequently, much of Egypt's ancient cities—such as Heliopolis, which is largely buried under the urban expansion of Cairo, and Thebes, where the current city of Luxor rests—remain inaccessible to archaeological research.

URBANIZATION

The people who lived in the Nile River valley of Egypt before 5000 B.C.E. were primarily hunters and gatherers. The oldest-known farming village existed about 15 miles outside present-day Cairo from about 5000 B.C.E. to 4000 B.C.E. With a population believed to be between 1,300 and 2,000, it included residential areas, work facilities, and public areas. As villages and settlements grew, however, the rural community

Ancient Egyptian city of Sesebi; the buried remains of the city wall and a temple and mounds covering houses are visible. (Courtesy of the Oriental Institute of the University of Chicago)

and environment would remain an integral part of the new urban complexes, serving essentially as extensions of the towns. In fact, many farmers and workers lived within the villages and settlements and worked in the nearby fields.

The early development of villages was based on a variety of factors, including security, economics and trade, administrative demands, religious cult influences, and political motives. For example, archaeologists believe that the village of Maadi was established around 3500 B.C.E. as a trade link between southern Egypt and the Levant, an ancient and large geographical region in southwestern Asia. Archaeologists have found silos and cellars, huts, and various other storage facilities along with assorted other items.

Most of the early settlements were little more than small villages or hamlets built on the edge of floodplains. Composed primarily of fragile huts, these hamlets were established around every mile along the Nile River, with the primary considerations for building being nearness to a waterway and high ground above the floodplains. According to historians and archaeologists, two factors led to the development of urbanization: a reduction of Nile flood discharge and an increased demand for trade goods by a growing population.

In addition to shrines and temples, a common feature of many Egyptian towns was the enclosure wall. Archaeologists consider the development of these walls as marking the separation from a time of scattered farming villages that predominated in the Predynastic Period (before ca. 3000 B.C.E.) and the more compact towns that primarily developed during the Early Dynastic Period (ca. 2920–2575 B.C.E.). Among

the most noted of these towns, both of which began in the Predynastic Period, are Naqada, which sat on the west bank of the Nile downstream from ancient Thebes, and Hierakonpolis, between the current cities of Cairo and Aswān.

Hierakonpolis is one of the largest Predynastic sites found by archaeologists and is believed to have been established around 3500 B.C.E. It included houses, temples, administrative buildings, and artisan areas. The houses were interlocking and built along narrow, irregular or seemingly unplanned streets. To date, archaeologists have discovered that some planning seems to have gone into the town but that it took place after the initial establishment because the innermost segments of Hierakonpolis are irregularly laid out. This early “city” also included a religious district and an area where artisans manufactured linens, stone vessels, baskets, beer, and other items in demand at the time. A stone wall surrounding the site was built around 3300 B.C.E. or possibly a bit later. Hierakonpolis is believed to have been abandoned around the time of the Middle Kingdom (ca. 2040–1640 B.C.E.)

EARLY TOWN PLANNING

The primary urban area in ancient Egypt by around 3000 B.C.E. was the city of Memphis, which had a population at its peak of 30,000 to 40,000 and served as the capital city of Egypt after administrative districts had been unified under a single theocratic dynasty. Built by the First Dynasty (2920–2770 B.C.E.) pharaoh Menes near the entrance to El Faiyūm (an area separated from the Nile Valley by a ridge and containing a large lake called Birket Qārūn), the city served as a place of consolidated power for the first kings of

Egypt. The city also sat at the meeting points between the Nile Delta and the Nile River valley, making it a good marketplace that could be taxed and controlled. Unfortunately, little is known about the actual city itself, as much of the remains of early Memphis are situated beneath thick alluvial deposits from the Nile and below the water table. However, recent archaeological excavations and new technologies are beginning to shed light on this ancient city. For example, archaeologists have found that the city shifted eastward over its history because of the shifting course of the Nile and encroaching sand dunes.

While Egyptian towns and cities seemed to have little planning underpinning their initial development, archaeologists have discerned some attempts at a rational approach to building urban areas. For example, the ancient city Kahun, which was founded by Sesostres II (r. 1897–1878 B.C.E.) and unearthed by Sir Flinders Petrie in the 1880s, is a workers' town for the builders of the pyramid of Sesostres II and was conceived as an administrative area inhabited by those who served the local pyramid cult, a funerary cult that acted to sustain the king in the afterlife. Inhabitants included priests, officials, and craftsman as well as the farmers who worked the agricultural land surrounding the city.

Following digs by Petrie and others, archaeologists found that the strict internal planning was undertaken for Kahun, whose population has been estimated at between 3,000 and 10,000. Kahun and other similar towns were developed primarily to support the royal cult by providing a living for those responsible for the cult's operation. In addition to celebration of religious ceremonies, inhabitants of Kahun were also primarily concerned with agriculture and construction.

A walled town built near the modern town of El-Lahun, Kahun's interior was divided into two sections by another wall. While the residents of different classes generally were not separated in ancient Egyptian towns and cities, Kahun included a wealthy residential area that contained houses with 60 to 70 rooms, making them as much as 50 times bigger than the houses of those living in the other part of the city. Careful planning went into Kahun's streets, with a system of parallel and cross streets. Alleys, where the workers lived, often ended in a cul-de-sac. The town's main street, which led to the palace, was approximately 30 feet wide, whereas streets and alleys were much smaller, often only 3 to 5 feet wide. Stone channels ran down the middle of the streets for drainage, and archaeologists believe that Kahun contained several large granaries. Overall, the city was densely built with mud huts and streets covering the landscape, leaving little room for large gardens, which Egyptians loved.

An example of a different kind of city planning can be found in the capital city of Akhenaton, which is now known as Amarna. Built by Akhenaton (also known as Ikhnaton and, early in his reign, as Amenhotep IV) during the Eighteenth Dynasty (1550–1307 B.C.E.), the city is situated about 365 miles south of Cairo along the Nile River in a natural amphitheater between two imposing cliffs. In designing the

city, planners created many public open spaces that included planted trees and gardens for some of the inhabitants. Built without an enclosure wall, Akhenaton included a large open area in the center of the city where temple complexes for the cult of the creator god Aton were situated. The city's main road ran north to south, with the Great Palace and king's residential palace located on the western side of the road and facing the Nile and the temple complexes located on the eastern side of the road. The central part of the city also included administrative and industrial buildings, such as those used for baking. Residential areas of various sizes were situated to the north and south of the central area. Clusters of houses indicated the existence of distinct neighborhoods. Unlike Kahun and other Middle Kingdom cities, Akhenaton's streets were irregularly laid out.

SPECIALIZED SETTLEMENTS SURROUNDING CITIES

In addition to the major towns and ancient cities, Egyptians also built numerous specialized villages and towns in close proximity to them. Integral to ancient Egypt's larger towns and cities was the workers' village. Workers' villages can be traced back to the Fourth Dynasty (ca. 2575–2465 B.C.E.) and are often associated with the building of the pyramids. One such site northwest of present-day Cairo, called Abu Ghalib, was twice the size of Kahun. The discovery of a rectangular grid uncovered during archaeological excavations indicates that the city was carefully planned.

In fact, workers' villages appeared to be well-organized settlements, each with its own economic administration separated from the nearby larger city or town. For the most part, workers' villages contained larger residential sites for administrative officials and many small, nearly identical residences for the workers. The smaller units were inhabited by both skilled and unskilled laborers and their families.

A prime example of the workers' village is one that was located at the edge of the desert about three-quarters of a mile east of Akhenaton. It contained 73 identical houses and one slightly larger for a total population of approximately 300 to 400 people. The workmen generally lived in small, barracks-like dwellings of approximately 650 square feet. In dwellings with a second floor, the living space expanded to approximately 1,100 square feet. The residents of such homes often included animals. Many of the houses included hearths shaped like keyholes and jars sunk into the floor. The long, narrow streets of the village were laid out parallel to each other and were approximately 6½ feet wide. Within this walled workers' village, houses took up almost the entire area. In addition to residences, the village included an area for the delivery of goods from the city (including water, since the village had no wells), a guardhouse, and quarry sites later turned into rubbish pits. In addition, the village had animal pens for livestock that were not housed with the workers. There is also some evidence that vegetable gardening took place within the town.

One of the best-known workers' villages of ancient Egypt is the village of Deir el-Medina, where workers on the Theban royal tombs in the Valley of the Kings lived. Founded under the reign of Eighteenth Dynasty ruler Thutmose I (r. 1504–1492 B.C.E.), the village was surrounded by a 21-foot mud-brick wall. Over the course of its 500-year habitation, the village was occupied initially by unskilled workers who lived in about 60 houses. As the work on the tombs increased, so did the size of the village, which eventually grew from 60 households to approximately 120 within an area of about 60,000 square feet. In addition to size, the socioeconomic makeup of the village changed in that its inhabitants soon included relatively affluent workers, such as masons, painters, and sculptors. Overall, houses varied in size from 430 square feet to 1,300 square feet, with the larger structures containing three big rooms, a kitchen, a yard, and underground cellars for storage. The homes typically contained wall niches for statues of gods. The village was abandoned after the last of the royal tombs were built during the reign of Ramses XI (r. 1100–1070 B.C.E.).

TEMPLE TOWNS AND DISTRICTS

The relationship between towns and temples was a fundamental aspect of ancient Egyptian life. Often the temple served as the central location for the eventual development of cities, such as Memphis and Thebes. During the New Kingdom (ca. 1550–1070 B.C.E.), settlements surrounded the temples and included domestic dwellings and industrial facilities.

A good example of the importance of temple towns and how later larger towns or cities built up around them is a temple site that existed on the west bank of Thebes in an area called Medinet Habu. Traced back to the Eleventh Dynasty (ca. 2140–1991 B.C.E.), the site contained a small shrine that was rebuilt and expanded under the reigns of Hatshepsut (r. ca. 1473–1458 B.C.E.) and Thutmose III (r. ca. 1479–1425 B.C.E.). During the reign of Ramses III (r. ca. 1194–1163 B.C.E.) a larger temple complex was built around the older temple buildings. The larger complex included temples, administrative buildings, workshops, storehouses, a garden, and a funerary palace. Beyond the wall surrounding the great temple were residential houses, stables, orchards, and a stockyard. Encompassing the entire site was a complex fortification system of walls, towers, and a moat. This walled city contained two entrances. The eastern gate facing the Nile River was several stories high and decorated with scenes denoting the king's authority. There was also a heavily fortified western gate facing the desert.

By the Twentieth Dynasty (ca. 1196–1070 B.C.E.) Medinet Habu served as an administrative center for the area, and the housing areas once restricted to temple staff were soon inhabited by the general population. During this time the Great Girdle Wall that surrounded the complex was destroyed, perhaps during fighting with nomadic peoples. Rebuilt during the Twenty-First Dynasty (ca. 1070–945 B.C.E.), the complex then included small, closely packed houses on the eastern side and larger villas with gardens on the west. Although the cult of Ramses III was eventually abandoned sometime during the Twenty-First

Dynasty, the area remained a focal point for religious practices and subsequently led to rebuilding and continued habitation through the Coptic Period (ca. 400–800 C.E.) of Egypt.

For the most part, temple districts were planned better than most of the early cities and towns. Individual temples were laid out symmetrically with surrounding walls, sometimes nearly 40 feet thick. Streets and avenues were designed to be wide, sometimes up to 16 feet, to accommodate processions and other religious activities. Unlike most streets in towns and cities, temple streets often were paved.

Initial planning of temple districts included a large open space around the temple, but as the population grew, houses were eventually built right up to the temple walls, which also served as a strategic place to make a last stand in case of attack. An interesting phenomenon concerning temple sites is that as houses around the temple were continually rebuilt over the older houses through the years, the temples themselves remained standing and often appeared to be sunk into the ground. The larger cities of Memphis and Thebes had a number of temple complexes that were at one time separate but eventually were interconnected by large avenues beginning around the 18th Dynasty.

FORTRESS SETTLEMENTS

Another form of specialized city was the fortified settlement, with some of the best known dating to the Middle Kingdom. Fortified settlements were also built in the northeast and northwest, where they helped protect borders from various invaders and mass immigration. Archaeologists have traced the existence of fortified settlements at least as far back as 2160 to 2040 B.C.E. A chain of fortified settlements known as the "Walls of Princes" was completed under Amenemhet I (r. ca. 1991–1962 B.C.E.). Various other fortress complexes were also built with functions such as supplying and protecting river traffic. One of the largest fortress settlements of ancient Egypt was excavated at Buhen, which is about 155 miles south of present-day Aswān. Built over an Old Kingdom site facing the Nile, the fortress was surrounded by a mud-brick enclosure that had walls 26 to 30 feet high and sometimes as thick as 16 feet. The enclosure also included external towers and was surrounded by a ditch and another brick-paved parapet wall. Water was provided from the Nile via a stone passage. In addition to an entrance facing the Nile, the fortress had a western entrance facing the desert.

The interior of the fortress was planned with a grid pattern of streets with rectangular buildings made of brick. Initial residents of the fortress included soldiers and their families as well as government officials who oversaw the treasuries and state granaries. Also inhabiting the fortress were interpreters, scribes, and craftsmen. Eventually, rotating troops and officers were replaced by a permanent settlement of soldiers and others within the fort. Much like the temple towns or districts, this site and others like it eventually developed into towns and cities that included residential areas and temples. The site was populated until around 1552 B.C.E.

THE ROYAL CITIES

By the time of the New Kingdom onward, most of the specialized towns or cities had been linked via geography and economics to larger urban centers that included extensive temple complexes, ceremonial palaces, residencies, and prominent cemeteries. In addition to the temples, these urban areas were held together by the kingship, which required massive workforces, thus providing the foundation for larger cities.

Within the ancient Egyptian capital cities, the royal palaces were enclosed and separated from the rest of the capital. The palaces housed the pharaoh's primary family and servants, along with secondary wives, concubines, and numerous children. Typically, the location of capital cities in Egypt shifted with changing rulers. As a result, royal residential palaces existed in numerous cities, including Akhenaton, Heracleopolis, Avaris, Napata, and Saïs.

Relatively few excavations have been able to uncover the most ancient aspects of these cities. As a result, little is known about them. Conjecture based on their functions, however, indicates that they all had a large and extremely diversified workforce and often included a large population of people who relocated, such as when palace authority was moved from one city to another. While the population of provincial capitals and towns has been estimated at about 1,400 to 3,000 people, royal capitals were much larger; Akhenaton was estimated to have a population of 20,000 to 30,000 people. Likewise, Memphis, which housed the first known royal residence, and Thebes may have achieved populations of 30,000 to 40,000 during their peaks.

ALEXANDRIA

The city of Alexandria is perhaps the best known of Egypt's ancient cities. Alexandria's fame can be traced to its rapid growth into an intellectual, cultural, economic, and political metropolis. Its mystique also comes from its magnificent history. Founded in 331 B.C.E. by Alexander the Great (356–323 B.C.E.), it was made the capital of Greco-Roman Egypt and quickly became one of the greatest cities of the classical Greek Hellenistic world. Legend has it that Alexander initially laid out his plans for the city using lines of grain, since he had no chalk or other writing materials available.

Like contemporary Alexandria, ancient Alexandria is northwest of the Nile Delta and inhabits a narrow strip of land between Lake Mariut and the Mediterranean Sea. When Alexander came to the site of a small, ancient Egyptian village called Rhakotis, which dates to the 13th century B.C.E., he admired it for its natural beauty and its location between Greece and the rest of Egypt. He quickly decided that the site would be an ideal regional capital. Although he was the founder of Alexandria, Alexander did not live long enough to see a single building constructed on the site; he was later buried there.

Alexandria was built by the Greek architect Dinocrates of Rhodes under the supervision of Alexander's viceroy,

Cleomenes, who oversaw its continued initial development. Growth of the city would thrive under the first three Ptolemies, who ruled much of the Egyptian part of the vast empire once conquered by Alexander. Ptolemy I (r. 304–284 B.C.E.) set out to make Alexandria the cultural and intellectual capital of the known world. Ptolemy II (reigned 285–246 B.C.E.) focused much of his efforts on building Alexandria, including construction on what would become the Royal Library of Alexandria. Ptolemy III (r. 246–221 B.C.E.) was a strong supporter of the sciences, which also contributed to the city's fame. Under these three men, Alexandria became the center of commerce among Europe, Arabia, and the Indian East. It grew so fast in successive generations that in a mere 100 years it was the largest city in the world. According to the census in 32 B.C.E., which was conducted three hundred years after Alexandria was founded, the city remained a major metropolis with 180,000 adult citizens, rivaling Rome in population at that time. Among the numerous exceptional achievements made under the rule of the first three Ptolemies were the Pharos Lighthouse, one of the seven wonders of the ancient world, and the Royal Library of Alexandria, known as the Mouseion. The Heptastadion Dike that connected the island of Pharos with the mainland was also built at this time and served additionally as a double harbor to the city.

Alexandria thrived primarily because it fulfilled the several functions intended for it, which included initially serving as a Greek city-state and as the capital of Egypt. In addition to fulfilling these functions, Alexandria's greater reputation was as a center for world trade and learning. One of its earliest inhabitants included the noted Greek mathematician Euclid (ca. 325–ca. 265 B.C.E.).

Because of the city's multiple functions, people from various lands came to it and intermingled on the streets, creating a population that included Egyptians, Macedonians and Greeks, Nubians, Persians, Indians, and perhaps the largest number of Jewish residents in any large city of the era. As a result, Alexandria was the basis for growing international business efforts. For example, an ancient maritime loan contract for importing incense included twelve partners of at least seven different nationalities. Likewise, scholarly life in ancient Alexandria was international in nature. Greek scholars, intellectuals from the Mediterranean, and numerous others embarked on various academic pursuits. In turn, scholars from Alexandria also traveled abroad, thus fostering international scholarship and a growth of scientific thought in the region. In fact, the Royal Library of Alexandria was one of the largest and most noted in the world at that time. It was subsequently destroyed by a fire or fires of unsure origins.

Alexandria's cosmopolitan environment was noted by Greek poet Herodas (ca. third century B.C.E.), who asserted that a person could find nearly anything in Alexandria, including "wealth, . . . power, prosperity, glory, shows, philosophers, gold, youth, the temple of the Adelpoi, the

generous king, Mouseion, wine, all the good things you may desire, and women more numerous than heavenly stars who could compete in beauty with the goddesses who sought the judgment of Paris.” Alexandria was annexed by the Romans around 80 B.C.E. and once again began to regain its notoriety and splendor, which had diminished through wars and conflicts, both external and internal, during the reigns of the later Ptolemies. During this time Alexandria served as a central granary of Rome. Later, in about the third century C.E., Alexandria became noted as a center of Christian theology and church government, but only after Saint Mark, who first introduced Christianity to the region, was martyred there in the first century C.E. Nevertheless, many of the early Christian church leaders, such as Clement, Origen, Arius, and Athanasius, were Alexandrians or had adopted the city as their home.

THE MIDDLE EAST

BY DAVID K. UNDERWOOD

The Near East, known today as the Middle East, is a region generally defined by archaeologists as that part of Southwest Asia that stretches from Iran in the east to the coast of the Mediterranean and Aegean seas in the west. The cities of the ancient Near East are located in four distinct subregions: Anatolia (modern-day Turkey), Persia (Iran, mostly west of the Zagros Mountains), the Levant (including Israel, Jordan, Palestine, and Syria), and Mesopotamia (Iraq). Many of the earliest and most important urban sites are found in Mesopotamia, which means “land between the rivers” in Greek and refers to the floodplain and sometimes fertile stretch of land between the Tigris and Euphrates rivers. In antiquity the southern part of Mesopotamia, between modern Baghdad and the Persian Gulf, was generally known as Sumer. The northern part, or upper Mesopotamia, was home to the Semitic cultures of the Akkadians and the Assyrians. Because of the low levels of rainfall in the region, especially in the southern lowlands, the growth of cities in ancient Mesopotamia depended on the development of intensive, irrigation-based agriculture.

NEOLITHIC SETTLEMENTS

It was not until the fourth millennium B.C.E. that there emerged, in Sumer, an “urban revolution” and the first true cities as opposed to towns. But the earliest traces of the move toward urbanization go back to the Neolithic Period and the agricultural revolution (ca. 8000 B.C.E.), when the domestication of plants and animals made possible a more settled lifestyle and the growth of villages and towns. Archaeological findings at such sites as Jericho, in modern-day Palestine, suggest that urbanization and its elements were under way there as early as 8000 B.C.E. Jericho had a significant, 10-acre settlement of mud-brick houses protected by impressive stone fortifications with a circular tower (28 feet tall and 33 feet in diameter at the base).

Another unique example of an early experiment in urban living is Çatalhöyük in Anatolia, where excavations have revealed a flourishing Neolithic culture (ca. 7000–5000 B.C.E.) that built its wealth from a regular trade in obsidian, a glass-like volcanic stone used for making tools with fine cutting edges. The curious absence of a street plan at Çatalhöyük is a product of the peculiar arrangement of the houses, which adjoin one another and have “entrances” through the roofs instead of doors. The advantages of such a system would appear to be a heightened sense of communal living and defense, not to mention a greater structural stability than would be afforded by freestanding walls of mud-brick and timber frames. A number of richly decorated interior spaces in the town seem to reflect a ritual or ceremonial purpose and have thus been called “shrines” by excavators. These decorations include wall paintings (some with hunting-related narrative scenes and one of the first “landscapes” in history), animal heads, *bucrania* (bovine skulls), and bulls horns (symbols of masculine virility), adjacent to plaster reliefs of female breasts (symbols of female fertility) projecting from the walls. The overall impression of Çatalhöyük at its height is of a prosperous Neolithic settlement with several of the material and artistic foundations of a proto-urban culture, but still more of a town than a city.

CITIES AND CIVILIZATION

The question of how to distinguish large towns from the earliest cities remains a problem for modern archaeologists. (Jericho’s estimated population in 7500 B.C.E. was only about 2,000.) It seems clear, however, that the rise of the first cities is inseparable from the problem of how to define “civilization.” The solution seems to lie in the equation of cities with a higher level of social organization and material culture, as defined by ten characteristics or criteria of civilization observed in early Mesopotamian cities, the most important of which were writing, the exact sciences, and a socioeconomic hierarchy.

The primary characteristics of civilization all relate to social organization: settlement in cities, specialization of labor, concentration of surplus production, class structure, and state organization (government). The secondary characteristics relate to material culture and reflect the impact of the primary characteristics: monumental public works (especially architecture and hydraulic engineering for irrigation), long-distance trade for precious resources, monumental artwork reflecting religious or governmental power, writing and record keeping, and math and science (especially geometry and astronomy). The significance of these categories lies in the fact that the earliest cities of the ancient Near East, especially in Sumer, possessed all of these characteristics. To this list should be added the invention of the wheel, the early use of basic metals and alloys (especially bronze), and a certain population size, perhaps between 7,000 and 20,000 people.

The weakness of such materialistic theories of civilization is ironically also revealed by the earliest cities of the an-

cient Near East, which were primarily ritual centers with a religious and ceremonial function, and not major economic magnets of surplus production. Still, the early development of such ritual sites as Eridu in Sumer (ca. 5000 B.C.E.) no doubt depended on the management of a surplus by an elite class of temple priests serving theocratic rulers in an increasingly stratified and hierarchical society. The growth of such ritual centers with “temple economies” would culminate in the formation of independent Sumerian city-states (eventually about 12), each of which would develop under the protection of a different Mesopotamian deity. The religious and ritual nature of the ancient city thus cannot be overestimated: The basic function of the city and its populace was to ensure the blessings and support of the deities, who were understood to control everything from the seasons to the course and flow of the two life-giving rivers, the Tigris and the Euphrates.

ERIDU AND MYTHICAL ORIGINS

The importance of polytheistic religion and myth as the driving force behind the development of the ancient city is nowhere better seen than in Eridu, the mythical place of origin not just for the Sumerians but for all of civilization. For the Mesopotamian people, Eridu represented the prototype for the idea of the city as a sacred place. It was here, according to the myth elaborated by the Babylonians, that the god Marduk created not only the world and humankind but also the first city from the primordial marshland. He did so by spreading mud upon a reed frame to form a platform for a temple (the god’s abode), to be placed on a mound of dry land surrounded by the swampy water of a lagoon called the *abzu*. Eridu’s

unique geographic position at the edge of the marshes and the alluvial river plain of southern Sumer (15 miles south of Ur) parallels its symbolic function as a transitional space where land and water came together to form a human civilization made possible by the gods. The *abzu* became synonymous with the religious core of the city.

Eridu was not only the cult center of the gods of freshwater but also, according to traditions recorded in texts going back to the fourth millennium B.C.E., the oldest shrine and most sacred city. Its very first building, a small and primitive chapel of sun-dried mud-brick, dates to 4900 B.C.E., but there is little evidence of monumental buildings beyond temple structures, among them, a ziggurat, or temple tower. As in the city of Uruk, later temple structures reveal the use of limestone, sandstone, and gypsum for wall structures and clay cone mosaics covered with thin copper plating for the decoration of the main temples. But Eridu never really became a fully functioning city or a center of political or economic power with its own kings; its importance was primarily symbolic, as a sanctuary and a holy place where land and water were brought together by the gods to enable humanity to take the first steps toward civilization.

URUK AND THE URBAN MATRIX

The first site in the ancient Near East to demonstrate the basic elements of a fully functioning city with both political and ceremonial components was Uruk, the biblical Erech, known to the Arabs as Warka. The Sumerian word for city was *uru*, which may have been the root for the Latin *urbs* and thus the origin of our modern term *urban*. Uruk has often been considered the “mother of cities” because of its

Panels with striding lions, Neo-Babylonian, during the reign of Nebuchadnezzar II (r. 604–562 B.C.E.), when Babylon reached its full glory as a city; this relief of a lion is one of a series of striding lions that lined the most important city street, the Processional Way, and guided ritual processions from the city to the temple. (Copyright the Metropolitan Museum of Art)

great antiquity (going back to the fifth millennium B.C.E.), its impressive size (3.4 square miles—bigger than Athens in the fifth century B.C.E.), and its provision of a matrix or pattern for future urban development. Possessing the earliest, largest, and most numerous monumental buildings in Mesopotamia, dating mostly from the fourth to the first millennium B.C.E., Uruk was the birthplace not only of monumental Sumerian architecture and planning but also of the cuneiform writing system (revealed on clay tablets and cylinder seals, engraved seals used to make impressions on clay) and a government bureaucracy with centralized, theocratic control. Representing the first phase of Mesopotamian urbanization, known as the Uruk Period (4000–3100 B.C.E.), Uruk appears to meet the basic criteria for both the first city and the first civilization of the ancient Near East.

Uruk's somewhat experimental urbanism is characterized by large, multifunctional buildings with diverse plans, arranged with a concern for open and fluid space and apparently designed for ease of access and circulation. Accurate description of individual buildings at any given point in time is complicated, however, by the tendency for later structures to cover over those of the earlier building phases, which were sometimes deliberately preserved or expanded upon. The most important structures date from the Uruk Period or later and are concentrated on the two largest mounds: Eanna (precinct of the goddess Inanna), which is the oldest and central part of the ruin, and Kullab (precinct of the sky god An), the western and highest mound, dominated by a towering ziggurat.

Excavations on the Eanna mound reveal that new materials and building techniques were used beginning with the Middle Uruk Period (ca. 3400 B.C.E.), most notably clay cone mosaics for wall decorations and especially imported limestone for foundations and walls, which tended to be both tall and thick—as in the Stone Cone Temple and the somewhat later Limestone Temple of Eanna. The most famous Uruk building, the White Temple, stood on a tall, archaic ziggurat—a sort of man-made mountain—towering high above the Kullab mound. The ziggurat and White Temple were dedicated to the sky god An, the father of all the gods. The temple takes its name from the coating of white gypsum plaster that covered its massive walls. Much of Uruk architecture thus conspicuously breaks with the local tradition of building with basic mud-brick that was favored both before and after the Middle Uruk Period.

At Uruk we find the prototypes for a wide variety of Mesopotamian temple designs. The basic plan was roughly symmetrical, consisting of a central rectangular or T-shaped chamber, possibly vaulted, with flanking corridors or attached rooms, some of which also opened to the outside. Within this basic formula, there was considerable variation in the layout, apparent function, and dimensions of the structures. A notable feature, especially on Eanna, is the tendency to arrange the buildings at different angles around large, open terraces faced with monumental colonnades of massive semicircular, engaged pillars decorated with mosaic patterns. The spatial

arrangement and structural system used at Uruk thus foreshadow those of the great terraces and temples of ancient Egypt and Greece.

Despite the archaeological excavations that provide basic information about the site, we actually know very little about life in Uruk. For instance, there is no evidence of residential quarters, graves, or commercial buildings or neighborhoods. The most important urbanistic episode in the city's history concerns the construction of its famed ramparts, undertaken during the Early Dynastic Period (first half of the third millennium B.C.E.), when the city was at its height, with a population of about 50,000. The walls extended about miles around the site and stood more than 23 feet tall. The tablets of the Gilgamesh epic credit Gilgamesh, king of Uruk, with this undertaking and describe the wall, "the likes of which no one can equal," as having "a foundation of baked brick" and being "as straight as an architect's string." This wall protected not only the sacred precincts of the gods and their pious worshipers but also the growing population of a place described by Mesopotamian poets as a festive city of singing and dancing, with a "population of beautiful and voluptuous women, women with luxuriantly curly hair and available women in general." The late Babylonian poem *Erra*, for example, talks about Uruk as a "city of prostitutes, courtesans, and call-girls," deprived of their husbands by Ishtar, who becomes associated with the rising "mother goddess" of Uruk, Inanna, and a cult of free love that witnessed erotic adventures in the city's streets and possibly even the institution of "sacred prostitution." The libidinous energy of Uruk looks forward to the infamous licentiousness of Babylon and the likes of modern Amsterdam.

AKKAD, UR, AND THE RISE OF THE MESOPOTAMIAN CAPITAL CITY

The continuing importance of the cult of the goddess Inanna for the development of Mesopotamian cities is clearly illustrated in a famous literary text, *The Curse of Agade*, written ca. 2000 B.C.E. The text deals with the rise of the city of Agade (Akkad) as the center of a successful international trading empire and the great capital of a powerful centralized state founded by the Akkadian king Sargon, who ruled from 2340 to 2284 B.C.E. Although the site of the city has not yet been identified, there is ample evidence of its existence and greatness in written documents and cuneiform inscriptions found at other sites and dating back to the third millennium B.C.E. The imperial state forged by Sargon during his 56-year regime incorporated all the formerly independent Sumerian city-states, including Uruk, whose impressive walls were no challenge to the military might of the Akkadians. Sargon's Akkad, believed by some experts to lie somewhere beneath modern-day Baghdad or in its vicinity, was the first city in ancient Mesopotamia to function as the true capital of a state and an empire.

Like Akkad, Ur became the capital of a powerful centralized state with grandiose city walls, rich furnishings,

and an extensive religious precinct. It is the site of two of the most impressive archaeological discoveries of antiquity: the monumental ziggurat of King Ur-Nammu (partially restored in the late 1970s) and the famous cemetery unearthed by the British archaeologist Leonard Woolley and a joint expedition of the British Museum and the University Museum of Philadelphia from 1920 to 1934. The interest in the site had been intensified by the discovery of ancient tablets that identified the city as Ur of the Chaldees, the biblical home of Abraham. The most impressive finds of the expedition were the 16 tombs identified as elite or “Royal Graves” because of the wealth and quality of the objects found in them and because of the unique arrangement of the main body alongside those believed to have been servants, ritual attendants, and possibly sacrificial victims.

The richness of the finds was unprecedented in Mesopotamian history: objects of gold, bronze, ivory, and semiprecious stones, and a wide variety of tools, weapons, headdresses, and hair ornaments. The most famous objects found were the remains of a decorated harp or lyre with the head of a golden bull wearing a beard of lapis lazuli and the Standard of Ur, the sound box of a string instrument decorated with shell and lapis lazuli inlays, showing scenes of war and peace on either side. We cannot say for certain that the cauldrons and goblets found in the tombs were used for the ritual mass poisoning, an interpretation that has been much popularized. What is clear from the remains is that there were more women than men buried in the cemetery and that the feminine ornaments and decorative objects found were used to define an increasing level of cultural and political status for many of the women found buried at Ur.

This apparent rise in the status of women officials at Ur was accompanied by the emergence of an efficient state administration that enforced monopolies on the most important commodities (linen and wool cloth), implemented a new calendar and standardized measures with accounting based on the use of silver rods, and regulated activities as diverse as cattle raising, date-palm horticulture, and advanced irrigation and large-scale architectural engineering. The two best examples of engineering advancements are the city’s massive walls and the monumental Ziggurat of Ur-Nammu (ca. 2113–2096 B.C.E.), which was part of the temple precinct dedicated to the moon god Nannar. The city walls were constructed with an innovative type of standardized brick, called planoconvex because it was flat on the bottom and rounded on the top. The main advantage of this new form was that the bricks could be laid more quickly, without mortar or a skilled labor force. It also was more conducive to the construction of rounded corners and curving walls.

The monumental dimensions of the main buildings at Ur indicate the use of a highly organized and disciplined but unskilled labor force, one of the main ingredients of an imperial civilization. The religious precinct at Ur also demonstrates this tendency toward greater monumentality. The entire area stood on a huge platform reinforced by heavy

brick walls, 24 yards thick and 8.7 yards tall. The ziggurat itself was a three-layered structure that stood within its own enclosure, occupying only a part of the precinct. On the southeast side was a large building called the Gipar, which functioned as the main residence of the high priestess of the city and of the goddess Ningal, the spouse of the moon god Nannar. The Gipar offers further testimony of the powerful role played by female gods and priestesses in the history of Mesopotamian cities. But ultimately Ur and its empire, like Akkad, would fall into decline. This process was described in a text entitled *Lamentation over the Destruction of Ur*, which, like the *Curse of Agade* upon which it was modeled, emphasized the power of the gods over humans and the endless cycle of rebirth and destruction.

ASHUR, NINEVEH, AND THE ASSYRIAN EMPIRE

The Akkadian imperial achievement set the stage for the emergence of the Assyrians, a Semitic people who built great palace-fortress complexes and a militaristic empire on the limestone plateau of northern Mesopotamia, beginning around 1365 B.C.E., under the leadership of King Ashur-uballit I. The ceremonial capital of the empire was Ashur, situated on a cliff overlooking the Tigris, from which point it commanded a lucrative Anatolian trade in tin and Babylonian textiles. The official religious center of the Assyrians, the city was dedicated to the god Ashur and became the sacred burial place of Assyrian monarchs, especially after 879 B.C.E., when King Ashurbanipal II moved his capital to Calah (Nimrud), itself soon to be eclipsed by the emergence of Nineveh as the administrative and residential capital of the empire.

The rise of Nineveh as the last official capital of the Assyrians began in 705 B.C.E. with King Sennacherib’s decision to move his administration and palace there from the palace-fortress complex of Dur Sharrukin (Khorsabad), which had been established by Sargon II to escape associations with the old capital Nimrud. Achieving a population of some 120,000 at its height, Nineveh would remain the capital of Assyria until it was sacked in 612 B.C.E. Located amidst the sprawl of modern-day Mosul, Iraq, the site of Nineveh was a roughly rectangular enclosure with a massive wall about 7.5 miles in length.

The palace, conceived as both royal residence and government headquarters, was only part of the extensive urbanistic undertaking sponsored by Sennacherib, the purpose of which was to transform Nineveh into a world-class royal city. Especially noteworthy was his pragmatic planning, involving not only the widening of streets and squares but also the provision of parks, orchards, and advanced hydraulic engineering to guarantee a fresh water supply for the city. It has even been suggested by some scholars that the famous Hanging Gardens, one of the Seven Wonders of the Ancient World, were more likely found in Nineveh than in Babylon. The subsequent creation in Nineveh of the first great cuneiform tablet library of the ancient Near East, founded by Ashurbanipal (r. 668–627 B.C.E.), demonstrates clearly that Assyrian capitals

were both the hubs of military administration and royal government as well as the cultural and symbolic centers of multinational empire.

NIPPUR, BABYLON, AND THE CULTURAL METROPOLIS

Just as the emergence of cities had depended on the specialization of labor within an evolving hierarchy of functions and classes, so too did the growth and spread of urban culture throughout the ancient Near East depend on the rise of a small group of elite centers of specialized, “symbolic” cultural production and religious privilege. Foremost among these were Babylon, the first great cultural metropolis of the ancient world, and Nippur, an academic city of scribes and higher learning. Although it was not the capital of a political or military empire, Nippur commanded its own kind of cultural power and religious prestige as the major center of Sumerian text production with a sizable “scribe quarter” and as the locus of an extensive religious precinct with a temple economy that employed hundreds of thousands of people in the service of the god Enlil. Its growth unimpeded by the presence of a secular government, Nippur was well known for the ethnic diversity of its population and came to acquire a reputation as a city where peoples of diverse backgrounds could come together to live peacefully and intelligently. Nippur thus stands as the paradigm of the “cultural” city and multicultural place, where the priorities of urban life involved much more than the wealth generated by a specific trade relationship or the politics of a particular dynasty.

The endurance of the cultural metropolis is best illustrated by the case of Babylon and the Babylonians, whose civilization flourished for centuries, despite multiple foreign invasions and changes of political regime. The city of Babel of biblical fame was decadent, corrupt, and very worldly, but in fact it was here that the Bible was first written down, something that would not have been possible in a less-tolerant environment. Babylon probably became a large city as late as the 19th century B.C.E., after the collapse of the Third Dynasty of Ur, and a world power by the 14th century B.C.E., when it covered an area of about three square miles, with broad, straight streets and a diverse population that spoke Aramaic. It was the Neo-Babylonian Empire (625–539 B.C.E.) that triumphed over the Assyrians and became the main power of the ancient Near East. King Nabopolassar undertook the reconstruction of the great ziggurat, a project continued by his son Nebuchadnezzar, who also developed the great Processional Way of Marduk (ca. 605 B.C.E.) and the Ishtar Gate, now housed in partial reconstruction in a German museum. In 539 B.C.E. Babylon was taken over by the Achaemenid Persians under Cyrus II. When Alexander the Great defeated the Persian king Darius in 331 B.C.E., he chose Babylon as the capital of his empire and, upon his death, left it under the control of one of his Macedonian generals, Seleucus I. During the Roman Period, Babylon fell into decline and became a provincial town on the outskirts of the Roman Empire.

THE CITY AS A FORUM FOR EMPIRE AND POWER POLITICS

The decline of Babylon saw the rise of the Persian Empire and its best-known palace complex, Persepolis, begun by King Darius I in 518 B.C.E. and further developed during the subsequent reigns of Xerxes and Artaxerxes I. This Achaemenid site was defined by a vast terrace, some 40 feet high, measuring 1,500 by 900 feet in area, and originally topped by a mud-brick wall about 50 feet high. The complex was approached by a wide, gently graded stairway protected by a gatehouse with monumental sculptures of bulls and human-headed bulls, recalling the earlier *lamassus* (human-headed winged bulls) of Assyrian palaces. The interior of the complex featured a spacious audience hall, a throne hall, and the famous Hundred-Column Hall, all of which made extensive use of square spaces and distinctively carved columns and pillars, some topped with human-headed bull capitals. The great stairways leading to the terraces and platforms on which these structures stood were decorated with bold carvings of a great procession of tribute bearers, which effectively modeled (or mirrored) the expected behavior of the human subjects entering the imperial precinct. Like the Assyrian palace-complexes, Persian sites like Persepolis were essentially imperial centers that sought to promote the ceremonial and prestige of the emperor and his court. The Persians’ manipulation of dramatic spatial sequences and the political potential of architectural sculptures, however, appear to have taken the propagandistic message of a vainglorious empire to even greater heights.

Polytheistic theocracy, with its temple economy and demanding ceremonial ritual, may have been the major driving force behind the initial growth of the ancient Near Eastern city, but over time there emerged a surprising and irrepressible diversity of form, function, and cultural personality among individual cities, as typified by places as diverse as Babylon and Persepolis. This diversity has both challenged and ultimately reinforced the region’s prevailing religious and political conservatism. It is this very duality—of attempting to uphold traditional religion and politics in the face of the multicultural diversity and modernization that would appear to destabilize it—that makes contemporary Near Eastern cities so dynamic and fascinating.

ASIA AND THE PACIFIC

BY NANCY SHATZMAN STEINHARDT

The date assigned as the beginning of urbanism in Asia and the Pacific varies from region to region. Group settlement in extended families or larger units, in which certain aspects of hunting, gathering, or planting may have been shared, predated the formation or construction of cities in Asia, often by millennia. Urban settlement also occurred in all parts of Asia before writing appeared, so that the dates assigned to cities have been derived from archaeological evidence. Based

on excavations and the analysis of their data, it is believed that the first cities in Asia were in China. Urbanism developed next in South Asia, particularly Pakistan, followed by Southeast Asia and, finally, Korea and Japan.

CHINA'S MOST ANCIENT CITIES

Not only are China's cities the oldest in Asia, but they also most readily lend themselves to definition. The Chinese word for city, *cheng*, is the same as the word for wall, and evidence of Chinese walls is at least as old as the evidence of cities. The first-known walled settlement in China is a Neolithic village of the sixth millennium B.C.E. in Li County in Hunan Province. An earthen wall 19.5 feet wide at the base that narrowed to about 5 feet at the top, roughly rectangular in shape, enclosed an area of 35,888 square yards. A ditch associated with the wall was also discovered. Several thousand miles to the north, in Aohanqi, Inner Mongolia, a ditch, but without any remains of a wall, enclosed a settlement of 28,700 square yards. Its date was determined by carbon-14 testing to be between 6200 and 5400 B.C.E. Houses in the Aohanqi settlement were arranged in rows. Remains of a cemetery dated to the mid-seventh millennium B.C.E., associated with a residential settlement but with no evidence of a wall or ditch, have been found in Wuyang County in the province of Henan. By the fifth millennium B.C.E. a settlement in Shaanxi Province included houses of at least three sizes, three cemeteries, a pottery workshop, and animal pens.

Walled settlements of the fourth millennium B.C.E. have been found in every region of China. A nearly circular wall surrounded by a moat enclosed a settlement in Zhengzhou, Henan. Also circular, enclosed by both wall and moat, was Chengtoushan, in Li County. At 95,680 square yards in area, it is more than twice as large as any other settlement known in Asia at the time. Both Zhengzhou and Chengtoushan had walls that were made using the rammed earth technique, associated with Chinese wall construction for the next four thousand years. (In the rammed-earth technique, walls are constructed of earth mixed with sand, gravel, and clay. The dampened material is poured into a form and then compacted, and the process is repeated until the desired height is reached.) By the fourth millennium B.C.E. Chinese cities were defined by walls, moats, residential architecture, cemeteries, and sometimes workshops.

It has been said that China experienced an urban revolution in the third millennium B.C.E., which was still nearly a thousand years before China entered the Bronze Age or had a written language. Cities from this period were huge in comparison to earlier times, sometimes between 1,195,990 and 3,587,970 square yards and serving a population that spread as many as 60 miles in either direction. It has been estimated that medium-size cities served a population of between 1,250 and 3,750 households, whereas the largest cities may have serviced as many as 50,000. Wall shapes appear to have become predominantly quadrilateral, in contrast to the more circular configurations found in the fifth and fourth millennia B.C.E.

Jade ritual reaping knife, from Henan province, northern China, during the Erlitou Period (17th-16th centuries B.C.E.); a large number of items made of such materials as bronze, jade, lacquer, and bone attest to a complex urban life at this site. (© The Trustees of the British Museum)

More than 50 walled settlements from this period have been uncovered along the Yellow and Yangtze river valleys.

This was also the time when great houses appeared, structures so large compared with other dwellings that they are believed to have filled palatial or ceremonial functions. Some of the most impressive evidence of urbanism in the third millennium B.C.E. in China is associated with the Neolithic culture known as Longshan. Longshan has been identified in eight Chinese provinces, but its most impressive cities are in Shandong. In Yanggu County, Shandong Province, a walled enclosure of approximately 236 miles has been found. China's most famous Longshan city is at Chengziya, in Zhangqiu County, Shandong. Dated to about 2600 B.C.E., the city had a wall that enclosed an irregular rectangle roughly 1,460 by 1,772 feet. Several Longshan city remains suggest that many walls existed in single cities. At Lianyungang, in Jiangsu Province, a Longshan city with inner and outer walled areas has been identified. By about 2500 B.C.E. a city in Pingliangtai, Henan, had a system of pottery drainpipes. (Their use is contemporary with a drainage system in the ancient Indus Valley civilization city of Mohenjo Daro in Pakistan.) A long avenue divided Pingliangtai into two sections, a feature that would be present in some Chinese cities for the next several millennia.

Also by this time, it is believed that ceremonies were a part of urban life. There was a distinct group of people in the society who performed rituals and a group of craftspeople who made ritual objects. Much of the evidence of ritual comes from the Neolithic site Niheliang, in Liaoning Province, dated to about 3000 B.C.E., which is an example of the Hongshan culture. The focal points of ritual at Niheliang included a large, high mound, more than 23 feet of which remains; a structure named the Female Spirit Temple for the pieces of female statues uncovered there; stone platforms; and burial mounds beneath which were objects made of jade and other expensive materials. In southern China at Yushan in Yuhang County, Zhejiang Province, near the city of Shanghai, ritual altars and jade objects that attest to ceremonies as part of urban life in the fourth and third centuries B.C.E. have been excavated.

By the middle of the third millennium B.C.E., China was composed of numerous city-states, most of them walled and some with several walls. Often a walled enclosure called an *enceinte* was the hub of activity of a larger region, but rarely was the territory within the jurisdiction of a city-state more than 62 miles in any direction. The city-states are believed to have had a ruling elite and economies based on agriculture, supplemented by stock breeding and fishing. There was a division of labor, meaning that builders of city walls and ritual architecture ate food grown or gathered by others.

The most important evidence of urbanism in China of the second millennium B.C.E. is along the Yellow River valley in North China. This was the time, before the middle of the second millennium, when writing appeared in China, though some believe pictographs were used in the third millennium B.C.E. China entered its Bronze Age early in the second mil-

lennium, even before the official beginning of China's first great historic period, the Shang Dynasty (1500–1045 B.C.E.). According to literary sources, Shang was preceded by the Xia Dynasty. Most historians believe that this dynasty began before the age of Neolithic cultures ended in China.

CITIES OF BRONZE AGE CHINA

A city that may well date to the Xia Period was excavated at Erlitou, near Luoyang in Henan. Large palatial complexes, bronze vessels, bronze plaques inlaid with turquoise, and remnants of jade, lacquer, bone, and pottery excavated at Erlitou attest to the complexity of urban life there, even though no wall remains have been uncovered.

North of Erlitou in Yanshi County is a city dated to about 1600 B.C.E. Sometimes it is referred to as Shixiangguo, named after a drainage ditch that ran through it. Consisting of an outer wall with an inner wall sharing its southern boundary and the southern part of its western boundary, the city measured 1,356 by 1,870 yards. Its outer wall was more than twice as thick as the inner one and was surrounded by a moat 65½ feet wide. Seven gates provided access to the outer city, and wide boulevards ran through it. Several palaces, large ritual sectors for animal offerings, pottery workshops, and a drainage system were among the urban features.

It has been surmised that Erlitou was the first of seven capitals from which the Shang kings ruled. There is little doubt that the Shang city at Zhengzhou was one of those capitals. Certainly the city was the most important urban center in the first half of the Shang Dynasty. Its main outer wall measured just short of 4 miles, and parts were as wide as 98 feet at the base. A little over 16 feet of wall have been uncovered south and west of the main wall, suggesting either that this was a significantly larger city or that it had many sections. The wall was made of pounded layers, lined by wooden planks, a technique introduced to China in Neolithic times. The largest palace foundation uncovered so far is 21,528 square feet.

Cities that were not capitals flourished in many parts of China during the Shang. Two of the best excavated have been found at Panlongcheng (near Wuhan, Hubei) and Gucheng (in Yuanqu County, Shanxi). At Panlongcheng a gate and two main buildings, believed to be a palace complex, stood in the northeast of the squarish city wall, which measured about 951 by 853 feet on each side. Contemporary with the capital at Zhengzhou, the city is important evidence that a similar level of urbanism was present in the Yellow and Yangtze river valleys by about 1400 B.C.E. The four wall segments of the city at Gucheng measured between 1,102 and 1,312 feet. The base of the wall was less than half the thickness of the wall at Zhengzhou, but portions along the south and west were doubled. The area believed to be the palace was roughly in the center of Gucheng.

Shang China's most important city was Yinxi, northwest of the city of Anyang, in Henan. It spanned about 14 square miles on either side of the Huan River. Excavation has occurred there almost every year since the late 1920s. Among the

remains are more than 3,000 tombs, 2,200 sacrificial burials, and about 200 residential foundations, along with thousands of artifacts in bronze, bone, ivory, jade, stone, pottery, and horn as well as a few fragments of painting. A rectangular Shang wall has been found at Anyang, but the most important part of the settlement is at Xibeigang, west of the walled area. Xibeigang was the location of the royal cemetery, with at least 13 large-scale tombs dated from 1250 B.C.E. or slightly earlier until 1046 B.C.E. Much of the residential architecture lay in yet another area, just north of the village of Xiaotun and south of the walled enclosure. Xiaotun is the site of the important tomb of Lady Hao, consort of King Wu Ding, who ruled in the 12th century B.C.E.

From Yinxu through the rest of Chinese history, the names of all primary capitals, their dates, and their rulers are known. Between 1045 and 256 B.C.E., the period of the Zhou Dynasty, China's main capitals were near Xi'an and Luoyang. Hundreds of other walled cities were built during this period as well. The first part of the Zhou, sometimes known as Western Zhou (1045 B.C.E.–771 B.C.E.) because its capital was in the western of the two locations, had two capitals, Feng and Hao, located southwest and northeast of each other, about 7½ miles southwest of Xi'an. Ten building foundations, more than a thousand tombs, and caches of bronze goods have been excavated in the area of the two cities.

The most important capital of the second half of the Zhou Dynasty, known as the Eastern Zhou (770 B.C.E.–256 B.C.E.), is one of China's most famous ancient cities. Wangcheng, literally "ruler's city," part of a larger city in the environs of Luoyang, is described in the "Kaogongji (Record of Craftsmen)" section of the *Rituals of Zhou*, a book that describes imperial and official rites and ceremonies of the Zhou Dynasty. The text sets forth a prescription for an idealized city, square in shape with three gates at each side from which three-lane thoroughfares run through the city. The only interruption to those streets is the centralized palace area. It includes the ruler's hall of audience, temples to the ancestors and to soil and grain, and markets. This idealized city plan may never have been achieved, but the description has been viewed as a standard against which all later Chinese imperial cities are compared.

Besides the major capitals, each of the states contending for power in the first millennium B.C.E. built at least one capital. More than 100 state capitals from this period have been excavated. Among the most famous is the city at Qufu, in Shandong Province, where Confucius taught around 500 B.C.E. Its plan may have followed the prescription for a royal city in the *Rituals of Zhou*. Like Qufu, other cities of major states of the Zhou, including Linzi, capital of the state of Qi in Shandong; Xiadu, capital of the state of Yan, just south of Beijing in Hebei province; Handan, capital of the Zhao state in Hebei; and Houma, capital of Jin in southern Shanxi Province, all had walled palatial sectors and at least one more walled area either adjacent to or surrounding the palace-city.

CHINA'S FIRST IMPERIAL CITIES

China's first emperor, Qin Shi Huangdi, who unified existing states in the formation of his empire in 221 B.C.E., built his national capital northeast of the early Zhou capitals Hao and Feng. Remains of palaces and countless other foundations have been uncovered, as well as pits that contained thousands of life-size warriors to guard the emperor in the afterlife. However, the outer boundary of the capital at Xianyang has not yet been determined.

Like their Zhou predecessors, the two great capitals of Han China—the earlier capital in the west, Chang'an, of the Western Han (202 B.C.E.–9 C.E.) and the later capital in the east, Luoyang, of the Eastern Han (25–220 C.E.)—are known through extensive documentation and equally extensive excavation. Chang'an is probably best known for the irregular shape of its outer wall: only the eastern boundary is a straight line. About 16 miles in perimeter, the length corresponds fairly closely to the 62 *li* (a Chinese unit of distance that varied over time) recorded in texts. The wall was between 39 and 52 feet at the base and rose more than 39 feet. The one accommodation to the ideal prescription for a city described in *Rituals of Zhou* was the presence of three gates on each side. From them emanated eight major streets, none stretching the full expanse of Chang'an in any direction.

More unusual was the presence of six palaces, five inside the walls and one beyond the western boundary. The palaces occupied most of the space inside the walls, and probably the placement of city walls was a response to the positions of palaces. Largest was Changle palace, a little over 2 square miles and built on the ruins of a palace from Qin times (221–207 B.C.E.). Weiyang palace, opposite it on the western side of Chang'an, was almost 2 square miles. Between them was an armory. Excavation and theoretical reconstruction have been conducted at each palace site. Extensive excavation has also been undertaken in the southern suburbs, the location of an ancestral temple complex that consisted of 11 individual halls and other ritual structures. Nine mausoleums for emperors and empresses spread north of the Wei River, north of Chang'an, and four more royal tombs lie in the southeast. Kilns, bronze foundries, and a mint were located in the market area in the northwestern area of Chang'an within the city walls. The population of Chang'an during the Han Dynasty was nearly 250,000.

Although its population was twice that of Chang'an and its shape more regular, the Eastern Han capital at Luoyang was less than half the size of the earlier capital. The nearly rectangular city, whose eastern and western walls, compared with the lengths of its northern and southern walls, were proportionately 3:2, had 12 city gates, 10 major street segments, and two palaces. The palaces were not used simultaneously. Like Chang'an, Luoyang had ritual structures for the same ceremonies and sacrifices in its southern suburbs. Luoyang, with its two palaces, should be viewed as a transitional imperial city in Chinese history, whereas Chang'an was largely

a city of palaces. After Luoyang, all Chinese capitals would have only one palace area. Moreover, beginning with the Eastern Han capital of Luoyang, all palace sectors would be positioned along a central north-south axis. Both Chang'an and Luoyang would be the locations of China's most important imperial cities for nearly a millennium following the fall of the Han in 220 C.E.

A strong economy and commerce throughout the country gave rise to important cities outside the capitals in Han China. Some of them, such as Linzi and Handan, had their roots in cities of the Zhou Dynasty. Others, also with earlier building periods, such as Nanjing in Jiangsu Province, Hefei in Anhui, and Chengdu in Sichuan, have remained important Chinese cities since the time of the Han Dynasty. Han military commands spread across the empire, beyond China's borders, and some cities built strong walls and defense systems that resembled castle towns of medieval Europe.

ANCIENT CITIES OF SOUTH AND SOUTHEAST ASIA

After China, remains of the most significant urban activity in Asia or the Pacific in ancient times can be found in South Asia, particularly in Pakistan and Afghanistan. In Baluchistan, Afghanistan, at the site of Mehrgarh, there is evidence of settlement in the seventh millennium B.C.E. Domestication of animals occurred in the sixth millennium, and within the next 2,500 years pottery and objects of stone and metal were produced. These developments set the stage for the Indus Valley's first true cities, represented by the largest ones, Mohenjo Daro and Harappa. In India the city of Dholavira, in Gujarat, developed at the same time.

Both Mohenjo Daro and Harappa have been known since excavations of the 1920s. More recently, Kalibangan, about 87 miles southeast of Harappa, has emerged as an important urban center. All three cities flourished during the period from about 2600 B.C.E. to 1099 B.C.E. The most striking feature of the cities was the orthogonal arrangement of streets. In other words, major streets were oriented on a grid that ran north-south or east-west. It is believed that builders first studied the movements of the sun and stars and then designed their cities based on them. There is evidence of massive walls and gates at both Mohenjo Daro and Harappa, but the cities are better known for high, wall-enclosed mounds on which buildings were raised. The highest mound, at Mohenjo Daro, rose 39 feet. Unlike the main streets, the mounds were not oriented to the four cardinal directions. Main streets were as wide as 236 feet, with narrower lanes dividing the spaces between the main streets into quadrilaterals. Both Mohenjo Daro and Harappa were situated beside rivers, the former near the Indus and the latter near a tributary of the Indus, a waterway called Ravi. Indus Valley cities had sophisticated drainage, bathing, and sanitation systems, including wells, reservoirs, and cisterns (a receptacle for holding liquids, such as rainwater). The bathing areas were separated from lavatories. Many houses had private wells, but there were also public wells in the

cities. Mohenjo Daro and Harappa were each approximately 3 miles in circumference, Mohenjo Daro slightly larger.

Harappa was marked by a large central depression, believed to have been a tank or reservoir. If this was a public space, it was not the only one. Indus Valley cities had large public buildings and great baths. Southwest of the great bath of Mohenjo Daro, beyond the outer city wall, was a large building elevated on a mound. It has been identified either as a great hall, perhaps for ritual use, or a granary. About 98 feet south of Harappa was a mound with its own houses, drainage system, and baths. This may have been a rest stop for travelers. Mud brick was the main construction material of Indus Valley cities, with wood being the next most common building material. It is believed that artisans who specialized in one material or the other worked together in city construction.

Ban Chiang, in northeastern Thailand, is the most important Neolithic and Bronze Age settlement in Southeast Asia. It is dated to about 3600 B.C.E. to 200 C.E. Bronze production in Ban Chiang is believed to have occurred by the mid-second millennium B.C.E., consistent with that of China but more than a thousand years before evidence of a Bronze Age in the rest of Thailand.

URBANISM IN NORTHEAST ASIA

Although Korea and Japan enjoyed long Paleolithic and Neolithic periods, urbanism was not part of them. There is no evidence of cities during either Japan's or Korea's Bronze Age. Korea's earliest walled cities may have been constructed as military commands of Han Dynasty China. In Japan, where the Bronze Age flourished well into the Common Era, there is little evidence of urbanism through the first several centuries C.E. It is probable that cities came about in Japan as a result of influences from continental East Asia, either from Korea or China, and that cities were first constructed as late as the sixth century C.E. City walls were built even later in Japan. Still, by the end of ancient times, cities flourished in every part of Asia. Soon thereafter, cities reached the Japanese islands in the Pacific.

EUROPE

BY JOHN COLLIS

Between 58 and 51 B.C.E. Julius Caesar conquered Gaul (modern France, Belgium, and parts of Holland, Germany, and Switzerland). In his detailed account of the Gallic Wars he talks about large defended sites that on occasion he had to attack; indeed, he spent a winter at one of them, Bibracte, composing his memoirs. Though he sometimes uses the word *urbs* (city) to describe these places, the term he normally uses is *oppidum*, meaning "defended place" or simply "town." Among the sites he lists are some that are still towns today: Geneva, Besançon, Paris, Bourges, Orléans. Others are now deserted hilltops like Bibracte (Mont Beuvray, in Burgundy), which was abandoned a couple of generations after the conquest for the more accessible Augustodunum (Autun).

Many of the sites mentioned by Caesar have been identified; they are characterized by massive ramparts, usually a single bank and ditch, surrounding areas of 100 to 1,000 acres, mostly on hilltops or promontories that could be easily defended. Caesar describes these ramparts, which he calls *murus gallicus* (Gallic wall). They consisted of several layers of timbers laid out in a rectilinear grid with iron spikes nailing them together where they crossed. The spaces between the timbers were filled with rock and soil, and the front and back were revetted (faced with a material that gives support) with walls of drystone (stones fitted together without mortar) through which the timbers protruded; an earthen ramp ran behind. Caesar notes that these barriers were resistant to fire, ramming, and sapping (excavating). Some 40 sites, including Mont Beuvray, have produced ramparts approximating Caesar's description, mainly west of the Rhine but also as far east as Manching in Bavaria. Caesar mentions other types of ramparts; one, with a massive earthen bank and wide ditch, was common in northern and central France, often replacing a *murus gallicus*.

Many sites not mentioned by Caesar have also been identified, not only in Gaul but east of the Rhine in areas he never reached: southern and central Germany, the Czech and Slovak republics, and Austria and Hungary. In these areas, however, the usual rampart is an earthen bank revetted in front by wooden posts, with the gaps filled by drystone walling.

Finds from these sites show that they were being constructed from the late second century B.C.E. onward, though some in central Europe may date to as early as 180–150 B.C.E. There had been a long tradition of constructing defended sites in temperate Europe extending back to the fourth millennium B.C.E., but the *oppida* tend to be much larger than these early sites, implying a higher level of social organization. Farther north, in Poland, northern Germany, and Scandinavia, urban sites did not appear until the late first millennium C.E. The *oppida* also contrast with the defended sites on the Mediterranean coast in southern France and eastern Spain, which were much smaller and more closely spaced, more like “city-states” than the “tribal” states that produced the *oppida*.

BEFORE THE *OPPIDA*

Although the *oppida* are often called the “earliest towns north of the Alps,” they did not appear from nowhere; sites with urban characteristics existed as early as the sixth century B.C.E. in western Europe. In 600 B.C.E. refugees from the Greek city of Phocis founded the colony of Massalia (modern Marseilles) near the mouth of the Rhône in southern France. Trade linking the developing civilizations of Greece and Italy with central and western Europe had started earlier, but it expanded rapidly after the foundation of the colony, and fine pottery from mainland Greece, wine amphorae (large pottery jars for shipping and storing liquids and other goods) from southern France, bronze vessels from Italy, and other luxury goods turn up on a number of trading sites that were established along the main river routes leading into the in-

terior. Bronze buckets from northern Italy are found as far north as southern Sweden.

The major route led northward along the Rhône and its tributaries the Saône and the Doubs. At Lyons, where the Rhône meets the Saône, a major settlement has been identified on the banks of the Saône. A bit farther south, at Vienne, a similar settlement was established where land routes between the upper Loire and northern Italy crossed the Rhône. Bragny on the Doubs, near its confluence with the Saône, controlling the route that leads northeast up to the Middle Rhine and the headwaters of the Danube. Although these sites seem mainly to have been ports for river traffic, Bragny was also involved in producing iron and bronze goods, and a site on the Dürrnberg in Austria was associated with salt mining, although its inhabitants engaged in other industries as well.

The most spectacular evidence for this trade system, however, comes from farther inland, from sites controlling the headwaters of rivers that lead away from the Rhône valley toward the Atlantic, the Baltic, and the heart of Europe. The Heuneburg, in southern Germany, overlooks the point at which the Danube becomes navigable; Asperg, near Stuttgart, controls the Neckar, a tributary of the Rhine; in France, Mont Lassois overlooks the upper Seine and Bourges the confluence of two tributaries of the Loire. At most of these sites there is a small central hill fort; at the site of the Heuneburg the fort was defended by a wall made of sun-dried brick with bastionlike towers, features unknown at this period anywhere else outside the Mediterranean area. Inside, a thriving settlement produced metal objects and other goods, and surrounding it a concentration of other settlement areas likewise engaged in industry and trade, as the imported Mediterranean artifacts show.

What makes some of these sites stand out are the exceptionally rich burials under massive tumuli (artificial hills or mounds of earth or stone). The Hohmichele at the Heuneburg, Hochdorf at Asperg, and Vix at Mont Lassois are the richest prehistoric burials from central or western Europe, featuring large wooden chambers, four-wheeled vehicles, rich gold objects, and spectacular imported luxury goods like, at Vix, a bronze vessel for mixing wine that stands nearly five and a half feet high. These graves are presumed to be those of “chieftains” who controlled and grew wealthy from the trade in goods gathered locally as tribute and “gift exchange.” Bourges is more enigmatic; the settlement is richer than the others in terms of the quantity of imported goods, but it lacks the exceptionally rich burials, and a central defended site has yet to be identified. The site consists of a cluster of areas of occupation, with extensive evidence of industrial activity, especially bronze production, manufacturing brooches and other ornaments. The site seems to have been occupied for only a short period in the late sixth and the fifth centuries B.C.E., perhaps three or four generations.

These developments toward urbanization were short-lived. The very rich burials disappeared, and Mediterranean

imports into temperate Europe became scarce. Mont Lassois and the Heuneburg had already been abandoned soon after 500 B.C.E. Bourges and Asperg may have survived until as late as 400 B.C.E., but the trading systems had collapsed, one factor being an economic downturn in southern France, perhaps owing in part to the political conflicts at that time in the Mediterranean among the Etruscans, Carthaginians, and Greeks as well as the unrest in northern Italy caused by the Gallic colonization.

In the third century B.C.E. the economic situation in temperate Europe revived. Although renewed contact with Italy (Etruria and Rome) was one element in the revival, it played only a partial role, as imported wares such as fine pottery remained rare until the second century B.C.E., when there was an enormous upsurge in imported goods, especially amphorae manufactured at sites on the west coast of Italy such as Pompeii, Cosa, and Albinia. These turn up by the thousand in central France; their main contents were wine, but they were also used for other goods such as olive oil and *garum* (fermented fish paste). From the third century coinage was also adopted, mainly based on Greek prototypes. Initially only gold was used, but by the second century lower-value coins of silver and bronze appeared, allowing lower levels of transactions and perhaps also the appearance of market exchange alongside the traditional gift exchange and barter.

This surge in economic activity led to the establishment of settlements that in some cases were the direct predecessors of the *oppida*, in that they were abandoned when the population moved to nearby hilltop sites, as in the cases of Levroux, Basel, and Breisach. These early sites were much bigger than normal farming settlements or hamlets, usually at least 25 acres in size, and they stand out not merely for their exotic imported goods but also for the presence of a range of industries working materials such as iron, bronze, glass, shale, and bone to produce weapons, tools, and ornaments. A few of these sites, like those of the fifth century, lie on major trade routes (Basel and Breisach on the Middle Rhine, Manching on the Danube), but most seem rather to have been administrative or market centers (Levroux and the newly discovered site of Bobigny in the northern suburbs of Paris).

In central Europe the sites seem more industrial in nature, as at Mšecké Žehrovice in Bohemia, which specialized in making shale bracelets that were widely traded, as well as iron from local ore. Clearly some inhabitants of these sites were artisans and possibly traders, and at Manching small wooden houses showing evidence of various industries cluster along the main east-west road paralleling the Danube. But Levroux and Manching also had fenced enclosures like those found on the later *oppida*, and they seem to have been farms that also engaged in industrial production; they are usually interpreted as the residences of a rich farming elite who were becoming increasingly important in these societies. None of these sites have rich burials like those of the sixth century. The cemetery at Bobigny, while wealthy for its period (male burials with weapons, a couple of imported Italian pots),

does not have the rich gold objects or high-status imports found in earlier burials, and the cemetery at Basel seems positively poor.

One site stands out as exceptional: Aulnat, just east of Clermont-Ferrand in the Auvergne of central France. Like the other sites, it is not on a major route; instead it sits on very rich agricultural land. It is a concentration of areas of dense occupation covering an area measuring at least one and a quarter miles by a third of a mile by the late second century B.C.E. Despite its large size, it reflects the general pattern of the other settlements, with a range of industries (minting of gold and silver coins, working of bronze and iron, manufacture of glass and bone objects, and probably production of textiles). In its early phases, in the late third century B.C.E., imported items were rare—some coral as inlay for brooches and a few fine vessels and cooking utensils. This was followed by the upsurge in the second century B.C.E. of importation of wine amphorae and fine pottery.

There is also a structure identified as a shrine, with associated offerings (notably the burial of a horse with its gear). There are many burials and small cemeteries scattered around the settlement, though again the very richest contain only items such as swords, and none are very rich by Iron Age standards. But for this area we have documentary evidence from Greek authors such as the ethnographer Poseidonius. He relates how the Arverni (after whom the Auvergne is named) were the most powerful state in Gaul in the second century B.C.E., controlling an area “from the Rhine to the Atlantic” and extending into southern France. Their king Luernios was described as the “richest man in all Gaul” and his son Bituitos, after the defeat by the Romans of his army in southern France in 123 B.C.E., was paraded in Rome in his chariot “of gold and silver.” Aulnat seems to have been the center of this powerful state.

THE FOUNDATION OF THE *OPPIDA*

Several of the open sites were direct predecessors of the *oppida*, as they were abandoned at precisely the time when new defended sites were established on nearby hills: Basel, Breisach, Levroux, and Aulnat. Only at Manching did the open site itself go on to become a defended site. There the open settlement had continued expanding until, by the time a *murus gallicus* rampart was placed around the site around 120 B.C.E., it was nearly a mile in length, enclosing some 1,000 acres. Almost the whole area, which included a port site on the Danube, was densely occupied.

For most of the *oppida*, however, we do not know where the population came from. There will probably be more open settlements discovered, especially underlying modern towns. But in some *oppida* we are probably seeing the nucleation of people from many smaller settlements of a nonurban nature—in short, the deliberate foundation of a city where none had existed before. This, of course, implies a central organization capable of making the decision to found a new site, with the vision and knowledge of what was needed and the

political, legal, and economic power to sustain the settlement once it was established. Caesar refers to the “tribes” of Gaul as *civitates*, a word best translated as “states,” and he talks about ways in which the states held meetings to govern their affairs (for example, the *senatus* of the Aedui or the popular gatherings of the Treveri), the election of magistrates (such as the elected chief magistrate of the Aedui), and the collection of taxes (for instance, the auctioning of the right to gather tolls from the traders among the Aedui).

The reasons for this abrupt change in settlement pattern, from open to defensive positions, is not clear, especially in central Europe, where we have no information on events from the written sources for the early second century when the *oppida* were founded. The dates for southern Germany, Switzerland, and France of around 120 B.C.E., however, correspond closely to the Roman invasion of southern Gaul in 125–123 B.C.E. and the defeat of the Arverni. With the collapse of the major coalition, there may have been a power vacuum that led to conflict by new competing powers. By the time Caesar arrived 60 years later, although the Arverni were still a major force, they had been eclipsed by the Aedui based in Burgundy and the Sequani to the east in the Franche Comté.

Not all of the *oppida* succeeded; some sites were founded and their defenses constructed, but we have little evidence for much occupation of them. In some areas, especially in western France, *oppida* were not established at all, even in places where we have evidence for major open settlements. So the pattern is not uniform.

Within the *oppida* there was considerable difference in the types of houses, indicating that the population covered the whole range of the society. At the top of the hierarchy were fenced enclosures containing a number of buildings, some of which seem to have been for agricultural purposes (stables, barns, and granaries) and others for industrial activities such as iron- and bronzeworking, coin production, as though some aspects of production were under close elite control. At Mont Beuvray one or two of these enclosures evolved, first into large timber houses and then, after the Roman conquest, into luxurious stone houses with courtyards, mosaic pavements, heating systems, and elaborate painted walls, comparable to the best Mediterranean houses. These were clearly the residences of the aristocrats who formed the leading groups within the oligarchic states that Caesar describes.

There are also industrial areas with small buildings such as those along the main street at Manching. The best preserved are those excavated at Mont Beuvray, initially built in timber but again, after the conquest, reconstructed in stone, indicative of an independent and increasingly wealthy artisan class. At Mont Beuvray the houses seem to have been of two stories, with double rooms on the ground floor, one of which was devoted to industry (the casting of brooches, forging of iron tools and weapons, production of glass ornaments, objects with enamel inlay, and so on). It is less easy to identify public areas such as market squares. Some of the sites had temples, but temples are more a char-

acteristic of the countryside in Gaul, where sanctuaries that were to continue into the Roman period started appearing from the fourth century onward.

Although many of these sites evolved into permanent settlements, in some areas they were inhabited for only a generation or two. This is most clear in the Aisne Valley in northern France and in the Auvergne, where we can identify series of sites, one succeeding the other; in the Auvergne parts of the earlier sites did continue to be occupied. The large open settlement at Aulnat was completely abandoned at the end of the second century B.C.E. in favor of a hilltop site at Corent, centered on a religious enclosure. Although the temple remained in use, the majority of the population moved to a more low-lying site at Gondole overlooking the river Allier, and this, too, had a ritual area just outside the defenses, where pits containing skeletons of men and horses have been uncovered. By the time Caesar arrived, the center of population was on a nearby hilltop, the site of Gergovia, which he besieged unsuccessfully. This site, too, was abandoned a couple of generations after the conquest in favor of the nearby town of Augustonemetum, though the temple site continued in use. Clearly the shifting of the town required considerable expense and resources, and the reasons for these shifts are unclear. It was more common for the sites, once founded, to continue in use, and many Roman towns in Gaul, both provincial capitals and smaller centers, are now known to have pre-Roman origins.

OTHER AREAS

The coastal areas of southern France and eastern and southern Spain had been subject to colonization first by the Phoenicians (for example, at Cadiz, though some settlements were little more than small intermediary trading centers with few urban characteristics) and then from 600 B.C.E. by the Greeks, most notably at Massalia (Marseilles) and Emporion and Rhode (Ampurias and Rosas, in northwestern Spain) which in their turn established their own colonies. The model for all these sites was the “city-state” controlling only a small amount of territory and mainly reliant on the sea for its external contacts.

These sites were certainly one factor that led to urbanization among the native peoples labeled as Ligurians and Iberians; a plethora of defended sites developed in the hinterlands of foreign colonies as well as along the river Guadalquivir in central southern Spain, though they certainly were not set up in the image of the Greek sites. They were mainly defended sites on hilltops surrounded by impressive drystone walls with projecting towers to allow cross fire, as at Entremont in Provence. However, certainly in southern France, the internal structure was very different from the colonial sites—lacking, for instance, the massive public buildings and temples that dominated Greek cities.

The road system, often rectilinear, was designed to give access to blocks of houses that were generally very uniform in plan, with rarely more than a couple of rooms on the ground

floor, though there is evidence that most had a second story. The only cult sites were unpretentious, incorporated into the blocks of domestic buildings and seemingly dedicated to hero or ancestor cults rather than a pantheon of gods. The enclosed areas varied considerably, from small villages to sites of several acres, but show nothing like the massive size of the *oppida* of central Gaul. By the time of the Roman conquest, when we start to gain information about the administrative units, they were generally small. Although some of these sites developed into major cities such as Nemausus (Nîmes) under Roman rule, many of them were not urban; rather they were a nucleation of the total population, with little evidence of smaller settlements around. Naturally, these sites were also centers of industrial and trading activity.

The Iberian Peninsula was complex, with almost the full range of types of societies found elsewhere in Europe, from major foreign colonies such as Ampurias, Cartagena, and Cadiz to communities based in small hill forts in the north and northwest. In the Iberian-speaking areas there is evidence for defended sites—for instance, in the Ebro Valley—as early as the Late Bronze Age (2800–700 B.C.E.), but only from the seventh century onward did complex defended sites appear in numbers in eastern and southeastern Iberia. Some of these were comparable to those in southern France, with towers and ramparts on stone footings. Some of the earlier sites, such as Cortes de Navarra and Cabezo de Monleón, consist of a series of almost identical conjoined houses with little sign of social differentiation, but by the sixth to fifth centuries at sites such as Puente Tablas near Jaén there are more elaborate houses with several rooms around a courtyard, indicative of a more complex society.

In the immediate hinterland of Ampurias, the 27-acre urban site of Ullastret, dating to the fifth century B.C.E., was enclosed by a massive stone wall with towers. In size these *oppida* are comparable to those in southern France. Inland, however (for instance, around Ávila), there are massive sites more like those of central France: Ulaca, whose double enclosures encompass about 200 acres, and La Mesa de Miranda, which in its final stage enclosed about 70 acres. Even within one tribal area there are very different patterns of settlement.

In Britain there is a group of sites labeled by archaeologists as *oppida*, but they are very different from the continental sites. They date somewhat later, from the late first century B.C.E. to the middle of the first century C.E. Several of them, such as Colchester, Saint Albans, and Silchester, developed into major Roman towns after the Roman conquest in the 40s C.E. They are characterized by linear boundaries or “dikes” that cut off large expanses of land, in the case of Colchester roughly 8 square miles, in which various activities were concentrated. We know that Colchester, the ancient Camulodunum, was the “capital” of the “king of the Britons” Cunobelin, who controlled much of southeast England in the period before the Roman conquest, and his gold coins bear the name of the site. It included a port area that shows evi-

dence of industrial activity, such as coin and pottery manufacture, and of extensive trade with the Roman Empire. There is also a temple enclosure, some probable royal burials under large tumuli, and a possible royal residence.

GREECE

BY TOM STREISSGUTH

To the ancient Greeks the city (*polis*) was the hallmark of civilization. The city provided the Greeks with an identity, with culture, and with the means to live well. Urban manners, arts, trade, and government—along with their language—marked the Greeks as civilized, in their own eyes, and not as barbarian outsiders.

While a Greek “nation” did not yet exist, Greek cities were the basic geographical, political, and social units. Every Greek citizen first identified himself with his family and clan and then with the city to which he belonged. He lived as the member of that city, no matter where he resided or moved, with his citizenship permanently conferred by birth. When voyaging abroad, he called himself by his given name, his father’s name, and by the city where he came from. He fought and died for the polis, if called on to do so, and aspired to serve it as a civic leader.

The ancient Greeks gave much thought to the form of the city. While their philosophers and mathematicians sought perfect forms in the natural world, their town planners strived to build a logical system of streets, districts, and public places. The Greek city was renowned for its orderliness and sense of proportion as well as the civic pride displayed in the form of buildings, monuments, temples, schools, theaters, and other structures that served the public interest.

EARLIEST SETTLEMENTS

The Greek world of the Mycenaean Age (to about 1200 B.C.E.) had no towns of any large size. It was a farming society ruled by kings who lived within palace complexes of homes, barracks, and markets. These strongholds relied on the surrounding farms for their sustenance; trade took place from harbor to harbor, and many coastal settlements also relied on piracy. During the Bronze Age in Greece (to about 1050 B.C.E.), farmers lived on communally owned land within extended families. The *genos*, or family, lived in or near a stronghold raised for their mutual defense. The families associated themselves with a tribe, whose members shared a common founding myth and ancestor and who belonged to a single religious cult.

The families of the tribe shared a meeting place and market center near their defensive stronghold, which was also known as an acropolis, or “high city.” The acropolis was situated on the crown of a hill, usually near a harbor but some distance from the shore to protect against raids from the sea. Beneath the acropolis was the agora, or marketplace, where the people could meet to buy and sell their livestock, tools, weapons, and crops. Although home industry provided most

of life's necessities, only craftsmen had the needed skill and equipment to forge good weapons and tools, to cast jewelry or armor, or to paint pottery with scenes of the gods and heroes. Workshops and forges raised near the agora provided access to the marketplace and to traders who bought and sold goods across the seas. Nearby forests and public quarries provided raw materials for construction, for pottery, and for iron and bronze forging.

Permanent settlements grew near the agoras and fortifications. The first large Greek towns were built on the island of Crete and in Ionia (the islands of the eastern Aegean and the nearby coast of Asia Minor), the most prosperous region of the early Greek world. The Ionian cities, including Miletus and Smyrna, had the essential ingredients for successful towns: an extensive hinterland that provided food, wine, and oil as well as a market for crafts such as pottery and tools. The cities of Ionia also lay astride busy trade routes between the Aegean, the Black Sea, Egypt, and the Levant.

In the early Greek cities regular blocks shared unpaved streets that led from the town gates to central public squares. The houses had several rooms, with some rising two stories in a wing set back from the street. Alleys separated the blocks and provided drainage for rainwater and wastewater. In the outer districts and in smaller settlements, haphazard, unpaved lanes meandered among the private homes and workshops.

From the beginning of the Archaic Period (ca. 600 B.C.E.) and the earliest Greek writing, many Greek settlements became entirely self-sufficient, their inhabitants having the skills or the wealth to live independently off the land. In contrast to farming settlements, these towns gave rise to distinct social divisions. At the top was an urban aristocracy, men who were responsible for civic affairs, for lawmaking, for settling disputes, and for leadership in war. The members of this class held full membership and rights in the city. Women, children, and foreigners did not hold the privileges of the citizenry; slaves—most gathered by war and piracy—had no legal rights whatsoever and could be disposed of in any manner their owners saw fit.

By the process of *synoikismos*, several villages unified themselves into a polis, or city-state. The most significant such event in Greek history was the confederation of several villages in Attica, a peninsula of southern Greece, to form the polis of Athens, an act that by the city's tradition was carried out by its founder-king, Theseus. Other leading city-states were Thebes, Sparta, and Corinth; Delos and Rhodes were prominent island-states in the Aegean region. In some places this unification took place without a physical center, and so the polis could simply mean a political alliance among extended families or villages. But in most cases cities had such a center, as well as a gymnasium or school, public halls, a theater, a temple, and water delivered through public fountains. The city reserved to itself the authority to mint coins, to regulate the calendar, to keep standard weights and measures, and to set down the proper timing and duration of religious festivals.

Grain inspectors, superintendents of the markets, and port overseers watched over commerce. A city might depend for its existence on the export of its marble, silver, wine, timber, or flax; to keep careful control over trade in this item was the difference between success or failure, wealth or starvation.

THE INNOVATIONS OF HIPPODAMUS

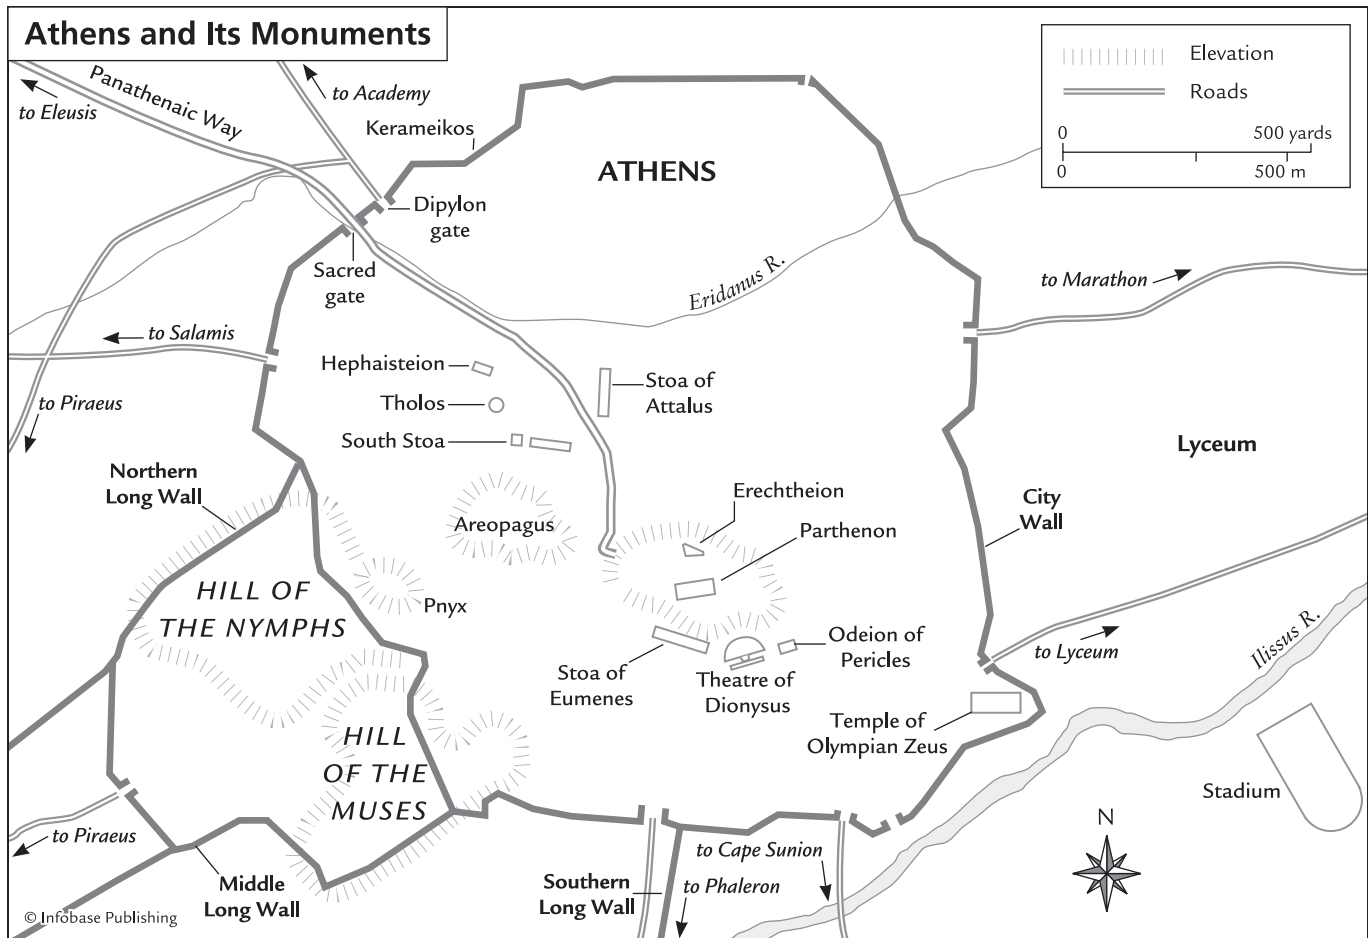

The architect Hippodamus of Miletus is the first-known city planner in Greek history. According to historical tradition, Hippodamus created the orthogonal (rectangular) pattern of streets that came into vogue during the Classical Period (starting in the fifth century B.C.E.). In fact, Hippodamus was not the first to create a regular street grid, but he did apply his philosophy of the ideal city to his Ionian hometown, thereby setting a standard for new Greek towns raised in the centuries to come.

In the ideal city of Hippodamus, the citizens of the polis were divided into artisans, farmers, and soldiers, while the land consisted of religious, public, and private zones. He carried this tripartite division to Miletus, which was rebuilt in 479 B.C.E. after its destruction by a Persian army. Hippodamus laid out three main sections, divided by the city's two harbors. The central agora and public buildings were raised in a low-lying precinct, while the city's theater was built into the side of a hill overlooking the main harbor; on the other side of the harbor was a temple dedicated to the goddess Athena (at the smaller harbor, known as the Lion Harbor, stood a temple of Apollo). A highway linking the city to sacred precincts in the countryside led away from the wall at the southern edge of the city. After it was rebuilt by Hippodamus, Miletus grew to a population of 100,000, one of the largest cities of ancient Greece, and boasted three large covered markets, one of them made of fine marble and surrounded by galleries two stories tall.

The renown of Hippodamus spread to Athens, which had become the wealthiest city of the Greek world. Athenian leaders invited Hippodamus to lay out the streets of the new harbor town of Piraeus, near Athens, as well as the colony of Thurii in southern Italy. The Hippodamian plan was imitated, or applied by him personally, at Olynthus in Macedonia, at the city of Rhodes, and at the town of Priene. The rectangular grid, and the idea of specialized precincts carefully laid out within that grid, became a convention throughout the Greek world, even on hilly ground and mountain slopes where the terrain made surveying and construction on such a plan difficult.

PUBLIC AND PRIVATE BUILDINGS

The cities of ancient Greece grew by absorbing nearby settlements and by commerce, which earned money and attracted foreign traders and fortune seekers. By proving their merit, these outsiders could win citizenship, granted by a vote in the public assembly. Wealthy rural landowners also built homes in the city to enjoy its services and entertainments, to conduct business in the agora, and take

Ancient Athens reached its zenith in the fifth century B.C.E., when its population numbered around 300,000, of whom 40,000 were citizens.

part in city government, which was considered a right and duty of every citizen.

Civic leaders regulated their city's physical layout by controlling the height of buildings and the width of streets and by restricting certain activities to particular zones. The agora remained the central meeting place or town square in addition to being the center of public commerce. Surrounding the agora were one or more stoas, long and low buildings with shops and arcaded walkways for the use of the public. The stoa provided shelter from the elements and served the public as a meeting place.

The *bouleuterion* was a place for the meeting of the boule, or city council, whose members arranged themselves on tiers of seats set around a central platform for speakers. The *prytaneion* was the ancient Greek city hall, which held the offices of the executive committee known as the *prytaneis* as well as offices for the magistrates who received state guests and ambassadors. The symbolic heart of the city, the *prytaneion* was home to a sacred flame, which was always kept burning. Some cities had a *tholos*, a circular building used for public ceremonies, such as sacrifices and state banquets, and for meetings and meals of the *prytaneis*.

An important function of the city was to provide pleasant occupation for a citizen's leisure time. A *balaneia* was a public bath that held bathtubs made from stone or glazed terra-cotta brick, set in rows, and with running water that could be heated over a fire. An *odeion* was a roofed hall used for musical performances. The earliest Greek theaters consisted of wooden benches set into a hillside in a semi-circular layout. From the fourth century B.C.E. on, theaters grew to rival the agoras as places of public assembly. The finest had several dozen tiers of raised seats built in stone or marble, often with an expansive view of a valley, harbor, or city from above.

Gymnasia were public buildings raised for education of the young. The gymnasium had an open courtyard for physical training, a running track, and a colonnaded hall similar to a stoa, with rooms for instruction and for public speaking. A *palaestra* was a building for athletic training, with small changing rooms surrounding a central courtyard. The stadium was a running track, with banked sides for the use of spectators.

Private homes were small and simple, built of dried brick or cob, a mixture of wet clay and straw. They were

built separately, though many large Greek cities had tenement blocks. The front entrance of the home faced south, with a small entrance hall beyond which was an enclosed central courtyard. Living rooms were at the back of the home, arranged around a portico or courtyard; separate servants' quarters, kitchens, and reception halls were also situated around the ground floor. Finer homes had bathrooms as well as second-story galleries over the porticoes, where separate women's quarters were located. City homes were furnished with beds, chests, tables, chairs, carpets, and tapestries and were provided with clay and metal drinking vessels and storage jars. Walls were whitewashed and sometimes painted with geometric designs. The homes of the wealthy displayed wall frescoes and mosaic floors.

NEW CITIES ABROAD

During the fifth century B.C.E. the polis of Athens reached the height of its power and prosperity. About 40,000 citizens belonged to Athens, among a total population of about 300,000. Sparta held far fewer citizens but included a large number of serfs and slaves and a group of autonomous people who lived in the city's vicinity; altogether the Spartan city-state included about 250,000 people.

As the cities of Greece grew, overpopulation prompted overseas colonization. Greek colonists built new cities on the coasts of the Black Sea, in Sicily, on the Adriatic Sea, in North Africa, and Egypt. Greek town planning in Magna Graecia, in modern-day southern Italy, had a strong influence on republican Rome. A Greek polis was first and foremost a body of citizens, and if it moved overseas to a colony site, the colonists still identified themselves as members of a city. They were dependent on their homelands for goods and trade, for protection from coastal raids and pirates, and for the masons, carpenters, and other tradesmen who could provide essential services in the new territory.

The conquests of the Macedonian general Alexander the Great (r. 336–323 B.C.E.) in the fourth century B.C.E. spread Greek culture and cities into western Asia, from Egypt to the Levant to Afghanistan. New Greek towns and camps were raised where Alexander's armies had passed, and in defeated foreign capitals Greek temples, columns, statuary, and public buildings appeared as monuments to Greek civilization.

As his most enduring monument Alexander envisioned a trading city on the Mediterranean shores of Egypt, at a sheltered point between Lake Mareotis and the island of Pharos. After Alexander's death in Babylon in 323 B.C.E. and under King Ptolemy I (r. 323–285 B.C.E.), Dinocrates of Rhodes laid out the city of Alexandria on the site of a small fishing village, Rhakotis. The new town had two main avenues, 200 feet wide and lined with colonnades, running north-south and east-west. The side streets crossed at right angles, in the Greek fashion. The city had abundant fresh water drawn from Lake Mareotis, as well as street gutters that drained into subterranean canals that lay underneath every street.

Alexandria prospered as the capital of Ptolemaic Egypt. A flourishing center of Greek learning and culture, which endured long after the conquest of Greece proper by the Romans, the city boasted impressive monuments, including the tomb of Alexander, the lavish royal palaces of the Ptolemaic kings, a monumental temple known as the Serapeion (also spelled Serapeum), a museum, and the Library of Alexandria,

THE DECLINE OF THE CITY-STATE

Rivalries among the Greek cities worsened in the fifth century B.C.E. as populations rose, trade routes grew more crowded, and the Persian Empire threatened invasion and conquest. The Peloponnesian War set Athens and her allies against a federation led by Sparta, and it forced all other Greek cities to choose sides. The war brought widespread death and destruction and ended the dominance of Athens over the Greek world. It prepared the Greeks for nationhood—and for the end of the independent city-state.

In the semibarbarous northern realm of Macedon, the ambitious King Philip II (r. 359–336 B.C.E.) aspired to lord it over a weakened Athens and the entire Greek world. He seized the gold and silver mines of northern Greece and raised allies to work for his own interests in all the major cities to the south. Thebes allied with Athens to resist the Macedonians, but the Greeks were soundly defeated at the Battle of Chaeronea in 338 B.C.E. Leading one wing of the Macedonian troops in this battle was Philip's 17-year-old son, the future Alexander the Great.

Chaeronea marked the end of Greek resistance to Philip of Macedon. Soon after the battle, he organized the League of Corinth to fight the Persians, who remained a constant threat. Each member of the league was allowed to keep its own constitution, but a national assembly began meeting at Corinth, and Philip raised a new Greek army, under his personal leadership, by levying troops from all the corners of the Hellenic world.

Although Philip was assassinated in 336 B.C.E., his goal of uniting all the Greeks under a Macedonian dynasty was realized by Alexander, a brilliant military tactician. Philip's young heir traveled to Corinth, where representatives from all the major Greek cities hailed him as their nominal king. He took the reins of the national army and, when the city of Thebes rebelled against him, besieged the city and burned it to the ground. The traditional, independent city-state of Greece, an institution dating back a millennium, grew obsolete under Alexander's reign and the subsequent conquest of Greece by the Romans.

the most famous and largest library of the ancient world, which held more than 200,000 books. Alexandria attracted a Mediterranean melting pot of Greeks, Jews, Phoenicians, Egyptians, Arabs, and many other nationalities. Textile, furniture, pottery, glassware, and papyrus industries flourished; Alexandria also served as Rome's principal Mediterranean grain port.

To handle the trading fleets that called at Alexandria, the city had two large sheltered harbors divided by the Heptastadion, a dike that ran nearly a mile from the mainland to the island of Pharos. At night the ships were guided by the tall lighthouse known as the Pharos of Alexandria, one of the seven wonders of the ancient world. The east harbor was known as the War Harbor and the west harbor as the Merchant Harbor. A canal linked these harbors with Lake Mareotis, from which another canal ran to the Nile River.

As a city, Alexandria was surpassed only by Rome in its reputation as a center of trade, learning, and culture. The city endured long after the fall of the Western Roman Empire, though most Alexandrian monuments vanished after Egypt was conquered by the Arabs, and the capital moved to Cairo, the basic layout of the city survived and is still in evidence. More important, the political institutions of the Greek city had a lasting influence in Europe, where citizenship is still prized and democratic government remains the ideal.

ROME

BY KIRK H. BEETZ

Ancient Romans regarded their cities as essential statements of what it meant to be a Roman. They built their cities to be centers of politics, commerce, and culture and, in newly conquered territories, to draw native peoples into the Roman way of life to the point that their ways were indistinguishable from those of Roman citizens. Indeed, where Roman cities took hold, even outside Italy, after a few generations the local people were often declared Roman citizens, with the same rights and responsibilities as citizens born in Rome.

The first Roman city was Rome itself. Ancient Roman historians placed the founding of Rome in 753 B.C.E., but modern archaeology has found graves in Rome dating at least a century earlier. Rome began as a small village on Palatine Hill, one of the famed "seven hills" of later Rome, overlooking the Tiber River. The settlers were probably Latins, an ethnic group that populated central Italy. Archaeological evidence indicates that another village on a nearby hill merged with the one on the Palatine, beginning an expansion that would produce the greatest metropolis of its time.

According to Roman accounts the brothers Romulus and Remus (probably Etruscans, the dominant military and commercial power in the area) settled in what was to become Rome, and Romulus founded the city. To the Romans, a city was not a true city unless it rested on sacred ground. Romulus laid out the town's dimensions by plow-

ing a square around Palatine Hill, leaving gaps for gates. (Because of this legend, Romans considered the Palatine the true Rome, the center of the city's spirit.) Wherever the ground was plowed, diabolical spirits from within the earth supposedly could rise to the surface. Thus people were forbidden to cross the ground Romulus had plowed; they could enter Rome only through gates. For ancient Romans anyone who entered a city over the plowed ground rather than through a proper gate had to be killed in order to save the city from ill fortune brought by the diabolical spirits. Romulus killed his brother Remus because Remus jestingly jumped over the plowed ground.

In building new cities, Romans traditionally engaged in a ceremony based on Romulus and his plow. After first checking for signs from the gods that the site was acceptable to them, the chief builder, while wearing a toga, used a bronze plow pulled by two white cattle, one male and one female, to cut a square or rectangular perimeter for the city, lifting the plow over the areas where the gates were to be. Walls were built around the outside of the plowed ground. (The walls could be serious structures for defense, but in secure areas they were often more for show, forming a statement that within them was a sacred Roman city.)

Every city that Romans built from scratch was oriented north-south and east-west as marked by two main roads. The north-south road was called the *cardo* and the east-west road the *decumanus*, and they crossed in the center of the city. It is not known why the *cardo* and *decumanus* were so important—possibly they had religious significance—but they were among the first things a city designer laid out, even before plowing the sacred barrier. In Rome building and rebuilding gradually covered over its original *cardo* and *decumanus* roads, and as the city's relations with the rest of the world grew, several other major roads radiated out from it into the countryside.

The Romans borrowed some of their rituals for founding a city from the Etruscans, including the creation of a *mundus*, a circular pit dug near the center of the city. Here again communication with the earth's diabolical spirits was possible. The *mundus* was covered with a stone slab, on which offerings such as food were left. Three times a year the slab was removed, giving the spirits access to the city, and on those days no business of any kind was conducted, because it would be doomed to failure. In Rome the *mundus* was occasionally paved over and seems to have been moved a few times to accommodate the city's growth.

THE CAPITOL AND THE FORUM

Essential to any Roman city's spirituality was its capitol, usually located in the center of the city. The capitol—the name comes from the Latin word for "head"—was not a governmental complex in the modern sense but contained temples dedicated to deities important to the city. Rome had three temples in its capitol, one dedicated to the chief god, Jupiter; one to his wife, Juno; and one to Minerva,

Roman silver coins, 275–260 B.C.E., depicting the founding twins of the city of Rome, Romulus and Remus (© The Trustees of the British Museum)

goddess of wisdom. All capitols were built on high ground; Rome's was on the Capitoline Hill. If there was no natural high ground, a platform was built to raise the capitol above the surrounding area. Residents believed that the gods represented in the temples were their city's protectors, and that they could only protect what they could see from the capitol.

In conquered territories a city's capitol might hold temples to local gods, with their names changed to those of Roman deities. For instance, in the cities of former Phoenician colonies the Romans conquered in North Africa, they built capitols with temples dedicated to the god Baal but changed Baal's name to Saturn. Beginning with Augustus Caesar (r. 27 B.C.E.–14 C.E.) Roman emperors themselves began to be declared gods, and capitols throughout the empire began to include temples to the emperors and members of their families who had been declared gods, such as Augustus's wife, Livia. In some parts of North Africa all the old temple gods were replaced by emperor-gods, perhaps because the armies of the emperors offered more obvious protection than did the old gods.

These practices led to conflict in some colonial cities such as those in Palestine, where Jews worshipped only one god and were forbidden by their faith to worship any others. To the Romans no city was protected from evil without a capitol on high ground, and they seem to have had trouble understanding why anyone would object to such a thing, especially when they were willing to let the local people worship whatever gods they preferred, if perhaps under the names of Roman gods. The process of Romanizing people included ac-

climating them to Roman ways of worship, and it worked almost everywhere, but not in Palestine.

Besides the capitol, every Roman city had another public area that was in some ways even more important: the forum. This was the center of civic life, the place where vital news first circulated and where citizens debated the key issues of the day. It was the heart of any Roman city. The typical forum was a rectangular, flat open space, usually paved, of varying size from city to city, and bordered by the buildings for the city's basic institutions. The forum did not originate with the city of Rome; earlier examples have been found in southern Italy, perhaps influenced by the ancient Greek agora (literally "marketplace" but extended to mean an open meeting place in a city). But the famed Roman Forum was the model for all that followed.

The Roman Forum was established in a marshy valley near the Tiber. In its early days it was plagued by mosquitoes and the diseases those insects carried, and the river sometimes flooded it. Between 616 and 579 B.C.E. King Tarquin had a canal dug to drain the area; in the 100s B.C.E. this canal was covered and became a sewer. At first people seem to have built homes haphazardly around the Forum, and apartment houses called *insulae* ("islands") were crowded together. The Forum itself was always kept clear and was reserved for pedestrians only.

Forums generally had colonnades on one or more sides, often with shops selling food or other goods. Nearby buildings commonly included a basilica and a curia. The basilica was a rectangular open building with a flat roof. Rome had one of the largest, the Basilica Julia, its floor

area only slightly smaller than a football field. The basilica was primarily a market space for private businesses, but it often included a dais called a “tribunal,” where courts of law held session. The curia was a hall where senators had their meetings. Senators tended to be from the social elite, mostly aristocrats. During the Roman Republic (509–27 B.C.E.) they were the primary governing body of the city and its empire. In cities other than Rome the curia housed meetings of officials who functioned much like senators for these localities.

FOUNTAINS AND PUBLIC BATHS

To the Romans no city was truly a city without enough water to meet the basic needs of its population. First and foremost this meant water to supply public fountains, from which anyone could gather it for free. Fountains became standard parts of a Roman city, and in Rome itself they were everywhere. Next there had to be enough water for people to bathe daily in the public baths. Public baths were built in every Roman city and were considered to be part of what made a city livable. Even small cities had several such baths. (Although it was not the norm, some private homes also had baths. When an earthquake hit Pompeii in 62 C.E., its public baths were too damaged to be used; one of the city’s many enterprising businesswomen, Julia Felix, found a way to profit by charging people to use her private bath.) Some city governments also charged for use of the public baths, but the fee was usually small; a city could expect unrest, even violence, if people did not have access to bathing facilities.

Public baths were called *thermae*, from the Greek word for “heat,” because some of the pools in them were heated. Typically a Roman bather disrobed in a room provided for the purpose and then dived into a large pool of cold water and swam its length. Next he or she bathed in one or more heated pools smaller than the cold pool; in large baths there were several of these pools, varying from tepid to very hot. Furnaces outside the building heated water that ran through pipes under the bottoms of the pools, warming them in turn. From the warm pool the bather went to a steam room and, after working up a good sweat, often returned to the cold pool for a final swim.

The baths were not merely for bathing; they were social centers. Big *thermae* had several large rooms set apart from the pools, and here Romans conducted business, met with friends, or simply rested. The Roman business day usually ended at about 4 P.M., and the bathhouses quickly filled with people who had finished work. People of all ages and both genders mixed freely, unclothed or nearly so (though it was customary to set aside certain times when only women were allowed in the baths, perhaps so they could comfortably relax without sexual pressures from men). *Thermae* were supposed to be open all hours of the day, and having the furnaces go out at any time was considered a major inconvenience and even cause for government inquiry.

If a city’s water supply exceeded what was needed for the fountains and public baths, some of it might be piped into private homes. The pipes were usually of lead. Water was first piped into private homes in Rome about 146 B.C.E. For the most part, however, only wealthy or at least middle-class people could afford this amenity, not only because the plumbing was expensive but also because cities usually charged for water used in this way. Another limiting factor was the water pressure. Although it was sufficient to feed low-lying fountains, the water pressure in Rome and other cities was never great enough to raise piped water above the ground floor of a home or other building.

THEATERS AND AMPHITHEATERS

Romans expected a true city to provide entertainment, including theatrical offerings of singing, dancing, and plays. Beginning in the 400s B.C.E. Roman theaters were made of wood and were temporary, taken down after the performance. In the 200s Romans began building stone theaters in their cities, and whenever a new city was planned, a spot for the theater was included. Almost every Roman city had a theater with seats arranged in a semicircle facing a broad stage, although Rome itself did not have a permanent theater until 55 B.C.E. At its height Pompeii had only 12,000 residents, including slaves, but its theater could hold 5,000 people.

On the other hand, an amphitheater was not essential to a Roman city, although many city plans made room for one. The most famous is the Colosseum in Rome. Built in 75–80 C.E., it was a massive structure that featured many of the best traits of Roman architecture. An amphitheater, with its spectacular events, such as chariot races and gladiatorial combats, was meant to serve an entire region, not just a city. In fact, some amphitheaters were built in open land away from cities, drawing audiences from the countryside. The amphitheaters had rows of stone benches. Seating was separate for different classes of society, with the best seats reserved for the emperor in the city of Rome and for the regional governor or chief administrator in other cities.

The amphitheater was not a Roman idea, but one borrowed from southern Italy. Yet Rome made the amphitheater an instrument of government. It served to pacify the public with entertainments, helped indoctrinate native peoples into the Roman way of life, and through its battles and human sacrifices inured audiences to violence and warfare. Most Roman men were expected to serve long terms in the army or navy, and the cruel entertainments of the amphitheater helped prepare them for the horrors of battle.

ROMAN CITIES ABROAD

Wherever Romans conquered, they built new Roman cities or added a strongly Roman touch to existing towns. In some cases the new cities were intended largely for the Roman soldiers themselves. The Roman government encouraged its soldiers to settle in conquered territories and built cities specifically for them because the retired soldiers would be tough,

tenacious, and hard workers who could ably defend the city from attack and build its economy.

North Africa had many such cities. An example is Timgad (Thamugadi), built in 100 C.E. for retired soldiers in Numidia (in present-day Algeria). It was laid out in a strict grid with its eastern and western gates opening on significant trade routes. Within its walls were a forum, basilica, market, and baths, but somewhat unusually its capitol was placed outside the wall. As the city grew, perhaps reaching 15,000 people, it added several baths outside the city walls.

In North Africa the Romans also built cities at the sites of existing Phoenician towns. Leptis Magna (in modern-day Libya) was a Phoenician colony that became part of the Roman Empire in 46 B.C.E. It gained fame as the birthplace of Emperor Septimius Severus (193–211 C.E.) and may have had a population of 12,000. Timgad and Leptis are examples of the different fates of Roman cities after the fall of the Western Roman Empire. Timgad survived because it was on an important trade route. Without Roman engineers to maintain its once splendid harbor and without the empire's market for its goods, Leptis Magna faded and was abandoned during the Arab invasion of the 500s C.E.

During its long existence the Western Empire itself contained had many examples of cities that became successful showcases for Roman life. In what is now Germany, Trier (the Roman name was Augusta Treverorum) began as a military camp under Augustus and was made a city between 41 and 54 C.E. It was laid out as grid, but its wall curved with the contours of the Moselle River. London (Londinium) was founded in 43 C.E. and grew to 45,000 people before, for various reasons, its population began declining in the 200s C.E.

POPULATION AND PROBLEMS

To Roman city planners the ideal city would have no more than 20,000 residents, and thus they designed new cities to hold no more than that. In a new city the initial residents, perhaps just soldiers and their families, might number only a few thousand. When a city filled up, the hope of the Romans was to build another several miles away, thus keeping each city to a size thought to be comfortable. This is one reason Roman cities seem to be everywhere in the lands that fell within the empire's borders—they were part of a continuous process of managing populations, and the building of them was not expected ever to end. Even so, some cities had exploding populations simply because they were ideally located for commerce or to be seats of government, and they drew so many people to them that the cities sprawled beyond their walls. One example was Lyons, in modern-day France. Under its Roman name of Lugdunum its population reached 200,000.

Rome itself provided the greatest example of out-of-control population growth. Even by 509 B.C.E. it had a population of 40,000, and during the first century B.C.E. that number reached a million. The city's original plowed circumference had to be redone outside the new city limits, with new outer walls built, but this was hardly the only problem associated

with mushrooming population growth. Rome had become a place with many tenements and, in the old quarters, narrow streets. During his reign Augustus attempted to bring some order to the situation through massive building projects and a reorganization of the city into 14 regions, each with its own administrator appointed by the emperor. He created a police department to battle a crime wave, and he organized a fire department. Every Roman city was vulnerable to fire, and large portions of Rome had burned on several occasions. The duties of Rome's fire department were mainly to organize bucket brigades (there was never enough water pressure for fire hoses) and to knock down buildings around a blaze to prevent its spread.

Augustus assigned to his son-in-law Marcus Agrippa the administration of many of Rome's building projects, and Agrippa also expanded and added to the city's aqueducts, increasing the flow of water by two to four times. Other public projects undertaken by Augustus were the dredging of the Tiber, which was filling with silt, and personally overseeing the distribution of food to the city's poor. Caring for the poor became institutionalized in the empire, with some cities even setting aside a covered area near the forum where homeless people could gather to stay out of bad weather.

INSIDE A ROMAN CITY

A traveler entering the typical ancient Roman city first passed through an enormous stone gateway. The Romans built grand gates to impress visitors with the feeling of entering sacred ground that was set apart from the ordinary world outside. Once within the gates, the traveler would notice the many small touches that enhanced life in a Roman city. The streets would be paved with either stone or brick and would be wide enough for two carts to pass each other with room enough left for a third cart. Most people walked wherever they needed to go in the city, whether for business or pleasure, and great care was taken to protect pedestrians. Streets had raised stone along their sides to prevent carts from straying onto the sidewalks, and sidewalks were everywhere, even among the residences of the poor. In commercial and residential areas alike the sidewalks were covered, either by roofs or by overhanging balconies. In some cities the law required homeowners to provide cover over the sidewalks adjacent to their buildings. There were also crosswalks consisting of rows of large, flat-topped stones set less than a stride apart, on the top of which pedestrians stepped. (The crosswalks also helped to slow traffic, rather like ancient speed bumps, because carters had to maneuver their wheels around the stones.)

A Roman city was typically laid out in a grid pattern of streets and was either square or rectangular. This was not a rigid practice; Roman city planners accommodated the local terrain, working around variations such as hills and valleys. Once the essential elements of forum, capitol, basilica, curia, and the theater were mapped, neighborhoods were laid out, usually divided into sections for the upper class, middle class, craftsmen, and the poor. If the city had been

built around or next to an existing settlement, that area was often left untouched, and its passages were not part of the grid pattern. These sections tended to become the homes of the working poor.

Planners were careful to leave open spaces for hotels, shops, taverns, parks, and gardens. Parks and gardens were important aspects of the Roman city, which typically devoted about one-third of its total space to them. The gardens might harbor vineyards, orchards, or farms generating produce for the local markets. The parks ranged from places intended for exercise to quiet spaces where people could simply relax among flowers and trees. As some cities prospered, drawing more residents than they could comfortably house, civic leaders had to struggle to preserve such areas from developers who would fill open nooks and crannies, as well as marshes and hillsides, with apartment houses three or four stories high with small rooms. Made hastily of brick, these buildings often collapsed because of poor construction.

Toward the center of the city the visitor would discover many shops offering local and imported goods and might perhaps stop in at a *thermopolium*, many of which were scattered throughout the city, with clusters near the forum and the theater. These establishments served hot wine that was kept warm in tubs set into the top of a counter; customers could also buy snacks or a meal. People went to a *thermopolium* for much the same reasons they might visit a bar today, including to meet friends, business associates, or members of the opposite sex.

In contrast to the many public venues, homes in a Roman city were designed for privacy. Walls facing the street had only small windows or none at all. The focus of the interior of the house was the atrium, an open, courtyardlike central area where a family did most of its living and entertaining. An atrium was usually covered except for a large square opening in the center that let in air, sunlight, and rain. Directly beneath the opening would be a square tub to catch and store the rainwater. Much of the atrium consisted of soil planted with bushes, flowers, and trees. In early Roman houses the atrium opened at the back onto a space for growing food. By the first century B.C.E. atriums were usually closed on all sides and surrounded by rooms. The rooms tended to be small cubicles intended for sleep, study, preparing meals, and such crafts as weaving or woodworking.

The Roman home provided privacy and the city at large a sense of community. Thus it was that Roman city builders hoped to create the ideal urban environment by fulfilling public spiritual and physical needs while making space for individual lives.

THE AMERICAS

BY J. J. GEORGE

Urban settlements originated during the social transformation of simple nonhierarchical farming societies into class-stratified states. While cities, towns, and villages were

prominent features in all of the Americas in the ancient period, only a handful could properly be called cities, even according to the most basic definition. Determining all the criteria is a matter of debate among scholars; thus, classifying a city is a fluid matter. Although many basic features were shared, settlements in the Americas showed a high degree of variation in size, function, and layout.

Part of the difficulty in analyzing cities is that *cities*, *urban society*, and *urbanization* are often left undefined, leading to overlap and confusion. Since there is no uniform agreement on what makes a city, one question is whether demography (the statistical study of populations, especially with reference to size, density, and distribution) or function (a definite end or purpose) is more important in defining and analyzing ancient towns and cities. From a demographic perspective a settlement with a large, dense population is evidence of social and economic complexity accounting for great diversity in ethnicities, classes, occupations, and activities. The Mexican city of Teotihuacán (1–650 C.E.) represents the ideal city in this scenario. From a functional perspective, which defines cities as settlements whose institutions affect a much greater hinterland, often for religious and ritual purposes, a Mayan site such as Tikal in northern Guatemala, of about the same time period as Teotihuacán, would be considered a city.

CHARACTERISTICS OF CITIES AND URBANIZATION

Cities are typically political, economic, and religious centers for surrounding territory and the focus for a wider range of specialized production and services than are found elsewhere in the region. As true as it is today, a city represents a central core of activities within which a greater and more diverse range of activities take place. According to the archaeologist V. Gordon Childe, a 20th-century urban theorist, definitions of “city” include the site as the head of a hierarchy of settlements that performs unique functions for a regional society for its time. A city is a permanent settlement within the larger territory occupied by a society, considered home by a significant number of residents whose activities, roles, practices, experiences, identities, and attitudes differ significantly from other members of the society who identify most closely with *rural* land outside such settlements. Cities are large settlements with many urban functions that affect a large hinterland, whereas towns are smaller settlements with fewer urban functions affecting a smaller region. In all of the definitions, size and sociopolitical complexity alone are not adequate criteria for defining a city, though it does seem that a population of at least a few thousand seems necessary to qualify a settlement to be urban and thus a city.

The hierarchy of settlements comes in various sizes and with varying functions. Major capitals, political towns, hilltop ceremonial zones, fortresses, administrative centers, regal-ritual sites, mercantile cities, and sites whose political status is unknown represent different classifications according to type and function. A major capital will obviously show a greater level of urban complexity than a fortress, whose

primary role is singularly defensive. Consequently, the urban texture of a hilltop fortress is limited and coarse by comparison and its social function more abbreviated. Considering its defensive nature, it can also be assumed that the occupants of a fortress site are primarily concerned with the business of defense, thereby limiting the overall social fabric to a narrower field of participants compared with what a larger general center might show.

Growth and complexity were constantly evolving urban traits throughout the ancient period, such that by 250 C.E., in Mesoamerica especially, the following political structures had developed, in this order: regional economic centers, elite classes, administrative centers, true urban centers, and some form of state structure. This last classification type, the achievement of some form of state-level society, presents a unique conundrum for defining the qualities of a city, because city and state are often tied together in a kind of circular redundancy, such that one scholar will say that there cannot be a city without a state, and another scholar will say that there cannot be a state without a city. Thus, the questions become these: In the absence of a so-called state, is a large, complex urban settlement necessarily a city? And if a city is, in essence, responsible only for itself and is not bound to its hinterlands by political, economic, or militaristic terms, is it then a self-sustaining state, a city-state, or still just a city?

Similarly, if there is a necessary correlation between city and state, is there a corresponding relation between city and civilization? What qualities of civilization, if any, are necessary for the development of a “city”? Suggestions presented by scholars include monumental public architecture, art styles involving artistic representations in many media, development of practical sciences and means of recording (astronomy, accounting systems, and, often but not always, writing), populations of a relatively great size and density often but not always including localized areas of great density, differentiations of the populations into a number of more or less distinguishable social classes ordered in hierarchical fashion, a concentration of natural and human resources for public enterprise, and extensive trade. The question of civilization is intimately tied to definitions of culture, and culture is a defining quality of cities.

FEATURES OF CITIES IN THE AMERICAS

Cities in and of themselves are a fairly recent phenomena. As late as 1900 C.E. there were only 16 cities in the world with populations in excess of 1 million, and 100 years earlier only 17 cities in Europe had populations over 100,000. A clear view of the nature of cities in the Americas in the ancient period is complicated by a lack of written texts and the fact that many urban centers were only then emerging. Although many settlements would not satisfy a strict urbanist’s criteria for a city, many achieved city status in the broader sense of civilization. Urban settlements everywhere varied in terms of size, social composition, economic institutions, adminis-

tration, religious institutions, and urban planning and layout, and each settlement needs to be examined individually. The examples mentioned here—San Lorenzo, Teotihuacán, Monte Albán, Tikal, Pukara, Tiwanaku, and Moche—reflect the variety and range of cities in the Americas.

It should be noted that weak and insufficient data plagues much analysis of North American sites prior to the 18th century and that nothing resembling the level of complexity found farther south in Mexico and in the Mayan civilization had developed by the time the Europeans arrived in the 15th century. Most North American indigenous settlements of this period are more properly classified in the spectrum of towns, villages, village clusters, ceremonial centers, burial mound sites, or camps.

MESOAMERICAN CITIES

The earliest example of a Mesoamerican urban center is San Lorenzo, an Olmec site that occupies a long ridge above surrounding riverine lowlands in Mexico’s Gulf Coast region. First settled around 1500 B.C.E., it covered 1,235 acres, had a population of several thousand residents, and exhibited all the major urban characteristics. It is generally defined as a regal-ritual city, an urban center with highly developed ritual functions but modest populations; relatively weak, decentralized rulership; and limited economic functions. One reason for San Lorenzo’s preeminence during this period is its choice of site: high enough to remain dry during the worst floods; close enough to fertile farmlands; easily defensible; near to freshwater springs and other natural resources such as sandstone, hematite, and limestone; and, owing to its location, exercising control over important river and land transportation routes. Prominent features include a great earthen platform complex honeycombed with an elaborate drainage system and perhaps laid out in a zoomorphic, or animal-like, shape. Colossal carved stone heads made of basalt from the Tuxtla Mountains 60 miles away, some weighing as much as 20 tons, indicate a level of complex coordination and centralized authority.

Teotihuacán (ca. 1 B.C.E.–650 C.E.) is the standard by which all other ancient American cities are judged. Located 40 miles north of contemporary Mexico City, Teotihuacán was the largest and most complex urban development in the Americas until the rise of Aztec Tenochtitlán in the 14th century C.E. By 600 C.E. Teotihuacán was the fifth-largest city in the world, with a population estimated at 125,000. Its design was based on a central grid plan, sometimes referred to as the Mexican imperial plan, aligned along a major north-south axis called the Avenue of the Dead. The primary architectural features of the site are two massive flat-topped pyramids called the Pyramid of the Moon and the Pyramid of the Sun, as well as a ceremonial structure toward the southern end of the site called the Temple of Quetzalcoatl contained within an area called the Ciudadela (or Citadel). Overall, the city’s development and its architectural expressions are a symbol of power.

Teotihuacán is the clearest example of a city in both functional and demographic terms. It was a large, densely populated urban environment with highly specialized economic, social, ritual, and ceremonial activities. Its influence spread far outside its own borders not only through trade and exchange and religious influences but also through military aggression and occupation. Teotihuacán's influence in the development of a greater Mesoamerican tradition cannot be underestimated. Its influence can be traced throughout Mesoamerica by the presence of its signature *talud-tablero* ritual architectural style, recognizable in profile as a series of horizontal platforms sitting on sloping panels and finished with fine plaster. This style shows up throughout Mexico and in the Mayan areas of Guatemala, including the sites of Kaminaljuyu, a highland Maya site; Monte Albán, in the Valley of Oaxaca; Cholula, in the Valley of Puebla; and Tikal, the major lowland Maya site in Guatemala's northern Petén jungle region. These are but a few primary urban settlements under Teotihuacán's influence.

Urban planning at Teotihuacán included an internal drainage system composed of a vast system of subterranean canals that flowed into a central canal, administrative and ceremonial buildings aligned along the Avenue of the Dead, congregational plazas at the Pyramid of the Moon and the Ciudadela, elite residential complexes ranging in size from 5,900 square feet to 39,000 square feet, and districts for workers and foreigners on the periphery believed to have been specific to specialized craftsmen, including obsidian carvers, figurine makers, stonemasons, and jewelers. One of the foreigner's districts was called the Oaxaca Barrio because it was supposed to include only individuals from Oaxaca. More than 500 craft workshops and 20,000 rectangular single-story residential compounds existed at Teotihuacán.

Farther south in the Valley of Oaxaca the settlement of Monte Albán (ca. 500 B.C.E.–900 C.E.) developed gradually and rose to become the principal Zapotec capital city. Settled at the conjunction of three valleys, the region was divided into three branch communities oriented toward agricultural production, pottery manufacture, and the extraction of salt. One suggestion is that Monte Albán rose as a center to coordinate the various sites in the valley and gradually developed its administrative, economic, social, and ritual functions into those of a major urban center. Primary settlement at Monte Albán is generally broken down into periods or phases noted as I, II, IIIa, and IIIb, with population and influence fluctuating through the centuries. Long after it diminished as an urban center, which some have linked to the fall of Teotihuacán to the north, it remained a ritual pilgrimage site and an active burial site. It was abandoned as a functioning city in the 10th century as power shifted to other Zapotec settlements in the valley, such as Mitla.

Development at Monte Albán focused on a hilltop site about a thousand feet above the valley floor with the population concentrated on the habitable terraces beneath the hilltop. The layout focused on a civic-ceremonial center atop

Pottery vessel of the storm god, Teotihuacan, Mexico (150 B.C.E. to ca. 700 C.E.); the god was portrayed frequently in stone and murals, suggesting that he was an important god in the city's pantheon. (© The Trustees of the British Museum)

the hill with multiple structures most often referred to as mounds flanking and framing a central plaza. The North and South Burial Mounds punctuate the ends of the plaza's ceremonial core and, along with the periphery mounds, form a kind of ceremonial way that recalls the Avenue of the Dead at Teotihuacán, albeit much smaller. A ball court, stone slabs covered in bas-relief, slabs with hieroglyphics including some evidence of a ritual 260-day calendar, and pottery produced on a large scale all suggest the greater cultural complexity indicative of true cities.

In the Maya territory, Tikal is often referred to as the greatest city of the Classic and Epiclassic periods (usually defined as 150–900 C.E.). Set in a dense jungle in the north of Guatemala, Tikal probably achieved full city status late in the Classic Period. The rise of Tikal is thought to have led to the fall of another community called El Mirador as villages and communities came into increased contact with one another and began vying for resources, control, and influence. It seems likely that El Mirador fell to Tikal as elites attempted to consolidate their power and range of influence until Teotihuacán became interested in the area's resources and exportable goods, including cacao, honey, salt, beeswax, and

medicinal herbs. The influence of Teotihuacán at Tikal was secure by 360 C.E. thanks to a ruler referred to as Curl-Nose in hieroglyphic inscriptions found at the site. Curl-Nose was apparently a collaborationist ruler who accepted military and political advisors from Teotihuacán, which gave Tikal an edge over rival Mayan centers and allowed for further expansion.

Architecture and urban planning at Tikal featured massive stone temples, funerary monuments, acropolis structures, great plazas, a residential or administrative complex consisting of small courtyards, the Great Plaza, a possible market area, a sweat bath, a ball court, stone sculpture that includes great chronographic (timekeeping) markers, memorials to ancestors, and bureaucratic structures. All Maya architecture was composed of elevated platforms and corbel-vaulted chambers organized in a variety of configurations. The similarity of all the building structures has made it difficult to differentiate between their functions. At its height Tikal was home to 40,000 inhabitants and its nuclear area alone included more than 3,000 separate structures and some 200 stone monuments.

Sometime in the fifth century C.E. the people of Teotihuacán began to pull back from their frontier positions. Their sudden departure seems to have upset development at a number of Mayan sites, with some areas plunging into open revolt suggesting civil war. Not until around 650 C.E. was Mayan civilization able to reorganize and function once again. Tikal continued for a couple hundred more years before its eventual collapse.

SOUTH AMERICAN CITIES

In South America all areas show vast numbers of archaeological sites, indicating widespread population since 8000 B.C.E., though relatively few have been fully excavated. Only the Peruvian cultures seem to have attained a complex level of civilization. Of the ancient Peruvian cultures, the cities of Pukará, Moche, and Tiwanaku (also spelled Tiahuanaco) stand apart.

The north coast Peruvian settlement of Moche (100–600 C.E.), evidently the capital of the Mochica state, comprised two huge adobe structures called the Huaca del Sol and the Huaca de la Luna, an immense plaza, and an extensive residential zone. The Huaca del Sol was a terraced platform that measured 1,100 by 500 feet at its base and rose to 130 feet. Trash heaps at its summit suggest that it may have served as elite living quarters. More than 143 million adobe bricks were used in the construction, many with identifiable markings indicating the individual mason's hand. The Huaca de la Luna consisted of a massive, terraced multiroom complex. Moche was traditionally regarded as an immense ceremonial center and thought to lack a substantial population. Recent excavations, however, revealed a residential zone able to accommodate a sizable population density.

The site of Pukará, which lies 75 miles northwest of the northern shore of Lake Titicaca, high on the altiplano (a high plateau), had a brief but important florescence between 200

B.C.E. and 300 C.E. Pukará's buildings were adobe on stone foundations. Its main structure was a temple, built on an artificial terrace and consisting of a rectangular sunken court. An extensive residential area lay in the plain below the acropolis. Beyond the southern end of the lake, at an altitude of 12,600 feet above sea level, Tiwanaku was a major settlement with a central core of monumental structures occupying an area of 125 acres surrounded by an extensive residential zone; the whole site covered 1½ square miles. Population estimates range from 30,000 to 70,000 people.

True urbanism happened at Tiwanaku because of balances in herding and agriculture that gave rise to surpluses. Extensive irrigation projects reclaimed fields for planting; as much as 200,000 acres were irrigated. By 100 C.E. monumental stone architecture was being built. There was no mistaking the power in the stone city the Tiwanakans built as their center. The principal buildings are a giant stepped mound called the Akapana and a semisubterranean temple called the Kalasaya surrounded by a moat that limited entrance and public use and separated the sacred from the profane. Excavations of the Akapana revealed numerous burials, one of which has been called the High Priest-Puma Shaman because it showed a seated man holding a puma effigy. For this reason it is believed the Akapana was a monument to shamanic transformation. (Shamans were believed to mediate between the world of spirits and the world of the living and to take on various forms.) These structures stood adjacent to another low flat temple called the Puma Punku. Reconstructing the exact look of Tiwanaku is an impossible task because it has been constructed, reconstructed, plundered, and rebuilt numerous times over 2,000 years. Tiwanakan dominance spread considerable distances as they tried to export religion and import foreign products. Like Teotihuacán, Tiwanaku influenced societies far outside its own boundaries.

► climate and geography

INTRODUCTION

In modern life, technology enables people to adapt the environment to their needs. If farm fields are dry, electric-powered or gas-powered pumps allow farmers to irrigate. If the temperature is too high, electric air-conditioning cools the air

in people's homes and offices; if the temperature is too low, furnaces provide heat. In contrast, ancient peoples had to adapt their needs to the environment. Obviously, they could modify their environment in simple ways, such as by building a fire to provide warmth. But overall much of the history of ancient peoples was determined by their physical environment and their efforts to adapt their lives to the physical conditions that surrounded them.

One major problem ancient peoples faced, however, was climatic change, which disrupted societies and sometimes forced the migration of people. An area that was wet and fertile during one era could become dry and deserty in a later era, as happened in parts of Mesoamerica, the region that comprises the southwestern United States, Mexico, and Central America. Meteorological events in one part of the world could cause climatic change in another part of the world, raising or lowering temperatures, increasing or decreasing rainfall, or touching off violent storms. Further, catastrophic events could wreak havoc with a people. A volcanic eruption, for example, could not only wipe out a population but also change the physical environment for survivors and for those living in neighboring regions. Similarly, earthquakes could destroy settlements and change the face of the earth for nearby settlers. Drought could lead to famine and population depletion.

Africa, in particular, has been subject to climatic swings. During parts of its ancient history, Africa was cool and dry, primarily as a result of the last ice age, when ice pushed southward and covered much of what is now Europe. Later, Africa became much warmer and moister, leading to monsoon rains. Later still, temperatures dropped again, and weather patterns dried out. These changes, which were not unique to Africa, led to changes in vegetation, sometimes turning forests into deserts and deserts into forests. After the advent of agriculture, such climatic shifts required Africans to adapt the crops and farming practices to the new conditions. They also contributed to African history in major ways. When the continent dried out, the Nile River became essentially the center of civilization. It also led to conflict between nations as they struggled for resources to support their people.

Ancient peoples were driven by their need to find ways to adapt to their environment. One of their primary needs, of course, was fresh water. Accordingly, early peoples tended to form settlements along the banks of rivers or adjacent to lakes, but living in these types of regions posed special problems. People in Asia and Oceania, where oceans were nearby, were subject to cyclones and tsunamis, and people in such places as ancient Egypt were dependent on the annual flooding of the Nile River along which they lived. In time, people learned to harness at least some of the natural forces that surrounded them. The ancient Egyptians, for example, developed a complex and highly sophisticated system of irrigation and water management, storing the floodwaters of the Nile for later use in irrigating their crops. The ancient Romans, too, developed sophisticated plumbing systems, with canals, dikes, and the like to manage water flow.

Temperature was also a critical environmental factor, but ancient peoples discovered that they were highly adaptable to temperature extremes, unlike some other species. The earliest settlers of the Americas, who probably crossed from Asia to Alaska along a land bridge that is now covered by the Bering Sea, found themselves in an inhospitable environment, with bitter subzero temperatures and large amounts of snow and ice. Their descendants migrated to desert regions of the American Southwest and Mexico, where they faced hot, dry conditions, with temperatures often exceeding a hundred degrees. And their descendants migrated farther south to cold and forbidding regions of South America.

At the same time, human beings discovered that they were also able to adapt to widely different elevations. The people of the Pacific islands lived essentially at sea level. The early inhabitants of the Andes range in South America discovered that they could adapt to elevations well over 10,000 feet, where the air is thin and their lungs had to expand to take in more oxygen. In time, humans, because of their adaptability, were able to occupy virtually every niche in the ecosystem, including mountains, forests, grassy steppes, deserts, tropical islands, and every region between. In doing so, they adapted their tools, technologies, and ways of life to the climate and terrain.

A major consideration for ancient civilizations was travel and transport. In an age of effortless air travel, it is easy to forget that geography and natural barriers were formidable obstacles as people tried to immigrate to new regions or simply to follow food supplies. The early Romans, for example, were unable to cross the mountains that divided Italy from the rest of Europe, though in time they were able to do so and expand their empire farther to the north. Later, they found that major rivers in northern Europe blocked their expansion in that direction, allowing the tribes that would eventually overrun Rome to settle and amass on the empire's northern border. Geographical obstacles also inhibited contact between peoples. In the Andes of South America the forbidding terrain left the communities that settled there isolated from other groups of people. By remaining isolated, they were unable to learn from other people, in contrast to other civilizations that enriched themselves by contact with others. Similarly, the Pyrenees Mountains cut off the people of the Iberian Peninsula from contact with other Europeans.

To solve the transportation problem, many early peoples settled along bodies of water. The Egyptians used the Nile to travel up and down much of the African continent, and various civilizations in such places as Mesopotamia and China navigated the rivers for trade and cultural contact. Using boats and rafts, these people were able to obtain goods—spices, salt, foodstuffs, ores, precious metals, fabrics, lumber—that were unavailable at home. Of course, one of the main reasons that the ancient Greeks and then the ancient Romans were able to extend their influence over a wide geographic region was that they controlled the Mediterranean Sea. (It is worth noting that *Mediterranean* means “middle of the world.”) Like other

peoples, including many Asians and especially Pacific islanders, geographical conditions made the Greeks and Romans excellent boat builders and mariners.

AFRICA

BY LEAH A. J. COHEN

Many systems (such as the celestial systems that dictate the movement of the earth around the sun and around its own axis) have driven climate change in Africa over the span of Earth's four-billion-year existence. Since most of these systems change very slowly (cycling on the scale of tens of thousands to millions of years), many of the systematic conditions that have affected climate change in Africa during the past 10,000 years have remained relatively similar.

THE GEOGRAPHY AND TOPOGRAPHY OF AFRICA

Africa's physical geography has been a key factor in its climatic conditions over this period of time. Africa is a large expanse of land, covering 11.7 million square miles. It is the second-largest continent (behind Asia) and represents 20 percent of the world's land. This is relevant to the study of climate in Africa, because land that borders large bodies of water tends to show less variation in temperature than areas at the same latitude (the east-west global location) that are landlocked. In other words, locations near the center of large continents (such as Africa) have much wider climate variability than locations at the same latitude that receive the same amount of solar radiation (sunlight) but are near large expanses of water. Because Africa is a large, consolidated landmass, much of the continent does not benefit from the tempering effect of water. Thus (all else being equal) temperatures inland in Africa tend to be either higher or lower than those on the coastlines.

Africa's major lakes include Lake Victoria, bordering Kenya, Tanzania, and Uganda (East Africa); Lake Tanganyika in western Tanzania (East Africa); Lake Malawi in western Malawi (southern Africa); and Lake Chad bordering Niger, Chad, Nigeria, and a small part of Cameroon (western Africa). Paleoclimatologists (scientists who study past climatic conditions on Earth) have learned a great deal about past climate change by collecting lake-bottom sediment cores from these and other African lakes. Sediment cores are samples of sediment taken using a long cylindrical tube that is driven into the lake bottom and closed, so that the layers of sediment, which represent different time periods, are preserved for the purposes of research. The data collected from sediment core sampling and other research techniques are set to a timeline using at least one of a variety of dating methods. The most commonly employed method for dating sediment core layers is radiocarbon (or carbon-14) dating.

The topography of Africa is varied, with lowlands, highlands, mountains, and valleys, but in general the continent of Africa is a large plateau. Africa is not known for an abundantly mountainous landscape. Its two tallest mountains are

Grass, sand, and volcanic formation in the Sahara, southern Algeria (© Board of Regents of the University of Wisconsin System. Photographer: Jeanne Tabachnick)

Mount Kenya at 17,058 feet and Mount Kilimanjaro at 19,340 feet, both in East Africa. The main reason that Africa has a relatively small percentage of mountainous landscape has to do with Africa's placement on the tectonic plate system. The African plate is moving toward the northeast, pushing into the Eurasian plate and separating from the Arabian plate. Since only the northern and eastern edges of the African continent are near the edges of the much larger African tectonic plate (which extends far into the Atlantic Ocean) upon which it sits, there is relatively little volcanic activity throughout the rest of the continent.

The major mountain ranges formed well before 10,000 years ago as a result of the movement patterns of the African tectonic plate. These mountainous regions are on the northern and eastern sides of the continent and include the mountains that divide eastern and central Africa and the Atlas Mountains in northwestern Africa. The other areas of Africa are not subjected to tectonic plate pressure or separation and therefore are not particularly mountainous. Mountains often have great effects on local weather conditions. In eastern Africa (Tanzania, Kenya, and Ethiopia) the climate is much drier than it is directly on the western side of the central mountains that divide central and eastern Africa, owing to the rain-shadow effect. Moist air comes from the west and when it hits the mountains, it is forced to rise; as it rises, it cools and is not able to hold the moisture, which produces rain. Thus, once this air reaches the other side of the moun-

tains, it is no longer moist, creating a much drier climate in eastern Africa.

The other major land features of Africa are the Sahara (which dominates the northern region of Africa, running west to east) and the Kalahari and Namib deserts (which dominate southern Africa). The Sahel is an east-to-west band of semi-arid savanna that separates the dry Sahara environment from the lush and moist tropical forests of central Africa.

AFRICAN HUMID PERIOD

At the start of the Holocene geologic epoch (10,000 years ago to the present), Africa had emerged from a long period of dry and cool temperatures associated with the last major ice age. Evidence from sediment cores from many of Africa's lakes, ice cores from Mount Kilimanjaro in East Africa, and animal and plant fossil records show that much of Africa (including the present-day Sahara region) was more humid during the first part of the Holocene than it is today. This period is known as the African Humid Period, which lasted from approximately 11,000 years ago to 4,000 years ago (though there have been numerous minor swings between humid and dry conditions during this generally humid period).

The African Humid Period can be explained in part by the earth's place within the overarching celestial cycles during this time period. Specifically, the increased moisture and warmth in Africa are associated with variation in the amount of solar radiation hitting the earth's surface during the North-

ern Hemisphere summer. About 10,000 years ago the amount of solar radiation during the summer was approximately 8 percent higher than it is today, because the Northern Hemisphere summer solstice occurred at the point when the earth is closest to the sun rather than at the point when the earth is farthest from the sun (as is the case today).

EFFECT OF THE INTERTROPICAL CONVERGENCE ZONE ON AFRICAN CLIMATE

The rainfall that is driven by increased solar radiation (and temperatures) is associated with a zone near the equator called the Intertropical Convergence Zone. Africa's global position during the past 10,000 years (straddling the equator) places much of the continent between the northern Tropic of Cancer and the southern Tropic of Capricorn, firmly within the Intertropical Convergence Zone, the intersection between two of the earth's major surface wind systems: the southern and northern trade winds. These two major winds systems are known as the Southeast Trade Winds (also referred to as the southern monsoon winds), which travel from west to east and pick up moisture as they move over the Atlantic Ocean, and the Northeast Trade Winds, which travel down from the northwest across the northern Atlantic Ocean. The intersection of these wind systems is associated with a wide swath of low pressure that is driven by solar heating. In the zone in which these trade winds come together, the low pressure lifts the moist air around the equator, which results in abundant rainfall when the moist air cools as it is lifted higher in the atmosphere and is forced to release moisture. The rain associated with the Intertropical Convergence Zone falls over Africa near the equator as the winds move east across the Sahel, just north of the equator and just south of the Sahara.

The location of the low pressure that is associated with the Intertropical Convergence Zone corresponds approximately to the latitude at which sunlight falls perpendicularly to the land's surface (when the sun is directly overhead, a time also known as the equinox). Since the latitude at which the sun strikes perpendicularly changes seasonally, so does the positioning of the Intertropical Convergence Zone and therefore the region of Africa that receives monsoonal rainfall. In modern times in the Northern Hemisphere summer, the latitude at which sunlight strikes the earth perpendicularly is at or around the Tropic of Cancer (23.5 degrees north of the equator); conversely, the low pressure associated with the intersection of the trade winds is found at or around the Tropic of Capricorn (23.5 degrees south of the equator) in the Southern Hemisphere summer. The north-south oscillation of the Intertropical Convergence Zone is primarily driven by the tilt of the earth and the seasons. Since this zone and the low pressure and rains associated with it move north to south twice in a year, the regions surrounding the equator in Africa experience two rainy seasons each year.

Since the swath of the Intertropical Convergence Zone and the intensity of its rainfall over Africa have varied over time, the landscape in this area has also varied. Relative dry-

ness or wetness shaped the ecological landscape, supporting expansion of forest areas (which require more moist conditions) in the areas of wetter periods and expansion of more drought-resistant open vegetation, such as grasslands or desert ecosystems, during drier periods. The border between the Sahara (arid desert) and the Sahel (semiarid savanna and grasslands) has shifted north and south over time as a result of either more or less rainfall, which is associated with more or less solar radiation reaching the earth.

IMPACT OF THE HUMID PERIOD ON AFRICAN ECOSYSTEMS

About 10,000 years ago, increased moisture from the Atlantic monsoonal rains (partly attributed to increased solar radiation in the Intertropical Convergence Zone) created tropical rainfall conditions in parts of the Sahel and Sahara in northern Africa. Some estimates place rainfall up to 50 percent higher in selected areas of Africa compared with that in modern times. Evidence shows a northward movement of vegetation from the Sahel into the Sahara and an expansion and thickening of forests, such as the Zambezi woodlands and the area around Lake Victoria (East Africa) during this humid period. Areas of the Sahara were even flooded at times. The rain forests of Ghana expanded from 9,000 to 15,000 years ago (after having completely dried out during the last ice age).

Lake-bottom sediments used for researching past climate change show that lake levels were high in central and eastern Africa, including those of water bodies in Kenya's Rift Valley and the upper part of the White Nile River, which originates from Lake Victoria (in East Africa), and the Niger River, inner Niger delta, the Senegal rivers (all in West Africa). Lake Chad, which during high times borders present-day Niger, Chad, Nigeria, and Cameroon (western Africa), occupies a very shallow basin, allowing for enormous variability in the area covered by water with changing depth. This lake is believed to have covered approximately 186,400 to 248,550 square miles 6,000 to 12,000 years ago (compared with 885 square miles in 2003). During this humid period areas of today's more arid Sahara were more densely populated, as people (and animals) moved out of the flooded areas of the inner Sahel into the more moderately wet and hospitable regions of the outer Sahel and farther north in the present-day Sahara regions.

Pollen samples from ice or sediment cores provide valuable evidence of plant type and volume and can paint a picture of vegetative cover and rainfall for a particular moment in history. Such samples from sediments in the dry desert region of eastern Libya have confirmed the presence of *Typha* and *Cyperaceae* (wetland plant families) about 9,700 years ago. Paleoclimatologists use the properties of these and other plants and animals from the present day to draw conclusions about past climate. For example, we know from present-day species of *Typha* and *Cyperaceae* that they are wetland plants; however, little is known about how ancient vegetation (those species that do not exist today) resisted drought or flooding.

The evidence paints an overall picture of increased warming and wetness across Africa over time, but the picture is fragmented both spatially and geographically. Climate-change data are not available for all locations or for each year. Furthermore, there is variability in the climatic conditions of particular regions during the general period of increased humidity. For example, there is no evidence that the desert areas of present-day Libya and western Egypt (northern Africa) also experienced a much more vegetated state. South Africa provides data that indicate a general warming trend with increasing moisture in some areas, but data from southern Africa's Kalahari and Namib deserts indicate more severe dryness. Evidence from Lake Tanganyika, an extremely deep lake in the Rift Valley, shows a reduction in forest cover in the surrounding area around the same time.

Some parts of Africa experienced a more minor dry period (compared with the last major ice age) again around 7,500 to 8,000 years ago. Ice cores from glaciers on Mount Kilimanjaro that also have been used to reconstruct the details of past climatic conditions show a brief but intense drying period some 8,300 years ago. In many areas of Africa there was another period of increased moisture until about 4,000 to 5,000 years ago. This humid period was apparently much shorter in the area north of the Algerian Sahara than in the central mountains. During this last humid period, areas south of the Sahara were often flooded, and the waters of Lake Chad, the Niger River, and the Senegal rivers were at record-high levels. Ice cores from Mount Kilimanjaro date this period of increased moisture to 5,200 years ago and associate it with cooler temperatures (rather than warm temperatures, which often seem to be associated with increased moisture in African climate history).

END OF THE HUMID PERIOD

About 4,000 to 5,000 years ago the temperatures started to drop again, and conditions became much drier. Vegetation began to change as forests shrank and sand dunes formed in the Sahara. The glaciers on Mount Kilimanjaro retreated. Animals and people migrated out of the inner Sahara to escape the increasingly dry hostile conditions. Data recovered from caves and cliffs in eastern Libya that show a gap in evidence of human occupation some 5,000 years ago have been compared with other climate data and have indicated increased dryness there. It is thought that humans migrated out of the area at the onset of drought conditions.

Cave paintings and human settlement remains from Mauritania (in northern Africa) suggest that humans migrated from farther north to this area around 4,000 years ago in an attempt to escape the onset of drier conditions. There is also evidence of the dispersal of cattle from the drier areas of western and northwestern Africa around 3,700 years ago and from the Sudan and Niger 4,000 to 4,500 years ago. Water levels lowered in the areas of present-day Ghana, Sudan, Ethiopia, and Uganda. This period, referred to as the First Dark Age, includes a severe 300-year drought in tropi-

cal Africa that began about 4,000 years ago. Starting some 5,000 years ago, many of the lakes in southern Africa also began gradually drying out, and about 2,000 years ago the forests of present-day Senegal and those surrounding Lake Chad had been depleted, causing a change in the composition of species inhabiting the area. Evidence of the start of this cooler drying period is also present in data from other tropical areas around the world, suggesting a global change in climate.

As the Sahara dried out, the Nile River valley, along with the area encompassed by the Tigris and Euphrates rivers, became a center for human civilizations. The Nile, at 4,146 miles long (8,671 kilometers), is the longest river in the world. It also has experienced predictable flooding through centuries, which has provided relief during dry periods for humans and animals living in the surrounding area. Annual floods continually renew the soils with a deposit of fertile silt on a continent characterized by very old soils that have over time lost many of the nutrients that support productive agriculture.

Humans have migrated to the Nile Valley many times throughout history during periods of harsh climatic conditions. Many scientists have found data, for example, that point to bursts in population and social development in this region during periods of drought in the Sahara. Fossil records of flora and fauna provide information on the presence and migration patterns of humans, domestic animals, and wild animals as well as data on vegetative cover. These data have been used to date major migrations into and out of today's Sahara that coincide with evidence of extreme conditions in the Sahara. Migrations out of the Sahara, associated with the environmental pressure of drought, may have contributed to increased conflict over hospitable land, such as the wars between the Egypt and Libya in about 1200 B.C.E.

Traditionally, migration has been a survival strategy commonly used by social groups in Africa to deal successfully with climate changes. For those peoples that did not migrate during periods of increased dryness in Africa, adapting livelihood strategies was essential. As a result of drought conditions around 4,000 years ago, livelihood activities such as pastoralism in East Africa and agriculture in West Africa, including the use of specific techniques such as terracing and dams, expanded as people adapted to the different environmental conditions. Other data reflect that during drought conditions in Africa from 1200 to 2100 B.C.E. some Saharan communities developed and extended mining activities in order to trade for food with communities to the south.

Africa's unique geography and global climatic context jointly have affected specific regions of the continent differently during ancient times. Resulting changes in ecosystems led to variations in human settlement and activity patterns during this time period. These shifting patterns did not occur in a vacuum but were part of a larger-scale system of global variation in geography and climate.

EGYPT

BY KELLY-ANNE DIAMOND REED

Egypt is located in the northeast corner of the African continent, its nearest modern neighbors being Libya to the west, Sudan to the south, and Israel to the northeast. The Gulf of Aqaba and the Red Sea lie to the east, and the Mediterranean Sea is to the north. The country occupies 386,650 square miles and is the 12th-largest country in Africa. The modern border between Egypt and Sudan lies just north of the second cataract of the Nile River. In the Predynastic Period (5000–3100 B.C.E.) or Early Dynastic Period (ca. 3000–2575 B.C.E.) the border lay at Gebel el-Silsila, where the limestone banks in the north give way to sandstone in the south. For most of antiquity the border lay at the first cataract, though on various occasions the Egyptians pushed farther south to expand their territory. In the New Kingdom (1550–1070 B.C.E.) the southern border of Egypt reached past the fourth cataract.

LANDSCAPE AND CLIMATE

The habitation of the Nile Valley began in Paleolithic times. By 15,000 B.C.E. there were many Paleolithic sites in the desert near the valley edge. In the Neolithic Period (ca. 5500–5000 B.C.E.) more people entered Egypt to enjoy the wild game, water, and pleasant climate. These people were wanderers and gatherers, not food producers. Some fruits, seeds, and roots could be found in the wild. The first settlements appeared around 5000 B.C.E.; the settlers could not go far from the water supply and settled near the Nile and in the Faiyûm, a large, fertile depression in Libyan Desert. It is generally thought that over time there was a gradual lack of rainfall and an increase in desert, which in the end led to a scarcity of game. In Neolithic times there was greater movement of people west of the Nile, especially in the north. It is quite likely that it was agriculture that anchored them there. Irrigation began only after the population could no longer survive on the food of the naturally inundated land.

The Egyptian landscape can be broken up into two main parts: the delta in the north and the Nile Valley in the south. The Nile River was, and still is, the heart of Egypt. Without this river Egyptian civilization might never have developed in the dry desert climate of northeast Africa. The Nile Valley and the Nile Delta are known as Upper Egypt and Lower Egypt, respectively. The term *Middle Egypt* is also sometimes employed to describe the region between the Faiyûm in the north to the modern city of Asyut in the south. Upper and Lower Egypt are two very distinct regions, both geographically and culturally. The delta and the valley cover approximately 13,000 square miles. The majority of the ancient Egyptian population lived in this region.

The Egyptian climate is hot and arid. In Cairo (ancient Memphis) the summer can reach temperatures as high as 95 degrees Fahrenheit and then as low as 45 degrees Fahrenheit in the winter. The climate is hotter the farther south one goes. In Aswân the temperature can rise as high as 107 degrees

Fahrenheit in the summer. There is rarely rain or even clouds in Egypt and hardly any rainfall in the Nile Valley; in the delta there can be from 4 to 8 inches of rainfall per year. The city of Cairo averages five rainy days per year, usually between November and January. Because of this lack of rainfall the ancient Egyptians were entirely dependent on the Nile inundation for the survival of their crops.

Measuring 4,189 miles, the Nile is the longest river in the world. It flows from south to north and empties into the Mediterranean Sea. In the south the Nile is formed by the confluence of the White Nile (the parent stream), the Blue Nile near Khartoum, and the Atbara some 200 miles north. The White Nile originates in Lake Victoria, and the Blue Nile originates in the mountainous region of northern Ethiopia, the Ethiopian Highlands. The Nile proper then hits the Mediterranean Sea some 1,700 miles away.

Just north of Khartoum the Nile is interrupted by the sixth cataract, the first of a series of six. A cataract is a rocky outcrop that produces rapids when the water runs over it. The fifth cataract is located in the Bayuda Desert, north of where the Atbara merges with the Nile. The fourth cataract is found near Gebel Barkal. The third cataract is just north of Kerma. The second cataract is found near the ancient site of Buhen. The first cataract marked the ancient boundary between Egypt and Nubia, located just south of the island of Elephantine.

NUBIA

The geography of Nubia is important for understanding ancient Egyptian culture. Aside from the fact that this territory was often dominated by the Egyptians, the natural resources that the Egyptians took from Nubia enriched their kingdom and gave them various means with which to prosper. The name Nubia is derived from the word *nwb*, meaning gold. Between the first and second cataracts was Lower Nubia. This was a relatively poor region with very little cultivable land, since the desert cliffs often came right to the river's edge. Lower Nubia was repeatedly being absorbed into the ancient Egyptian territory. The ancient Egyptians regarded Nubia as rightfully theirs and exploited it for its natural resources, used it as a corridor to retrieve exotic African goods, and recruited men for the Egyptian army and police force.

The Egyptians had penetrated into this southern land as early as the Early Dynastic Period, as evidenced by the rock inscriptions and reliefs located in the area of the second cataract. During the Old Kingdom (ca. 2575–2134 B.C.E.) King Snefru brought back to Egypt 7,000 Nubian captives and 200,000 head of cattle, according to the Palermo stone, which records events from the first five dynasties. Additionally, the Egyptians built a fortress at Buhen, which may be interpreted as their having control over the region. During the First Intermediate Period (ca. 2134–2040 B.C.E.) the Egyptians lost hegemony over the area, despite the fact that there were very few settled people. They regained control of the area in the Middle Kingdom (ca. 2040–1640 B.C.E.) and erected a series

of enormous mud-brick fortresses to control the gold extraction and drive back the Nubians. The Second Intermediate Period (ca. 1640–1532 B.C.E.) also marks a period of Nubian independence; in fact, at this time the kingdom at Kerma was thriving. With the advent of the Eighteenth Dynasty (ca. 1550–1307 B.C.E.) there was renewed domination of the area, reaching as far south as Kurgus, past the fourth cataract. The Egyptian presence in this area was important for later Egyptian history because the culture that emerged from the Upper Nubian site of Napata was later responsible for the Twenty-Fifth Dynasty (770–712 B.C.E.) in Egypt proper. At this late point, some of the ancient Egyptian customs and traditions were dying out, and the Nubian Dynasty helped to reestablish them. The Napata-Meroitic Empire remained in existence until the fourth century C.E.

UPPER EGYPT

The Nile Valley, or Upper Egypt, is long and narrow, and the width nowhere exceeds 13 miles. At some points the floodplain is very thin, and the rocky cliffs of the eastern desert hit the water's edge. At other points the cultivable land is more substantial. The ancient Egyptians called this area *kemet*, or black land, in reference to the color of the soil. They contrasted this with *deshret*, or red land, which referred to the desert. The boundary between these two areas is very abrupt. One can actually stand with one foot in the vegetation and the other foot in the desert.

The summer monsoon rains, occurring in Ethiopia between the months of June and September, trigger an increase in the water levels of the Blue Nile. In the past this caused an inundation in Egypt between July and October. The inundation occurred earlier in the south and later in the north. In Cairo the river was at full height around the end of September. The Nile remained high for another two weeks, and then the water began to subside. The Nile was at its lowest in April. Any part of the land that was not inundated by the Nile was desert. The Nile waters brought tons of soil and rock fragments, which would have washed over the riverbanks. This annual event left fresh layers of silt on the floodplain, making the soil fertile. This rich soil made the use of fertilizer unnecessary since new soil was being deposited annually. There was much variation in the water amount and the dates of its deposition on the surrounding land. A low Nile would have had a drastic effect on the ancient culture, possibly leading to famine. This situation, however, is no longer the case in modern Egypt.

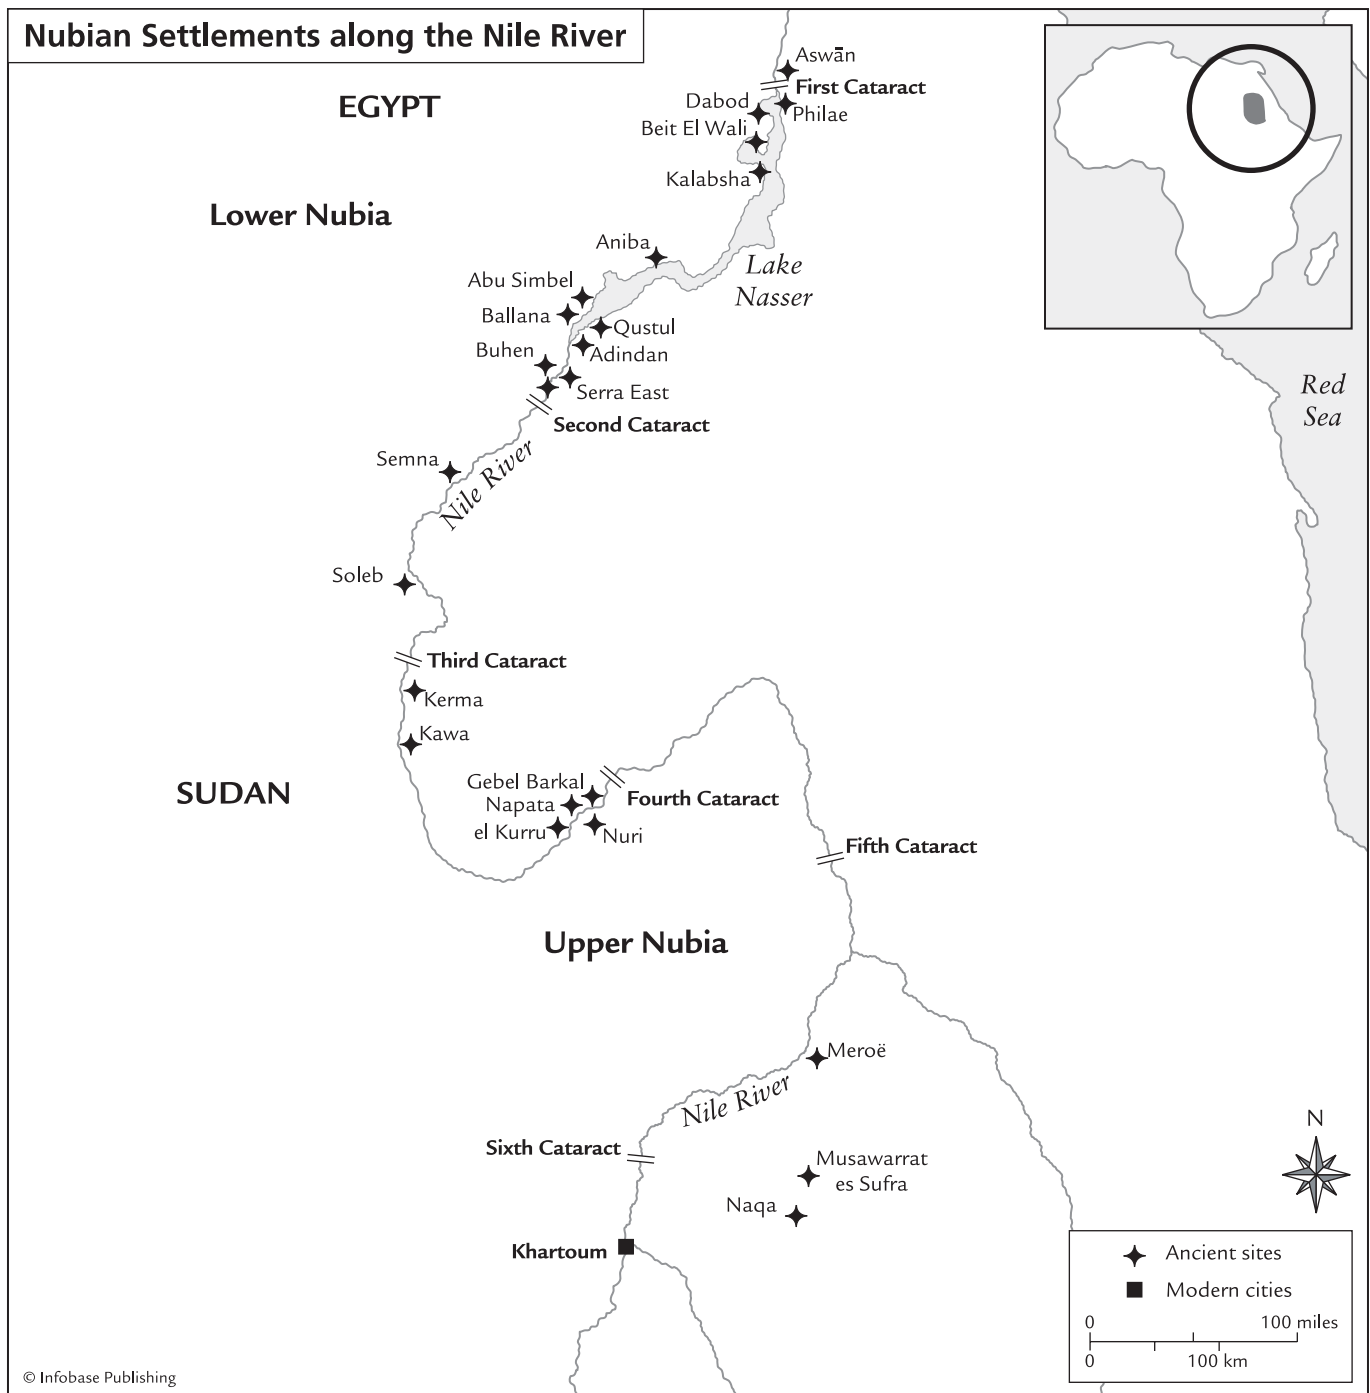

Since the 1830s a series of dams have been erected that allow for perpetual irrigation between Sennar in the south and the apex of the delta. Due to the construction of the Aswān High Dam, the course and pattern of the Nile inundation have changed considerably since ancient times. The dam was finished in 1971, and with its completion Lake Nasser was created and Lower Nubia destroyed. Between 1934 and 1960 the population of Egypt grew to almost 28 million inhabitants. This growth proved to be too much for

the available agricultural land. Because of necessity the decision was made to build a dam that would span the entire width of the Nile. This dam prevents the annual inundation from occurring in Egypt proper and allows for consistent irrigation patterns and constant agriculture. These circumstances prevent observation of the seasonal patterns that would have existed earlier; historical documents need to be relied upon in order to determine the old flood patterns. Because the Nile's course has changed over time, some of the ancient monuments, which originally lay on the banks of the Nile, now appear to be floating in the desert with no means of access from the waterway.

The inundation was extremely important to the ancient Egyptians—so important that they worshipped it in the form of the god Hapy. The inundation is not to be confused with the river itself, which was called *itrw*. The ancient Greek philosopher Herodotus remarked that “Egypt is the gift of the Nile.” The Egyptians even created their calendar based on the stages of the Nile's transformation. The Egyptian year was divided into three seasons: *akhet* (inundation), *peret* (growing season), and *shemu* (drought season). The names of the seasons were associated with the stages of the inundation. The inundation began in July with the peak water levels occurring in the middle of August. The inundation did not completely overflow the banks but instead ran off through channels into the fields beyond the riverbanks. The banks of the Nile would have been raised so as to prevent the flooding of nearby villages. These channels, or canals, were then blocked off in order to keep the water for future use. The dikes would then be cut when necessary. However, even up to the end of the 19th century the river at times would have overflowed and flooded the surrounding areas, except for the roads that were raised above it. When the waters had receded in October or November, the farmers plowed their fields and laid their seed. In the months from January to April the crops matured. The main crops were barley, emmer, einkorn and spelt.

It is possible that the employment of these canals dates back as early as the Predynastic Period, as evidenced by the macehead of King Scorpion (ca. 3150 B.C.E.). The area of cultivable land was increased in New Kingdom times by the invention of the *shaduf*, an irrigation tool, and increased again in Ptolemaic times with the advent of an animal-powered waterwheel (*sakkia*). With improved methods of agriculture more land was cultivated, and the marshy areas disappeared. The reduction in marshy land is one of the reasons for the extinction of the papyrus plant, which used to grow in the marshy delta regions.

The Nile also functioned as the primary mode of transportation. If people wanted to travel north, they could go with the flow of the Nile. If they wanted to travel south, then they would simply hoist their sails, since the wind blew south. When looking at ancient Egyptian nautical depictions, the modern scholar can discern which way the boat was traveling simply by noting whether the sails were up.

As the Sahara dried out between 3000 and 2000 B.C.E., the Nile River valley became a center for human civilizations, including those in ancient Nubia.

With the invention of the Nilometer the Egyptians could record the river levels and attempt to predict their crop yields. A Nilometer consisted of a series of steps that were used to mark the height of the Nile inundation as well as regular water levels. Surviving Nilometers exist at the sites of Philae, Idfu, Isna, Kom Ombo, Dendera, and Aswān. In Cairo there

is also an Islamic Nilometer from about 705–715 C.E., which may have been built on the site of a Pharaonic Nilometer.

LOWER EGYPT

The ancient capital of Memphis (modern Cairo) sits at the apex of the Nile Delta. The delta, or Lower Egypt, is wide and

marshy and quite different in appearance from the Nile Valley. There are also many lakes and patches of low, salty ground. These landscape differences may be the reason that the ancient Egyptians distinguished between the Two Lands. The area of the delta creates a fertile triangle that is shaped like the Greek letter delta. In ancient times there were five major branches of the Nile that flowed into the Mediterranean Sea: the Damietta, the Rosetta, the Canopic, the Sebennytic, and the Pelusiac. Now there are only two: the Damietta in the east and the Rosetta in the west. It is possible that a rise in the ground level of the eastern delta caused the other branches to dry up. Despite the fact that the delta contained many waterways, there was not much available land more fertile than that in the Nile Valley. Much of the area was marshy and too wet to farm, but it did contain wildlife and fish. Many of the archaeological sites located in the delta cannot be fully explored owing to the high water table. It is thought that the delta played a fundamental role in the earliest periods, especially in the religious sphere. Unfortunately, the material evidence does not fully reveal the area's importance. The delta was an important region because of its agricultural potency as well as its proximity to the Mediterranean Sea and to the Near East.

ANCIENT PROVINCES

The ancient Egyptians divided Egypt into nomes, or provinces. Upper Egypt had 22 nomes, and Lower Egypt had 20, equaling 42. The nomes in Lower Egypt developed much later than those of Upper Egypt. The area occupied by the Faiyûm and the western oases were not organized according to this scheme. One way that the size of the individual nomes can be reconstructed is through a list of their lengths along the Nile recorded in the kiosk of King Sesostris I (r. ca. 1971–1926 B.C.E.) at Karnak. Each nome had a capital city and a nomarch who ruled the nome. Some capitals changed over time, and others are still uncertain. Each nome had its own symbol, and standards were used in Upper Egypt to make such identifications. Over time new titles emerged, and certain localities became known by such designations as the “ibis nome.”

An auxiliary region, called the Faiyûm, was located to the west of the Nile Valley and south of Memphis. This area measured about 4,633 square miles and created a fertile depression in the Libyan Desert. The Faiyûm was consistently inhabited, and archaeological remains date back to around 8000 B.C.E. Some of the remains date to as recently as the Christian Period (641 C.E.). During the Paleolithic Period this depression consisted of a salt lake, which eventually changed into Lake Moeris (modern-day Birket Qārûn). Lake Moeris is linked to the Nile by the Bahr Yusef Canal, which diverges westward north of Asyût. In Pharaonic times the water level was lowered, and it was used to irrigate the surrounding land for agriculture. It is thought that an area of 174 square miles was gained during the reclamation projects of the Middle Kingdom. This area was increased in Ptolemaic times (ca. 304–30 B.C.E.) to approximately 463 square miles and was used for agriculture. At this time the Faiyûm was one of the most prosperous areas in Egypt.

OASES

The oases in the western desert running from north to south are as follows: Siwa, Bahariya, Farafra, Dakhla, and Kharga. They were settled by the Egyptians, but in ancient times this area was known as Libya. Siwa Oasis is located about 348 miles west of Cairo and was first settled in the Twenty-Sixth Dynasty (ca. 664–525 B.C.E.). This site is famous for the oracle that was visited by Alexander the Great. The Bahariya Oasis was another fertile depression, located about 124 miles west of the Nile. This site was founded earlier than Siwa and contains remains from the New Kingdom. Farafra Oasis is the smallest of the major Egyptian oases. It is located about 186 miles west of modern Asyût. So far no Pharaonic archaeological remains have been discovered there; however, the site is mentioned in Old Kingdom sources, and by the time of the New Kingdom it was known as a Libyan settlement. The Dakhla Oasis is located even farther south, about 186 miles west of Luxor. This site is of interest because it has Old Kingdom settlement remains, which testify to the expansive control the Egyptians held in the Libyan Desert at this time. Kharga Oasis is the largest of the major Egyptian oases. It is located only 108 miles west of Luxor. The Pharaonic remains are scarce, but what is left dates to the Ptolemaic period. These oases were held only in times of strong government. They were valuable because they produced grapes and dates, acted as caravan posts for long journeys, and functioned as outposts for dealing with the Libyans. Additionally, this area is where thieves fled to escape the law and where exiles were banished. Some scholars have called it the Egyptian Siberia.

ALEXANDRIA, THE SINAI, AND THE NEAR EAST

The city of Alexandria, located at the western end of the Mediterranean coast of Egypt, was an important city in the Ptolemaic Period. It was founded by Alexander the Great and was established on a less important ancient Egyptian town called Rakote. Alexandria was a prosperous, cosmopolitan city that replaced Memphis as the capital of Egypt. The coastal region west of Alexandria is where the majority of the Libyan population resided. This area was also home to a series of forts built by Ramses II (r. ca. 1290–1224 B.C.E.) as far as 210 miles west of Alexandria. The Ptolemies pushed all the way to Cyrenaica (about another 400 miles west).

The Sinai, a peninsula lying between the Mediterranean Sea and the Red Sea, was also important for the Egyptians. The Wadi Maghara and Serabit el Khadim are two of the main Egyptian sites in the Sinai. It was by way of three main routes through the eastern desert that the Egyptians traveled to the Red Sea and ultimately to the Sinai. These routes also gave access to various quarries located in the eastern desert. The Egyptians would have had to cooperate with the local nomadic populations in these regions. As far as is known, the Egyptians navigated the Red Sea in order to trade with the Sinai and Punt, whose exact location remains unknown.

The Great Temple at Abu Simbel on the banks of the Nile; the Nile is the heart of Egypt and without it Egyptian civilization may never have developed in the dry desert climate of northeast Africa. (Courtesy of the Oriental Institute of the University of Chicago)

The proximity of the Near East to Egypt's northeastern border also played a primary role in the development and evolution of Egyptian culture. Connections between these two regions were established as early as the Predynastic Period. Evidence of trade in the Old Kingdom can be seen in the Lebanese cedar used to make King Khufu's (r. ca. 2551–2528 B.C.E.) boat. In the Middle Kingdom the Egyptians traded with the Near East, mainly through the port of Byblos located on the Mediterranean coast, north of modern Beirut. Official Egyptian seals have been found in Israel, Syria, and Turkey. Royally sponsored trade activities reached as far as Ugarit in the north, and objects from Minoan Crete have been found in Egypt. Local trade took place between the people of the eastern delta and those living in the region that is now southern Israel. Similarities existed in the material cultures of these two populations. In the New Kingdom the Egyptian military held parts of the Near East for over 200 years; this situation was repeated in the later periods.

NATURAL RESOURCES

The natural resources that were available to the Egyptians in antiquity are quite impressive. The northern part of the Nile

Valley is made up of limestone; beginning in Gebel el-Silsila the sandstone comes down on both sides of the Nile and replaces the limestone all the way into Sudan. Limestone is a softer stone, and the Nile has been able to carve some of it away, thus creating a broader floodplain in the north. Such is not the case with the sandstone in the south. The Egyptians used both limestone and sandstone for construction. There were many resource sites within easy reach. Schist could be found between Qena and Quseir, quartzite came from Gebel Ahmar, alabaster came from Hatnub, and granite was quarried at Aswān. Although some of the resources were nearby, others required large-scale expeditions, such as greywacke in the Wadi Hammamat and gold in the Nubian mines. The Egyptians also mined copper, turquoise, malachite, and amethyst in the eastern desert and the Sinai. There is no evidence that the Egyptians themselves conducted the mining operations in the Sinai; they most likely had a local crew working for them.

The Wadi Natrun in the western desert was the source of natron, which was used for mummification and purification rituals. Above all Egypt acquired a wealth of gold through its mining activities along the Nile in Nubia and in Nubia's east-

ern desert. Aside from gold, Nubia also supplied Egypt's hard stone: pink and black granite, diorite, and porphyry, all of which were much desired by the Egyptians. From the natural resources, the Egyptians were able to produce and trade faience, glass, gold, jewelry, precious and semiprecious stones, linen, papyrus, and stone vessels. They used these natural resources to trade with their neighbors for other commodities that they lacked, like timber from Lebanon, lapis lazuli from Afghanistan, and ebony, ivory, various spices, and incense from Africa. Furthermore, the Nile itself provided the material for making pottery and mud-bricks, two essentials for everyday life.

In ancient times Egypt's culture prospered in relative isolation. To the north was the Mediterranean Sea; to the west were mountains with the desert running almost all the way to the Atlantic Ocean; to the south was Lower Nubia, where six cataracts blocking the Nile from Aswān to Khartoum made it impossible to navigate; and to the east rocky cliffs and desert gave way to the Red Sea. The only area that was left vulnerable was the corridor in the northeastern delta that met with the Sinai and led to the Near East. The Egyptians made great attempts at securing this defenseless point. Although this seclusion allowed an independent culture to flourish and postponed the invasion of Egypt, it was through this northeastern corridor that the Assyrians, Persians, and Macedonians would eventually enter Egypt.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Historical events in ancient times were greatly influenced by climate and proximity. People who lived in areas with good climates and fertile soil had a much easier time thriving than those who lived in areas in which daily living was more difficult. People who lived close to centers of civilization were more likely to come in contact with that civilization, exchanging learning and trading goods, than those who lived on mountaintops or on distant islands where no visitors ever came. In the ancient Near East a combination of water sources and drought forced people to master agriculture and band together in cities; these activities in turn resulted in the creation of some of humanity's first centers of civilization.

The world's very first agricultural societies appeared between 6000 and 8000 B.C.E. in an area called the Fertile Crescent, which stretches 1,200 miles from the Mediterranean coast of Israel and Lebanon to the Zagros Mountains in Iraq and Iran. Climate change made agriculture possible. At the end of the last ice age, about 11,000 B.C.E., the climate in the Fertile Crescent grew warmer and wetter. This change improved growing conditions for many local grains and other plants. Grasslands and forests expanded, increasing the available habitats for both animals and humans. Good living conditions allowed human populations to grow and fill the ancient Near East.

MESOPOTAMIA

The Tigris and Euphrates rivers define the area known as Mesopotamia, which has long attracted human settlers. Both rivers originate in Turkey. The Euphrates, south of the Tigris, flows through Syria before entering Iraq's northwest corner. Several large tributaries flow into the Tigris from the eastern mountains, including the Khabar, the Great Zab, the Little Zab, and the 'Uzaym. The Tigris and the Euphrates meet 115 miles before they jointly reach the Persian Gulf. Both the Tigris and the Euphrates are prone to flooding and changing their courses. The upper reaches of both rivers are rough, unpredictable, and difficult to travel by boat. People living in the area never adopted either river as a major trade route, though some intrepid merchants did transport goods on wooden rafts from Anatolia to the cities in lower Mesopotamia.

The area southeast of the modern city of Baghdad is a broad, flat delta. Just above the point where the Tigris and Euphrates meet is a large marshland. Northeast of Mesopotamia are the high Zagros Mountains. These form a physical boundary between fertile Mesopotamia and points east. The Zagros Mountains were home to forests of oak, maple, pistachio, and hawthorn trees. Many wild animals lived there, including sheep, goats, and gazelles. To the south and west of Mesopotamia are deserts. There is also a sizable desert between the Tigris and Euphrates north of the modern cities of Hīt and Sāmarrā.

Mesopotamia has always been dry and prone to violent extremes of weather. Rain falls between December and March, but even then only a few inches fall each year. More rain falls in the mountains. The prevailing winds in this area are a dry cool wind blowing from the north and the warmer sirocco from the southeast. Summers are very hot, reaching temperatures of 120 degrees Fahrenheit, and winter temperatures are cold but not devastatingly so. This pattern has varied slightly over the past 10,000 years, with some periods in the ancient world being slightly wetter than others, but lack of water and unpredictable weather have always defined life in the region.

The population of the area first started to grow around 5800 B.C.E., when the climate suddenly improved after a brief "mini ice age" that afflicted all of Europe and Mesopotamia and lasted for about 400 years, starting in 6200 B.C.E.. Scientists believe that Mesopotamia may have received about 25 percent more rain than it does in modern times, and more of the year's rain may have fallen in the summer, making it more useful to farmers. The annual floods of the Tigris and Euphrates were higher then, too, providing farmers even more water. The climate changed, however, around 3800 B.C.E. For the next thousand years Mesopotamia and the entire eastern Mediterranean region were afflicted by a severe drought. Rain stopped falling in the summer, and when it did fall, it arrived too late to water crops.

From that time onward Mesopotamians relied almost entirely on their two rivers to provide water for their crops. The

Tigris and Euphrates overflowed their banks every spring, fed by melting snow in the Anatolian highlands. These annual floods were a mixed blessing. They provided necessary water for fields, but they were unpredictable; some years they arrived with such force that they swept away entire villages. Mesopotamians spent much of their effort containing the waters of the rivers, building levees to keep the overflowing rivers within their banks. Some years the floods were much lower than in other years, or they arrived later than expected, causing farmers to lose their crops. Sometimes the rivers changed course, leaving towns high and dry. Farmers had to control water flow in order to water their crops reliably. People living close to the river banks could use groundwater or floodwater to grow plants, but people farther away had to dig irrigation canals or build dams to harness water for their own fields.

As the droughts continued in the centuries after 3800 B.C.E., it became harder for people to live in the countryside away from the rivers. People clustered on the river banks in settlements that gradually turned into cities. Cities provided the only means of keeping large numbers of people alive in the arid environment. All food had to be grown in a small area just beside the river, and water had to be allocated and dispensed carefully to make the most of the small amount that was available. City officials organized farming and irrigation, stored food to prepare for droughts, and dispensed carefully rationed portions of grain to residents. By 3100 B.C.E. about 80 percent of Mesopotamians lived in cities. Sumerians and Babylonians constantly negotiated and fought with one another over scarce water resources.

Though these cities provided some protection against climatic fluctuations, they were extremely vulnerable to catastrophes. The Sumerian city of Ur died as a result of one such catastrophe. Ur was a huge city on the Euphrates. In 2200 B.C.E. a major volcanic eruption somewhere in the Northern Hemisphere sparked a major drought that lasted for 278 years and affected the entire Mediterranean world. Snow stopped falling in Anatolia, and as a result the Tigris and Euphrates stopped flooding. The city found it increasingly difficult to grow enough food for the population. At the same time nomads who had lived in the countryside moved into the cities in an effort to feed themselves. The combination of overpopulation and lack of food was disastrous for the government; by 2000 B.C.E. it had collapsed, and most of Ur's population was dead or dispersed into the countryside in a quest for water and food. By 1900 B.C.E. the rains had returned, and farming once again became possible. Nevertheless, water shortages remained a perennial problem, as they do to this day.

LEVANT

The Levant is a common name for the part of the Near East that includes Israel, Lebanon, Jordan, Palestine, and Syria; it is bounded by the Mediterranean Sea, the Taurus Mountains, the Arabian Desert, and Mesopotamia. Most of the region is hilly, except for the Mediterranean coastal plain. The climate

is Mediterranean, with long, hot, dry summers and cool, rainy winters. Winters are usually not very cold, but snow can fall in the mountains. Many types of plants and animals lived there in ancient times, including sheep, goats, migratory birds, date palms, and olive trees. Lebanon was famous for its cedar trees, the wood of which was coveted throughout the Mediterranean region.

The Levant has a warm climate and fertile soil, but it has always been plagued by lack of water. Much of the area is desert. The Jordan River is the largest river in Israel; humans have always lived near it to take advantage of its water, and they have often fought over it. The largest body of freshwater in the area is the Sea of Galilee, a freshwater lake that lies several hundred feet below sea level in modern Israel. Many fish lived in this lake, and many of the humans who lived around it worked as fishermen.

One of the area's largest bodies of water is the hypersaline (extremely salty) Dead Sea. The Dead Sea is almost nine times as salty as the ocean. It was salty in ancient times as well and was one of the world's first tourist attractions. The biblical king David took vacations there, as did King Herod the Great. The Dead Sea's waters were of no use for agriculture, but local people did extract minerals from the waters to sell as fertilizer or as ingredients in making Egyptian mummies.

The Levant was located in the center of the ancient world and was prone to being occupied and fought over as a result. Its Mediterranean coastline made it desirable to traders who carried goods between Greece, Rome, Egypt, Mesopotamia, and the Persian Empire. It was surrounded by large powers, including Greece, Rome, Egypt, Mesopotamia, and the Persian Empire, and most of them marched through it or occupied it at one time or another. Anyone walking to or from Egypt passed through the Levant; these passersby included numerous armies. A road along the shore, which the Romans called the *Via Maris* (sea road, or way of the sea), linked Egypt with the northern empires; it was built long before the Romans arrived to name it, probably during the Bronze Age.

PERSIA

Persia occupied the area that is now called Iran. It was to the west of Mesopotamia and separated from it by the Zagros Mountains. The Zagros Mountains run along the Gulf of Oman and the Persian Gulf up to Armenia and Pakistan, a fertile but mountainous area. Central Persia consisted of a large, flat plateau surrounded by mountains. It was inaccessible and saline, covered with salt marshes and salt flats, and very few people ventured there in ancient times. Northern Persia is also lined with mountains, the Elburz and Talish mountain ranges, which extend eastward to modern Afghanistan. The area near the Caspian coastline is flatter. Iran's modern eastern border is another series of mountains that form a boundary between Iran, Afghanistan, and Pakistan; in the heyday of the Persian Empire, however, Persia included this mountain range in its territory, and Persian territory extended all the way to the Indus River.

Persia's climate was and is characterized by extremes of temperature. Some of the world's highest modern temperatures have been recorded in the central plateau, reaching highs of 132 degrees Fahrenheit. Winter temperatures are below freezing; mountainous areas have the coldest temperatures. Most of the country is quite dry; the central plateau receives almost no rainfall. Some parts of Persia have long been subjected to periodic violent windstorms.

The most fertile area of Persia in ancient times was along the coast of the Caspian Sea. This part of the country received by far the most rain and has always had the highest human population of the region. The Caspian lowlands were heavily forested with many kinds of trees, including orange, lemon, date, fig, pomegranate, willow, and oak. Animals native to the area included Persian gazelles, onagers (wild donkeys), many types of goats and sheep, porcupines, badgers, partridges, and pheasants. The Caspian Sea itself was a rich source of food, such as white fish, herring, and the valuable sturgeon.

Persia was located at a crossroads between Asia and Europe. By the fifth century B.C.E. Persians were regularly trading with their neighbors in India, Mesopotamia, Greece, and Egypt. They built and maintained a road from Susa, on the Tigris in Mesopotamia, all the way to Smyrna, the modern Aegean city of İzmir, Turkey, principally to facilitate royal communication throughout the empire but also to permit easy trade with the West. This road was called the Persian Royal Road.

On the other side of Persia, traders from China and India frequently appeared with silks, jade, and other Asian goods. Alexander the Great opened a route through Persia and brought eastern traders all the way to Europe. By the first century B.C.E. there was an established trade route running from China to Rome; this trade route is known as the Silk Road. The Silk Road ran through Persia just south of the Caspian Sea and followed the Persian Royal Road to the Mediterranean. From there traders could take ship or walk overland to the Aegean coast of Turkey, Egypt, northern Black Sea ports, Rome, North Africa, and Spain. Traders carried goods in caravans of carts and pack animals, such as camels and donkeys, selling Chinese and Central Asian goods to people in the West and bringing Western goods back to Asia. By the first century C.E. Romans were regularly trading with merchants in China, Sri Lanka, India, and Southeast Asia, all of whom transported their goods through Persia and the Near East.

ARABIA

South of Mesopotamia and the Levant lies the Arabian Peninsula. It has coasts on the Red Sea, the Persian Gulf, and the Indian Ocean. Almost all of this vast expanse of land is desert. The climate is extremely dry and excessively hot, and very few people lived in it in ancient times. The few who did were experts at water conservation. The Arabians of the ancient world clustered on the coasts of the Red Sea and the Persian Gulf.

Arabia was of interest to ancient Greeks and Romans chiefly because its coasts provided convenient ports for trade

with India. Greeks and Macedonians traded with Arabs who brought goods from India and the southern Arabian Peninsula (modern Yemen and Oman) overland by camels; major trade routes ran from Yemen to Medina and from Petra to Syria. During the early empire sailors mastered the weather patterns caused by the monsoons in the Indian Ocean, and from then on most trade with India was done by sea.

ANATOLIA

Anatolia is the region that today forms the large Asian portion of the nation of Turkey. The western parts of Anatolia are very close to Europe, and during ancient times these regions were the main point of cultural exchange between Asia and Europe. People traveling from Mesopotamia, Persia, the Levant, or Egypt went either overland through Anatolia or in ships, hugging the southern Anatolian coast.

Anatolia is a giant peninsula with coastlines on the Black Sea, the Sea of Marmara, the Aegean Sea, and the Mediterranean Sea. The Mediterranean coastline is pocked with coves and bays that are virtually indistinguishable from one another and hence difficult to navigate. In ancient times these coves and bays made ideal hideouts for notorious pirates, such as the pirates who kidnapped Julius Caesar in 75 B.C.E. The island of Cyprus lies in the northeast corner of the Mediterranean, in the angle formed where the Anatolian peninsula meets the Levant. The Aegean coastline is also rocky and full of islands just offshore. Both the mainland coast and the islands attracted large numbers of human inhabitants in ancient times; Lesbos, Kos, Smyrna, and Ephesus are all in this area. The area was not good for growing grain, but residents took advantage of other opportunities, such as shipbuilding, marble quarrying, and trade.

The Dardanelles form a strait between the Aegean and the Sea of Marmara. They were a prime strategic location in ancient times; the ancient city of Troy was built on a hill overlooking the southern entry to the straits. The Bosphorus was another strategic strait, running between the Sea of Marmara and the Black Sea. The ancient city of Constantinople was built on the southern point of the Bosphorus. The area south of the Sea of Marmara was fertile and proved an ideal location for agriculture. This fertile plain included the area east of the Bosphorus and the western Anatolian Black Sea coast; the ancient kingdom of Bithynia occupied these areas. The eastern part of the Black Sea coast was somewhat isolated from the rest of Anatolia by its steep coastlines.

The Anatolian plateau itself is high and surrounded by mountains. The northern mountains, called the Pontus Mountains, parallel the Black Sea coast. The Taurus Mountains parallel the Mediterranean coast. Central Anatolia is situated between these two mountain ranges. To the east of the plateau the Taurus and Pontus ranges meet, creating the highest peaks in the region; Mount Ararat is the highest point in Anatolia. The Tigris and the Euphrates both originate in this region and are fed by snowmelt from the mountains. Southeast of the mountains the terrain slopes down to Syria.

The most fertile parts of Anatolia are the Mediterranean coastal plain and the area south of the Sea of Marmara. These regions and the area on the Aegean coast all have a Mediterranean climate, with long, hot, dry summers and cool, wet winters. Crops from these areas included grapes, olives, citrus fruits, figs, and wheat. Central Anatolia has a much harsher climate, with very cold winters and more rain and snow than coastal regions. In ancient times much of Anatolia was covered with forests. Cyprus was also heavily forested, and ancients used its forests for timber. Natural rock structures within the Anatolian plateau lent themselves to interesting housing arrangements; many people in Cappadocia lived in caves that had formed naturally in the rocks. People who lived in central Anatolia typically made their living by trading in some local substance. For example, the settlement of Çatalhöyük (first colonized about 7500 B.C.E.) was built near a large deposit of obsidian, a volcanic rock used to make tools in the ancient world; its economy was entirely based on the obsidian trade, which residents sold to Syrian and Mediterranean traders. Despite the existence of trade routes, people living in the Anatolian plateau tended to be isolated from one another and from the larger Mediterranean civilization.

Human settlement surrounded the Black Sea and extended into the region between the Black Sea and the Caspian Sea. This region was the home of the ancient kingdoms of Pontus, Colchis, and Armenia; Colchis was considered the legendary source of the Golden Fleece and the destination of Jason and the Argonauts (a mythical story involving heroes searching for treasure, plus love, betrayal, and murder). Colchis was situated on a plain east of the Black Sea, but aside from that flat area, the region is rugged and mountainous. The Caucasus Mountains have a cold climate. The mountains, the dense forests, and the harsh weather combined to make the region northwest of Anatolia inaccessible to most travelers. As a result, the people who lived there tended to be isolated from one another and from the larger ancient world.

THE BLACK SEA DELUGE THEORY

The body of water that is now known as the Black Sea has not always been a body of saltwater. After the last ice age it was the Euxine Lake, a vast freshwater lake that may have had no physical connection to the Sea of Marmara. Its surface was about 450 feet below the level of the Mediterranean Sea. The lake's shores were fertile and full of wild game, and the climate was mild. Humans settled on the shores of the lake, farming, hunting, and raising animals.

Around 6200 B.C.E. the giant Laurentide ice sheet in Canada began to melt; as it melted, it fed icebergs into the Atlantic Ocean. This event caused the planet's overall temperature to drop, resulting in a mini ice age that lasted about 400 years. Anatolia and the Levant became much drier; farmers could no longer count on being able to grow their crops. Numerous inland settlements were abandoned as people moved closer to Euxine Lake. When the warm, wet

weather returned around 5800 B.C.E., the population on the lake's shores increased.

Around 5600 B.C.E. the lake changed. According to a modern theory, a massive flood turned the Euxine Lake into the Black Sea in about two years' time. Rising sea levels in the Atlantic raised sea levels in the Mediterranean, which fed into the Sea of Marmara. The land separating the Sea of Marmara from the much lower Euxine Lake was thin and narrow. One day the water started lapping over the edge. This trickle of water eroded away some earth, allowing more water to flow downhill. Within days saltwater was rushing from the Sea of Marmara into the Euxine Lake. The water level of the Euxine rose six inches per day. Within two years the Euxine Lake's surface was at the same level as that of the Mediterranean, and the water was no longer fresh but was instead brackish. The villages that had lined the shores of the lake were completely inundated.

This theory, sometimes called the Black Sea deluge theory, is now the topic of much debate. Many people believe that this event, if it happened, could have been the historical inspiration for the story of the Biblical flood and Noah's ark. What appear to be ancient buildings and freshwater snails have been discovered about 300 feet below the surface on Turkey's Black Sea coast. These items date to about 5000 B.C.E., providing evidence to support the theory. Some geologists, however, insist that water flowed between the Black Sea and the Sea of Marmara for thousands of years before the deluge supposedly happened.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

Asia and the Pacific region encompass an enormous area, from the Arctic to the Antarctic and from the Ural Mountains to the eastern Pacific Ocean. This area includes all imaginable variations of climate and geography, from the highest mountains on earth to some of the flattest floodplains, from extremely wet environments to places with no rainfall at all. The Asian continent has several large river systems, many of them originating in the Himalayas. The whole area is affected by monsoon patterns in the Indian Ocean and cyclones that form in the Pacific.

The Asian landmass includes a large coastline on the Indian and Pacific oceans surrounding a huge central landlocked area. The coastal areas, including India, China, and Southeast Asia, all fostered early civilizations that developed around rivers; the Yangtze, the Yellow, and the Indus River valleys were home to some of the earliest agricultural civilizations in Asia. These regions had good climates and ample water, which allowed their residents to build towns, grow large populations, and create culture and technology, including writing. Coastlines facilitated travel and exchange of goods and culture. The east-west axis of the continent made it easy for people to transport agricultural products and techniques from one place to another.

CENTRAL ASIA

The region west of Persia (modern Iran) and the Caspian Sea encompasses a variety of terrains. The southern coast of modern Pakistan lies along the Arabian Sea. Just north of the coast is the Central Makran Range. The central area is a large, flat plateau. Most of this area is extremely dry with almost no rainfall. To the west the Indus River flows south from the Himalayas. The river creates an extremely fertile valley that was a center of human settlement in ancient times. The Hindu Kush Mountain Range runs through northern Pakistan and most of modern Afghanistan. These mountains are high and snow covered, and they prevented ancient people from moving freely in this area. The same mountain chain continues north into modern Tajikistan and Kyrgyzstan. This entire region is prone to earthquakes.

The Caspian Sea coast drew ancient human settlers who caught fish, such as sturgeon, in its waters; the northern coast where the Volga River enters the sea was especially attractive. To the west of the Caspian Sea and north of Persia lies a huge, flat area of deserts and steppes. The Amu Darya River crosses this region from the Pamir Mountains to the Aral Sea, a large body of freshwater. Aside from this water, this area (modern Turkmenistan and Uzbekistan) has been arid desert with little rainfall for many centuries. The ancient Chinese Silk Road passed through this region, going north of the mountains to the southeastern end of the Caspian Sea in Persia. North and northeast of the desert is a large area of grassland pocked with small lakes and salt flats. The Syr Darya River flows from the Kyrgyz Range to the Aral Sea; in ancient times, it had a wide, well-watered delta that could support agriculture.

INDIA

The Indian subcontinent is a giant triangular peninsula that juts southward into the Indian Ocean. The Arabian Sea forms its west coast, and the Bay of Bengal lies to the east. Narrow mountain ranges called Ghats run down both coasts, the Eastern Ghats in the east and the Western Ghats in the west. Between the Ghats and the ocean are fertile, wet coastal plains.

The Thar Desert lies to the east of the Indus River; though historians are not sure exactly when it formed, it was certainly a dry, rocky desert by ancient times. The Ganges River runs from west to east across northern India and drains into the Bay of Bengal. The river drains a large, flat area that has very fertile soil, is easily irrigated, and has been intensively farmed and densely populated for thousands of years. The Brahmaputra River joins the Ganges just above the delta. It flows through the Assam valley, one of the wettest and most fertile places on earth.

The Himalayas, the Thar Desert, and the Indian Ocean rule India's climate. The mountains block cold winds from central Asia, keeping winters warm in India south of the Himalayas. The Thar Desert attracts rain-bearing clouds that bring the seasonal monsoon. The monsoon is a wind pattern

that follows the same course every year; the Indian monsoon blows out of the Arabian Sea in early summer, causing heavy rains on the subcontinent after about June 1, and reverses direction in the fall, taking the rain with it. The monsoon rains can also be dangerous, causing floods and thunderstorms. Ancient farmers did their best to time plantings with the monsoons. Although the monsoon rains were generally predictable, some years they came later or failed entirely, devastating crops. Droughts plagued India as they did most of the ancient world. The people looked to their kings to end droughts by placating the gods. One ruler, Chandragupta, abdicated his throne in 301 B.C.E., hoping to end a drought by dedicating his life to prayer; he is said to have fasted to death.

All of India was fairly accessible to the outside world. The northeast was close to Persia, facilitating commerce as well as cultural and religious exchange with the Middle East. It was also vulnerable to invasion from northern cultures, including the Persians and the Scythians, because of its proximity to central Asia. The southern part of the subcontinent was well positioned to trade with other ancient empires, especially once sailors mastered sailing with the monsoons around the first century C.E. The Dravidian people of southern India used this ability to trade with the Middle East and even the Roman Empire, sailing around Arabia to get close to the Mediterranean. Many Indians emigrated east from south India during the first 500 years C.E., settling in Thailand, on the Malay Peninsula, and in Indonesia, and even reaching as far as Taiwan or the Philippines.

HIMALAYAS

The Himalayas lie to the north of the Indian subcontinent. The southern edge of the range stretches 1,500 miles northwest to southeast from the Hindu Kush to the headwaters of the Brahmaputra River. The Himalayas are the world's highest mountains; 14 of the peaks, including Mount Everest, are over 26,427 feet high. The Indus, the Ganges, the Brahmaputra, and the Yangtze rivers all originate in the Himalayas. The Himalayas were formed by the collision of the Indo-Australian plate with the Tibetan plateau; this geological plate has been moving slowly northward for the past 70 million years and keeps the Himalayan region geologically active. Earthquakes were common in ancient times. Ancient peoples in the Himalayas and India certainly experienced earthquakes; ancient texts such as the Vedas (perhaps written around 3000 B.C.E.) often mention them and suggest supernatural causes.

The terrain of the Himalayas varies more by altitude than by latitude. The lower slopes of the southern Himalayas are fertile lands with deciduous forests. Above this area is a region called the Terai belt, an area of clay, sandy soils, and seasonal floods that turn the terrain into marsh. Indian rhinoceros were plentiful here in ancient times. Above the Terai is a zone of rocky soils and subtropical pine and broadleaf forests. Next come temperate broadleaf and mixed forests, and above them subalpine conifer (trees with needles for leaves)

forests. Several glaciers run through the upper Himalayas; these glaciers periodically drop chunks of ice, which can create extremely rugged terrain.

The mountains affect the climate throughout Asia, blocking winds from every direction. Cold northern winds cannot reach India, keeping India warm. In turn, India's monsoon cannot reach Mongolia, keeping Mongolia dry and possibly accounting for the formation of the Gobi and Takla Makan deserts. The Himalayas themselves have harsh weather, which limited human settlement.

The mountains formed a barrier to the intermingling of peoples. Ancient people did most of their traveling on foot, and it took a great deal of time and effort to climb slopes and find mountain passes. Consequently, few people traveled between India and China. Nevertheless, the Chinese Silk Road passed through the Himalayas, going through the Nathu La Pass between China and Tibet and the Jelep La Pass between Tibet and India. Merchants used this road to transport Asian merchandise to Persia and points farther west.

CHINA

North of the Himalayas is the huge, high plateau of Tibet. This region is covered with lakes created by glaciers. Winters in Tibet can be very cold and snowy, and the rugged terrain kept the area sparsely populated and ensured that the people living there were isolated from other areas. North of Tibet is the Takla Makan Desert, a sandy, barren area. East of the Takla Makan is the larger Gobi desert, which extends north into Mongolia.

Eastern China is much wetter and more fertile. Many rivers run from west to east, originating in the Tibetan highlands or the Himalayas and emptying into the Pacific. These include the Pearl, the Hai, the Yangtze, and the Yellow rivers. China has coasts on the Gulf of Tonkin, the South China Sea, the East China Sea, and the Yellow Sea.

The Yangtze River in southern China is China's longest river. It begins in the Tibetan Plateau and enters the Pacific Ocean near the site of the modern city of Shanghai. The Yangtze basin is warm and wet and has a stable temperate to subtropical climate. Rain falls year-round, though about half of the annual rainfall occurs in the three months of summer. The soil is very fertile, making this area one of the first places that humans domesticated plants, starting around 8000 B.C.E. The river had become a major transportation route by the first century B.C.E.; ships could sail 600 miles upriver from the ocean, allowing foreign imports to reach well inland. Many cities rose up on the river's banks; one of the most important was modern Nanjing, built around 500 B.C.E. The Yangtze was wide and difficult to cross, making it an effective boundary between ancient kingdoms.

The Qin Ling Mountains north of the Yangtze divide northern and southern China. North of these mountains is the Yellow River valley. The land surrounding the Yellow River is buffeted by the cold, dry winds blowing east from the central Asian plains. The soil here is fertile, and early humans

domesticated crops here as well, starting around 8000 B.C.E. For centuries the Yellow River region was richer and more populated than the Yangtze River valley, despite the Yangtze's warmer climate; the Yangtze gained prominence starting in the Han Dynasty between 202 B.C.E. and 220 C.E.

Summer rains in the Yellow River region are unreliable, and winters can be severe. The climate is harsh and unstable, prone to droughts and unexpected violent floods, both of which killed millions of people over the centuries. China was afflicted with numerous severe droughts during its ancient history. Writings from the sixth century B.C.E. mention techniques for coping with drought and methods of praying for rain, some of them suggested by the philosopher Confucius. Rulers also put a great deal of work into holding back floods.

Northeast China, called Manchuria in the 20th century, was heavily forested in ancient times. The climate in this region varies widely from season to season. Summers are very hot and rainy, as Pacific rain blows in from the southeast. In the winter winds blow from the northwest, bringing Siberian cold; the winds are dry, so little snow falls.

The Korea Peninsula juts southeast into the ocean from northeast China. It is separated from China by the Yalu River and a mountain range. North of Korea is the Sea of Japan; south of it is the Yellow Sea and Korea Bay. The Korea Strait separates Korea from Japan. Korea's climate is similar to that of northeast China, with warm, wet summers and cold, windy winters. Northeast Korea is mountainous, but the rest of the peninsula consists of flat, fertile plains. Rivers flow southwest from the mountains, providing water and floodplains suitable for rice cultivation.

SIBERIA AND MONGOLIA

Siberia stretches all the way across the northern portion of Asia from the Ural Mountains to the Pacific. Eastern Siberia consists of grasslands with some marshy areas. The central Siberian plateau has a number of lakes. The ground in northern Siberia is permafrost, earth that never thaws, even in the summer. The northern coastline of Siberia lies along the Arctic Ocean. Siberia has always been known for its harsh climate and extreme winters, which have discouraged settlement. Few people aside from some nomadic herders attempted to live there in ancient times. The land is covered with ice and snow for half the year, most of the rivers and lakes are frozen for months at a time, and winter temperatures in modern times reach minus 90 degrees Fahrenheit.

JAPAN

Japan is a chain of islands stretching along the Pacific coast of mainland Asia from just south of Sakhalin Island in the north to Okinawa in the south. Although the archipelago contains around 3,000 islands, four large islands make up the main body of Japan. These are Hokkaidō, Honshū, Shikoku, and Kyūshū. All of Japan is mountainous and experiences frequent earthquakes; several volcanoes were active there in ancient times. Most of Japan was covered with forests.

Hokkaidō is the northernmost island of the chain and has the coldest climate. The Sea of Okhotsk lies off its north-east coast, and it is separated from the island of Sakhalin (now part of the Russian Federation) by a narrow strait. This strait was one of the two main points of entrance to Japan in ancient times. Hokkaidō has the highest mountains in Japan. It was heavily forested in the past, making it difficult for people to travel in the interior.

Honshū is the largest island with a range of latitudes. Its western coast is on the Sea of Japan, and its east coast is on the Pacific Ocean and the Philippine Sea. The western side of Honshū receives winter winds from the northwest; it has colder weather and receives more snow than the eastern side. The central mountains have a mountainous climate, with cold, snowy winters and hot, humid summers as well as a large temperature difference between night and day. On the Pacific coast summers are hot and humid, and winters are warmer than in the west; the central mountains block the western winds, so this region receives its weather from the Pacific to the southeast. All of Honshū is covered with mountains except for the low-lying marshy area where the city of Tokyo was founded. Mount Fuji, Japan's most famous volcano, is in central Honshū.

The southern islands of Kyūshū and Shikoku have warm, wet climates. The islands that stretch south from Kyūshū are even warmer and wetter, with a subtropical climate. They are at particular risk of tropical storms and typhoons (tropical cyclones). Southwestern Kyūshū is separated from Korea by a narrow strait; this was the other spot where people entered the islands from mainland Asia.

The ample rainfall and fertile volcanic soil made most of Japan a good place to grow rice and other crops, though the mountains and forests did present obstacles to travel and agriculture. Geographical isolation, however, slowed the development of Japanese culture. Japanese people did not learn about agriculture until around 300 B.C.E. and did not appear in contemporary histories until the first century C.E. Japan's separation from mainland China affected cultural practices; Japanese people adopted Chinese culture and writing as their own, but they transformed them into something completely different.

MAINLAND SOUTHEAST ASIA

Mainland Southeast Asia lies on a peninsula south of the southeastern part of China. This area includes the modern countries of Myanmar, Thailand, Laos, Vietnam, Cambodia, and Malaysia. The Gulf of Tonkin and the South China Sea lie off the east coast of Vietnam. The Gulf of Thailand lies to the south of Thailand and Cambodia and to the east of the Malaysian isthmus. To the west of Southeast Asia are the Andaman Sea and the Bay of Bengal. The extensive coastline gave ancient people easy access to the sea, and they became expert sailors, sailing to islands south and east of the mainland. Southeast Asian societies also traded with India, and Southeast Asian ports often served as middle stages for the

transport of goods between India and China; trade was vigorous during the first five centuries C.E.

Several rivers flow through this region. The Irrawaddy flows south from the northern mountains of Myanmar and empties into the Bay of Bengal; its delta is large, fertile, and well watered, making this area a prime location for human settlement. The Mekong River originates in the mountains of southern China, flows through northern Myanmar, and crosses Laos, Thailand, and Cambodia before reaching southern Vietnam, where it creates a vast delta before emptying into the ocean. In ancient times this delta was one of the most productive agricultural regions in all Asia. The upriver stretches of the Mekong flow through mountainous terrain, creating rapids and waterfalls; the lower stretches are more placid and easily navigable. The Red River flows from China to northern Vietnam, where it also forms a fertile delta near the modern city of Hanoi.

This region has a tropical climate, with warm weather year-round except in the mountains. The monsoons affect the weather, creating an annual rainy season; ancient farmers and sailors relied on the predictable weather and winds. Because of its proximity to China, the region was readily colonized by Chinese people moving southward. These Chinese brought with them agriculture, which was easily adapted to the Southeast Asian climate and terrain, and their own culture, which local people quickly adopted.

INDONESIA, NEW GUINEA, AND THE PHILIPPINES

South of mainland Southeast Asia lies maritime Southeast Asia, a huge collection of islands between Asia and Australia. Most of these islands are mountainous but have fertile soil and ample rainfall to grow crops. People living in these areas adapted the landscape to create fields; they dug terraces on many hillsides to create flat fields for their rice and other crops.

The sea was essential to the dissemination of culture and trade. Whether these islands were heavily populated and developed complex civilizations depended very much on how close they were to the mainland and to one another. Generally the closer a location was to China, the more likely that it would be exposed to Chinese culture and agriculture. The remoter islands never acquired much technology in ancient times. Java and the Philippines were densely populated and had some educated residents; Borneo and Sulawesi were not.

The Strait of Malacca separates Malaysia from the Indonesian island of Sumatra. Sumatra is a large island, mountainous on its southern side and flat everywhere else. The Indian Ocean lies to the south of Sumatra. To the west of Sumatra is the island of Java; the Java Sea lies to its north. To the east of Java lie the islands of Bali, Lombok, Sumbawa, Flores, Timor, and many others.

This region is part of the Pacific "ring of fire," a chain of active volcanoes that circle the Pacific Ocean. The volcano Krakatoa is one of the most famous. It lies in the straits between Java and Sumatra. The Javanese *Book of Kings* describes an event that may have been a 416 C.E. eruption of Krakatoa,

though geologists are not sure this happened. Krakatoa seems more likely to have erupted in 535 C.E., disrupting the global climate for several years.

To the east of the Indonesian archipelago lies New Guinea, a giant island. New Guinea is very mountainous. Although it has a tropical climate, the hilltops can be cool. The terrain is extremely rugged, and travel through the interior is difficult. As a result, people living there in ancient times tended to be isolated from one another, to the point that islanders developed numerous different languages that were all mutually unintelligible.

OCEANIA

The Pacific Ocean is home to numerous islands. These islands were gradually populated during ancient times, as people set out from their homes in boats. Over the years humans traveled by boat to the far-flung islands of the Pacific. They started with the closest islands and moved from there farther afield. Samoa was settled around 1200 B.C.E.; Hawaii and Easter Island were much later, around 500 C.E.

The island group called Micronesia lies to the east of the Philippines. The Marshall Islands lie east of Micronesia. East of Papua New Guinea are the Solomon Islands, Vanuatu, Nauru, and New Caledonia. Farther east are Fiji, Samoa, Tonga, Kiribati, the Cook Islands, Tahiti and French Polynesia, the Marquesas Islands, and Pitcairn Island. Hawaii lies far to the north of these, and Easter Island far to the east.

Pacific islanders were expert seafarers. Boats were the only way to travel among the islands, and people regularly set out in outrigger canoes for voyages that lasted several days. They navigated by the stars and the sun. They also used boats at home for fishing. People could not inhabit new islands without food; when they went on voyages of settlement, they brought with them their agricultural and hunting habits, adapting them to local conditions. This practice did not always result in balanced or adequate diets. Many groups of islanders were extremely isolated from outside influences and hence developed their own unique cultures.

AUSTRALIA AND NEW ZEALAND

Australia is a continent south of Indonesia and New Guinea. It is separated from Asia by the Arafura Sea, the Timor Sea, and the Torres Strait. The Indian Ocean lies to its west, the Southern Ocean to its south, and the Tasman Sea, Coral Sea, and Pacific Ocean to its east. The Great Barrier Reef, a giant coral reef, runs over 1,200 miles along the northeast coast.

The continent is mostly flat. The majority of the mainland consists of several plateaus of limestone with some highlands in the coasts and in the very center. The Nullarbor Plain on the southern coast is one of the flattest places on earth. The Simpson Desert in the eastern central area has numerous salt basins. A chain of mountains called the Great Dividing Range runs along the eastern coastline. The Australian Alps

MICRONESIA, MELANESIA, AND POLYNESIA

The islands of the South Pacific are divided into three groups: Micronesia, Melanesia, and Polynesia. The native populations of these island groups look very different from one another. Melanesians have dark skin and tightly curled dark hair and resemble Australian aborigines. Micronesians have dark skin, somewhat lighter than that of Melanesians, and straight or wavy dark hair. Polynesians are taller than Micronesians and Melanesians; they have light skin, straight or wavy dark hair, and Asian facial features. How these ethnic populations arose where they did is very much a function of geography.

Melanesia (“black islands”) lies south of Micronesia. It includes Papua New Guinea, Fiji, Vanuatu, and the Solomon Islands. Melanesia was first populated around 38,000 B.C.E. by dark-skinned people who traveled there from Southeast Asia. These people probably descended from humans living in Java (in Indonesia) at least a million years ago, giving them time to evolve features typical of people living in the tropics, such as dark skins. Micronesia (“small islands” in Greek) lies in the western Pacific northeast of Australia. This region was also colonized by dark-skinned people from Asia around 28,000 B.C.E.

Polynesia (“many islands”) is a much bigger region to the east of Micronesia and Melanesia. It was populated much later, between 1600 B.C.E. and 500 C.E. Polynesia’s population came from China. (Historians refer to these people by their language group, Austronesian). The Austronesian people had a fertile homeland and mastered agriculture early, allowing them to spread out from their homeland. They moved into Taiwan and Southeast Asia and displaced the native populations there; they then built boats and started sailing east.

The peoples of Melanesia were firmly ensconced in their homes, with solid agricultural systems, and they managed to keep their homelands despite the invasion of technologically advanced Austronesian invaders. New Guinea’s forbidding geography helped isolate its natives and preserve their ethnic features. Micronesians seem to have mixed more with the Chinese. Polynesia, however, had no native inhabitants, so the Austronesian colonists furnished all ethnic stock. For this reason, Polynesians look East Asian.

lie in the southeast corner. The island of Tasmania lies south of this area; its mountainous terrain is a continuation of the Australian Alps. Tasmania is covered with temperate rain forest. East of the mountains is a narrow coastal plain that receives regular rainfall.

Because of its extreme isolation, Australia did not see an influx of settlers in the ancient period. Its aboriginal inhabitants apparently arrived over land bridges attached to Southeast Asia more than 40,000 years ago; the bridges were covered by water soon thereafter, and Australia's human population evolved by itself. The only exception was the region of the Torres Strait and Queensland, both close to Indonesia and New Guinea; the people here had more contact with Asia and were culturally different from the aborigines.

Australia's climate presented major difficulties to human settlers. Aside from the eastern and northern coastal areas, most of the land is desert; it receives little or no rainfall, and there are very few sources of water. Aboriginal people learned techniques for surviving in the desert, but these required great ingenuity. Agriculture was impossible on most of the continent, owing to the dryness and the poor soil. Northern Australia has a tropical climate similar to that of neighboring New Guinea and Indonesia. It has rain forests, mangroves, and other woodlands; in ancient times the rain forests on the Cape York Peninsula contained a huge number of plant species.

New Zealand is an archipelago formed by a pair of large islands and numerous small ones 1,250 miles to the southeast of Australia, separated from the Australian continent by the Tasman Sea. New Zealand extends about 1,000 miles from northeast to southwest. Both islands are mountainous and volcanic. Most of the land was covered with forests in ancient times. New Zealand was home to many unique plants and animals that evolved in isolation from other species. The climate is temperate; the southern island is wetter and cooler than the northern island.

EUROPE

BY PETER BOGUCKI

The study of ancient European society depends on an understanding of the ancient environment. Archaeology, especially prehistoric archaeology, is very closely related to environmental science and geography, and archaeologists work closely with the botanists, climatologists, and geologists who provide information about the ancient environment. The environment, which includes climate, vegetation, fauna, drainage, and soils, provided prehistoric peoples with resources for economic and social development but also placed constraints on their activities.

MAJOR DIVISIONS OF EUROPE

The two environmental zones that have the most relevance for ancient Europe are the Mediterranean evergreen zone and the temperate deciduous forest. A third major European envi-

ronmental zone, consisting of the northern boreal coniferous forest of northern Scandinavia and European Russia and the treeless zones of northern Scandinavia, did not figure prominently in the major developments of European prehistory.

The Mediterranean evergreen zone encompasses most of the regions that are now Greece, Italy, and Spain along with the southern coast of France and the Adriatic coast of Croatia and Albania. The vegetation is the result of an arid summer and winter rain. The vegetation in this zone must retain foliage in the winter in order to grow, and its deep roots and thin leaves reduce evaporation during the summer drought. Today only remnants of this natural vegetation remain, owing to grazing and agriculture.

The temperate deciduous forest encompasses most of western, central, and eastern Europe, including the British Isles and southern Scandinavia up to about latitude 60 degrees north. Its vegetation consists primarily of broad-leaved trees, such as oak, elm, linden, alder, and beech, that grow in the summer and shed their leaves in the winter. In modern times only small tracts of the primeval European deciduous forest remain, surrounded by farmland, industry, and towns.

KEY REGIONS

Within Mediterranean and temperate Europe are several geographical zones that had particular significance for ancient European societies. At many points during the last 10,000 years, these regions had distinct cultural personalities but were not so separate from their neighbors that connections could not be perceived as well. Greece, including Crete and the islands of the Aegean all the way to western Turkey, was one such area with a distinctive cultural personality during later prehistoric times. A distinctive sequence of prehistoric cultures culminated in the civilizations of the Bronze Age and Classical Greece (480–320 B.C.E.).

Italy, including Sicily, forms another distinct unit of cultural geography when linked with the coastal areas of Croatia and Albania across the Adriatic Sea, though the Apennine spine of Italy divides this area even further. A sequence of prehistoric cultures culminated in the Etruscan and Roman civilizations.

The Iberian Peninsula, cut off from continental Europe by the Pyrenees Mountains, is the third major subdivision of Mediterranean Europe. Although the prehistoric societies of this region did not culminate in urban civilization, their artifacts and settlements have a very distinctive character that reflects their distance from the other societies of both Mediterranean and temperate Europe.

The mountain systems of central and eastern Europe, the ranges that make up the Alps and the Carpathians, were of significance for prehistoric society in temperate Europe insofar as they formed barriers that needed to be crossed and that in turn separated other geographical zones from each other. "Ötzi," the famous frozen and mummified man found in the Alps in 1991, was attempting such a crossing. Later these ranges were also important as areas for the acquisition of raw

materials, such as copper and salt, as well as for their lush upland pastures in their foothills.

The arc of the Carpathians encloses a bowl known as the Carpathian Basin, which is the territory of modern Hungary and adjacent areas. Part of this area is covered by open grassland, the Great Hungarian Plain, while elsewhere there are fertile floodplains. The Danube River runs through this area on its way to the Black Sea while the Tisza is an important tributary that attracted prehistoric settlement in its drainage.

East of the great curve of the Carpathians stretch the grasslands of Ukraine and southern Russia that form the western end of the vast Eurasian steppes. Since it occupies much of the area north of the Black Sea, this region is also called the Pontic steppe. The valleys of the major rivers that drain through this region—the Dniester, the Dnieper, and the Volga—were forested, but the areas between them were dry, cold grasslands. These natural grasslands provided rich grazing lands for livestock-herding peoples in prehistoric times and were also the region in which the horse was first domesticated.

The hills of central Europe contain the headwaters of many of the major European rivers, including the Danube, the Rhine, the Elbe, the Oder, and the Vistula. Among these hills are basins filled with very fertile soil called loess, which was deposited by winds during the ice age. Beginning with the earliest farming settlements, these basins were centers for prehistoric settlement throughout later prehistory. Flint outcrops in the hills were the source of raw material for stone tools.

North of the uplands is the North European Plain, which stretches from Holland across northern Germany and Poland into the Baltic states and Russia. The North European Plain was shaped by the ice age glaciers, either having been covered by ice or being buried in the sand and gravel that were deposited by melting ice in front of the advancing and retreating ice sheet. Sandy outwash plains, gravel and clay ground moraine, marshy hollows, small ponds and large lakes, and meandering streams characterize this flat area.

The Atlantic facade is the part of Europe whose environment is closely linked to the Atlantic Ocean. Western and northern France, Britain and Ireland, and much of the Benelux countries are all part of this zone. The sea provides not only the weather but also food, and the prehistoric inhabitants of this region were at home on the coast and on the water. Straits such as the English Channel and the Irish Sea were easily crossed with watercraft. Interior regions benefited from the rain and from the proximity of the sea as well.

The final geographical zone of temperate Europe with particular significance for ancient societies is southern Scandinavia, which encompasses modern Denmark, the southern third of Sweden, and the extreme southern tip of Norway, along with the Baltic islands of Gotland, Öland, and Bornholm. Southern Scandinavia, like the North European Plain, was also shaped by glaciers, but in addition it has a strong maritime influence

from the North Sea and the Baltic Sea. Numerous estuaries and bays were locations for prehistoric fishing settlements while interior regions of Denmark and southern Sweden contained fertile plains. Gotland, in the middle of the Baltic sea, has its own distinctive character and a rich archaeological record reaching back to Stone Age seal hunters.

ANCIENT CLIMATE AND ENVIRONMENT

The prehistoric environment in these regions was far different from that of the present day. From the mid-19th century, scientists—geologists and botanists foremost among them—have been able to reconstruct the prehistoric environment. Analytical tools are continually improved, so there is still much that can be learned about the prehistoric environment in Europe.

The principal sources of data on the prehistoric environment come from landforms and sediments, their composition and structure, and the pollen and other biological elements they contain. Since much of Europe was shaped by glaciers and their meltwater, geologists can trace their advance and retreat through the relic landforms they left behind, like moraines and eskers. Other landforms are formed through erosion, which in turn can indicate increased rainfall. River terraces show ancient water levels and episodes of sedimentation and downcutting. The sizes of particles in sediments can reveal information about their transport and sorting.

One of the most important tools for the study of the ancient environment is pollen analysis. Each species of plant produces pollen that has a distinctive shape. The pollen is then blown away from the plant and eventually settles out of the atmosphere. When it falls into lakes and bogs, it sinks to the bottom, accumulates among the sediments building up, and is preserved. Botanists are able to extract cores from the sediments and study the range of pollen types and their quantity present in each layer. In this way they can reconstruct the vegetation around the lake or bog based on the proportions of different types of pollen. Broad regional changes in vegetation can also be traced on the basis of a sufficient number of samples. Changes in vegetation can also be correlated with changes in climate.

The scientific tools for the study of prehistoric environments would be of only limited value if there were not a means of dating them. Carbon-14 (radiocarbon) dating is the principal tool available to scientists to obtain dates from ancient sediments or pollen cores. This technique, developed in the late 1940s and improved dramatically in the 1980s, works best for samples between 48,000 B.C.E. and 1000 C.E. It involves the fact that the radioactive form of carbon, an isotope known as carbon-14, is absorbed by plants and the animals that eat them. When such organic remains are found, it is possible to measure how much carbon-14 remains and determine the age of the organic substance and the sediments in which it was found. The dates derived from carbon-14 cannot be expressed in precise years but are given in ranges of years within which the actual date lies.

Valuable information both for studying ancient climate and for dating comes from tree rings. Ancient timbers and old trees dredged from rivers or preserved in waterlogged sediments can be sampled to examine their growth rings. Thin rings indicate poor growing conditions, most often correlated with low rainfall and summer temperatures, while thick rings appear when the growing conditions are good. Patterns of thick and thin rings can be matched from one timber to another, and regional sequences of growth rings can be built up. Scientists have been able to develop over much of temperate Europe tree-ring sequences that cover thousands of years. Dates obtained from tree rings are often to an exact year or even season. For example, all the timbers used in a Bronze Age ceremonial monument on the coast of eastern England popularly known as “Seahenge” were cut in 2049 B.C.E., probably in the spring or early summer.

These are only a few of the techniques used for reconstructing the prehistoric environment. Recently ice cores from Greenland have provided important evidence that bears on the environment of ancient Europe. Land snails in ancient soils can show whether the landscape was forested or open. Computer modeling of ancient climates has revealed potential periods of increased rainfall and winds.

THE END OF THE ICE AGE

The environment and geography of ancient Europe are very much the product of the ice age, known as the Pleistocene. Even in areas that were not covered by ice, the presence of the ice sheets and the tundra and other periglacial conditions that extended in front of them influenced almost every corner of the continent. For example, the loess that fills the basins in the hills of central Europe and covers vast parts of the Carpathian Basin was deposited by winds sweeping up soils on the desolate unvegetated parts of western Europe and dropping it hundreds of kilometers to the east. Even Mediterranean Europe felt the presence of the ice in the form of colder temperatures and lower sea levels.

The ice sheets advanced and retreated many times over the course of the Pleistocene. Four major advances and retreats were punctuated by many minor ones. Although humans have inhabited parts of Europe since at least 700,000 B.C.E., this discussion traces the environmental changes during the final millennia of the Pleistocene and during the Holocene, the period of modern conditions during which we live today.

Around 17,000 B.C.E. the large ice sheet that had covered northern and parts of central Europe for thousands of years began to retreat from its maximum advance. The ice front ran in a line southeast from the North Sea across Denmark and northern Germany, reaching its southernmost point in southwestern Poland and then northeast across Belarus and Russia. Smaller glaciers were found in the Alps and in the Scottish Highlands. The ice retreated in fits and spurts, leaving debris and moraines in its wake across northern Europe. Except for mountain glaciers in northern Scandinavia, the

Ax made from reindeer antler found at Earls Barton, Northamptonshire, England, dating to about 8,500 B.C.E. and characteristic of similar items from Denmark, the Netherlands, and Germany; this is one of several finds that links Britain to Europe at the very end of the last ice age, when sea levels were still low and there was dry land between Britain and Europe. (© The Trustees of the British Museum)

Pleistocene Ice Sheet of northern Europe was almost completely melted by about 7000 B.C.E.

The melting of the glaciers meant that large amounts of water were released into the oceans, dramatically affecting sea levels and coastlines. The phenomenon of rising and falling sea levels is known as eustasy. Postglacial eustasy caused sea levels to rise over 100 meters, drowning the continental shelves of North America and Europe. In the Mediterranean, the northern Adriatic sea, which had been a large plain, was inundated. The entrance to Cosquer cave in southern France with its spectacular ice age paintings made between 25,000 B.C.E. and 17,000 B.C.E. is now just over 120 feet below the surface of the Mediterranean, whereas it was once high above the water.

In northern Europe eustasy had even more dramatic effects. In 8000 B.C.E. Britain was connected to the continent by a vast land bridge across the southern North Sea. It was possible for hunter-gatherers to walk from Poland to Yorkshire, getting wet only when they had to swim across the rivers. Over the next 5,000 years, rising sea levels inundated this terrain, creating the English Channel (which was previously a large Atlantic bay) and the current coasts of the North Sea. Recent research using seismic data produced by oil exploration has enabled archaeologists at the University of Birmingham to map a remarkable drowned landscape with river channels and hills, essentially the western end of the North European Plain.

In Scandinavia, which had borne the greatest burden of the Pleistocene ice sheets, another force was at work to counteract eustasy. Released from the weight of the ice, the earth's mantle rebounded upward, a process known as isostasy. The effects of isostasy are best seen in northern Denmark and in central and northern Scandinavia. In the northernmost reaches of Sweden, land is now about 820 feet higher than it was before the ice melted, and it is still rising. Near Stockholm, Neolithic sites far inland were previously on the coast, and hunter-gatherer shoreline sites are now 262 to 295 feet above sea level. Bronze Age rock carvings made on coastal boulders are now 82 to 98 feet above the water level.

The European vegetation and climate changed dramatically as the ice sheets retreated, for the tundra and other periglacial landscapes that lay before the ice front also moved northward. Warm and cold periods alternated during the last stages of the ice age. A rapid increase in temperature about 12,000 B.C.E., followed by general warmth, was suddenly interrupted by a sharp cold period, known as the Younger Dryas, about 9000 B.C.E., when tundra again characterized the landscape across the North European Plain and northern England. After about 600–700 years the climate warmed up again, and around 8300 B.C.E. a transition to an essentially modern climate and vegetation occurred across much of Europe. This transition marks the beginning of the postglacial period known as the Holocene.

As the ice sheet retreated northward, the reindeer herds that roamed the periglacial landscapes of western and cen-

tral Europe also moved northward. The establishment of the Holocene forests brought the forest fauna that characterized later European prehistory, including red deer, roe deer, brown bears, beavers, wild horses, wild cattle, and wild pigs. Fish were abundant in the lakes and streams while flocks of waterfowl and solitary forest birds populated their preferred habitats. Along the coasts shellfish and seals were abundant. The result was an extraordinarily rich menu of resources for the hunters and gatherers who lived in these forests, known to the archaeologists as Mesolithic societies. The change was not nearly so dramatic in Mediterranean Europe, but rising sea levels made it possible to take advantage of fish and shellfish that had previously been far offshore.

THE HOLOCENE CLIMATIC OPTIMUM

The onset of warmer temperatures resulted in the growth of forests across temperate Europe, first birch and later pine. By about 7000 B.C.E. the first oaks, elms, and hazel began to appear. During the millennium that followed, a type of woodland, known as “mixed oak forest” but whose primary constituent was linden, appeared throughout much of temperate Europe. In the Mediterranean zone, broad-leaved deciduous trees still dominated the woodland, although the typical evergreen forests and shrubs that characterize modern vegetation in this area were beginning to appear.

During the Holocene the climate became progressively warmer such that between 6000 and 5000 B.C.E. it reached what is called the Postglacial Climatic Optimum. Summer temperatures averaged about 2 degrees warmer than they are today, and the winters were very mild, yet abundant rainfall resulted in lush vegetation. Such favorable climatic conditions were a major factor in the spread of farming across much of temperate Europe, resulting in the introduction of domesticated plants and livestock. The climate of Mediterranean Europe, however, appears to have cooled off somewhat at the same time, according to recent evidence.

COOLER, MOISTER CLIMATE

A sharp cold period called the Piora Oscillation, during which glaciers in the Alps again advanced significantly, brought the Postglacial Climatic Optimum to an end between 4000 and 3000 B.C.E. The climate of temperate Europe remained warm and dry between about 3000 and 1000 B.C.E. but then became progressively cooler and moister. By 700–500 B.C.E. temperatures were much lower than even 500 years earlier, though the weather in the British Isles remained relatively mild, and everywhere north of the Alps was much wetter and windier. Then the climate warmed again, such that the first few centuries C.E. were milder.

During these final millennia of prehistoric Europe the environment was irrevocably modified by human settlement, cultivation, and stockbreeding. Just after 4000 B.C.E. agriculture was introduced to Scandinavia and the British Isles, and by 3000 B.C.E. its spread throughout Europe was virtually

complete. Once the most fertile lands were colonized, farming spread to poorer quality soil, which the invention of the plow made it possible to cultivate.

DEFORESTATION

The most visible effect of cultivation and stockherding was the cutting of the forest for fields, pastures, construction material, and firewood. This deforestation appears in the pollen record as a dramatic and unnatural drop in the amount of tree pollen and a simultaneous increase in the amount of grass pollen. The ribwort plantain (*Plantago lanceolata*) flourishes in pastures, and its abundance in pollen samples from 4000 B.C.E. onward across temperate Europe reflects the high degree of deforestation. Deforestation in turn promoted soil erosion. When the climate turned wetter around 500 B.C.E., increased sediment deposition, or alluviation, occurred in valleys.

BLANKET BOG FORMATION

In Ireland and parts of Britain the removal of the forests by early farmers caused soil nutrients to be washed away, making the soils more acidic. Heather and rushes grew on the acid soils, and in areas of poor drainage the acidity inhibited the decomposition of dead vegetation, which formed peat. Layer upon layer of peat accumulated over the next several millennia, burying entire landscapes. The field walls and house remains of early farmers at the Céide Fields in northern County Mayo in Ireland that date to 3500 B.C.E. were subsequently covered by blanket bog over the last 5,000 years, preserving them for archaeologists.

During the later part of European prehistory, resources that had very localized sources came into widespread demand. Key among these were metal ores, especially the copper and tin needed to make bronze, which came into use around 2500 B.C.E. Copper comes from sources in the Balkans, the Alps, Wales, and southwestern Ireland, while tin has a much more limited distribution. Cornwall and Iberia were most often mentioned as its sources. Since copper and tin have to be smelted together to make bronze, it was necessary for people to mine the ores and then transport them to the same location.

Gold was extracted from placer deposits in streams and then hammered to make ornaments. The goldwork of the Late Neolithic in southeastern Europe, most notably found at the Varna cemetery, and of the Bronze Age in Ireland, is truly remarkable. Even more noteworthy is that much of it was deliberately buried in graves or in ritual deposits in bogs.

Later in prehistory, around 800 B.C.E., iron came into widespread use, though bronze continued to be used extensively. Iron ores are more widely distributed and easily mined, but smelting the iron from its ore requires high temperatures and the addition of carbon and limestone to the furnace to complete the chemical reaction. Iron manufacture was thus technically more advanced than bronze production, despite the fact that the raw material is easier to obtain.

Another commodity that was widely in demand in prehistoric Europe was salt, which was used for food preservation. Along the coasts and near salt springs, salt was produced through evaporation. When prehistoric people found deposits of rock salt, they mined them. Some of the most famous Iron Age salt mines, dating between about 800 and 500 B.C.E., are found at Hallstatt, near Salzburg in Austria. The shafts and tunnels of the Hallstatt mines reached deep into the mountain, and artifacts found nearby reflect trade networks that stretched from the Baltic to the Mediterranean.

Among the materials obtained in exchange were amber from the Baltic and coral from the Mediterranean. Amber is fossilized pine resin, and it is still abundant along the coasts of Poland and Lithuania even today. Another Mediterranean substance highly desired by the Iron Age chiefs of central Europe was wine, for grape cultivation and fermentation had become major agricultural activities in the warmer parts of Europe by the last millennium B.C.E.

The demand for copper, tin, salt, gold, amber, and coral as well as agricultural products, tools, and weapons led to the establishment of regular trade routes. Wagons pulled by oxen and horses, and large watercraft that could cross open bodies of water, were crucial in sustaining the trade connections between the communities of prehistoric Europe. Large boats built from planks, like the one discovered near Dover in 1992, crossed between the continent and the British Isles. Along with the goods, people and ideas also moved.

Such was the world that the Romans encountered when they extended their empire into temperate Europe. The Roman historian Tacitus (ca. 56–117 C.E.) described the Iron Age geography of temperate Europe in his book *Germania* and of the British Isles in *Agricola*, although his information was not generally based on firsthand knowledge. A key geographical boundary in Europe at this time was the Roman imperial frontier, which ran roughly from the mouth of the Rhine to the mouth of the Danube and across the neck of the British Isles just below Scotland. Yet the rest of Europe was not ignorant of the Roman world. The spectacular gold artifacts that date to about 400 C.E., found in Sweden, were made from gold coins brought back by Scandinavian mercenaries who had served in the Roman army.

GREECE

BY CHRISTOPHER BLACKWELL

The ancient Greek world had the mainland peninsula, the site of modern Greece, at its center, surrounded by the Mediterranean Sea and including a cloud of islands to the east and west. The sea to the immediate west of the peninsula was known as the Ionian Sea, between the southern end of the Adriatic and the Mediterranean itself; to the east was the Aegean Sea. The Gulf of Corinth divides the peninsula almost in half, east to west, bounded on the east by the Isthmus of Corinth and opening on the west to the Ionian Sea, separating northern Greece from its southern territory, the Peloponnese.

Because water has a specific heat at least four times greater than land—that is, it takes on heat and gives up heat four times less readily—seas have a moderating effect on temperature. In territories around the Mediterranean, one consequence of this effect is to make latitude less significant in terms of climate and temperature than proximity to the sea. Greek cities near the coast enjoyed similar climates, whether they were far to the south in Crete or far to the north in Thrace. But inland areas might differ in climate greatly from coastal areas at the same latitude. So the city of Corinth, close to the sea both to its east and west, had a very different climate from Delphi, less than a hundred miles inland but farther from the water.

The Mediterranean world enjoys mild, wet winds from the Atlantic Ocean to the west during the winter and dry, relatively cool winds from the northeast during the summer; the ancients called these latter winds the Etesian winds (the Greek historian Herodotus, for example, in his discussion of the climate of Egypt). Long, hot, and dry summers, followed by mild, wet winters, provided long growing periods, which suited grains, olives, and fruit (olives and figs, especially).

This climate probably accounts for the location of the earliest great civilizations of the Greek world, the Minoan and Mycenaean civilizations of the Bronze Age (the third and second millennia B.C.E.). The remains of these cultures show that they flourished in coastal areas of the mainland and on the Greek islands. Food was plentiful there, both agricultural produce and seafood—the wall paintings and pottery found in Bronze Age settlements on Crete and in the Aegean islands feature many scenes of sea life and fishing. The large, open-air palaces of the Minoans suggest that those people took full advantage of the mild climate, spending their time largely outdoors. Classical Greek architecture, too, reflects the climate. The great temples of Athens and Olympia, for example, have very little room inside them; they were intended not to contain worshippers but to be the centerpiece for outdoor rituals.

Ancient culture profited from this climate and geography. The sea provided easy travel, and closely spaced islands made navigation easy. Thus, Greeks could mingle with each other and with the peoples of the civilizations to the east and south—Babylonians, Assyrians, Persians, and Egyptians. The mild weather encouraged public congregations outdoors, in marketplaces and in parks. So the Stoic philosophers got their name from meeting in public colonnades, or stoas, and Plato's famous school of philosophy, the Academy, got its name from the park in which the philosophers met, the Akademe at Athens.

HIGHLANDS AND LOWLANDS

A spine of mountains runs the length of the Greek peninsula, from north to south, from the northern highlands between Macedonia (in the northeast) and Epirus (in the northwest), including Mount Olympus, down through Phocis (the site of the famous sanctuary of Apollo at Delphi, on the slopes of Mount Parnassus), and reemerges south of the Gulf of

Corinth to form the highlands of Arcadia in the Peloponnese. These mountainous regions have a climate similar to that of the more northerly parts of continental Europe—including regular snowfall in the winter months. These mountain ranges are the result of the intersection of tectonic plates, whose regular shifting makes the whole of the Greek world subject to earthquakes, accounting for the volcanic activity in the Aegean.

The majority of the population of Greece has always lived in the lowlands, near the coast, but both mountains and coastal plains played an important role in the lives of the people of ancient Greece. The mountains, less prone to drought in winter, provided grazing for livestock, mostly smaller animals like sheep, pigs, and goats, but cattle as well. Shepherds, goatherds, and swineherds would pasture their flocks in the mountains during the summer and bring them down to the plains, near the inhabited areas, during the winter. The nomadic life of these pastoral workers led to their status as both “insiders,” important members of the community, and “outsiders,” living at the margins of communities, a status that plays an important role in the literature of ancient Greece. Figures such as Eumaeus, the “noble swineherd” of Homer's *Odyssey*, and the shepherd of Sophocles' *Oedipus the King* provide insights into the workings of dysfunctional communities by virtue of the characters' marginal status.

The mountains were forested, providing fuel for heat, timber for building houses and ships, and other important forest products, such as oak tannin, used for curing hides into leather. As the population increased, though, during the first half of the first millennium B.C.E., overuse of this resource led to deforestation. By the fourth century B.C.E. ancient writers were commenting on the relative scarcity of wood. A character in Plato's *Critias* says of Greece in the early fourth century that “there are some mountains which now have nothing but food for bees, but they had trees no very long time ago, and the rafters from those felled there to roof the largest buildings are still sound.” This scarcity of timber affected the shipbuilding industry especially—the famous “cedars of Lebanon” became an important import during the Classical Period.

The coastal lowlands hosted most of the population and most of the land for growing crops. While the mountains provided animal products—meat, milk, and leather—the lowlands provided grains, fruits and vegetables, and olives, whose oil was not only an important source of fat and calories for the ancient Greeks but also a source of light when burned in lamps, hygiene when used as soap, and mechanical lubrication.

GEOGRAPHY AND TRAVEL BY LAND

There are no navigable rivers in Greece. In antiquity a few rivers could convey boats a short distance from the sea, but Greece had nothing equivalent to the Seine, the Danube, the Volga, or the Mississippi, comfortable thoroughfares for travel and communication. Those rivers that existed were narrow and shallow, and tended to swell to raging torrents during the

rainy winter and spring, as snow melted off the mountains, only to dry to trickles or dry up altogether during the dry summer. This lack of rivers, combined with the mountainous terrain, made commerce and communication by land extremely difficult and expensive. Travel by land tended to hug the coasts, moving north and south along the Ionian and Aegean coasts and east and west along the coast north of the Gulf of Corinth. This restriction of land travel to a few routes helps explain why battles occurred in the same places, century after century. Thermopylae, for example, a site where the north-south road from Boeotia and Thessaly passes through a narrow pass between the mountains on the west and the sea on the east, was the site of battles between Greeks and Persians in the fifth century B.C.E., among Greeks in the fourth century B.C.E., and between Romans and Seleucids in the second century B.C.E. During the Roman Empire the main Roman roads bypassed the Greek peninsula altogether, passing to the north.

THE IONIAN SEA

Along the western coast of the Greek peninsula, the Ionian Sea offered the least hospitable waters for travel. Close to the coast, protected by the chain of islands just off Epirus, the sea offered relatively predictable winds—blowing toward the land during the day and blowing out to sea at night. The islands offered many protected harbors, and there was easy entry to the protected waters of the Gulf of Corinth.

But to the west, beyond the single chain of islands off the coast, there are no islands between Greece and Italy and none south between the Peloponnese and Africa. To the north the Ionian Sea joins the Adriatic where the latter narrows, like a funnel, between the heel of Italy and what is now Albania. Because of this narrow passage between the seas, the same Etesian winds that brought cool, dry summers could whip up sharp storms in the channel. The passage between Italy and Greece, between Greek Corcyra (modern Corfu) and Italian Brundisium (modern Brindisi), was notoriously dangerous, both because of these sudden storms and because ships would lose sight of land, both to the east and to the west, at the midpoint of the passage.

A letter from the Roman Cicero to his friend Tiro, written in November 50 B.C.E., illustrates the fickle nature of the sea here, which could afford an easy passage or sudden death. Cicero wrote in *Epistulae ad familiares* (Letters to Friends), “At Corcyra we were detained by bad weather till the 15th. On the 16th we continued our voyage to Cassiope, a harbor of Corcyra, a distance of 120 *stades* [about 12 miles]. There we were detained by winds until the 22nd. Many of those who in this interval impatiently attempted the crossing suffered shipwreck. On the 22nd, after dinner, we weighed anchor. Thence with a very gentle south wind and a clear sky, in the course of that night and the next day we arrived in high spirits on Italian soil at Hydrus, and with the same wind next day—that is, the 24th of November—at 10 o’clock in the morning we reached Brundisium.”

THE AEGEAN SEA

The Aegean Sea, to the east of the Greek peninsula, is more hospitable. The Etesian winds are predictable out at sea during the summer, and the inshore and offshore breezes during the day and night are predictable near the coast. The many islands of the Aegean serve to reduce fetch, the distance wind travels over water unimpeded, reducing the maximum size of waves. The eastern coast of Greece is protected for a long stretch by the island of Euboea, and that coast, as well as the coasts of the many islands, provides innumerable protected harbors. The dry summer ensures good visibility by day and night for navigation (which was not a highly developed science among the Greeks of antiquity).

Storms, when they did arise, could be treacherous, producing sharp, unpredictable waves in the shallow waters and arising without much evident warning in the landlocked sea. Ships at sea could find themselves being blown downwind toward a lee shore, which often was rocky and steep. During the rainy, and windier, winter months the ancient Greeks regarded the sea as mostly impassible. The festival of Dionysia at Athens, for example, which was that city’s occasion to show itself off to people from the rest of Greece, was held in March, specifically because that month marked the beginning of the “sailing season.” But despite the unfriendly winter months, the Aegean served as a crossroads of commerce between the Greeks and the peoples of Asia and Africa. Greeks have been famous for their trade by sea, from Odysseus of Homer’s *Odyssey* to the Onassis dynasty of the present.

EPIRUS (NORTHWESTERN GREECE)

Epirus was the northwestern territory of Greece, west of the Pindus Mountains. It enjoyed heavy rainfall and was known in antiquity for its rich forests and ample pasturage for grazing livestock. Dodona, a flat plateau, in Epirus was the site of a famous sanctuary of Zeus, who was said to utter oracles from within an oak tree. According to Homer’s *Odyssey*, the hero Odysseus’s wealth was largely in the form of livestock, which grazed on the mainland, in Epirus and Amphilocheia, just to the south, while the hero’s own home was on the island of Ithaca.

MACEDONIA (NORTHEASTERN GREECE)

To the east of the Pindus Mountains was Macedonia. High and rugged in the west, it descended to fertile plains near the Thermaic Gulf, which opens into the northwest Aegean. Macedonians were looked on as only semicivilized by the southern Greeks during antiquity, but by the end of the fifth century B.C.E. the people of Macedonia had embraced high Greek culture. The Athenian poet Euripides retired to the Macedonian court, and 50 years later Philip II hired the philosopher Aristotle to tutor his son, Alexander. To the south of Macedonia was Mount Olympus, almost 9,600 feet high, whose summit, often wrapped in clouds, was the mythological home of the Greek gods.

THESSALY, PHOCIS, BOEOTIA (CENTRAL GREECE)

South of Mount Olympus, on the east coast of Greece, was Thessaly. Homer calls this territory “Horse-rolling Thessaly,” and its flat, grassy plains were among the relatively few areas conducive to raising horses and training cavalry. The soil of Thessaly, carried down as sediment by snowmelt from Olympus, was extremely fertile, and in antiquity Thessaly was an exporter of food. Between Thessaly and the area to the south, Boeotia, the mountains came close to the sea, near the gulf of Magnesia, forming a narrow pass through which ran the main road. This pass was also the site of geothermal springs, giving it the name *Thermopylae*, or “Hot Gates.”

Boeotia, the territory of the ancient cities of Thebes and Plataea, was ringed by mountains, including Mount Helicon to the west, site of an important cult of the Muses, the nine daughters of Zeus and patronesses of the arts. Poetry associated with this cult claims that the Muses taught the art of singing to the rustic farmer Hasid, making him an epic poet and entrusting him with agricultural and theological wisdom. Boeotia was fertile, although its climate tended toward extremes of heat in the summer and damp cold in the winter. Its main city, Thebes, was the home of the poet Pindar, the site of many of the myths that are the subject of Greek tragedy, and a great military power during the fourth century B.C.E. under the generals Epaminondas and Pelopidas. To the south of Thebes was Plataea, long an important ally of Athens, farther to the south, and famous for its participation in the Greco-Persian Wars at the beginning of the fifth century B.C.E.

West of Boeotia, in the high mountains around Mount Parnassus, was the territory of Phocis, site of Delphi. The ancient Greeks considered Delphi to be the center of the world, the site where Apollo spoke to humans through his oracle. The sanctuary at Delphi was considered a possession of all Greeks, was governed by an international council, and contained treasuries belonging to many individual cities, in which were stored the gifts that those cities had dedicated to the god. Even non-Greek nations sent gifts to Apollo, most notably King Croesus of Lydia, whose lavish dedications are described in Herodotus’s history.

ATTICA (THE SOUTHEASTERN MAINLAND)

The southeastern corner of the Greek peninsula, north of the Isthmus of Corinth, was Attica, the region around the city of Athens. Originally a region of many independent cities, the ancient Greeks claimed that the legendary king Theseus united the area into a single unified political entity with Athens at its head. Attica is bounded by the sea to the east and south. It connects with Boeotia to the north. To the west is Eleusis, once an independent city but said to have been conquered by Theseus. Farther to the west is Megara, a neighboring state and often an enemy of Athens. Just offshore to the south are the islands of Salamis, the site of the great victory of the

Greeks over the Persian fleet in the 480s B.C.E., and Aegina, another Athenian possession.

THE PELOPONNESE (THE SOUTHERN PENINSULA)

The southern peninsula of Greece, the Peloponnese, is connected to the northern mainland by the Isthmus of Corinth, whose principle city, Corinth, was an important center of trade. There is a canal across the Isthmus today, but in antiquity any commerce moving between east and west by sea would have either to make the (potentially dangerous) passage around the south of the Peloponnese or to stop at the Isthmus, unload cargo, and have the ships dragged across the land on rollers. This enterprise was profitable for the Corinthians, not least because the crews of these ships would be tempted to spend money in the city. Likewise, all north-south commerce by land, between the northern mainland and the Peloponnese, had to pass through Corinth. The Isthmus lies between the Gulf of Corinth to the west and the Saronic Gulf to the east. Immediately to its south is the area of the Argolid, named for its principal city of Argos.

The Argolid, site of the palace of Mycenae, was an important center during the Bronze Age. Another Bronze Age settlement on the coast, just across the Saronic Gulf from Athens, was Troezen, legendary birthplace of the Athenian king Theseus. The Argolid in antiquity was mostly self-sufficient, with access to the sea, fertile plains, and mountainous pasturelands to the west, as was its southern neighbor, Laconia, the region that included the ancient city of Sparta and the territory of Messenia. The Spartans, famous for their rigorous lifestyle and warlike abilities, had by the Classical Period reduced Messenia to a client-state, its population little more than slaves for the Spartans. As was often the case among ancient Greek cities, Sparta was regularly at war with its neighbor Argos, as Athens was with Megara.

The central Peloponnese, Arcadia, was isolated. High and rocky, far from the sea, it was a relatively sparsely inhabited land of forests and pastures, and the mythological home of wild spirits of the mountains. The main city of Arcadia was Megalopolis, in the south, closest to the sea, on the river Pamisus, which drained the high Arcadian plateau. To the west of Arcadia were Elis and Olympia. The latter was the site of the Olympic Games, in honor of Zeus, an international event founded in 776 B.C.E. and held every four years until closed by Theodosius, the Christian emperor of Rome, in 393 C.E. The games at Olympia are now the most famous of these ancient festivals, but there were many such events in antiquity: the Nemean Games in the Argolid, the Isthmian Games at Corinth, and the Pythian Games at Delphi in Phocis.

THE IONIAN ISLANDS

The islands of the Ionian Sea offered protected ports; the western coast of Greece did not. So, most trade between the mainland of Italy and Greece came through the islands of Cephalonia, Zacynthus, Corcyra, and Ithaca. The island

of Corcyra, modern Corfu, was especially prosperous. Its active trade to the east and west, combined with its high rainfall, led it to have the densest population of any area in ancient Greece. Corcyra was the site of a vicious civil war during the 430s B.C.E. that was one of the sparks which ignited the conflict between Athens and Sparta known as the Peloponnesian War.

The other islands of this area share similar characteristics. They are rocky and good for grazing, with easy access to the mainland, close by to the east. Ithaca was said to be home of Homer's hero Odysseus, though a precise identification between the real island and its poetic counterpart is impossible. Cephallenia was famous in antiquity for its pine forests, of which nothing remains today.

THE AEGEAN ISLANDS

The islands of the Aegean were even more inviting to settlement, combining the most attractive elements of the Mediterranean climate, the diversity of mountains and coastal plains in close proximity, with easy access abroad by sea. Aegina at the mouth of the Saronic Gulf, controlling access to the Argolid in the Peloponnese, Corinth on the Isthmus, and Megara and Attica on the mainland, was an early power until it came under Athenian control in the sixth century B.C.E.

The long island of Euboea, very close off the eastern coast of the mainland, was another early power in the Greek world. During the eighth century B.C.E. the cities of Lefkandi and Eretria sent out trade and settlements as far as Asia Minor and Sicily. By the Classical Period, however, Euboea had receded in importance after the rise of cities like Athens and Thebes.

The group of islands known as the Cyclades, because they form an uneven circle at the south end of the Aegean, is actually a continuation of the mountain range that runs down Euboea and across Attica. The islands of Naxos, Páros, Ándros, Delos, Syros, and Melos all possessed rich quarries of stone (which could be transported by sea much more easily than stone from landlocked quarries) as well as gold and silver. The islands' position in the path of trade between Greece, Asia, and Egypt ensured their prosperity.

The island of Thera (modern Santorini) was the site of prosperous settlement during the Bronze Age but was largely destroyed by a volcanic explosion during the 15th century B.C.E., an event, with the inevitable earthquakes and tsunamis radiating from it, to which many scholars point as the cause of the decline of Minoan civilization.

South of the Peloponnese the islands of Cythera and Anticythera form stepping stones from the Greek peninsula to the large island of Crete. Ships sailing from Greece could reach Crete without ever leaving sight of land, and Crete's coastline offers many safe harbors on the north side. The same is not true south of Crete; the island's southern shore is much less convoluted, and there are no islands for almost 200 miles southward toward the shores of Egypt and Libya.

Crete, then, was unified with the Greek world not only in climate but in culture and was the site of the earliest civili-

zation of people speaking a language recognizable as Greek. Crete was legendary in antiquity as the home of King Minos, who was said to have ruled over a maritime empire and extracted tribute from Athens. It was for Minos that the Athenian inventor Daedalus built the labyrinth at Knossos.

THE ISLANDS OF THE ASIAN COAST

East and north from Crete the islands of Kasos and Carpathus form two more stepping stones toward the large island of Rhodes, which is within sight of the mainland of Asia Minor, near what is now southwestern Turkey, and was the territory of Caria in antiquity. Caria, and the city of Halicarnassus, was the birthplace of the historian Herodotus, who came to Athens to compose his ethnographic account of the peoples of the Greek world and the conflict between the Greeks and the Persians. Along the coast of Asia Minor, in the eastern Aegean, were the large, prosperous, and often powerful islands of Lesbos and Chios. These were prosperous in agricultural products and in culture, enjoying their ethnic relationship with the Greeks of the mainland and constant contact with the many peoples of Asia.

The deforestation noted in antiquity was not the only significant factor changing the ecology and environment of the Greek world since antiquity. Under Byzantine and Turkish rule, cultivation of both grapes and olives increased, since these were valuable export crops during the period of Roman rule and afterward. Both of these crops have deep taproots that do little to hold soil in place. The practice of polyculture, planting other crops amid the vines and olive trees, held erosion at bay for a time but increased grazing of goats among vineyards and orchards led to the loss of a vast amount of rich topsoil. The dry, rocky landscape of exposed limestone evident in Greece today would have seemed very unfamiliar to a Greek of the sixth century B.C.E.

Erosion also caused the silting up of the mouths of rivers, and erosion from southern Russia, into the Black Sea and thence into the Aegean, has altered coastlines. The city of Pella, Alexander the Great's capital in Macedonia, used to be accessible by boat from the Mediterranean but today is shallow and choked with boulders. A modern visitor to Thermopylae, to take another example, might wonder why this place was called a pass. Today the sea is several miles from the old coastal road while in the fifth century B.C.E. waves would have broken at the base of the roadbed.

ROME

BY AMY HACKNEY BLACKWELL

The location of Rome combined a pleasant climate with good soil and other important advantages. The city was built on the Tiber River where it met with the smaller Anio (Aniene) River. Situated near the center of the Italian peninsula and close to the Adriatic coast, Rome was well placed to control both the peninsula and, ultimately, the lands surrounding the Mediterranean.

Rome was a hilly city. The ancient town was built on top of a hill on the east bank of the Tiber near a point where the river could be easily crossed because of an island in the middle of the stream. Before the founding of Rome itself, people lived in the area in smaller hilltop settlements; archaeologists have found evidence of towns dating to 1000 B.C.E. People built their homes on the hills for defense against attackers. These settlements gradually grew and spread into one another to cover the famous Seven Hills of Rome, an area that makes up about 4 percent of the modern city. The Seven Hills were the Palatine (traditionally believed to be the hill on which the legendary Romulus founded Rome), the Aventine, the Capitoline, the Quirinal, the Viminal, the Esquiline, and the Caelian. The lowlands between the Seven Hills were marshy in ancient times, but the residents had drained the marshes by the time Rome was known as a city.

Rome has a Mediterranean climate, with long, hot, dry summers and cool, wet winters. The climate appears to have been warmer in ancient times than it is today. The hot summers contributed to diseases in the densely populated city. Food-borne gastrointestinal diseases spread easily. The Tiber is a relatively short river, though it is the third-longest in Italy. It flows about 250 miles from its origin at Mount Fumaiolo in the Apennine Mountains to its mouth in the Tyrrhenian Sea. On its way it curls through the modern provinces of Tuscany and Umbria. After Rome the Tiber continues another 15 miles to the Tyrrhenian Sea. The Aniene meets it in the city. The Tiber and the Aniene provided Rome with two necessities: transportation and fresh water.

In its early days Rome had water adequate for its population from the Tiber and from local springs and wells. By the fourth century B.C.E., however, the growing city had to import some of its water from elsewhere. Romans began building aqueducts to bring water from distant streams. Many aqueducts took water from the Aniene River or its tributaries and brought it to locations in central Rome. One of the most famous was Acqua Marcia aqueduct, which transported water from the Aniene to the Capitoline Hill; it was known for water of high quality. (The city's sewers emptied directly into the Tiber, which somewhat disqualified it as a source of drinking water.)

Rome itself was too far from the sea to be a port. For shipping it used Ostia, the port city at the northern mouth of the Tiber. Romans believed that Ostia was founded by their fourth king in the seventh century B.C.E. Ostia was originally built to defend Rome from attackers sailing up the Tiber, but the port quickly took on much more commercial than military importance. River access from Ostia to Rome was easy, and most of Rome's grain and other goods imported from Mediterranean locales passed through Ostia on their way to the city. Starting with Tiberius, several emperors improved Ostia to better equip it for both shipping and military purposes. So much business passed through Ostia that the city became quite prosperous; some 50,000 people lived there in the second century C.E. When the empire ended, Ostia faded

away, partly from lack of shipping and partly because the Tiber had gradually filled with silt over the centuries and had become unnavigable.

By the second century B.C.E. Rome either controlled or wanted to control all of Italy, which was already home to numerous peoples, such as the Etruscans. Italy occupies a long peninsula running northwest to southeast into the middle of the Mediterranean Sea. The peninsula resembles a high-heeled boot with the heel pointing to western Greece and the toe not quite touching Sicily. The Italian peninsula is mainly mountainous; only about a third of the land is flat. The largest flat area in Italy is the plain around the Po River in northern Italy. There were also marshlands in various areas, such as the Pontine Marshes that lay between Rome and Capua (a city north of Naples). When people settled in Italy, they clustered in locations where travel and agriculture were easy. Water transport on rivers and along the coastline was easier than land transport, so many settlements arose on rivers and near the sea.

Italy has an extremely long coastline relative to its land area. The total coastline is about 4,600 miles long. To the north of Corsica is the Ligurian Sea, which has its coast along the northwestern corner of Italy. The Tyrrhenian Sea lies along its southwestern coast, bounded by the islands Corsica, Sardinia, and Sicily. Southeast of the sole of the boot is the Ionian Sea. Along the northeast coast lies the Adriatic Sea. Italy's long coastline provided locations for numerous ports. Puteoli, on the north side of the Bay of Naples, was a major port for grain shipped from Egypt. Tarentum was a port city situated in the sole of the Italian boot. Like many southern Italian cities it was founded by Greeks. Brundisium, modern Brindisi, on the Adriatic coast in southern Italy, was the main port for embarkation to Greece and points east. The famed road known as the Appian Way went from Rome to Brundisium. The coastline also furnished spots for vacation homes for wealthy Romans who spent their summers at the seashore away from the heat and humidity of the crowded city.

The Apennine Mountains run from northwest to southeast down the center of the peninsula. Rocky but not as steep or rugged as the Alps, they never impeded traffic through the countryside nearly as much as high mountains like the Alps did. Well-traveled roads such as the Appian Way were built right over numerous hills. Nevertheless, people whose homes were separated from Rome by mountains found themselves culturally isolated from the city; Roman authors talk of the different diets and habits of people in the countryside. The physical barrier imposed by the mountains did have an advantage, however: it kept attackers from being able to march quickly across the entire peninsula. If Italy was attacked on one coast, the mountains would keep the attackers on that coast long enough for Rome to assemble its defenses.

The Apennines split Italy into two main geographic zones. The western side of the peninsula had fertile soils with ample phosphates and potash (minerals that enhance soils for

plant cultivation) and easily navigable rivers such as the Tiber and the Arno. The east side had rivers that were narrow or dry in summer but swelled to floods in winter, carving gullies through the hillsides. The soil there was less fertile, and there was less of it: the mountains were closer to the sea and the flat coastal plain was narrow, in some places only about 20 miles wide. Throughout ancient times more people settled in the west than in the east.

The Po Valley in northern Italy was the largest patch of flat land on the peninsula. Before the Romans settled on the Po, the region was mostly marshland. These marshes helped deter the Carthaginian general Hannibal's invasion in 218 B.C.E., but they also made it difficult for Romans to live there because the ground was too wet to build roads and farms and the swamps incubated diseases such as malaria. During the first centuries B.C.E. and C.E. Romans developed techniques to drain swamps, using canals and dikes to channel and contain water. Rome's immediate vicinity was drained by the censor (a top government official) Marcus Aurelius Scaurus in 109 B.C.E. The emperor Augustus (r. 27 B.C.E.–14 C.E.) continued draining the area, intending to turn it into farmland. After the land was drained, the Po Valley became the richest agricultural area in the empire. The surrounding region was heavily forested with oaks and other hardwoods. The acorns from the oaks furnished ample fodder for a thriving pork industry. Much of the meat eaten in ancient Rome came from this area.

The length of the peninsula isolated north from south, resulting in the emergence a variety of cultures and languages throughout Italy before the rise of Rome. Southern Italy, especially the "heel" region called Apulia, was particularly isolated from events in Rome. Greeks settled in Apulia before the Romans conquered it in the third century B.C.E. Even during Roman times Apulia was never densely populated.

Italy's mountains included several active volcanoes, some of which remain active today. The most famous is Vesuvius, near Naples. Vesuvius erupted in 79 C.E., inundating the cities of Pompeii and Herculaneum with lava and ash. Mount Etna in Sicily erupted from time to time, including one eruption in 396 B.C.E. that was said to have prevented the Carthaginians from attacking the city of Syracuse and another in 251 C.E. that supposedly coincided with the martyrdom of the Christian saint Agatha. Ancient authors place Etna in many myths; the Cyclops (a one-eyed monster who appears in Homer's *Odyssey*) and the god of the forge, Hephaestus (Vulcan in Roman myth), both supposedly kept blacksmith shops beneath Etna. The Aeolian islands north of Sicily had several very active volcanoes, including Stromboli and Vulcano; these also were said to be the physical locations of mythical events. The presence of volcanoes was a sign of geological instability, and Italy suffered numerous earthquakes.

To the north of the Italian peninsula lay the Alps, a major but not insurmountable barrier to travel and attack. In summer travelers regularly crossed the mountains on foot trails, which were in use throughout the ancient period.

Crossing the Alps in the winter was considered an extreme measure and required extensive preparation; when Julius Caesar brought his soldiers across the Alps to suppress the Gauls in the winter of 52 B.C.E., contemporary observers considered it evidence of brilliant generalship and courage. Regardless of season, Romans preferred to avoid the Alps entirely by traveling along the flatter coastline of Liguria. The Alps never entirely prevented attacks from the north, but they hampered and weakened invaders. For example, when Hannibal crossed the Alps to attack Rome in the autumn of 218 B.C.E., his passage through the mountains impressed the Romans but cost him about half his army and most of his war elephants.

The Italian peninsula had more climatic variation than the city of Rome. Coastal regions shared Rome's Mediterranean climate, with hot, dry summers and cool, wet winters. Southern areas were warmer than northern ones. The Adriatic coast had colder winters and hotter summers than the Tyrrhenian coast. Rainfall in most of the Italian peninsula was low and could be erratic; winter could bring severe rainstorms, but then no rain would fall at all during the summer, precipitating droughts. The Apennines had mild winters and hot summers. The climate in the Po Valley was semicontinental, with long, cold winters and warm, humid summers. The Alps in northern Italy had mountain weather, with warm summers and cold, snowy winters.

MEDITERRANEAN SEA

Italy's long coastline and many ports gave Rome access to the entire Mediterranean world. By the time of the empire, Rome controlled the whole Mediterranean shoreline. In ancient times travel was much faster by sea than by land. It was easier to ship large items by sea than to haul them overland; marble, for example, cannot easily be dragged over rough countryside in a wagon, but it moves quite nicely on a boat. A Roman army in Greece could sail to Egypt much faster than it could march.

In the immediate neighborhood, Sicily was so close to Italy as to be almost attached to it. From Sicily it was a short sail to Carthage and North Africa. Sardinia and Corsica were not as close but were still readily accessible. Sailing around the coastline that is now the French Riviera took travelers to Spain. To the east Greece was a quick voyage across the Ionian Sea. From there Roman travelers could make their way through the Aegean to ports in western Asia Minor or even voyage through the Sea of Marmara into the Black Sea. They could also sail along the southern coastline of Anatolia to ports in Asia Minor or in the Levant. By continuing to hug the coastline, sailors could go as far as Egypt.

The Mediterranean presented many challenges to seafarers. It was large enough that they were often out of sight of land and had to navigate by other means than coastal sightings. The winds were fickle, and it was almost always necessary to supplement wind power with human rowers. The weather was notoriously changeable, especially in winter;

winter travel could mean seasickness at best and shipwreck at worst.

SICILY, SARDINIA, AND CORSICA

Sicily is a large island southwest of Calabria (the toe of the Italian boot). It is separated from Italy by the Strait of Messina, which is not quite 2 miles wide. This strait has always had rough waters; a natural whirlpool forms there and caused many shipwrecks of ancient sailors attempting to sail between Sicily and Calabria. This whirlpool and its accompanying rocks may have given rise to the legend of Scylla and Charybdis, two nautical obstacles faced by the hero Odysseus in Homer's *Odyssey*. Despite the dangers of the Strait of Messina, however, Sicily has always been fairly accessible by sea. It had several ports, notably the formerly Greek port of Syracuse in the southeast.

Sicily's location in the center of the Mediterranean made it a popular target for kingdoms looking for good colonies. Phoenicians, Carthaginians, and Greeks all lived there before the Romans took over the island in 242 B.C.E. Sicily has fertile soil and warm, sunny weather, ideal for growing grain. As a result Rome used it for centuries to supply grain to the city. The warm climate also attracted rich landowners who built sumptuous villas; one of the best preserved is the Villa Romana del Casale, built near Piazza Armerina in the fourth century C.E. and known for its elaborate mosaics.

Sardinia is a large island due west of the Italian peninsula across the Tyrrhenian Sea. Phoenicians traded with Sardinians beginning around 1000 B.C.E., and the island became a Carthaginian province around 500 B.C.E., but it was too remote for Carthage to administer effectively. Rome took Sardinia from Carthage in 238 B.C.E. Sardinia has a cooler climate than Sicily but equally fertile soil, and it, too, was a source of grain for Rome. Most of Sardinia's interior is mountainous. The mountains prevented Roman culture from spreading efficiently among the native people; Sardinians revolted frequently, and the geographical restrictions of the island made it impossible to entirely subdue them. The mountains contain many deposits of iron, copper, lead, and silver, all of which the Romans mined; mineral riches and agriculture made some areas of Sardinia quite prosperous.

Corsica, an island north of Sardinia, is considerably smaller than its southern neighbor. Etruscans and Carthaginians occupied it before Rome took it over around 231 B.C.E. Corsica's interior was mountainous and wild, and Rome never exercised complete authority over the people who lived there. Corsica's climate and landscape were conducive to forestry and shipbuilding but not to most forms of agriculture.

CLIMATE AND THE EMPIRE

Some historians believe that climate change was partly responsible for Rome's expansion from Italy into Europe, and then for the decline of the Western Roman Empire. Rome began to grow powerful while Europe's climate went through a warm period, and it fell when the climate sudden-

ly grew colder several centuries later. Much of the empire's stability was due to Rome's ability to grow crops throughout its territory.

During the fourth century B.C.E. Italy was not especially warm and Rome was not particularly powerful. Celts raided Rome from the north in 390 B.C.E., marching straight down the peninsula through the Apennines. It seemed that they meant to settle in Italy. By 300 B.C.E., however, the Celts had moved back north. Historians believe that this retreat was necessitated by warmer weather that arrived in Europe during the fourth century B.C.E. As temperatures rose, the Mediterranean climate zone moved north as far as Burgundy in France. Celtic crops and living habits were based on a colder, wetter European climate, so the Celts returned north to find more amenable conditions.

The Romans moved into southern Europe in the wake of the Celts and established Roman-style farms growing wheat, millet, grapes, and olives. By 200 B.C.E. Mediterranean weather had reached southern France, and Rome had taken over that land. Rome created its first European provinces in the regions that had suddenly acquired a Mediterranean climate, Gaul and Spain.

Cisalpine Gaul ("Gaul on this side of the Alps") lay south of the Alps and north of the Apennines, in today's northern Italy; it encompassed the fertile Po Valley. During the Republic, this region was not considered part of Italy. The Rubicon River formed the border between Cisalpine Gaul and Italy. It was a symbolic as well as a physical border. To protect Rome from coups by its own military, Roman generals were forbidden by law from crossing the river with a standing army. When Julius Caesar took an army across the Rubicon in 49 B.C.E., all Romans knew that he had declared civil war.

Transalpine Gaul ("Gaul across the Alps") occupied the area that is now called France, from the Mediterranean French coast to the Pyrenees, north and west to the Atlantic and the English Channel, and east to the Rhine River. Its native inhabitants were Celts, many of them called Gauls. Between 300 B.C.E. and 300 C.E. Gaul had ample fertile soil for crops and a pleasing climate, and Romans found it an ideal location for agricultural villas.

Southwest of Transalpine Gaul lay Spain, which Rome took from the Carthaginians in 206 B.C.E. Romans used Spain to produce wheat, olive oil, wine, and metals. The hot, dry Spanish climate resembled that of Italy and thus was ideal for growing Roman crops. There were two main routes between Rome and Spain. Armies and merchants could walk along the Mediterranean coastline of eastern Spain and the French Riviera to northern Italy and vice versa; along the way, they might stop in seaside towns esteemed for their seafood and scenery. Faster, but riskier at certain times of year, was sending men and goods by sea; the weather during the Mediterranean winter made sailing dangerous. Most large shipments of cargo traveled by boat simply because it was so much more difficult to transport them along the rough terrain of the coastline. Spain's eastern coast had numerous port cities. The

southern city of Cordoba, located on the river Baetis, was also accessible by water.

To the south of Italy, directly across the Mediterranean, lay North Africa. Its proximity to Sicily and Italy made for easy travel from one place to the other. North African peoples had occupied Sicily before Rome took it, and Carthage, in what is now Tunisia, was geographically close enough—barely 100 miles by sea from Sicily—to present a military threat. All of North Africa, including Egypt, was also close enough to be an ideal location for Roman farms and military installations. During the Roman Republic and the Roman Empire much of Rome's food came from North Africa and Egypt. The climate was warm and sunny most of the year; during the 500-year period between 200 B.C.E. and 300 C.E. the weather was especially warm, making the region extremely productive, even despite its perpetual water shortages. Roman troops were often sent to North Africa to subdue local people and consolidate Roman control of the area. Roman generals also based troops there during Roman civil wars, such as those involving Julius Caesar in the mid-first century B.C.E.

By the time of the empire, the warm weather zone had reached northern France. During the first two centuries B.C.E. Roman landlords created large-scale farms in northern Gaul, producing cereals for cities and military installations. The well-being of Roman civilization depended on the government's ability to grow food in its northern territories; this made it possible to feed the armies and citizens who maintained order in the more far-flung provinces.

Rome's more northerly territories, Germany and Britain, never received the attention or the level of Roman control that the more southern possessions did. This neglect was due to a combination of geographic distance from Rome and a colder climate. Germany lay north of the Alps and east of the Rhine. It was densely forested and had a colder climate than Italy, making it unsuitable for Mediterranean agriculture. Britain was separated from Europe by the English Channel, so Romans could only reach it by sailing. The sea voyage was difficult and dangerous and proved a substantial disincentive to settlement. The sheer distance of Britain from Rome also made it difficult to govern the province. Britain's climate was much colder and wetter than that of the Mediterranean, and Mediterranean crops did not thrive there.

The warm period persisted until about 400 C.E., when conditions suddenly grew cooler and wetter. The Mediterranean zone moved back south into Italy, and southern Europe ceased to be suitable for Roman agriculture. At this point it became clear how much the Roman Empire had relied on the climate to sustain its control of Europe. Britain and Germany were the first regions to be abandoned. Gauls and Germans began encroaching from the north again as the warm climate band crept south. By the late 400s the Mediterranean climate zone had moved entirely south of the European continent; Mediterranean crops continued to thrive in North Africa, but Italy itself now had a colder continental climate. Romans

could no longer withstand the attacks of Gauls and Germans, and the Western Roman Empire fell apart, at least in part the victim of climate change.

THE AMERICAS

BY AMY HACKNEY BLACKWELL

In the Americas difficulty of travel and isolation from other cultures kept people from developing large civilizations until well after the ancient period. Humans came to Alaska from Siberia during an ice age between 18,000 and 13,000 B.C.E. By 10,000 B.C.E. they had reached the southern tip of South America and inhabited all parts of both American continents. By 8000 B.C.E. the climate had warmed considerably all around the world, the passage between Asia and the Americas was blocked, and Americans lived separately from humans on other continents until Europeans crossed the Atlantic in ships in the 1400s.

ALASKA

Humans moved into the Americas sometime between 18,000 and 13,000 B.C.E. They appear to have traveled from Siberia across the Bering Strait to what is now Alaska, though whether they walked across a land bridge, paddled in boats, or combined the two methods is a matter of debate among scholars. In any case, the first place humans inhabited in the Americas was western Alaska. Western Alaska has a long coastline on the Bering Sea. Many inlets and bays lie along the coast. The Yukon River empties into the sea in southwestern Alaska, creating a wide delta. To the east the Aleutian Islands stretch in an arc westward across the northern Pacific Ocean. Early settlers probably stayed in these areas, fishing and hunting as they had done in Siberia.

Northern Alaska is very cold. The Brooks Range of mountains runs from east to west, south of the northern tundra. North of Alaska is the Arctic Ocean. People living in this region had to adapt to long winters during which the sun almost never appeared. The ground is permafrost, never thawing even in summer, and agriculture is impossible. Central Alaska is heavily forested and is home to many wild animals. The Alaska Range runs along Alaska's southern coast, which is pocked with glaciers and fjords. This coastal area has rich fisheries that attracted human settlers who already had the skills needed to live there.

The weather in Alaska can be very bad. The winters are long and cold, even in the southern areas. Many of Alaska's rivers stop flowing entirely in the winter. The western and southern coasts have cool summers and cold winters. Fog and storms on the ocean are common, especially in winter; these weather phenomena killed many ancient sailors and kept others from going to sea in the winter.

NORTHERN NORTH AMERICA

From Alaska humans walked into what is now Canada's Yukon region. This area is cold, forested, and mountainous. The

northern Rocky Mountains begin in northwestern Canada and run down the western coast. To the east of the mountains, the Great Plains begin. The northern plains are pocked with glacial lakes. The climate in this region is harsh, with cool summers and cold, snowy winters. During the last ice age this region was completely covered with snow and ice. Historians believe that around 11,500 B.C.E. an ice-free corridor opened in the western part of the region, allowing people to travel south into what is now the United States. By 10,500 B.C.E. the region was much warmer, and plants and animals had returned.

Much of northeastern Canada is part of the Canadian Shield, a region of thin soil on top of bedrock; it consequently cannot support much agriculture. The climate is cold and snowy, and the land is heavily forested. Hunter-gatherers lived mainly by hunting the ample wildlife in the region. Southeastern Canada, including the Appalachians and the region surrounding the Great Lakes and the Saint Lawrence River, has more fertile soil and a more hospitable climate than northern Canada. In ancient times the region was covered with mixed evergreen and deciduous forests. The northernmost portions of Canada, Baffin Island, and Greenland all have Arctic climates with year-round snow and ice. The only people to settle there were those who knew how to survive in such conditions.

WESTERN NORTH AMERICA

Several mountain ranges run north to south in the Pacific Northwest. Inland from these mountains is a broad plateau that climbs gradually to the Rocky Mountains. The Pacific Ocean just offshore is rich in fish and shellfish that supported large communities of ancient humans. The region has ample rainfall, especially on the coast. In ancient times this region was heavily forested; some of its trees, notably redwoods and sequoias, were among the largest in the world.

The coast of what is now California has historically been quite dry. The climate there was stable from the end of the ice age until about 2000 B.C.E. and then began cycling through wet and dry periods characterized by droughts that lasted a century or more. People began settling in the region around 3000 B.C.E., during a period of good weather and high food production. When the climate became unpredictable 1000 years later, the people adapted to less productive fisheries and forests. Droughts and storms plagued the inhabitants of the region for the rest of the ancient period.

What is now the southwestern United States is much warmer and drier than the Pacific Northwest. Like the Pacific Northwest several mountain ranges run north to south, paralleling the Pacific coast; these mountains continue southward to what is now Mexico. Rainfall has always been low, and much of the region is desert. Ancient farmers had to devise means of maximizing the available water. One strategy was to maintain family networks in different regions; rainfall varied from place to place, so households in wet areas could help others in places where the rains failed. Central Ameri-

can agriculture appeared in this region around 1000 B.C.E., brought by people moving north on foot from Mexico. The area that is now Arizona and New Mexico had a rough landscape with many mesas and steep-walled canyons created by water and wind erosion. The early people of the area took advantage of this natural landscape by creating homes called pueblos in the cliff faces.

The Rocky Mountains form the highest mountain chain in North America. The Rockies are high, steep, and cold in winter, when they could be a nearly impassible obstacle for people on foot. Many animals lived in the mountains, and ancient hunters went there for seasonal hunts but then returned to their homes on the plains.

The Great Plains are an enormous grassland or prairie east of the Rocky Mountains stretching from modern Canada to central Texas. Many animals lived there in ancient times, including giant herds of bison. The climate could be harsh; summers were very hot, and winters could bring multiple blizzards and heavy snowfall.

EASTERN NORTH AMERICA

The Mississippi River has long formed a boundary between the modern western and eastern United States. It drains the entire region between the Rocky Mountains and the Appalachians. The Mississippi by itself is the second-longest river in North America. When the length of its tributary the Missouri River is added to it, it becomes by far the longest. All the major rivers in central North America flow into the Mississippi; they include the Illinois, the Ohio, and the Arkansas Rivers. The Mississippi empties into the Gulf of Mexico in what is now Louisiana. The river has long been a major transportation artery for people with boats; it presents some challenges for sailors but is fairly easily navigable with primitive watercraft. The river is quite wide, especially in its southern reaches, and was very difficult for ancient people to cross. The river's width is one reason that Central American agricultural practices and crops did not reach eastern North America until after 1 C.E., long after they were common in Mexico and the Southwest. In ancient times the river flooded regularly and was prone to changing course unexpectedly. The river deposits silt at its mouth; these deposits create the Mississippi delta, an ever-changing landscape of marsh and extremely fertile soil.

The Great Lakes are five large freshwater lakes on the border between modern Canada and the United States. They are connected to one another by narrow rivers, and the easternmost lake, Lake Ontario, drains into the Saint Lawrence River. These large contiguous waterways allowed ancient people to move about the region more quickly than they could have moved overland. The climate in the Great Lakes region is fairly cold, and some portions of the lakes freeze in winter. The lakes themselves attract heavy snow. The lakes absorb heat in the summer, cooling summer temperatures and then warming autumns as the waters release heat back into the air. The land around the lakes is fertile and good for agriculture.

The Appalachian Mountains stretch from what is now eastern Canada down to northern Georgia. They are fairly low, gentle mountains and in ancient times were heavily forested with many different species of trees. They also had a large population of wild animals, both carnivores and herbivores. They form a physical barrier between the eastern and western portions of the region; walking through them was difficult, though by no means impossible. The highest mountain in the chain is Mount Mitchell in North Carolina. The higher elevations have colder temperatures than the lowlands to the east and west.

The southern coast of what is now the United States lies along the Gulf of Mexico. This region has fertile soil and warm temperatures, though it has always been prone to hurricanes in the late summer and autumn. In fact, researchers have found that hurricanes struck the Gulf Coast much more frequently between 1500 B.C.E. and 1000 C.E. than they do today. The region was heavily forested in ancient times, and the forests were full of wild game animals. The Gulf of Mexico itself supported many fish and shellfish. The gulf has gentler tidal patterns than the larger oceans and is more easily navigated in small boats.

CARIBBEAN

The Caribbean region lies to the southeast of North America and north of modern Venezuela in South America. It consists of an arc of islands that run from the Bahamas and Cuba in the northwest to Trinidad and Tobago in the southeast. The only way to travel from island to island in ancient times was by boat. People who lived on the islands tended to be very isolated from other cultures. It appears that humans colonized the Caribbean from South America and moved northward. The first evidence of humans on the islands was found in Trinidad, just off the coast of Venezuela, and dated to about 5000 B.C.E. The journey from the mainland to Trinidad would have been very short, unlike the voyages to more distant islands, which would have required sailors to leave sight of land and navigate ocean waters.

The Bahamas are low, flat islands in shallow water. Most of the other islands of the Caribbean have more variation in elevation. Modern Cuba and Hispaniola contain a mix of hills and flat plains. Puerto Rico and Jamaica are hilly, as are most of the islands in the Lesser Antilles, the chain of islands forming the eastern boundary of the Caribbean chain. Many of these islands are volcanic in origin, and some of them contain volcanoes that are active to this day. Eruptions and earthquakes were common occurrences in ancient times.

The Caribbean climate ranges from subtropical in the Bahamas to tropical in the southernmost reaches. The islands supported lush vegetation and thick forests that were home to many species of animals, including some unusually small birds and snakes and other animals unique to the islands. The oceans around the islands teemed with fish and shellfish.

Coral reefs lay just offshore of most Caribbean islands, attracting fish and other marine life to their rich habitats. Hurricanes presented one of the greatest risks to people living in the islands. A hurricane could completely destroy towns and kill thousands of people in a single day.

MEXICO AND CENTRAL AMERICA

Mexico and Central America were home to several large civilizations. The Olmec lived on the coast of the Gulf of Mexico between 1500 B.C.E. and 400 C.E. The city of Teotihuacán, near modern Mexico City, was inhabited from 150 B.C.E. to 750 C.E. The Mayan Empire encompassed parts of what are now Guatemala, Mexico, Honduras, and Belize, and lasted from about 1800 B.C.E. to the 17th century C.E. All of these civilizations supported themselves by farming, and all worshipped rain gods, a sign that they were preoccupied with receiving enough rain to nourish their crops.

Modern Mexico lies south of the main North American continent. Two-thirds of Mexico is mountainous. The Sierra Madre Occidental and the Sierra Madre Oriental are the main ranges; they run north to south and have an average elevation of 10,000 feet. They were formed by volcanic activity, and many of them were active in ancient times. The Pacific Ocean lies to the west and the Gulf of Mexico to the east of Mexico.

Mexico's climate varies depending on altitude, latitude, and distance from the ocean. Warm areas, including the coastal zones, southern Mexico, and the Yucatán, have mean temperatures of about 80 degrees Fahrenheit, though they can reach 120 degrees Fahrenheit. The central region has mean temperatures of about 60 degrees Fahrenheit. Rainfall is low throughout Mexico except in the southern Gulf Coast area (modern Tabasco). El Niño activities affect weather patterns on the Pacific coast, and hurricanes sometimes batter the Gulf Coast. In ancient times about two-thirds of Mexico was covered with forests; numerous types of plants and animals lived there in various ecosystems.

Central Mexico is covered with rolling hills and valleys; the soil in the valleys is generally much more fertile than that on the hillsides. Many of the hills are former volcanic cones. Mexico City, the former Aztec capital, is located in the southern part of this area. A wide coastal plain lies along most of Mexico's eastern coast. The Yucatán peninsula juts north into the ocean between the Gulf of Mexico and the Caribbean Sea. The Yucatán is very hilly. It lacks major rivers. In ancient times this region was covered with seasonal tropical forests; it received rain between May and October but also experienced some dry times in the spring. The region experienced periodic droughts when little rain fell for many years; these droughts seem to have occurred every 200 years or so. No major rivers supplied water to the region, so the Maya had to depend on rain.

The Yucatán has ample freshwater underground, but this is not always accessible to humans. Much of the Yuca-

tán is underlaid with subterranean sinkholes called cenotes, and the Maya dug wells to reach the freshwater contained in these. Lack of water and hilly terrain forced people to build rainwater reservoirs, construct irrigation systems, and dig terraces on hillsides for their crops. Historians believe that rainfall fluctuated in the area during the ancient period. From 5500 to 500 B.C.E. the region was relatively wet, followed by about 250 years of drought. The Classic Maya civilization arose during another period of high rainfall between 250 B.C.E. and 125 C.E. Another drought between 125 and 250 C.E. led the Maya to abandon some of their settlements, such as El Mirador. Large portions of the Maya population died out during dry periods, only to be built back up when the rains returned.

The Maya who lived in this region became very skilled at maximizing their use of available water. In much of the southern Yucatán the ground is made of porous limestone; water runs straight through the rock into the ground here, and people could not make use of it for crops. In this area people dug holes in the limestone and plastered their bottoms to create artificial reservoirs. Even during wet times Maya faced food problems; the humid climate made it difficult to store corn for any length of time, so they could never build up a surplus of food to stave off famine in years of bad harvests. Throughout the region people lived in small city-states positioned on watersheds, which gave them the flexibility to handle sudden droughts.

South of the Yucatán the mountains continue through modern Guatemala, Honduras, and northwestern Nicaragua. The distance between the Pacific and the Caribbean Sea is narrower here than in Mexico. A number of rivers flow through this area, and it has several large lakes, notably Lago de Nicaragua. This region was covered with forests in ancient times. It is wetter than Mexico; the coastal regions have a wet, tropical climate, though the highlands are cooler and drier. Most rain falls between April and October. Hurricanes have always been a danger here.

From modern Costa Rica to the point where modern Panama joins northern Colombia the land forms a narrow S-shaped pattern. In this region the Pacific coast lies to the south of the land, and the Caribbean Sea lies to the north. The mountains continue to run down the center of the isthmus with swampy lowlands on the coasts. The climate is warm and wet. The climate and the range of habitats made this region a hospitable home for thousands of species of plants and animals, many of which were good sources of food.

ANDES AND WESTERN SOUTH AMERICA

The Andes Mountains run the entire length of the western coast of South America. The name *Andes* comes from a Quechua (a local Indian language) word meaning “high crest.” At 4,400 miles long, the Andes chain is the longest mountain range in the world. The Andes are the second-highest mountain chain, after the Himalayas; Mount Aconcagua

(22,841 feet) in modern Argentina is the highest mountain in the Americas. The Andes range is about 150 to 200 miles wide along most of its length, except in Bolivia, where it is about 400 miles wide. Most of the tallest peaks are covered with snow year-round. The snow line varies from north to south. The southernmost peaks have very low snow lines and permanent glaciers. The snow line in the central Andes of Chile and Peru is actually higher than that of the tropical Andes; the wetter climate in the north allows for more snow to fall.

The Andes harbor several active volcanoes. The most famous is Cotopaxi, which assumed its current shape about 3000 B.C.E. This geothermal activity heats underground water, which comes above ground in numerous hot springs. The Galapagos Islands, about 1,000 miles west of Peru on the equator, were also formed by volcanic activity.

The Andes in the north begin in Colombia, Venezuela, and Ecuador. In this area they exist as two parallel mountain ranges, currently called the Cordillera Occidental (Western Rope) and the Cordillera Oriental (Eastern Rope). The Caribbean Islands of Aruba, Bonaire, and Curaçao are actually part of the range, with most of their landmass submerged. Two branches of the chain border either side of Lake Maracaibo. The Maracaibo lowlands of western Venezuela are flat and swampy and have never attracted much human settlement.

The Central Andes lie in modern Peru, Chile, and Bolivia. The snow line begins at about 15,700 feet. The western portion of the mountain range is quite dry, though the eastern mountains toward the Amazon region receive fairly heavy rainfall, over 100 inches a year in modern times. A flat coastal plain lies between the western mountains and the Pacific Ocean. The climate here is normally very dry but is greatly affected by periodic El Niño events, which can cause large amounts to fall all at once. At high elevations temperatures do not vary much over the course of the year but can change drastically from day to night, dropping from 75 degrees Fahrenheit to 32 degrees Fahrenheit in a matter of hours. Rivers on the east side of the Andes drain into the Amazon, and rivers on the west drain into the Pacific. Lake Titicaca, one of the highest lakes in the world, lies in the Andes on the modern border between Peru and Bolivia.

Between 1500 B.C.E. and 500 C.E., the Lake Titicaca region had higher rainfall than it does now. Between 300 and 500 C.E. Lake Titicaca was higher than today, making agriculture easier. The area around Lake Titicaca was a fruitful habitat for the people of Tiwanaku, a civilization that flourished in southern Peru and northwest Bolivia starting around 400 B.C.E.; by 650 C.E. it had a large population. Rainfall was unpredictable, so the people of the region used the fluctuating waters of Lake Titicaca to water crops in raised fields. A centralized bureaucracy helped the people organize themselves enough to cope with the harsh climate. The Tiwanaku civilization eventually died out during a major drought starting around 1000 C.E.

Travel in the Andes was extremely difficult and had to be done almost entirely on foot at high altitudes. Andean peoples evolved large lungs and thicker blood that helped them make the most of their oxygen-poor air. They also chewed coca leaf, a drug that helped them metabolize their food and function better in the thin air. The physical difficulty of traveling to and from the mountains kept Andean people from trading or engaging in cultural exchange with other South Americans. Water shortages were a constant problem, and people developed complicated irrigation techniques to water their crops. The steep slopes of the mountains made it difficult to grow crops; people learned to cut terraces into the mountainsides to create flat fields.

In ancient times the mountains of the central Andes were covered with forests. The trees were adapted to the climate and altitude and included unique species, such as the *queñua* and the *yagual*. The southern Andes run through modern Argentina and Chile down to the Tierra del Fuego. Chile's coast contains numerous fjords, islands, ice fields, and glaciers. Snow cover in this area gets progressively higher toward the south; in the Tierra del Fuego, the snow line can be below 1,000 feet. The terrain and climate discouraged much human settlement in ancient times.

Tierra del Fuego is separated from mainland South America by a narrow strait, now called the Strait of Magellan. There appears to have been a land bridge or glacier between the island and the mainland around 8000 B.C.E., which would have allowed human settlers to walk there. The climate is cold and stormy, and the terrain is rocky. The mountains feed glaciers into the ocean. Only three species of trees are native to the area. In ancient times agriculture was impossible due to poor soil and harsh climate, so humans in this area lived by hunting and fishing.

AMAZON AND NORTHEASTERN SOUTH AMERICA

The Amazon River and its basin dominate northeastern South America. The river originates in the Andes and is fed by numerous tributaries. Most of the tributaries are difficult to navigate in the mountains because of their numerous waterfalls and rocky rapids. Outside of the mountains, however, the Amazon experiences very little change of elevation along its length, and it is fairly easy to navigate. The Amazon and its tributaries were the main means of traveling through the region before the advent of airplanes and helicopters and the building of modern roads.

The Amazon is 6 miles wide in some places. About 400 miles from the ocean, it narrows to about a mile wide but about 200 feet deep; the water flows very quickly there. Closer to the mouth the river overflows its banks regularly. The mouth of the river encompasses a wide area of outlets and land about 207 miles wide. The Amazon does not have a delta. A tidal bore, or wave that travels from the ocean upriver, prevents silt from accumulating at the mouth.

The Amazon drains a huge area. The Amazon basin contained about seven million square miles of rain forest

in ancient times. This rain forest was extremely dense and difficult to travel through. The river supports a huge variety of wildlife, including river dolphins, carnivorous piranha, giant snakes, and a number of edible fish, crab, and turtle species. The rain forest also harbors a plethora of species of plant and animal, both beneficial and dangerous to human occupants. In ancient times few people lived deep in the rain forest. Those who did lived mostly as hunter-gatherers, though some practiced slash-and-burn agriculture, a method of farming in which farmers cut down vegetation and burn it to create fields for crops. The soil in most of this region is not especially fertile and cannot sustain permanent agriculture; the slash-and-burn technique allowed farmers to exploit the fertility of an area and then move on to allow it to recover over many years.

Northeast of the Amazon is the Rio São Francisco, which was also used as a major transportation artery. South of the Amazon the Paraná River flows into the Rio de la Plata. The origin of the Paraná lies in the Pantanal, a giant marshland just west of the modern southwestern border between Bolivia and Brazil. The Pantanal experiences annual floods during the rainy season of December to May. This flooding made the land very fertile and suitable for agriculture, much as the Nile's annual floods made Egyptian agriculture possible.

SOUTHWESTERN SOUTH AMERICA

The Pampas is a large fertile plain encompassing nearly 300,000 square miles in modern northern Argentina and southern Brazil. The name Pampas comes from a Quechua Indian word meaning plain. The area was almost entirely grassland before humans began cultivating it, but since then it has been used very successfully for agriculture. The soil is rich, and the rainfall is moderate (about 39 inches per year) and steady throughout the year, with no particular rainy or dry seasons, though more rain falls in summer than in winter. Rainfall is heaviest in coastal areas and lighter near the mountains to the west. Winters are cool, and summers are warm and humid.

The landlocked Gran Chaco region lies in modern northwestern Argentina, Paraguay, Bolivia, and a small piece of southwestern Brazil. This area is very dry and hot. Western Gran Chaco has almost no vegetation; in the east the main plants are thorn bushes and grasses. The land is almost entirely flat. Ancient humans in this region lived as hunter-gatherers because of the difficulty of growing anything.

Patagonia is the area encompassing the southern half of Argentina and all of southern South America, including some portions of the southern Andes. Most of Patagonia is a flat or hilly plateau, rising in abrupt terraces toward the mountains. The western portions are forested with southern beech and other deciduous trees and evergreens. The eastern portion contains some rain forests and bogs in areas of high rainfall. Eastern Patagonia is grassland. Humans lived there

as hunter-gatherers starting about 8000 B.C.E.; by 1000 B.C.E. people were cultivating crops in the eastern plains.

Africa

~ Strabo: *Geography, excerpt on Africa, ca. 22 C.E.* ~

The country deep in the interior is called Tenessis [modern-day Eritrea]. It is occupied by those Egyptians who took refuge from the government of Psamtik III. They are surnamed Sembritae, as being strangers. They are governed by a queen, to whom also Meroë, an island in the Nile near these places, is subject. . . . From Meroë to this sea is a journey of fifteen days for an active person. Near Meroë is the confluence of the Astaboras [modern Atbara], the Astapus [the White Nile], and of the Astasobas [Blue Nile]. . . .

Far in the interior was a place called Endera [modern Axum], inhabited by a naked tribe [the Gymnetae] who use bows and reed arrows, the points of which are hardened in the fire. They generally shoot the animals from trees, sometimes from the ground. They have numerous herds of wild cattle among them, on the flesh of which they subsist, and on that of other wild animals. When they have taken nothing in the chase, they dress dried skins upon hot coals, and are satisfied with food of this kind. . . . Further still towards the south [near modern-day Addis Ababa] are the Cynamolgi, called by the natives Agrii, with long hair and long beards, who keep a breed of very large dogs for hunting the Indian cattle which come into their country from the neighboring district, driven there either by wild beasts or by scarcity of pasturage. . . . Next to the harbor of Antiphilus is a port called the Grove of the Colobi (or the Mutilated), the city Berenice of the Sabae, and Sabae a considerable city; then the grove of Eumenes.

Above is the city Darada, and a hunting-ground for elephants. . . . The district is inhabited by the Elephantophagi (or Elephant-eaters), who are occupied in hunting them. When they descry from the trees a herd of elephants directing their course through the forest, they do not then attack, but they approach by stealth and hamstring the hindmost stragglers from the

herd. Some kill them with bows and arrows, the latter being dipped in the gall of serpents. The shooting with the bow is performed by three men, two, advancing in front, hold the bow, and one draws the string. . . . The nomads call the hunters Acatharti, or impure.

Above this nation is situated a small tribe—the Struthophagi (or Bird-eaters), in whose country are birds of the size of deer, which are unable to fly, but run with the swiftness of the ostrich. Some hunt them with bows and arrows, others covered with the skins of birds. . . .

Bordering on this people is a nation blacker in complexion than the others, shorter in stature, and very short-lived. They rarely live beyond forty years; for the flesh of their bodies is eaten up with worms. Their food consists of locusts, which the south-west and west winds, when they blow violently in the spring-time, drive in bodies into the country. The inhabitants catch them by throwing into the ravines materials which cause a great deal of smoke, and light them gently. The locusts, as they fly across the smoke, are blinded and fall down. They are pounded with salt, made into cakes, and eaten as food. Above these people is situated a desert tract with extensive pastures. It was abandoned in consequence of the multitudes of scorpions and tarantulas, . . . which formerly abounded to so great a degree as to occasion a complete desertion of the place long since by its inhabitants.

Next to the harbor of Eumenes, as far as Deire and the straits opposite the six islands, live the Ichthyophagi, Creophagi, and Colobi, who extend into the interior. Many hunting-grounds for elephants, and obscure cities and islands, lie in front of the coast. The greater part are nomads; husbandmen are few in number. . . .

There are three islands which follow in succession, the island of Tortoises, the island of Seals, and the island of Hawks. Along the whole coast there are plantations of

(continued)

(continues)

palm trees, olive trees, and laurels, not only within, but in a great part also without the straits. There is also an island called the island of Philip; opposite to it inland is situated the hunting-ground for elephants, called the chase of Pythangelus; then follows Arsinoë, a city with a harbor; after these places is Deire, and beyond them is a hunting-ground for elephants. From Deire, the next country is that which bears aromatic plants. The first produces myrrh, and belongs to the Ichthyophagi and the Creophagi. It bears also the persea, peach or Egyptian almond, and the Egyptian fig. Beyond is Licha, a hunting-ground for elephants. There are also in many places standing pools of rain-water. When these are dried up, the elephants, with their trunks and tusks, dig holes and find water. . . .

The mode of life of the Ethiopians is wretched; they are for the most part naked, and wander from place to place with their flocks. Their flocks and herds are small in size, whether sheep, goats, or oxen; the dogs also, though fierce and quarrelsome, are small. . . . They live on millet and barley, from which also a drink is prepared. They have no oil, but use butter and fat

instead. There are no fruits, except the produce of trees in the royal gardens. Some feed even upon grass, the tender twigs of trees, the lotus, or the roots of reeds. They live also upon the flesh and blood of animals, milk, and cheese. They reverence their kings as gods, who are for the most part shut up in their palaces.

Their largest royal seat is the city of Meroë, of the same name as the island. The shape of the island is said to be that of a shield. Its size is perhaps exaggerated. Its length is about 3000 *stadia*, and its breadth 1000 *stadia*. It is very mountainous, and contains great forests. The inhabitants are nomads, who are partly hunters and partly farmers. There are also mines of copper, iron, gold, and various kinds of precious stones. It is surrounded on the side of Libya by great hills of sand, and on that of Arabia by continuous precipices. In the higher parts on the south, it is bounded by the confluence of the rivers Astaboras [modern Atbara], Astapa [the White Nile], and Astasobas [the Blue Nile]. On the north is the continuous course of the Nile to Egypt, with its windings, of which we have spoken before.

Asia and the Pacific

≈ *Pliny: Natural History, excerpt*
on India, ca. 77 C.E. ≈

And it will not be amiss to set out the whole of the voyage from Egypt, now that reliable knowledge of it is for the first time accessible. It is an important subject, in view of the fact that in no year does India absorb less than fifty million sesterces of our empire's wealth, sending back merchandise to be sold with us at a hundred times its prime cost. Two miles from Alexandria is the town of Juliopolis. The voyage up the Nile from there to Keft is 309 miles and takes 12 days when the midsummer trade winds are blowing. From Keft the journey is made with camels, stations being placed at intervals for the purpose of watering; the first, a stage of 22 miles, is called Hydreuma; the second is in the mountains, a day's journey on; the third at a second place named Hydreuma, 85 miles from Keft; the next is in the mountains; next we come to Apollo's Hydreuma, 184 miles from Keft; again a station in the mountains; then we get to New Hydreuma, 230 miles from Keft. There is also another old Hydreuma known by the name of Trogodyticum, where a guard is stationed

on outpost duty at a caravanserai accommodating two thousand travelers; it is seven miles from New Hydreuma. Then comes the town of Berenice where there is a harbor on the Red Sea, 257 miles from Keft. But as the greater part of the journey is done by night because of the heat and the days are spent at stations, the whole journey from Keft to Berenice takes twelve days. Traveling by sea begins at midsummer before the dogstar rises or immediately after its rising, and it takes about thirty days to reach the Arabian port of Cella or Caned in the frankincense-producing district. There is also a third port named Mokha, which is not called at on the voyage to India and is only used by merchants trading in frankincense and Arabian perfumes. Inland there is a town, the residence of the king of the district, called Sapphar, and another called Save. But the most advantageous way of sailing to India is to set out from Cella; from that port it is a 40 days' voyage, if the Hippalus is blowing, to the first trading station in India, Cranganore not a desirable port of call,

on account of the neighboring pirates, who occupy a place called Nitriae, nor is it specially rich in articles of merchandise; and furthermore the roadstead for shipping is a long way from the land, and cargoes have to be brought in and carried out in boats. The king of Muziris, at the date of publication, was Caelobothras. There is another more serviceable port, belonging to the Neacyndi tribe, called Porakad; this is where king Pandion reigned, his capital being a town in the interior a long way from the port, called Madura; while the district from which pepper is conveyed to Becare in canoes made of hollowed tree trunks is called Cottonara. But all these names of tribes and ports or towns are to

be found in none of the previous writers, which seem to show that the local conditions of the places are changing. Travelers set sail from India on the return voyage at the beginning of the Egyptian month Tybis, which is our December, or at all events before the sixth day of the Egyptian Mechir, which works out at before January 13 in our calendar—so making it possible to return home in the same year. They set sail from India with a southeast wind and after entering the Red Sea continue the voyage with a south-west or south wind.

Greece

~ Pausanias: Description of Greece,
Book I: Attica, second century C.E. ~

[1.1.1] On the Greek mainland facing the Cyclades Islands and the Aegean Sea the Sunium promontory stands out from the Attic land. When you have rounded the promontory you see a harbor and a temple to Athena of Sunium on the peak of the promontory. Farther on is Laurium, where once the Athenians had silver mines, and a small uninhabited island called the Island of Patroclus. For a fortification was built on it and a palisade constructed by Patroclus, who was admiral in command of the Egyptian men-of-war sent by Ptolemy, son of Ptolemy, son of Lagus, to help the Athenians, when Antigonos, son of Demetrius, was ravaging their country, which he had invaded with an army, and at the same time was blockading them by sea with a fleet.

[1.1.2] The Peiraeus was a parish from early times, though it was not a port before Themistocles became an archon of the Athenians. Their port was Phalerum, for at this place the sea comes nearest to Athens, and from here men say that Menestheus set sail with his fleet for Troy, and before him Theseus, when he went to give satisfaction to Minos for the death of Androgeos. But when Themistocles became archon, since he thought that the Peiraeus was more conveniently situated for mariners and had three harbors as against one at Phalerum, he made it the Athenian port. Even up to my time there were docks there, and near the largest harbor is the grave of Themistocles. For it is said that the Athenians repented of their treatment of Themistocles and that his relations took up his bones and brought them from Magnesia. And the

children of Themistocles certainly returned and set up in the Parthenon a painting, on which is a portrait of Themistocles. The most noteworthy sight in the Peiraeus is a precinct of Athena and Zeus. Both their images are of bronze; Zeus holds a staff and a Victory, Athena a spear. . . .

[1.1.4] The Athenians have also another harbor, at Munychia, with a temple of Artemis of Munychia, and yet another at Phalerum, as I have already stated, and near it is a sanctuary of Demeter. Here there is also a temple of Athena Sciras, and one of Zeus some distance away, and altars of the gods named Unknown, and of heroes, and of the children of Theseus and Phalerus; for this Phalerus is said by the Athenians to have sailed with Jason to Colchis. . . . Twenty stades away is the Coliad promontory; on to it, when the Persian fleet was destroyed, the wrecks were carried down by the waves. There is here an image of the Coliad Aphrodite, with the goddesses Genetyllides (Goddesses of Birth), as they are called. And I am of opinion that the goddesses of the Phocaeans in Ionia, whom they call Gennaides, are the same as those at Colias. On the way from Phalerum to Athens there is a temple of Hera with neither doors nor roof. Men say that Mardonius, son of Gobryas, burnt it. But the image there to-day is, as report goes, the work of Alcamenes. So that this, at any rate, cannot have been damaged by the Persians.

► clothing and footwear

INTRODUCTION

Very little is known about clothing in ancient times. There are few original garments that have survived the passing of the ages. Those that remain in existence are mostly from dry regions in the Near East. There are almost no examples of clothing from Europe. Hints about the dress of ancient people have to be taken from depictions of clothing in art and written sources as well as studies of the disintegrated remains found at burial sites. Psychologists and sociologists have attempted to identify the motivations that prompted people to dress themselves. Clothing is not essential for survival in every part of the world, particularly in warm regions, but there were several basic reasons for dressing. Clothing was worn for protection, for decoration, out of modesty, and to denote status. Ancient people apparently wore clothing for all of these reasons.

The earliest clothes were animal skins and pieces of plants, such as leaves and bark. The garments of the ancient world, with a few exceptions, were draped. The basic form of much ancient clothing was a length of square, rectangular, or semicircular fabric draped to create a variety of styles, each of which was distinctive and characteristic of the particular culture and period within that culture. These draped garments were fastened together, when fastening was required, by pins or threads. Heavier garments were required in

northern regions for protection against cold weather, while lighter-weight fabrics were used in southern regions. By the start of the Common Era, European peoples dressed chiefly in wool and linen, while Asian civilizations preferred silk and cotton clothing.

Ancient people dressed in loincloths, skirts, tunics, shawls, cloaks, and veils. The skirt, in the ancient world, was a garment that began at the waist and hung loosely around the body. Skirts were worn by both men and women and varied in length. The loincloth was a length of cloth wrapped in any of several ways to cover the genitals. The tunic was a simple, one-piece, and typically T-shaped garment, cut with an opening for the head and arms. Tunics were usually long enough to cover the trunk and were made in as many different lengths as skirts. Shawls were rectangles, squares or ovals of fabric that were commonly combined with skirts or tunics. These ranged from pieces that covered only the upper body to larger pieces that could be wrapped to make a complete garment. The veil was a smaller rectangle that covered the head and, sometimes, part of the upper body. It was worn exclusively by women. A cloak, worn outdoors, was a capelike garment tied or pinned around the shoulders. Sandals were the most common type of footwear, with boots popular in colder climates. Fancy materials and certain colors, such as purple among the Romans, were often restricted to the elite classes. Decorations often indicated status or military rank.

AFRICA

BY JUSTIN CORFIELD

The dress throughout Africa during ancient times varied considerably with the climatic conditions and the status of the people. Many Egyptian, Greek, and Roman accounts and images describe the North Africans. There are also records and images from the travels of Egyptians, Carthaginians, Greeks, and Romans. Archaeological remains have been recovered from elsewhere in Africa. From this evidence it is clear that yarn spinning and weaving were done throughout most of ancient Africa.

Rock art from the Atlas Mountains (modern-day Morocco) dating from as early as 6000 B.C.E. shows people dressed only in loincloths. Over time, trade led to many changes. The clothing of Greeks and Romans in northern Africa was similar to the clothes they wore elsewhere in the Mediterranean region. The standard item of clothing for a man was a tunic, and a woman wore either a simple or a pleated dress. Although Greeks and Romans always wore belts, the Carthaginians probably did not, possibly because of the extreme heat in Carthage and other parts of North Africa during the summer. Evidence of this style of dress is in the play *Poenulus* by Titus Maccius Plautus (254–184 B.C.E.). The character Milphio challenges a Carthaginian merchant, “Hey, you there without a belt, why have you come to this city?” The Romans used a belt to hold a purse for their coins, and it is likely that

the Carthaginians used moneybags strapped to their wrists or on a cord around their necks.

Most Carthaginians dressed modestly, covering most of the body. Because the nights were cold, many Carthaginians wore cloaks, and several cloak clasps have been found in Carthaginian graves. Many Carthaginians also regularly wore hats, and it seems to have been one feature that differentiated free men from slaves, who were often bare-headed. Carthaginian women wore dresses similar to those worn by Greeks, often with heavy embroidery. Shoes were similar to those worn by the Greeks, with men wearing leather sandals. Carthaginian soldiers dressed in the Greek fashion with a plumed Thracian-style helmet, breastplate, and tunic colored red for officers and purple for men of the noble cavalry. In battle Carthaginians wore high open-toed boots. Most of the infantry, the men who made up the Carthaginian citizen spearmen, were barefoot in battle.

The clothing of Numidian and Mauritanian rulers tended to imitate Carthaginian and then Roman clothing. Many of the subjects wore simple, short tunics that allowed movement and exposure to the sun. The cavalry tended to wear a loose, unbleached singlet, or loose shirt, held at the shoulders with two brooches. Some men also wore a strip of leather or wildcat fur around their heads. When horsemen were riding, the lower part of the tunic was pulled up, leaving most of the legs exposed. They did not use footwear. It seems likely that these fashions were also followed in Cyrenaica, in modern-day Libya. The Libyans who fought in the Carthaginian army tended to wear very short tunics made of soft red leather, later called Morocco leather. Many images of Simon of Cyrene show a black man wearing long, loose-fitting robes helping Jesus on the day of the Crucifixion. According to the Greek historian Herodotus (ca. 484–430/420 B.C.E.), some women in Libya wore a bronze ring on each leg, while others wore leather bands around their ankles.

In the Sahara loose tunics similar to those worn by Carthaginians seem to have been favored by the merchants who followed the ancient trade routes through central Africa. Even the Romans in North Africa wore a hooded woolen garment known as a *birrus*, similar to the burnoose, a one-piece hooded cloak worn by Arabs. Most of the people crossing the Sahara, men and women, wore headscarves and possibly dyed their robes bright colors, making their dress little different from that of the Tuareg people of modern-day West Africa. People in the desert often wore a cloth over the face, giving them the nickname “men of the blue veil.” Excavations of graves at the monument to the early Tuareg leader Tin Hinan show that Morocco leather was used in clothing. Herodotus describes a competition in Ethiopia involving the stringing of a bow, at the end of which a scarlet robe is awarded, indicating that the color was unusual in the area at the time. At Meroë, in Sudan, small fragments of textiles dating from the ancient period are cotton, showing the importance of this material in clothing of the region.

Farther south, in modern-day East Africa, there are no surviving descriptions of ancient clothing. Diogenes (ca. 320 B.C.E.), whom the geographer Ptolemy (fl. second century C.E.) suggests visited modern-day Kenya, makes no mention of clothing or lack of clothing of the local people. The dress may have been little different from that in Nubia at the time and probably was similar to the cotton garment worn by traditional Masai today. These cloths were often brightly colored and worn over one shoulder, leaving the other parts of the body bare. Few of these peoples would have worn shoes, though it is possible that some people might have worn sandals imported from other regions. It also seems probable that the dress of the Bantu of southern Africa and of tribes such as the Khoikhoi and the San would have changed little from ancient times to the early 20th century. In Madagascar, though most clothing was made from cotton, wool was worn in the south, and silk, obtained from Asia, was worn in the northeast.

Petroglyph of a human figure wearing a loincloth, from the Sahara Desert at Tassili, Algeria, North Africa (© Board of Regents of the University of Wisconsin System. Photographer: Jeanne Tabachnick)

In West Africa several surviving terra-cotta figurines from Nok, on the Benue plateau of modern-day Nigeria, survive. First discovered in 1928, these objects date from the fifth century B.C.E. They show people with beaded hair but wearing very little except a small, tight loincloth, occasionally seeming to be a piece of rolled cloth or rope. There are suggestions that this was the style of the artwork of the Yoruba people of Nok, who were keen to emphasize the detail of hairstyles.

EGYPT

BY CARYN E. NEUMANN

The wealth of ancient Egyptian works of art, ordinary objects, and written records that have survived through the ages has provided scholars with a fairly good picture of Egyptian clothing and footwear. Egyptian civilization existed at about the same time as the civilizations of the Mesopotamian region, but the warmer climate in Egypt led to creation of a clothing style very different from that of those civilizations.

The Egyptians, like many ancient peoples, initially dressed in animal skins. Quite early they developed the art of tanning and dressing leather. Even after cloth had been developed, the Egyptians continued to use leather for clothing, particularly for belts and shoes. More so than the Greeks and Mesopotamians, the Egyptians dressed in linen. Egyptian dress relied on linen because it kept the wearer cool in a hot climate. The basic style of clothing complemented the natural lines of the body. The preference for one fiber and a consistent style is typical of ancient civilizations. Egyptians used wool for many garments but often used linen underneath the wool clothing. The Egyptians also apparently originated the practice of interweaving linen with wool, probably to take advantage of the softer properties of linen. The Egyptians were noted for fine embroidery. In the later period of their civilization the Egyptians embroidered with gold thread made of beaten and rounded strips of metal. Overall, the Egyptian style of dress involved more luxurious fabrics and styles than the style of contemporary civilizations in other regions.

The Egyptians had a style that was essentially timeless. They dressed in the same fashions for thousands of years. The basic garment worn by men of the Old Kingdom (2575–2134 B.C.E.) was a white loincloth, or *schenti*, that was wrapped around the body several times and held in place by a girdle, or wide belt, that kept the *schenti* fitted closely around the hips. The type of fabric and amount of fabric in the *schenti* indicated status. The garment was made of linen for the pharaohs and priests, but common people dressed in leather or woven vegetable fibers. Wealthier Egyptians had their *schentis* decorated with gold thread. Decoration was also achieved by rounding one end of the fabric to form a diagonal line across the front, by pleating the end or by placing decorative panels at the front. Paintings indicate that some men wore a network of fabric, possibly leather, over the *schenti*.

People of both sexes in the Old Kingdom wore wide collars decorated with embroidery and beads. Women wore

white linen, tubelike, tight-fitting dresses held in place by two straps. The straps might or might not have covered the nipple. The dresses were highly decorated with embroidery, painted designs, appliqués, leather, beadwork, or woven patterns.

Only important men wore a *schenti* that was decorated. The common people did not drape a large amount of material and used a simpler design that reflected their relatively insignificant social standing. Lower-caste women wore tunics. Slaves and dancing girls either went naked or dressed in a small loincloth held up with a narrow waistband. As is typical of every Egyptian period, in the Old Kingdom children either dressed like adults or went naked. Some artwork shows girls wearing a belt at the waist. After beginning school, boys dressed in the *schenti*. Girls went naked until puberty, when they adopted adult garb.

In the Middle Kingdom (2140–1640 B.C.E.) men wore the *schenti* and added a linen cape knotted on the chest. A short version of the cape sometimes exposed the midriff, and a long version was tucked into a skirt or was belted. Some cape fabrics were very sheer. The skirts were elongated, sometimes reaching to the ankle, but workers, soldiers, and hunters wore shorter versions. A double skirt, the under layer opaque and the outer layer sheer, appeared in the Middle Kingdom and was worn into the New Kingdom (1550–1070 B.C.E.).

Pharaohs and priests of the Middle Kingdom wore pleated linen skirts, occasionally with a leopard or lion skin as a shawl. Animal skins were reserved for the most powerful members of Egyptian society because of a belief that wearing the skin of a fierce beast magically transferred the animal's powers to the human. Soldiers wore a loincloth, leather apron, and linen breastplate. The linen was folded in a manner to deflect attacks. For women, the Old Kingdom style of dress extended into the Middle Kingdom.

By the time of the New Kingdom increased trade brought new clothing styles to Egypt. Longer tunics, similar to those worn in Mesopotamia, appeared. These garments were worn over loincloths and skirts or underneath skirts. Both men and women dressed in a *kalasiris*. This linen tunic, made of transparent gauze, had a design at the base and was worn over a loincloth. Some tunics were seamed at the sides, and some had either short or long sleeves made separately and then sewn on. The *kalasiris* might cover the body so snugly as to restrict movement or might be worn very loosely. It might have a band over one shoulder, or it might reach up to the neck. A *kalasiris* could be short, as working people wore to allow greater movement, or long, as worn by the wealthy. The material of a *kalasiris* was either woven or knitted and typically was pleated. In one variation the fabric was arranged so that the pleats fell in different directions at different points on the body. A girdle usually was worn with a *kalasiris*. If no girdle was worn, the rectangular shape of the material was altered so that it narrowed at the shoulders. A woman's *kalasiris* would be more ornately embroidered than a man's and often was pleated with batwing sleeves. It became fashionable for women to use only one shoulder strap, leaving the other

Pair of child's leather sandals from Thebes, Egypt, New Kingdom (© The Trustees of the British Museum)

shoulder bare. In the New Kingdom every color except black was used for clothing.

Footwear was initially unusual in Egypt. Good terrain and a warm climate made footwear unnecessary. Only priests wore sandals, which consisted of leather, papyrus, or wooden soles held on by straps. These sandals gradually were adopted by the general population. Both men and women wore the same design. Wealthier people wore more elaborate sandals with jeweled ornamentation. Children probably went barefoot.

THE MIDDLE EAST

BY CARYN E. NEUMANN

The Sumerians, Babylonians, Persians, and Assyrians of the ancient world had the same consistency in dress over the centuries and the same preference for draped materials as other ancient peoples. Unlike their contemporaries the Egyptians, the people of the Near East developed clothing that suited a range of climates from the cold of high altitudes to the hot, dry desert regions.

Mesopotamia produced so much wool that it became one of the region's chief exports. Accordingly, wool was the preferred fabric for clothing. Wool cloth was produced for domestic use and traded to other regions, as ancient records indicate. Linen has been discovered in archaeological excavations, and flax is occasionally mentioned on clay tablets, but linen was clearly less important than wool. Evidence of details of Mesopotamian dress comes largely from visual materials such as seals, statues, tombs, and wall paintings.

Sumerian civilization existed from 3500 to 2500 B.C.E. In that era both men and women wore sheepskin skirts with the fleece still attached. Length varied according to the physical tasks performed by the wearer and the status of the wearer. Servants and soldiers wore shorter skirts, while royalty dressed in long skirts. The skirts apparently wrapped around the body. If it was long enough, the fabric was passed up under a wide, padded belt and over one shoulder. Cloaks made of animal skins, leather, or felt were worn over the upper part of the body. Children typically dressed as adults did or, if they were very young, went naked. Men, women, and children typically went barefoot.

Babylonian civilization extended from about 2500 to 1000 B.C.E. The slow rate of change in ancient fashion means that it is difficult to distinguish between late Sumerian and early Babylonian clothing styles. However, dress gradually increased in complexity. While men's and women's clothing continued to have similar elements, the trend was toward greater distinctions in dress according to gender.

By the time of the Babylonians skirts were no longer made of sheepskin and were woven from wool. Soldiers wore skirts with fringed decoration around the lower edge and often wore shawls with the skirts. The center of the shawl was placed across the left shoulder, with ends crossing the chest and carried back to be knotted over the right hip. Soldiers wore helmets of leather or metal with horn-shaped decoration. They wore simple sandals when rough terrain made foot covering necessary. Civilian men wore a skirt, loincloth, or tunic.

Wealthier members of Babylonian society, including the nobility, wore a draped square of fabric about 118 inches wide and 56 inches long. The fabric was fringed or had woven or embroidered edging. The men wore turban-like hats with a small brim or padded roll at the edge. As did soldiers, men wore sandals when traveling through rough terrain. There is evidence that men, possibly only royalty, sometimes wore leather shoes imported from cold, mountainous regions. The toes of these shoes were curved upward and adorned with a pompon. Babylonian women wore garments that covered the entire body. They dressed in skirts with short capes cut with an opening for the head or in tunics with openings for the head and arms. Wealthier women wore sandals, though bare feet were common.

The Assyrians dominated Mesopotamia from about 1000 to 600 B.C.E. They adopted Babylonian costume, and a clear break between the late Babylonian and early Assyrian styles cannot be seen. While they wore Babylonian-style dress, the

Assyrians added their own decorations. Woven or embroidered patterns were used in the dress of royalty and nobility. In about 700 B.C.E. the Assyrian king apparently introduced cotton, but there is no evidence that the new fabric was used by the Assyrians. Wool remained the preferred fabric. Persian clothing was similar to the Assyrian style. Persian textiles were often decorated with golden clothing ornaments such as gold plaques with loops on the back to allow for attachment to cloth.

At some point the Assyrians abandoned the skirts preferred by the Sumerians and Babylonians and began wearing tunics. Ordinary Assyrians wore a tunic that ended above the knee. It was worn with a belt and showed little decoration. Soldiers wore a knee-length tunic with a corset of mail armor and a wide belt. The mail was probably made by sewing small metal plates onto leather or heavy cloth. The corset might cover only the upper torso, particularly for soldiers on horseback, or the entire torso. Soldiers additionally wore helmets that came to a peaked point at the back of the head. In the late Babylonian and Assyrian periods women began wearing veils. The veils, which either covered the face or hung over the hair on either side of the face,

indicated marital and social status. Free, married women wore veils, while slaves and prostitutes did not. A concubine was allowed to wear a veil only when she accompanied a wife. The Assyrians and Persians wore sandals with thick or thin soles, depending on the intended use. Closed shoes were available, though they were not common, and high boots were worn by soldiers on horseback.

As is typical of the clothing styles of many civilizations, royals dressed more elaborately than ordinary people. Royalty wore a floor-length tunic under several long, fringed shawls. The weight and draping of the numerous shawls probably inhibited movement to such an extent that simpler dress was probably worn for everyday activities such as hunting. The clothing was heavily decorated with either embroidery or weavings. The specific garment worn by the king on any given day was determined by priests. The Assyrians believed that some days were more favorable than others, and the priests settled on the appropriate attire, fabric, and color for each day. On some unfavorable days the king was not permitted to change clothing. Assyrians wore high, brimless hats, and the king wore the tallest hat. The king also wore a false beard to supplement his own beard. Children had little status in Assyrian society and probably were dressed as cheaply and minimally as possible.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Factors that govern types of clothing are climate, the availability of resources for making cloth, and the wealth of the people wearing the clothing. Pictures drawn on rock faces by the Australian aborigines suggest that throughout their long history they wore either loincloths made of animal skin or nothing at all. In Oceania males typically wore no clothing, and women wore skirts of grass or leaves. Both men and women went barefoot, which made sense given the warm climate in which they lived.

In eastern and northern Asia the nomadic peoples wore animal skins, with loincloths being the primary garment for both men and women. In cold regions a simple tunic was worn sometime before recorded history; it consisted of a rectangle of animal hide with a hole cut in it to facilitate pulling the garment over the head. This tunic could be bound at the sides and probably evolved into a warm jacket. Throughout Asia, from the Yellow River south and including India, loincloths were all that everyone but the rich and powerful wore. As late as 100 B.C.E. men and women in Japan wore only loincloths while going about their everyday work. In most of Indochina loincloths were all that was worn by peasants, and they were also the basic garments in India until the Muslim invasion in the 1700s C.E.

The region that is now China has the earliest remains of clothing in Asia and the Pacific, where shoes made of straw from about 5000 B.C.E. have been found. By 2000 B.C.E. the many ethnic groups in the region were making shoes from

animal hide. By the end of the Zhou Dynasty (256 B.C.E.) most Chinese were wearing shoes made of silk interwoven with grass fibers, nettle cloth, or hemp. Such shoes were durable enough that soldiers could wear them even while marching. But by 85 C.E. silk was in such short supply that commoners had taken to walking barefoot. Before 1550 B.C.E. the Chinese developed the *san* and the *ku*. The *san* was a jacket; it could be padded with straw to provide warmth in cold weather. The *ku* were trousers. Until the first century B.C.E. most clothing of poor Chinese, which included almost everyone, was made from hemp, a plant with tough fibers. Linen, made from flax, slowly overtook hemp as the preferred fabric. The ancient Chinese shunned wool because they associated sheep with barbarian shepherds, which made wool disgusting to them.

Silk fabric had been developed in the Yellow River area, perhaps about 1900 B.C.E., and it was the preferred cloth of the rich because of its durability, shine, and ability to hold colorful dyes. For the rich, silk was usually made into robes. By 200 B.C.E. the emperor of China was expected to wear robes of different colors for different seasons, to encourage the gods to change the seasons in a reliable order. During the Han Dynasty of 202 B.C.E. to 220 C.E., the *ju* became standard wear. Known in the West as the mandarin shirt, it had a stiff collar; it remained common into the 1900s C.E. The *chun* also became common. It was a skirt with pleats and was worn instead of trousers. During the Han era, it became illegal for poor people to dress well; they were forbidden to wear robes, silk, or colorful patterns.

Silk reached Korea and Japan probably in the first century C.E., with Chinese geographers of the third century recording that the Japanese made a very high grade of silk cloth that was coveted by Chinese merchants. Before 200 C.E. the ancient Japanese invented the *zori*, the forerunner of modern-day "flip-flops." *Zoris* were sandals of wood or woven grass with a grip that fit between the big and second toes and straps that extended back over both sides of the foot. In about 500 C.E. the Japanese created the *katagimu*, a vest with broad, stiff shoulders that became popular with swordsmen because it gave their arms freedom of movement. Korean footwear tended to follow the fashions of China, with Koreans in the north more likely to wear Chinese-style shoes and Koreans in the south more likely to go barefoot.

The people of the Philippines tended to follow the clothing customs of the peoples of Oceania, but in 2000 B.C.E. they began weaving cloth and therefore sometimes had more choices in clothing than others in Oceania. At first using bark, they later learned to grow hemp, cotton, and flax, which they used mostly for loincloths, though shirts and blankets became common, perhaps in the first century B.C.E. To the southwest, an independent tradition of clothing and footwear developed in India. It was a tradition of colorful fabrics that tended to be lightweight and worn loosely, appropriate to warm weather. In India and southern Asia the loincloth remained the principal and often the only article of clothing

for ordinary people at work, but it was also used as an undergarment for occasions outside of work.

Perhaps the earliest garment known from India is the sari, which was in use by 3000 B.C.E. It is a piece of cloth about 10 feet in length that is wrapped around the body in various patterns. As fashion dictated, it could be tight or loose, and it could be wound in elegant patterns for special occasions or wound loosely to give freedom of movement for work. It was made either from cotton or silk and was worn primarily by women. Also ancient is the *uttariya*, worn by both men and women. Perhaps as old as the sari, the *uttariya* was a scarf used to cover the upper body and could be made from bark, hides, or silk, though it was usually cotton.

Somewhat later the *lungi* developed. This cloth, worn by both men and women, was wrapped around the waist and tucked in, resulting in a skirt that stopped above the knee for work and at the ankle for formal occasions. It was usually made of cotton but was sometimes silk and more rarely wool. Similar to the *lungi* was the dhoti, which probably developed before 1000 B.C.E. Wrapped similarly to the *lungi*, the dhoti looked more like loose, short trousers that ended above the knee and was worn by both men and women. These garments were typically worn alone, with women generally remaining bare-breasted in everyday life until the Muslim invasion.

For warmth Indians often wore the *chadar*, which predates 200 C.E. and is still worn in modern times. It was used mostly in northern India and was made of heavy cloth, usually cotton, about 10 feet long and 3 feet wide and acted as a blanket or shawl that could give the upper body protection from the cold. Another somewhat heavy garment was the *purdah*, imported from Assyria in about 1000 B.C.E. It was adopted in some Hindu communities and was worn only by women, covering their entire bodies and restricting their movements. It was intended to symbolize the loss of all social rights of women by making them nonentities.

By and large the Indians preferred freedom of movement and color in their clothing, and they preferred the same for their feet. They began wearing jewelry on their feet before 2500 B.C.E. but tended to be barefoot. In the first century C.E., *khapusa* were invented. They were knee-high boots worn in the mountains of northern India as protection from the cold, and they were probably a style imported from nomads in central Asia. They tended to be made of animal hide and were decorated in colorful patterns. In the 200s C.E. *chappals* became common. These were sandals made of animal hide, with straps over the big toe and the upper foot.

EUROPE

BY AMY HACKNEY BLACKWELL

Clothing in ancient Europe was simply made and functional. Sewing and tailoring techniques were not advanced, and most people made their own clothing. Most people across Europe dressed in simple tunics and untailored cloaks that varied in design according to regional climate. Few ancient people had

extensive wardrobes; many of them had one set of clothing and wore it day after day for months or years.

One of the earliest examples of European clothing is that worn by the well-preserved frozen body of a man found in 1991 in the Alps. It was estimated that the man had died before 3000 B.C.E. His entire ensemble was perfectly designed for keeping a person warm in the Alpine climate. It contained no cloth at all, possibly because Europeans at that time did not make cloth. The man wore deerskin moccasins attached to wooden frames that probably functioned as snowshoes. Historians believe that the man may have stuffed hay into the shoes as insulation. Above the shoes, fur leggings were tied with leather thongs. The man wore a loincloth made of goat hide sewn into shape and fastened around the waist with a belt. On his chest he wore a knee-length shirt made of goat hide that may or may not have had sleeves. Over his shoulders he wore a cloak woven of grass. His hat was made of brown bear skin and tied under the chin.

As they began to raise sheep and settle down in villages, people perfected techniques of making thread and weaving cloth. Most Celtic and German clothing was made of wool. Sheep thrived in the European climate, and Celtic people kept herds of them for meat, milk, and wool. The Celts also made clothing of linen, much of which was imported from regions to the south. Europeans occasionally used silk thread to embroider their garments with patterns such as meanders or swastikas (a symbol that had no racist meaning in ancient times). The silk probably came from China, and people may have unraveled old silk garments to use the thread. The Celts who lived in Hallstatt, near Salzburg, Austria, between 1200 and 500 B.C.E. practiced advanced weaving techniques. They wove cloth in various patterns, including stripes, checks, and twills. Archaeologists have found stamps that people may have used to decorate their clothing with dye.

By the time of the Roman Republic (510–27 B.C.E.) most Europeans were wearing cloth garments, with leather and fur pieces sometimes being added for warmth. Few ancient Celtic or German garments have survived. The Romans, however, spent centuries fighting with and then living with Celts and Germans, and they wrote detailed descriptions of their clothing. One of the first things Romans noticed about Gauls was that they dressed in brightly colored patterned or checked cloth. These patterns were known as plaids, or tartans. The Celts and Germans were experts at dyeing their woolen thread with natural dyes made from plants. They used plants such as madder to make red dye, weld to make yellow, and woad to make blue. The people wove threads into patterns that looked just like modern Scottish tartans. Different tribes became identified with particular patterns. Linen does not take dye well, so most linen remained its natural light color.

Most ancient European garments required minimal sewing. Cloaks were often not sewn at all but were worn as lengths of cloth straight off the loom. Celts and Germans shaped sleeves and made trousers, but they also made simple tunics that required only a piece of cloth, pins at the shoulders, and

a belt at the waist. To sew, people used needles made of iron, bronze, or bone and thread of wool or linen. During the late Iron Age (500 B.C.E.–1 C.E.) Celtic clothing resembled Greek clothing. The Celts in continental Europe had long traded with Greeks, and they knew what Greek people wore. Celts made cloth out of wool or linen. Celtic women dressed in long-sleeved tunics covered with another tunic called a chiton by Greeks. The tunic sometimes was belted at the waist. Men wore tunics with long or short sleeves.

Celtic men often wore breeches or pants under their tunics. Pants came in various styles: wide, narrow, or wide at the top and narrow below the knee. Both sexes wore clothing with ornate decorations. They added fringes to hems, embroidery to cuffs and collars, and sometimes sewed on beads. They used colored wool to embroider on linen and white linen to embroider on colored wool. Men and women also wore a pouch at the waist to hold personal items. Before Celts went into battle they styled their hair with lime to make the hair stand up in spikes, and they also bleached their hair blond. Especially courageous Celts sometimes went into battle naked except for sandals and a gold necklace called a torque. According to the Greek philosopher Aristotle (384–322 B.C.E.), Celtic children were accustomed to nakedness from an early age. Aristotle wrote that to make children tough, parents had them go around in minimal clothing in cold weather.

German clothing was similar to that of the Celts. Because of their colder climate Germans also wore heavier clothing made of leather and fur, such as fur-lined capes and trousers. The historian Tacitus (ca. 56–120 C.E.) wrote that some primitive German tribes wore only rough animal skins. The Romans considered the German and Celtic habit of wearing trousers barbaric. Romans never wore pants. Clothing styles across the rest of Europe followed the basic styles of the Celts and Germans. People in Ireland wore a long linen tunic called a *léine*. It had long sleeves or was sleeveless and was usually decorated with embroidery around the hem, cuffs, and neckline. Women wore a longer tunic than that of men. People who did outdoor labor wore shorter tunics than people who did not. On top of the tunic, people wore a cloak or shawl, usually fastened at the shoulder with a pin. This woolen shawl was often woven of wool in bright colors and decorated with embroidery and gold or silver thread.

Throughout Europe people used clothing to show their status. The armor of noble Celtic and Germanic warriors was more elaborately decorated than that of ordinary men. Nobles wore helmets made of bronze or iron instead of the plain leather of common soldiers. The wealthiest men wore chain mail, which was very expensive. The Celtic torque was a mark of elite status, as was elaborate jewelry, especially of gold. In general, the clothing of noble people was more finely made and more ornately decorated than that of common people. In some areas linen was considered a finer fabric and was reserved for the wealthy, while peasants were forced to wear rougher wool cloth.

Ancient Europeans often went barefoot, but in the winter shoes were a necessity, and throughout the Continent shoes were a mark of status. Some shoes were of a very simple design, just a rectangular piece of leather with holes punched in the sides. The wearer threaded a leather thong through the holes, wrapped the leather around the foot, and drew it tight as if it were a drawstring bag. More meticulous shoemakers cut the leather to the shape of the foot and sewed portions of it to help it keep its shape. Many Celts borrowed the shoe design of the Roman soldiers, attaching a carefully designed piece of leather to a hobnailed sole. This shoe was tied on with leather thongs.

GREECE

BY CARYN E. NEUMANN

As numerous surviving statues and painted vases show, clothing among the ancient Greeks varied little from century to century. From the tenth to the first centuries B.C.E., both men and women dressed similarly in draped material of wool or linen and in sandals. This largely unchanging Greek costume gave a sense of stability and permanence.

Ancient Greeks first dressed in a simple, woolen, thickly woven sleeveless tunic known as an *exomis*. The *exomis* evolved into the chiton, a woolen rectangle of seamless cloth open on the right side, fastened on the left, and held in place with two belts, the top one wider than the other and between which the wearer made a wide tuck of cloth. Without a belt this tunic hung loosely and served as a night garment. Lengthened, the tunic was worn as a ceremonial costume; it also replaced the short tunic in winter. The chiton was woven in varying sizes according to its intended use and the height of the wearer. Usually the opening over the right thigh was closed by a few stitches. The shoulder was fastened with threads of the cloth, which formed natural, strong fastenings, or the two upper corners of the rectangle of cloth were simply knotted together. Women wore an ankle-length version of the chiton. The cloth was always draped, never shaped or cut. Children generally dressed in the same manner as adults of the same sex or, if they were young enough, went naked. Only slaves wore breeches, which were regarded as barbarian dress fit only for foreigners.

The woolen fabrics preferred by the Greeks shows their resistance to the luxurious fabrics, such as silk, preferred by the peoples of the East. The early Greeks, however, were influenced by other civilizations. The same groups that shaped Greek architecture shaped Greek dress. The Dorians, from Illyria, invaded Greece in about 1200 B.C.E. and introduced the Doric tunic. In the sixth century the Greeks came into contact with the Ionians of Asia Minor and adopted their finer linen style of dress.

The Dorians gave the Greeks a wide woolen cloak, the himation, and its military derivative, the chlamys. The Doric tunic, which measured about twice the width of the wearer from elbow to elbow, was basically a folded oblong of material

Caryatids from the Porch of the Maidens at Erechtheion, a temple on the north side of the Acropolis at Athens; the maidens are dressed in the simple tunic called the peplos. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

that was folded again, placed around the body, pinned at the shoulders, and often worn with a girdle. The himation, made of a single six-by-nine-foot piece of cloth, swathed the body without fixed fastenings and was often worn under a tunic. The poor sometimes wore only a himation. The *tribon* was similar to the ordinary himation except that it was typically brown or black and tattered. It was worn to demonstrate poverty and contempt for earthly vanities. In Athens the *tribon* also was worn by advocates at the bar.

Women wore a long tunic known as a peplos. The peplos was basically a shawl completely open down one side, usually the left. The open peplos was not normally belted at the waist, but Greek women made a closed peplos by seaming together the two free edges of the garment instead of leaving them open to the thigh. They folded up the edge of the garment, shortening it to waist length, and used the flap to cover the head or veil the face. Spartan girls wore short tunics, slit at the sides, to make it easier to compete in athletic events.

The use of wool kept most garments in a tonal range of off-whites, but ordinary people seem to have worn lighter-colored tunics and cloaks in dark colors, such as rust reds and reddish brown. Color distinguished the costume of warriors, and the chlamys was generally decorated with bands of color, either along the upper edges on the neck and shoulders or down the side seams. The borders had patterns of flowers or geometric designs. Youths in earlier times wore black tunics, and those in later centuries wore white.

Linen was introduced to Greece by the Ionians. The Ionic linen tunic had more elegant drapes than a woolen tunic. Often pleated, the Ionic tunic was so long that the extra material was pulled through the waistband to give a bloused effect. Unlike the Doric tunic, the Ionic one did not require fastening pins. Women dressed in Ionic style wore brilliant colors, known as flowered colors, including greens. It became fashionable for women to wear a ground-length tunic with a peplos on top. The peplos either hung loose to just below the waist or was worn longer and fastened with a girdle. An alternative, known as a *diploidion*, was a piece of material left very long in front and folded at the shoulders so that an extra flap of material fell to waist level. Women from all parts of Greece and a few men wore a *tarentine*, a white gown so thin that the body was visible through it.

The Greeks usually went barefoot, wearing shoes only as protection or for special occasions. Sandals worn by both sexes were fastened with light leather thongs that left the foot almost bare. Soles were made of cork or leather and occasionally studded with nails. Closed shoes fit either foot and had elevated soles that added height to the wearer. A binding was fastened to the sole and passed between the big toe and the second toe, divided into two and passed through a latchet, or a narrow leather strap, to secure the sole of the shoe to the foot. The two bands were criss-crossed high on the legs and then fastened. Greek women, who rarely left the house, wore only sandals in public. By the fourth century B.C.E. shoes had become more elegant, often red with yellow-edged soles.

A variety of hats were worn by Greek men and women to protect them from the blazing sun of the region. Hunters and travelers wore wide-brimmed hats. The petasos was a flat, cylindrical head covering worn by young men. Women wore a similar round, semiconical head covering called a *tholia*.

The simplicity of Greek dress influenced the people who came into contact with the Greeks, especially the Romans. Greek dress reflected the ancient habit of wearing tunics, and the styles and patterns preferred by the Greeks spread throughout the ancient world.

ROME

BY LARISSA BONFANTE

Garments in ancient Rome were made of wool or linen. In the time of Alexander the Great, in the 300s B.C.E., cotton was introduced, as was silk, which was always an extravagant luxury. Wool was woven in a great variety of textures, weights, and colors, from the sturdy dark cloth of slaves' tunics to the fine purple wool of imperial togas. Linen, much of which was imported from Egypt, was usually left in its natural color and could be extremely fine-woven.

The basic dress of Roman male citizens, which visually distinguished them from Greeks wearing rectangular mantles, was the woolen toga, a mantle with rounded borders like the earlier Etruscan *tebenna*, a shorter semicircular woolen mantle. With the toga were worn boots or *calcei*, formal laced shoes worn with the toga outside the house. Working men wore their tunics belted. Unlike the Greeks, who normally wore sandals everywhere, the Romans wore them only indoors.

Again unlike the Greeks, Roman men did not exercise in the nude. They shared the universal taboo against appearing naked in public, though in their art they represented youthful male figures in an idealized "nudity as costume," adopting the Greek artistic convention. They did strip in the public baths, but when they exercised or had to be free of clothing to work, they wore a type of loincloth, called a *subligaculum* or a *campestre* because it was worn for military exercises in the Campus Martius.

Citizens and slaves, male and female, old and young wore shirts or tunics of various lengths, materials, and colors. Greeks and lower-class Romans also wore a plain rectangular woolen mantle called a pallium, which could double as a blanket in cold weather. Roman women wore linen tunics that were longer and wider than those of men, but this garment was basically unchanging in shape, being made up of one or more rectangular pieces of cloth, which were sewn, buttoned, or pinned at the shoulders; belted at the waist; and draped on the body, creating pleasing folds. The *stola*, which looked much like a slip with thin straps, was worn over the tunic from at least the time of Augustus (63 B.C.E.–14 C.E.) by the Roman *matrona*, or married woman. The outer garment of women was a rectangular mantle (*palla*). Only young girls and disreputable women wore the toga.

Otherwise, Roman women's clothing did not have the same varieties and distinctions as those used to mark the status of men. A higher-class woman depended on the elegance, color, and luxury of her garments, her jewelry, and her hairstyle to set her apart. Women's sandals, normally made of leather, had straps arranged in a variety of styles and attached to soles of various heights and ranged from the sturdy, simple styles of working women and slaves to the luxurious, extravagantly decorated footwear of sophisticated Roman ladies. Women athletes or entertainers wore a sports costume consisting of short pants and brassieres; this was probably the underwear of women, which was usually not visible.

Babies were swaddled in strips of cloth or went naked, depending on weather and other circumstances. Children were not distinguished by gender before they reached adolescence. Until then, whether slave or freeborn, they all wore simple narrow tunics and sandals. Both freeborn boys and girls wore rounded togas. Over the tunic the boy wore the characteristic toga praetexta, decorated with a purple-red stripe at the border, which was meant as a good-luck charm to keep him safe. For a boy, the formal rite of passage marking the change from childhood to adulthood took place sometime between his 15th and 17th year, at which time he laid aside his purple-bordered toga and put on the plain white toga virilis of an adult, full-fledged Roman citizen.

The equivalent rite of passage for girls was the wedding. As was the case with boys, a formal change of dress marked a girl's initiation into womanhood and her new status as a married woman. Just as the boy laid aside his toga praetexta, the girl put aside her dolls and toys and her toga before the wedding. As in many cultures, the bride's wedding costume was traditional and symbolic. The night before the wedding, she slept in a narrow, white tunic, like a boy's, and wore a yellow hairnet, both of which she had woven herself. Her wedding dress was tied with a square knot, the Hercules knot, and her hair was dressed in a special, primitive style. It was parted with a spear and twisted or braided on top of her head in a kind of bun made up of six braids or coils. Her head was then covered with a flame-colored, yellow veil and a wreath of flowers and herbs.

Roman culture, more than any, used dress to mark a person's status, rank, and wealth. Social roles were fluid, and perhaps for this reason they had to be visually recognizable. The son of a freedman, or former slave, was a full-fledged Roman citizen, with all the rights and privileges of a freeborn citizen, including wearing the toga. The color, decoration, and manner of wearing a toga indicated various roles or ranks. A plain toga distinguished an adult male from a boy, who needed the magical protection of a purple-bordered toga praetexta. This purple-bordered toga worn by a man, on the other hand, meant that he held one of the highest important Roman offices, a curule magistracy. The dark toga pulla was worn by mourners. The priests pictured on the famous altar Ara Pacis in Rome wore traditional leather hats with a peak or apex, and their togas were draped in front in a semicircular shape. The

triumphal toga, purple in the early days and later decorated with gold, became the imperial costume. Ritual gestures were rigidly observed: when citizens carried out a religious ritual, they covered their heads with their togas; another ritual gesture involved wrapping the toga tightly around oneself.

The costume and hairstyle of the important public priesthood of the vestal virgins resembled those of brides; they also covered their hair with veils and added woolen fillets, or ribbons. From the time of Augustus, a woman's marital status was visually marked by her *stola*. There are literary references indicating that the toga rather than the *stola* was worn by prostitutes and adulteresses.

THE AMERICAS

BY JULIA MARTA CLAPP

Because it was made of perishable or delicate materials, such as woven textiles, leather, and feather work, little clothing of the ancient Americas has survived, especially from tropical or wet climates. Archaeologists and art historians have hypothesized about ancient American dress on the basis of evidence from a few burial sites that contained salvageable clothing. Art and artifacts from the era also provide clues. Complicating the issue is that some figures, especially in Mesoamerican art, are depicted nude or in clothing that is represented abstractly and is difficult to interpret.

Excavations in the Valley of Mexico have uncovered remains at the site of Tlatilco, which was settled in about 1300 B.C.E. Figurines at such burial sites wear clothes that differ by sex. The attire is rendered in a simple manner that makes it challenging to recognize. Anthropologists have speculated that the female sculptures wear a form of grass skirt and that the male sculptures wear loincloths.

Little is known about the Olmec (1500–400 B.C.E.), who occupied the wetlands of the southern Gulf Coast of modern-day Mexico. Because the land was tropical and wet, textiles have not survived. The Olmec are a relatively unknown culture compared with later and better-researched civilizations such as the Maya and the Aztec. Limited knowledge of Olmec clothing comes from sculpture of the era. Figures are depicted in animal costumes, such as a figure in one Olmec mural in the Oxtotitlan Cave, Guerrero, Mexico, that wears a birdlike costume with a scalloped-edge cape. It is unknown, however, whether this representation is symbolic or is representative of the actual dress of religious leaders.

In the realm of ordinary daily attire, a figurine of a seated woman found in a tomb at the Olmec city of La Venta (occupied 900–400 B.C.E.) has a ridge carved across her folded legs that seems to indicate a skirt. Male figures in works such those in a monument found at Potrero Nuevo, Veracruz, wear what appear to be simple loincloths. Outside the Olmec heartland, in the modern-day Mexican state of Guerrero, archaeologists have found a wall painting in the Juxtahuaca cave. The figure in the painting wears jaguar skins on his arms and legs, a red-and-yellow striped tunic, and a feather

headdress. Other findings of the Olmec period are figures wearing varying elements of dress for an ancient ball game that was an important ritual throughout pre-Columbian Mesoamerica. Early representations of the Maya also support the findings that center on forms of skirts or loincloths. A Mayan incised stone from about 100–400 C.E. shows a figure wearing a patterned skirt and leg coverings in addition to extensive jewelry and other adornment.

In South America people of the early Chavín civilization (900–200 B.C.E.) did not wear constructed, or sewn, clothes. They wore large cloths wrapped as mantles or skirts, a practice that continued in the Andes even after the incorporation of shaped or sewn clothes. Burial excavations have unearthed

belts, sandals, and caps from the Chavín era. Excavations of ruler burials from the Paracas civilization (600–175 B.C.E.) give a limited amount of information on ancient South American dress. Because the burial sites contain the remains of deceased elite, not common, people, the items found may not be typical. In addition, the garments buried with a person might not have been the garments he or she wore in daily life. The articles of clothing found may have been ceremonial, produced for daily life, or made for burial.

Many of the items found by archaeologists continue to be worn by Andean people. One such garment is the mantle, which is a large, rectangular cloth arranged around the neck and over the shoulders. The cloth would have been woven

Pottery figures of a drummer and a woman and child, Tala-Tonalá style, Jalisco, Mexico 300 B.C.E. to 300 C.E.; the woman is wearing earplugs, a necklace, and a typical wrap skirt, while the man wears the same ornaments and a mantle over one shoulder. (© The Trustees of the British Museum)

with a pattern or embroidered. The woven patterns and embroidery were not simply ornamental but told important facts about the wearer, such as social status and family lineage. Weaving was an important cultural tradition in the Andes that flourishes in modern times. The weavers are known for their skill in creating complex, often abstract designs that require intensive planning and labor. The tradition of Andean weaving and embroidery began with the early civilizations.

Also found in ruler burials were ponchos, large pieces of cloth with slits cut into them so that the garments could fit over the head. An elaboration on the poncho was the tunic, which was sewn up the sides. Skirts were of the wraparound style and often were embroidered. Some people of the Paracas era wore rectangular loincloths with two ties pulled between the legs and fastened around the waist. Excavated examples of loincloths were not decorated except for the border.

Little is known about clothing and footwear in ancient North America.

► crafts

INTRODUCTION

When archaeologists study ancient sites, including the remains of villages and individual homes, one of the things they look for is evidence of occupational activity. In par-

ticular, they look for the remains of tools and materials that might have been used in the production of crafts. Among the materials can be precious metals, other metals (such as copper, iron, and lead), semiprecious stones, glass, ceramics, and stone shards, as well as tools used for cutting, carving, grinding, sanding, polishing, and the like. Any of these materials can provide evidence that a family or group of people were involved in the production of crafts.

The earliest humans were highly dependent on the crafts items they could make themselves with whatever materials were at hand, typically wood, stone, shells, bones, antlers and horns, and the like. Most of these crafts would have served entirely practical purposes. Examples include arrow and spear points for use in hunting, pottery to hold water and food, primitive cooking utensils, and similar items. Occasionally, too, archaeologists find carved items that may have had religious significance, including amulets (or charms), small statues, and other objects to which their owners might have attached spiritual significance.

As human civilization advanced, the production of crafts progressed as well. While the earliest humans had to be generalists in the production of crafts, producing anything they needed to make their lives more livable, people in later eras began to specialize in crafts production, creating objects that were not only useful but beautiful as well. They typically passed their skills down to their descendants, who continued the family tradition of crafts production. Some of these specializations would have included metalworking (including coin making), woodworking, glassmaking, stonework, the production of fabrics, and so on. Even such persons as brewers and vintners (winemakers) could be considered crafts workers. Some of these craftspersons would have been involved in the building trades. Some, for example, became experts in thatching roofs, while others became stonemasons who carved ornamental stonework for public buildings and monuments. Others would have focused on metalworking for farming, producing implements for plowing and harvesting, or they might have specialized in pots, bowls, cups, and other household items.

Still other crafts workers devoted their attentions to jewelry and other items used for personal adornment. Some worked with metals, including both precious metals like gold and silver and ordinary metals like copper and iron. Others learned to make glass objects, turning glass into beads, amulets, and other objects. In ancient Egypt, for example, many people were skilled in the production of faience, a glasslike material that consisted of a paste made of quartz crystals that was then glazed. Faience was used in a variety of applications, including not only jewelry, pots, and bowls but also walls and floor tiles. Among Native Americans, beadwork and leather crafts were particularly important.

The expansion of trade opened new opportunities for crafts workers. They were no longer limited to materials they could find locally. Particularly as trade to the Far East and Africa grew, crafts workers in Europe, the Middle East, and

around the Mediterranean Sea had access to precious gemstones, ivory, exotic hardwoods, new types of minerals and stones, silks, fabric dyes, pigments, and mother-of-pearl. Trade contact also exposed crafts workers to new technologies and techniques, enriching crafts production for all.

AFRICA

BY KIRK H. BEETZ

It is possible that ancient Africa's greatest achievements in crafts involved perishable materials, such as wood and reeds, with only rare traces of those materials surviving to the present. Thus, ancient crafts are represented mostly by ceramics and metal artifacts. Most early African metalwork was in copper, tin, or bronze. Copper by itself was hard to work with, and making it keep its shape during casting was a problem with which ancient African metalworkers struggled, but combining copper with tin made bronze, and bronze held its shape well. In Nubia, the land south of Egypt, bronze was at first used for casting bowls and other vessels. Bronze gradually replaced stone for use in weapons, with spears still being tipped with stone as late as 900 B.C.E., when the kingdom of Kush arose.

The Kushites cast bronze using clay molds that were probably sculpted by hand, instead of by the lost-wax method that involved sculpting a figure out of wax and shaping a mold around it. The National Museum in Athens, Greece, has a bronze casting of the Kushite king Shabaka, who was also pharaoh of Egypt (ca. 716–ca. 702 B.C.E.). The artifact shows the skill that Kushite bronze casters had attained: Shabaka's face is an individual portrait taken from life, and the body is well defined and proportioned. Kushite casters made even such everyday objects as bowls and pitchers decorative. For example, the British Museum has a handle shaped like a girl, probably for a pouring vessel, such as a pitcher, from the 400s–200s B.C.E. Bronze was used for religious practices, with the most unusual perhaps being the legs of beds on which the dead were laid in their graves.

The Kushites cast in other metals besides bronze. They made silver objects with the same fine skill as their bronzes, including realistic human images on such objects as silver mirrors. They developed ironworking in about the 600s B.C.E., perhaps after being exposed to the iron weapons of the Assyrians when the Assyrians drove them out of Egypt in about 656 B.C.E. The monarchs of Kush moved their capital from Napata to the city of Meroë, far south along the Nile River, in about 590 B.C.E. The area of Meroë is rich in iron ore, and a few archaeologists have suggested that Meroë became a great iron-manufacturing center. But of the city's iron-smelting furnaces the earliest so far discovered date to around 370 B.C.E., and it is likely that before then the Kushites imported iron ingots from the Near East. After 370 B.C.E. Kush may well have exported iron ingots to other parts of Africa.

Another significant center for smelting iron was in the region of modern Nigeria, where a mysterious people called

the Nok lived from ca. 500 B.C.E. to ca. 300 C.E. The Nok are named for the village where some of their pottery was first found. By 300 B.C.E. the Nok had iron-smelting furnaces. Some archaeologists think that the Nok learned to smelt iron from Berbers who brought the technology south from Phoenician colonies in North Africa or from Kushites who migrated to the west, but the existing evidence largely suggests that the Nok developed smelting of iron independently. How they did so is unknown.

Trade in metals was extensive in ancient Africa. Metal may have been in use in the ancient land of Ghana, about 100 miles north of modern Ghana, from 1000 B.C.E. to 500 C.E. There were copper mines in modern Niger, in central Africa, that may have supplied copper to much of central and eastern Africa. The Bantu-speaking peoples who began expanding through Africa from central Africa in the last 200 or so years B.C.E. worked with copper. They probably worked metal inside their houses, and they seem to have favored copper. They wound copper wire into bracelets, made copper beads, and even made copper money, shaped into crosses. If they were like the Bantu-speaking people of later eras, their metalsmiths were highly regarded members of the community and were credited with having supernatural powers.

Trade in materials that could embellish the body were common. The magnificent metal jewelry of Africans is representative of this practice. In addition to metal, glass beads were traded extensively and were popular in most of Africa in ancient times, but at present evidence for local manufacturing of glass in Africa dates no earlier than the medieval era. In ancient Africa glass came from Egypt, Rome, and India.

Other crafts are harder to identify because of the perishability of materials. The oldest wooden object may be a vessel from about 1000 B.C.E. found in a cave in southern Kenya. It is shaped like vessels used by modern cattle herders to carry milk and may indicate a cultural tradition for the area that is mostly lost because wood usually decays rapidly in the area. Masks, which are an important part of the culture of much of Africa, were usually made of wood, and archaeologists must make do with depictions of masks in stone and ceramic figures, mostly from northeastern Africa.

In Kush wood was used for footboards of burial beds as well as for doors and probably other objects. Kushite doors to important buildings were wondrous, often made of ebony, carved with geometric and realistic figures, inlaid with ivory, and embellished with bronze or gold. Magnificent doors were made well into the modern era in eastern Africa, especially in cities and towns that traded with people from Asia. Furniture of any kind came late to much of Africa, especially western Africa, where chairs were first seen when Europeans brought them. In Kush furniture tended to imitate Egyptian forms, with wooden headrests being common.

Basketry seems to have been important in most of Africa, but as with wooden objects, most surviving indications of the types of basketry are found in ceramics and on stone images. Many designs for ceramic vessels seem to be imitations

of forms of baskets, and there is logic to this practice. Even in modern times people make baskets that are watertight and can be used to carry liquids; it is not surprising, then, that ancient Africans created pottery designed like baskets. In Africa basketry has had other significant uses besides carrying or holding objects. The walls of houses were sometimes made entirely of woven reeds. In modern Chad there are farming communities in which not only houses but also the walls surrounding family compounds are woven, preserving a skill that developed in ancient times. Thus, some of the crafts of historical times offer clues to the craft of ancient times, helping to fill in the gaps among the metal and ceramic remains of ancient African cultures.

EGYPT

BY ERIN FAIRBURN

The type of crafts found and the way crafts were made help researchers flesh out the practices of daily life. Objects made by Egyptian craftsmen were often prestige items, and the materials used and quality of workmanship can indicate the social ranking of their owners. Egyptian craftsmen made items in stone, metal, wood, glass, faience, and basketry, among other materials. Stone was used for a variety of objects, including jewelry, amulets, and tools, and the use of stone for vessels was common from the earliest times. Different types of stone, most of which were found near the centers of production, were used in the creation of vessels. The exteriors were shaped with stone tools and smoothed and finished with stone and quartz sand, and the interiors were probably drilled.

Stone vessels were produced in a number of forms. Stone bowls and jars were common throughout ancient times and were the most common types seen until the New Kingdom (1550–1070 B.C.E.). Alabaster, diorite, gneiss, limestone breccia, and porphyry were popular materials for vessels in the Predynastic Period (5000–3100 B.C.E.) and Early Dynastic Period (2920–2770 B.C.E.). Modeled vessels of blue anhydrite, often decorated with monkeys or ducks, came into fashion during the Middle Kingdom (2040–1640 B.C.E.) and Second Intermediate Period (ca. 1640–1532 B.C.E.). Diverse forms were created in the New Kingdom. Kohl tubes and applicators, often made of alabaster, were very popular types of stone objects from this period on. (Kohl was a cosmetic preparation often used to darken the eyelids and rims.)

Metals were worked into tools, figurines, jewelry, and sculpture in Egypt, but they were also used to create vessels, which were almost invariably hammered, rather than cast. Metal was likewise used for model tools, cylinder seals (used to stamp impressions into clay), mirrors, and *ushabtis*, or small figurines that were buried with the dead to accompany them into the underworld and work for them in the afterlife. Most Egyptian metal products were made of a copper alloy, silver, or gold. Not many examples of metal craft survive, perhaps because they were reused or melted down in later periods. However, a silver box lid is known from a Predynastic con-

text, and a copper ewer and basin date to the Second Dynasty (2770–2649 B.C.E.). Silver vessels were found in the el-Tod treasure dating to the Middle Kingdom, and silver was used for a number of decorative vessels in the New Kingdom.

Egyptian craftsmen created objects from such native woods as acacia, tamarisk, and sycamore beginning in the Predynastic Period. They also used imported woods such as cedar, ash, elm, and oak from North Africa and the eastern Mediterranean region as early as the First Dynasty (2920–2770 B.C.E.). Native woods could be utilized in woodworking, but they are of generally poor quality; imported wood was preferred if longer pieces were required. Wood was joined using variations on butt, miter, or mortise and tenon joints. Furniture and wooden objects could be finished in a number of ways. Wood was often plastered to even out any imperfections and create a surface on which to apply gilding or paint. Pieces were sometimes inlaid with decorative woods like ebony as well as with the nonwooden materials of ivory, faience, glass, or precious stones. Veneers of decorative wood were used on some furniture. Varnish was sometimes applied to pieces in the New Kingdom, and beeswax was used to seal painted pieces.

In the Predynastic Period carved wood relief panels have been found in tombs of private individuals, 11 of them in the tomb of Hesire, a high official during the reign of the pharaoh Djoser. From the Old Kingdom (2575–2134 B.C.E.) there is furniture of the royal mother Hetepheres, which included a canopy frame, two armchairs, a bed frame, headrest, chest, and carrying chair. A diverse variety of wooden chests appear at this point. Stools and boxes are seen with great frequency in Middle Kingdom and New Kingdom contexts. Little furniture is preserved from the Late Period (712–332 B.C.E.), though cabinetry became a highly developed form by the Graeco-Roman Period (332 B.C.E.–395 C.E.). Royal furniture, such as that of Hetepheres and Tutankhamen, was similar in form to that of private domestic furniture but of better quality and workmanship.

Faience is a unique material that had been developed by the Predynastic Period. It is a composite of crushed quartz or sand mixed with lime and plant ash or natron (a sodium compound), which is glazed and fired. Glazing was usually accomplished by including an alkali in the core material, which would crystallize on the surface as it dried and then melt, becoming glassy, upon firing. Because of copper inclusions the finished product is often a bright blue-green, though Egyptians developed techniques that created a wide spectrum of glaze colors, from opaque white to violet.

Faience was used in the Old Kingdom in the production of molded figurines of both humans and animals. Tens of thousands of blue-green glazed tiles were found in the chambers beneath the step pyramid of Djoser (r. 2575–2551) at Saqqara. Figures of hippopotami and hedgehogs were popular during the Middle Kingdom, as were vessels decorated on both the inside and the outside. The range of colors increased during the New Kingdom, as seen on the polychrome tiles of

Group of bronze tools for woodworking, from Thebes, Egypt (New Kingdom, around 1300 B.C.E.) (© The Trustees of the British Museum)

the period depicting cartouches (oval or oblong decorations framing a ruler's name), hieroglyphs, and human figures. Bowls and chalices were common vessel forms. In the Twenty Sixth Dynasty (ca. 664–525 B.C.E.) *ushabtis* and model *sistra* (musical instruments of the percussion family) became increasingly popular forms.

Little glass is found in Egypt before the New Kingdom, and research indicates that what has been found was probably imported. Because glassmaking appears as a fully formed industry early in the New Kingdom, it is possible that foreign glassmakers were brought to Egypt to develop a native industry. Regardless of who produced New Kingdom glass, this period was the peak of Egyptian glass production. Production was in full swing and highly developed by the reign of Thutmose III (r. 1479–1425 B.C.E.) A number of workshops are known from the New Kingdom, especially from the palace of Malkata, near Thebes, and from Amarna. Glass production was on the decline by the late Twentieth Dynasty (1196–1070 B.C.E.) and continued on a reduced scale from that time.

During the New Kingdom several techniques were used to create glass objects. Vessels were almost entirely core-

formed, or shaped around a center rod; they could also be mold-made. Glass could be worked like stone using a technique known as cold cutting, with the glass being chipped away and sculpted with a hammer and chisel. Molding and cold cutting were often combined to create glass sculptures in the round, a unique practice in the ancient world. Core forming was slowly replaced by blowing as the most common vessel-making technique in the Graeco-Roman Period.

Nets, bags, baskets, and matting were created by ancient Egyptians out of a limited range of materials, usually palm leaves and grasses but occasionally reeds and rushes. Basketry has been found in some quantity at certain sites. Additional information can be gleaned from mud impressions that were often made when old matting or basketry pieces were incorporated into building materials for new constructions as a means of reinforcement.

Several techniques were used to create basketry in ancient Egypt, but coiled basketry predominated from Prehistoric until Ptolemaic times. In the Predynastic Period matting was incorporated into housing. Throughout the Dynastic Period bed frames and chair seats were woven with matting. Twined

bags appear to have been common in the Old and New Kingdoms. Matting and basketry were used throughout the Dynastic Period in both domestic and funerary contexts. Coiled basketry continued in Ptolemaic times, but plaiting became a commonly used technique as well, especially for decorative containers and fans. Sewn-plait mats were widespread in the Graeco-Roman Period.

THE MIDDLE EAST

BY TOM STREISSGUTH

Ancient Mesopotamia was a land of fertile soil and little else in the way of natural resources. Base metals, precious stones, gold and silver, marble, and timber were all scarce in the Fertile Crescent, the semicircle of fertile land stretching from the eastern Mediterranean coast of the Levant to the Persian Gulf. But as trade increased along the rivers and seacoasts and between the growing cities of Mesopotamia, the Levant, and Egypt, artisans began making use of a wider variety of materials in shaping household objects, tools, and weapons. Silver and iron ore arrived from Anatolia; the cedar and pine forests of Palestine provided timber, and lapis lazuli was brought west from Afghanistan. These trading contacts, maintained through seagoing vessels and overland caravans, fostered the sharing of new technologies, and the spread of Mesopotamian craft styles and techniques to other regions.

The rise of urban civilization stimulated the growth of new manufacturing industries. While farming was the dominant occupation of Mesopotamian villagers, the cities became a focus of labor, money, and trading activity. Independent merchants bought and sold goods, while the taxes collected from craft workshops in turn contributed to the region's political and military power. The city of Ur, for example, drew vast revenues from trade in its textiles, which were renowned throughout the Middle East. Mesopotamian kingdoms conquered through military power but prospered through trade in their finished goods, which were produced by private workshops and then exchanged for the raw materials they lacked.

The first crafts of the region drew on the few easily available natural resources. Red clay dug from riverbeds was shaped and fired, creating useful pottery and brick, which went into basic construction and the paving of city streets. Mesopotamian marshlands provided material for floor mats, for baskets, for shoes, and for house construction, in which wooden frames were filled in with thickly woven reeds. Baskets, used to carry fruits, nuts, grains, and fish, were woven from reeds and fiber—the precursor to the carpet and textile industries of the Middle East—and waterproofed with bitumen. Basket weavers worked in a variety of techniques, interweaving the material in a coiled basket or “twilling” it in diagonal strips. The size and shape of the finished piece depended on the pliability and thickness of the material used. These perishable materials survive only in the form of small fragments, some dating to 7000 B.C.E. Houses in the south-

ern marshlands were also made from cut and woven plants, a technique that survives to modern times. Artisans also used woven plant materials to produce boats and small furniture.

For their farming tools and their weapons, the Mesopotamians first replaced stone with copper, an unalloyed metal that occurs in natural deposits. Copper remained the principal metal of tools and weapons as late as the fourth millennium B.C.E. The use of copper was later displaced by the discovery of bronze (a more durable alloy of copper and tin). Weapon smiths crafted knives, axes, daggers, and body armor out of bronze before turning to iron, a much harder and more durable substance that, at first, was collected from meteorites. By 1200 B.C.E. iron smelting was coming into wider use throughout the Middle East, though Mesopotamian ironworkers had to import the raw ore from distant regions.

Timber was as rare as iron in Mesopotamia, meaning that wooden furniture was a scarce luxury item. Because wood deteriorates with time and weather, authentic furniture from the region is very uncommon, and archaeologists have to depend on painting and sculpture to learn how it was made and used. Basic wooden furniture was often combined with reed matting. Wooden benches, beds, and cabinets were provided to the homes of the wealthy. These pieces were assembled from sawn timber, joined with pegs, and decorated with mosaics, paintings, and marble or ivory inlay. The most elaborate items were reserved for Mesopotamian kings, who saw to it that any city they conquered was carefully searched for its finest furniture, a prized spoil of war.

The most skilled artisans worked in the new medium of glass, which was first developed in northern Mesopotamia in the early second millennium B.C.E. Glass vessels were made by core forming, in which a core of stone or coal was placed into molten glass around a core. The thin layer of

Stone bowl, from Khafajeh, Iraq, Early Dynastic Period, about 2600–2400 B.C.E. (© The Trustees of the British Museum)

cooling glass was then wrapped with extra glass fibers. The glass itself was made by heating silica-bearing sand and soda ash, which created a clear vitreous substance as it cooled. Glassmakers decorated their wares with designs gently carved into the cooling material. They used familiar colors that imitated semiprecious stones: copper and cobalt dyes produced blue colors, manganese produced purple, and lead and antimony produced yellow. Glassblowing techniques that originated in Syria in the first century B.C.E., under the Romans, quickly spread to Mesopotamia and throughout the empire.

Glassmakers and all other skilled artisans held a respected place in Mesopotamian societies. The Code of Hammurabi recognizes the class of *amelu*—citizens of full rights and high status, in which were included royalty, government officials, landowners, aristocrats, and craftsmen. Craft workers commonly followed the profession of their ancestors, but they were also developed through a system of apprenticeship. Boys were often adopted into the family of an artisan and given a full course of training, after which they were free to establish themselves as independent professionals.

To the east, the wealthy Persian Empire founded in the sixth century B.C.E. fostered the work of skilled artisans in stone, metal, and ceramic. Monumental sculpture and painted friezes decorated the mammoth palaces of Persepolis and Susa, the seat of power of the Persian rulers. The wealthy of ancient Persia decorated their bodies with heavy gold and silver jewelry. Their homes and palaces held furniture crafted from cedar imported from Lebanon and Anatolia. Potters used great creativity in fashioning drinking cups, bowls, and jars in imaginative shapes, many inspired by mythological creatures and tales. Persian craftsmen made use of a variety of abstract shapes as well, beginning a tradition in the visual arts that would survive the fall of the empire and continue in the Parthian, Sassanian, and Islamic realms of later times.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Along the Indus River metal casting emerged early in the Harappan culture, perhaps in about 2300 B.C.E. Harappans made household goods, such as bowls and cups, from bronze and copper, and they made small depictions of animals, some of which may have been religious symbols and others toys. Harappans had a large inventory of symbolic graphs whose meaning remains unknown, which they used on seals carved in steatite (also known as “soapstone”), probably in imitation of Near Eastern seals. Harappan seals included portraits of gods and realistic portrayals of animals. Two famous Harappan seals are the image of a rhinoceros in the National Museum of Pakistan and the image of a Brahman bull in the British Museum. The rhinoceros stands firmly on four legs and has an elaborately carved hide; its proportions are lifelike. The Brahman bull is also well proportioned and stands firmly; it

THE MYSTERY OF SHANG BRONZE CASTINGS

The Chinese Shang Dynasty bronze casters made molds out of several parts that fit together like pieces of a puzzle. Molds were made of clay. A mold had a base on which the other pieces were set. The base had openings for molten bronze to be poured in and for hot gases to escape. The base would actually become the top when the metal was poured in, but it contained the part of the mold that would form the base of the object.

The central core of the mold was a solid piece. It provided the shape for the inside of whatever was being cast. In the case of an eating vessel, it might be shallow for a serving plate or deep for a soup bowl. It could be carved with symbols or depictions of animals or people. It was the core that allowed a Shang bronze caster to produce an object as completely decorated on the inside as the outside.

There might be several outer parts to the mold, but there had to be at least two so that the mold could be opened to release the bronze object without breaking the mold. The outer pieces were shaped to fit around the core while allowing space for the molten metal to flow in. The interiors of the outer parts of the mold would be carved with the images that were to be displayed on the outside of the bronze object. It is possible that no Shang bronze was without carved decorations.

The pieces would be put together using notches as guides so that the outer ones did not touch the core. After the metal cooled, the pieces could be pulled apart. The seams that formed where the outer pieces joined together would be filed or sanded to match the surface—except, in the late Shang, some bronzes were cast using this method that had no seams to file, sand, or polish. How these seamless bronzes were produced remains a mystery.

is an image common among Harappan remains and is most likely representative of the status Brahman bulls would have later in Hindu culture.

The Harappan civilization began to decline by about 1900 B.C.E. and was overrun by northern nomads in about 1500 B.C.E. These nomads, called Aryans, began the Vedic culture in India, a culture with a caste social system. The Sudra caste included the craftspeople, who were supposed to serve the higher castes. The crafts of carpentry, stonemasonry, metalworking, basket weaving, and garland making were usually hereditary. Over time large extended families were

Bird head made of stone, thought to be from the first millennium B.C.E., Papua, New Guinea; the image may represent the head of the cassowary, an ostrichlike bird regarded as a supernaturally powerful animal endowed with magic powers. (Copyright the Metropolitan Museum of Art)

devoted to a single craft, sometimes taking up an entire area of a town or city. By the 200s B.C.E. craftspeople were settling outside cities in entire villages devoted to one particular craft. Craftspeople often formed guilds that protected their members and collected money for public works, as well as setting the standards of workmanship that craftspeople had to meet. The leaders of the guilds usually became the leaders of those villages that were devoted to one craft.

Indian carpenters employed foresters to find trees to use as lumber. Before the foresters would cut down any tree, the carpenters would apologize to the god who lived in the tree and ask for forgiveness. Carpenters helped construct buildings, and they also made furniture, primarily beds. Few Indian homes had much furniture, because people sat on the floor most of the time, but they did have beds. Homes often had small cabinets made of wicker, which were the work of basket weavers. Basket weavers made bowls and baskets from grass, flexible branches, or bamboo. Basket weavers were usually women, and they often worked alone, at home. Sometimes they worked for a big manufacturer, bringing their finished work to a warehouse to be paid. When women of the three higher castes had to work for such manufacturers because they needed to earn money, the master of the warehouse was

forbidden to look at them or speak of anything other than work, or he would be fined.

Blacksmiths made household goods such as water vessels, as well as weapons. It has yet to be established when Indian blacksmiths learned to make steel, but they made very durable steel weapons. Whereas blacksmiths pounded their goods into desired shapes, metal casters used molds. They were responsible not only for practical goods, such as plain cups and serving dishes, but also for decorative bronzes cast with images of gods and goddesses, plants, and animals.

Garland making was the work of both men and women who shaped and wove garlands out of flowers and stems. A wealthy person had to have a fresh garland every day, so garland makers tended to live near cities, where the rich were likely to be. They had homes with small plots of land on which they grew the exotic flowers they used. It took three years for a new garden to begin producing flowers that could be made into garlands and sold.

In ancient China most of what can be learned about craftspeople comes from archaeological research. The products of metalworkers are the best known because of the durability of metal. Working with copper probably began before 2100 B.C.E. Bronze came into use for toys, burial images, and vessels in the Yellow River region in the 1600s B.C.E. and was an important medium for artistic expression at the beginning of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.). During the Shang Dynasty, bronze was used for water vessels, for grave goods such as decorated bowls to honor ancestors, and for works of art. The Shang typically cast bronze by pouring molten metal into molds that were cut in halves, so that they could be separated to be used again. This usually left visible seams on the sides of bronze objects, but by the last century of the dynasty the Shang became so skilled that the seams could not be seen.

Ironworking came into prominence in the 500s B.C.E., when metalworkers learned how to build kilns that could heat to 2,800 degrees Fahrenheit. Iron was more brittle than bronze, but it was easier to make than bronze, which required hard-to-find tin. Chinese nobles preferred to use bronze weapons and shields, leaving iron ones for the peasants in their armies. But the primary use of iron was for agricultural instruments such as plows.

Little wooden furniture survives from the Shang Dynasty, but examples survive from the Zhou Dynasty (1045–256 B.C.E.). Peasants could not afford furniture. The rich owned wooden chests, tables, and couches decorated with lacquer paintings. The makers of furniture tended to cluster in cities near where the wealthy buyers of their work lived. Little is known of their lives, but they probably were independent workmen, whereas metalworkers often worked in large factories, manufacturing tens of thousands of ordinary objects. During the second half of the Han Dynasty (202 B.C.E.–220 C.E.) even peasants commonly owned metal objects, such as cooking pots and frying pans.

Little is known of the crafts of the Asian islands and Oceania prior to 500 C.E., when Japanese metalwork becomes common. Knowledge of metalworking was carried by Koreans to the Japanese Islands, perhaps in the 200s C.E., when the Japanese still used stone for most objects, even swords. Basket weaving was quite likely important throughout southeastern Asia and the islands, but almost nothing is known about the weavers or their products.

EUROPE

BY MICHAEL J. O'NEAL

Compared with the ancient empires of Greece, Persia, and Mesopotamia, Europe remained relatively undeveloped until the arrival of the Roman Empire in the first century B.C.E. and, later, the advent of Christianity. At the dawn of history much of Europe was covered with ice, so the population was sparse at best. Only after the ice receded in about 8000 B.C.E. did people move into the region, where they found fertile ground for crops and an abundance of game. They survived purely by means of what they could raise and grow for their own use, settling in widely separated hamlets that consisted of low huts and barns for their livestock. There the ancient Europeans developed crafts that made their lives at least slightly more comfortable. Because the passage of time is kinder to stone than it is to other, less-durable materials, the archaeological record consists largely of examples showing that the ancient Europeans worked with stone to form such objects as tools (primarily for cutting), arrowheads, and spear points as well as pottery for food and water storage. Less commonly found are examples of craft items made of ivory, bone, and wood.

In discussions of ancient European peoples the terms *Celt* and *Celtic* are often used. In modern life these terms typically refer to the people of Ireland, but historians use the words more generally to refer to the peoples who migrated into Europe, probably about 3000 B.C.E., from the steppes of central Russia. Early on they settled in Hungary and Romania, but in time they moved on to Italy, France, Switzerland, Germany, the Iberian Peninsula (Spain and Portugal), the Balkans, and Poland. Later still, they settled the British Isles. For centuries the Celts were the dominant people of the European continent.

The ancient Romans regarded the Celtic peoples to the north as crude “barbarians.” The Roman writer Polybius wrote, “Their lives were very simple, and they had no knowledge whatsoever of any art or science.” In fact, the Celts developed a great deal of sophisticated technology, including crafts production. They became especially adept at metalwork, and one of their major achievements was the substitution of the more durable iron for bronze. The ancient Celts invented such items as chain-mail body armor, the plowshare (that is, the plow’s blade), handsaws, and chisels, and they were the first people to put iron shoes on horses. Tombs found throughout southern and eastern Europe contain large numbers of craft items, including cups, bowls, jewelry, helmets, horse gear, and

the like. The famous Agris helmet, found in western France in 1980, is a magnificent piece made of iron with gold plating, silver rivets, and decorative stripes, along with inlay made of coral. The ancient Celts were also skilled at leatherwork.

Archaeologists refer to two periods of Celtic dominance on the Continent. The first is the Hallstatt Period (1200–500 B.C.E.), referring to a small town not far from Salzburg, Austria, which is still the site of huge salt mines. The remains of a great many craft items have been found in the region, most of it relatively unsophisticated metalwork. The other period was the La Tène, named after a metalworking site in Switzerland. The La Tène began in 480 B.C.E. and lasted until the Romans entered the picture in about 1 C.E., and historians regard it as important because of the flowering of craftsmanship and technology in the region at this time. One of the distinguishing characteristics of the La Tène culture was the use of a great deal of ornamentation and decoration on craftwork, particularly metal. Much of this ornamentation was based on plant and animal forms, though a lot consisted of purely geometric designs; it is believed that La Tène craftsmen used geometric compasses to inscribe decorative elements on their work. In addition to iron the La Tène craftsmen worked extensively with gold and, to a lesser extent, silver.

Art historians identify three distinct styles of La Tène craftwork. One they refer to as the vegetal style, referring to the use of decorative plant motifs. The second is the sword style, referring to sharply geometric designs inscribed on such items as sword scabbards. The third is the plastic style, referring to the three-dimensional depiction of objects, primarily on jewelry. The La Tène craftsmen were skilled not only at metalworking but also at “fired” crafts, that is, those that used fire in the making, such as inlay work, enameling, glass, and pottery. Finally, some examples of woodwork survive. Unused timbers of up to 40 feet long have been found, along with a variety of woodworking tools, including lathes, adzes, and saws. La Tène woodworkers produced wooden bowls and turned tool handles on lathes, but their most noteworthy achievement was the construction of ships and land vehicles. An important craft was that of the wheelwright, who constructed wheels made of wood that were then bound by iron “tires.” La Tène wheels were more soundly constructed and durable than any wheels the Roman Empire ever produced for its famous chariots.

The Celts were not the only cultural and linguistic group to occupy Europe. In addition, various Germanic tribes dominated Scandinavia and northern Germany, including the Angles, Vandals, Burgundians, Danes, Norwegians, Goths, and Saxons. The development of crafts among these Germanic tribes in many respects paralleled that of the Celts. During the Bronze Age (2800–700 B.C.E.) the early Germanic tribes worked primarily with bronze, but later these tribes worked with iron. Archaeological findings include pots and bowls, tools, and various ornamental items.

In the late centuries before the beginning of the Common Era, the Celts lost power on the Continent. In

the north they were overrun by the Germanic tribes, and in the south they were under pressure from the expanding Roman Empire, which imported its technologies and craftwork into the regions it conquered. The Celts found themselves isolated on the British Isles, the only place in Europe where they continued to flourish. They carried with them the craft traditions they had learned on the Continent, continuing to work with bronze, silver, gold, and enamel as well as with iron and wood. After the advent of Christianity, craftwork was directed to the production of objects of religious significance, including such items as chalices and crosses.

GREECE

BY SPYROS SIROPOULOS

The appreciation of craftsmanship by the Greeks is evident in the fact that one of their supreme gods was Hephaestus, the craftsman-god, responsible for the construction not only of weapons (such as the famous armor of Achilles or the thunderbolts of Zeus) but also of various objects for daily use, such as tripods and statues. In addition to Hephaestus, the goddess Athena was the protector of craftsmen; not only was she wise, she was also an expert in ceramics, weaving, and woodworking. In the National Museum of Berlin there is a red-figure vessel (with red figures on a black background) dating to the fifth century B.C.E., on which Athena is depicted finishing up with great care the clay molding of a large horse, while woodworking tools hang behind her.

The economy of almost all Greek cities depended mainly on farming, fishing, small industry, and trade. However, during the height of the fifth century B.C.E. the Athenians established an almost civic way of life, meaning that many people turned away from farming for a living. A new cast of skilled craftsmen developed, practicing special skills necessary for the well-being of the polis, or city-state, and its citizens. Not all professions enjoyed the same respect, and not all workers were considered worthy of being free citizens. Manual labor was frowned upon, considered something only slaves or *metics* ("resident aliens," who did not enjoy citizenship) did. For free citizens only professions such as the practice of medicine, rhetoric, or sculpting, painting, and teaching were considered appropriate.

In Sparta it was inconceivable for freeborn citizens to work and be paid for working, but this was not true everywhere. In Corinth, for example, people respected and honored craftsmen and manual labor. The *Republic* of Plato (ca. 427–347 B.C.E.) is a valuable source of information about the kinds of crafts and professions that developed within an organized city. In the *Republic*, Socrates and Adeimantos discuss a great number of the crafts and professions necessary for the smooth functioning of the civic mechanism. Equally useful is an excerpt from *Pericles*, written by the Roman Plutarch (ca. 46–120 C.E.), in which the statesman Pericles, the leader of the Democratic Party in Athens during the fifth century

B.C.E., names all the crafts and professions necessary for the construction and decoration of the Acropolis.

It seems that glassmaking was passed from Egypt to Greece via Crete, where findings date from the second millennium B.C.E. The earliest glass objects were beads. Various vessels begin to appear about 1500 B.C.E. Some fine artifacts of dark blue glass, in imitation of lapis lazuli, are found in Mycenae. Glassworkers adapted techniques used by potters and metalworkers, modeling molten glass around a core of hardened glass and pressing it into open molds to produce inlays, small vases, jars, and bowls. A more complex process was the heating and fusion of preformed rods of glass.

Not much glass survives from Greece during the Archaic (600–400 B.C.E.) and Classical (480–323 B.C.E.) periods, and it seems that pottery was the craft used to provide tableware. Small vases found in Greece, made by the sand-core technique are dated to the sixth century B.C.E., but their origin is unknown. (In the sand-core technique threads of molten glass were wound around a shaped core of sand. After the glass hardened, the sand was removed.) It was not until the Hellenistic Period (323–31 B.C.E.) that glassmaking became more common, when the invention of glassblowing in the first century B.C.E., probably in Syria, made work simpler for glassmakers.

Baskets were a very functional item of daily use, the oldest preserved artifacts dating to the Mesolithic Period (8000–4000 B.C.E.). Basket making takes skill but only simple tools, such as a knife, a needle, and a pair of pliers. In Classical Greece, lower-class women or *metics* would supplement their income by constructing baskets and bags, mats, rugs, and other items using weaving, plaiting, or coiling techniques. Materials varied from reed, cane, rush, and sisal fiber to ash-wood splints. Baskets were used by traders in the market, fishermen, and even miners. A vase of the sixth century B.C.E. from Corinth shows miners loading baskets with clay from a pit, while younger slaves pull the baskets up with ropes.

The construction of weapons was not the only task of metalworkers. A number of items for daily use, for farming, hunting, fishing and other work, were constructed by freeborn citizens or *metics* with the help of slaves. Vase paintings often depict a tall shaft for melting metals. Blasts of air were introduced at the back by hand, while the mass of wrought iron was extracted at the base. The most common fuel was charcoal. Iron was especially difficult to work; the furnace had to be broken in order to extract the wrought iron, so it could be used only once.

Woodworkers skilled at sawing, joining, and finishing produced a wide variety of useful and ornamental objects, from jewelry boxes to furniture. Woodcarving, a quite different craft, produced objects such as bowls, toys, and other items that could be created from a piece of wood with only a saw, a mallet, files, gouges, and sandpaper. Even items used in worship were constructed from wood. A red-figure cup by Epictetus (fl. 520–500 B.C.E.) shows a youth adding the final details to a wooden herm. A herm is a statuette of the god

Hermes, usually placed at house gates or as a marker on roads. An impressive finding is the wooden *xoanon*, a simple statue, from the island of Samos, dating to the seventh century B.C.E. *Xoanons* were cult objects venerated for the deities that they represented. Only a very small number of these fragile statues survive, mostly from waterlogged sites that preserved the wood.

A variety of materials were used for the construction of furniture throughout the centuries. Homer (ca. 900–800? B.C.E.) describes bedsteads, chairs, and footstools with inlays of gold, silver, and ivory in the palaces of Mycenae. Marble and stone thrones were reported, and their remains were discovered at the palaces of Knossos, in Crete, and at the palace of Pylos. Less-durable materials were used during the Classical Period, and so our knowledge of Classical Period furniture and cabinetry comes mainly from written descriptions and representations in art. Already by the sixth century B.C.E. carving wood on a lathe, a technique called *turning*, was introduced and, together with curving techniques, enabled skilled craftsmen to construct a variety of forms, the principle ones being the *klismós* (chair), a light construction for domestic use, without arms; the *threenýs* (footstool), in various shapes and sizes; the *thrónos* (throne), a more elaborate high-backed chair for special occasions; the *trápeza* (table), small in size, oblong or circular; the *cline* (couch), used for sleeping as well as for reclining upon during banquets; and the *lárnax* (chest), for storing clothes and bedding.

ROME

BY KIRK H. BEETZ

In Roman society there were senators, knights, members of the third estate (or common people), and slaves. Craftspeople were either members of the third estate or slaves. They tended to form guilds, but guilds were not meant to protect their members or to set standards of workmanship. Instead, they were intended to be meeting places where members could gather and mix comfortably together, without worrying about paying the required courtesies to members of the upper classes. Although one might find a guild in a Roman city or town that encompassed all the area's metalworkers, it was more likely that there would be separate guilds for those who worked in copper, tin, bronze, brass, or iron. A single guild might take over an entire block in a city, with its members living in rooms behind or above their shops, but shops could be located almost anywhere in a city. Craftspeople often rented ground-level rooms in other people's homes. As Rome grew in population, the demand for crafted goods increased. Thus, over time, a few shops in a town could multiply into dozens, even hundreds.

Blacksmiths were found in every town and city and almost every village. They not only made new items but also repaired old ones. They often sat on low stools while they worked, using hammers to shape sheets of metal against a solid stone table. They made iron pieces for joints on carts,

parts of bridles for horses, and weapons; bronze pieces for utensils, pots, pans, and chamber pots; and copper and tin pieces for cups and bowls. Almost any man who was not rich had to know how to hammer copper sheets into basic tools. Thus, blacksmiths learned to make complex and specialized metal objects that ordinary people could not make. They seldom smelted their ore themselves, instead purchasing ingots. Metal was usually smelted near where it was mined, using kilns designed to make a powerful updraft of air that provided the oxygen needed for high heat. Blacksmiths often enhanced the metal they received by reworking it with hammering and heat. For example, they could toughen iron by softening it with heat, mixing it with carbon from charcoal, and then hammering it, turning and folding it on itself, hammering again, and so on until it was several compressed layers of iron mixed with carbon. Blacksmiths were often specialists in one kind of metal or even in one kind of tool, such as medical instruments. Although they worked their ingots with large tongs and hammers, they used small hammers of different sizes and shapes, as well as pliers of varying sizes, to shape and squeeze their metal.

Some stonemasons worked in the actual rock quarries. They used metal tools to carve out stones of the shape and size they wanted. They took such care in this work that when the stones were removed from the quarry, they needed little further dressing. They used metal hammers, chisels, and picks,

Steatite vase (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

as well as a mason's square that was usually metal but could be wooden, for making corners square. The stones would go to homebuilders or, in the case of marble, to stonemasons who specialized in carving statues and columns. Statues were usually painted. Although stonemasons often went to construction sites for their work, they also might keep shops that sold small decorative items or markers for tombs. Although modern-day people regard the statues as art, the ancient Romans usually did not. Creating images to decorate buildings or the interior of the home was considered just a routine part of the stonemason's work. Types of stone would be chosen for different types of work. For instance, hard stone would be used for building aqueducts and walls intended to bear heavy weight, whereas soft were preferred for sculptures to decorate the interiors of room. Marble was often used for carving because it was soft but held its shape well but not for its looks, because it would be painted.

Woodworkers were probably found in every city, town, and village, because their products were in great demand. They seldom cut their own trees. Instead, they purchased wood brought out of local forests or imported from other lands. A European Roman woodworker was prosperous if he could afford to purchase wood from Africa; furniture made of African wood sold for high prices. Woodworkers used tools probably purchased from blacksmiths: saws, augers for drilling holes, chisels, and hammers. They needed to know how to shape and fit metal fastenings for constructing furniture.

Romans made exceptionally fine glass. There were important glassmaking centers throughout the Roman Empire in Italy, Egypt, Syria, and northern Gaul. Egyptians, in particular, were famous for the unusual colors of their glass. The town of Aquileia on the Adriatic Sea in Italy was an important center for manufacturing glass. When the town was sacked by Huns in 452 C.E., the people fled to islands in the lagoon, founding Venice, where the skills of their craftspeople helped keep glass making alive after the fall of Rome.

Roman glass was made from sand, lime, and sodium bicarbonate. These would be mixed together in a vessel, probably made of stone, and heated in a kiln that may have been a duplicate of one used for heating ceramics. At first, glass objects were made using three different techniques: One was to pour molten glass into a mold the way metal was cast. Another was to coat a stone or wooden shape with molten glass. The third was to layer not-yet-hardened warm glass in strips, slowly building up the sides of jugs or other vessels somewhat the way strips of clay were used to build the sides of a ceramic pot. Molded glass was often carved to depict chariot races or other exciting scenes.

Then, in the first century B.C.E., glassmakers in Syria invented glassblowing. This involved taking molten glass out of a furnace on a hollow tube through which the glassmakers blew air to inflate the cooling glass. By twisting, lifting, and lowering the tube, the blowers could make glass objects of different shapes. In addition, glassblowing was fast, enabling glassblowers to manufacture many simple objects, such as

bottles, quickly. Glass factories developed, with many blowers working together not only to create a variety of glass objects but also to make enough quantities to mass-market them. Thus the Roman Empire had a profusion of glass objects for everyday use that were affordable to almost anyone.

This ordinary glass for bottles and other household objects was usually bluish green, but glass could be mixed with pigments to create other colors. Roman windows were often made out of wooden screens with glass panes in the spaces, allowing light in but not the weather. Bathhouses sometimes had large skylights made of glass that allowed sunshine in but kept out cold winds. Glass jugs came in a variety of curvaceous shapes that pleased the eye, and molded glass often was cast to make jars shaped like fruit or animals.

THE AMERICAS

BY ANANDA COHEN SUAREZ

The ancient inhabitants of the Americas produced crafts ranging from the utilitarian to the ritual. Crafts of the ancient world are generally defined as objects hand made of natural materials such as wood, metal, or plants. They often possessed a dual significance, serving basic human needs as well as having associations to a cultural belief system. Crafts were produced in many different cultural, social, and economic contexts, from households in rural areas to highly specialized workshops in large cities. Many crafts, particularly those of such perishable materials as plant fibers and wood, have not survived. The unequal preservation level of these objects in the archaeological record means that secondary evidence, such as tools associated with crafts manufacture or painted depictions of crafts, helps to provide information about them.

Present-day craft production among indigenous communities throughout the Americas offers critical ethnographic evidence of ancient traditions whose technique and form have survived the test of time. Baskets, metal ornaments and tools, wooden and bone implements, and other utilitarian goods can be found in all regions of the continent but with much variation in appearance as well as in cultural significance. A great deal of cultural interchange existed in the ancient Americas, increasing in intensity as societies became sedentary. Thousands of different cultural groups coexisted in the vast territory now known as the Americas, each with their own histories and distinct cultural practices that influenced the appearance, mode of production, and function of their particular craft items.

Around 10,000 B.C.E. hunter-gatherers began to populate North America, Mesoamerica, and South America, traveling in bands and settling in different locations depending on the time of year. These were all preceramic cultures that domesticated squash and pumpkin, used to make gourds for transporting water and food. The sites of Guila Naquitz in central Mexico and the Tamaulipas caves in northeastern Mexico provide some of the earliest surviving evidence of craft pro-

duction in the Archaic Period (7000–1800 B.C.E.). At Guila Naquitz archaeologists found bone awls and needles, copper bells, wooden digging sticks and weapons, finely woven basketry, and even fragments of sandals. Given the extreme dryness of these particular caves, they provide ideal conditions for the preservation of very fragile and perishable artifacts. At the Tamaulipas caves, ground stone tools for processing food, chipped stone tools and weaponry, along with coiled baskets, nets, and woven floor mats crafted out of maguey fibers were found.

The Andes, encompassing modern-day Peru and Bolivia as well as parts of Chile, Ecuador, Venezuela, and Colombia, witnessed a rich and complex history of craft production, extending from the Lithic Period (10,000–3000 B.C.E.) up to the present day. During the Lithic Period the inhabitants of the Andes developed diverse utilitarian craft, such as nets for catching fish, textiles, and simple undecorated baskets made of plant fibers as well as stone tools for hunting and food processing. Some well-preserved archaeological sites have yielded wooden earplugs, gourds with simple carved designs, and wooden bowls.

North America's indigenous inhabitants began to create beautifully executed basketry as early as 4500 B.C.E. In the region now known as the southwestern United States and northern Mexico, baskets were made from a variety of plant fibers, including yucca and willow wood. In eastern North America there is evidence of continuous human occupation since about 10,000 B.C.E. The North American Archaic Period roughly coincides with that of Mesoamerica and South America's Lithic Period, lasting until about 1000 B.C.E. The first evidence of metalwork produced in the Americas, in the form of simple copper spear points and bells, comes from Archaic Period archaeological sites.

With the advent of agriculture in Mesoamerica, the Andes, and throughout the United States, populations became less mobile and settled into communities ranging from small villages to major urban centers. As communities settled, craft specialization developed, meaning that a distinct group of craftspeople and artisans emerged. In Mesoamerica throughout the Formative (1800 B.C.E.–150 C.E.) and the Classic (150–650 C.E.) periods, craft objects appear in increasing abundance, many associated with sedentary life. Wooden digging sticks for planting and wooden spindles used in conjunction with ceramic spindle whorls (circular parts of spindles, used to rotate the spinner) for spinning cotton and maguey fibers into thread can be found. Baskets appear to have declined in importance as ceramic vessels rapidly became one of the most common features of sedentary life. Functional items used in food preparation, such as certain specialized tools used to grind corn, occupied a central place in domestic life. Surviving luxury goods tend to consist of ceramics and objects made of obsidian and precious stone, but evidence suggests that objects of perishable material such as feathers, wood, and cloth were widely produced and disseminated.

Although in Mesoamerica metallurgy had yet to play a significant role in craft production, artisans in the Andes began to produce large quantities of portable goldwork as a form of tribute for the first major urbanized pilgrimage center, Chavín de Huántar (900–200 B.C.E.). There are examples of repoussé vessels (shaped or ornamented by hammering on the reverse side), masks, and headgear with finely executed geometric designs and symbolic representations of deities. The Moche culture, which dominated the north coast of Peru from about 100 to 600 C.E., developed specialized systems of craft production, with workshops producing fine copper and gold decorative objects such as ornate earspools, necklaces, bracelets, and hammered shields. *Spondylus* shells, imported from Ecuador, were worked into objects of ritual significance frequently found in Moche funerary contexts. They took on a number of different forms, sometimes left in their natural state and other times fashioned into small sculptures, incorporated into mosaics, or crafted into beads.

Archaeological evidence of basketry abounds in North America as the region emerged from the Archaic Period; in fact, the period from 100 B.C.E. to 700 C.E. in the American Southwest is known as the Basketmaker for the presence everywhere of this cultural product in the archaeological record. Basket making was traditionally performed by women. Different basket designs and decorative motifs might distinguish the hand of the maker or signify the particular family, region, or cultural group within which the basket was produced. The discovery of engraved stone tablets at several Middle Woodland Period (300 B.C.E.–1000 C.E.) archaeological sites in the eastern United States provides further insights into ancient North American craft production. Archaeologists believe the tablets were probably used for printing decorations on cloth or other perishable materials.

Although they were made from the same basic materials, crafts produced throughout the ancient Americas had a diversity of forms, decorations, and functions. Climate, geographical location, access to natural materials, and human needs and desires mostly determined this variation. The basic large-scale continuities across the Americas are a common preceramic material culture, the development of crafts associated with sedentary life, and the rise of domestic and institutionalized craft specialization. With the development of cities, chiefdoms, and empires from the middle of the first millennium until European contact, however, crafts began to diverge widely from their shared cultural foundations and took on ever more varied forms to satisfy the needs of increasingly complex and stratified societies.

► crime and punishment

INTRODUCTION

Crime was dealt with harshly in the ancient world. Early human settlements had no legal codes, courts, prisons, or other systems for dealing with crime, so most often crime was punished by family retribution. If someone committed a crime against another person, that person's clan would hunt down the perpetrator and mete out punishment. Crime was always a personal matter. Because there were no nation-states, there was no such thing as a crime against the state or "society." The victim of a crime was always a person.

The world's earliest legal code, developed in Mesopotamia, specified particular punishments for particular types of crime. While historians know about the existence of this code, no record of the code itself survives. However, the later Code of Hammurabi, also from Mesopotamia, provides historians with a comprehensive legal code developed by a king for his people. Historians are particularly interested in the

prologue to the legal code, which outlines its rationale and moral underpinnings. Hammurabi was one of the first rulers to see punishment not just as a form of retribution but also as a deterrent to crime. His code was also the first to incorporate the notion of "an eye for an eye," a phrase later used in the Bible to refer to the notion that a punishment should be proportional to the crime committed.

Early legal codes were also developed in China and India. These codes were harsh by modern standards. In China, for example, five forms of punishment were typically carried out. Tattooing and disfigurement served to identify the person as a criminal, but still harsher punishments included castration, mutilation, and death. Often, the manner of death differed for different sorts of crimes, also a common practice later under the Roman Empire.

Punishment could also vary by a person's social class or, in the case of India, caste. While the Code of Hammurabi purported to treat all people equally, in practice people of higher social classes often did not face the same harsh punishments that people of lower classes did; in fact, crimes were defined differently depending on the social classes of the perpetrators and victims. In India the caste of a person often played a major role in the harshness of a person's punishment.

Ancient Greece was the source of the modern jury system. Until then, legal codes and administration were dictated by kings or a king's delegates. The ancient Greeks, however, devised the first system in which citizens took part in hearing cases and meting out punishment. The ancient Romans were the first to distinguish between private crimes, such as assault and burglary, and public crimes, such as treason and bribery.

Prisons were not common in the ancient world, though ancient Assyria had some fairly large prisons. Convicted criminals were swiftly punished in a variety of ways, including beating, having arms or hands cut off, or being put to death by various means, including hanging and crucifixion. Another common form of punishment was exile, meaning that a criminal was forced to leave the community. Sometimes criminals were sold into slavery, and sometimes they were abandoned in remote areas, where they faced death by starvation or attack by wild animals.

AFRICA

BY SAHEED ADERINTO

Conceptualizations of crime vary from one part of Africa to another and from one time to another. An act that constitutes a criminal offense in one culture might be permitted in another culture; an act treated as a criminal offense today might have been condoned in the past and vice versa. As African societies moved from one period to the next in the course of their history, perceptions of crime, its control, and the punishment of offenders changed. Any analysis of the history of crime requires a critical understanding of the socioeconomic, cultural, political, and other changes a society experienced in succeeding decades and centuries.

Ancient African societies were made up of the living, the ancestors or gods, and the generation unborn. The living deified and worshipped the ancestors as god and goddesses because of their roles in protecting and enhancing the welfare of the community. Criminal offenses were not only against the living but also against the ancestors. The place of the ancestors in the day-to-day activities of the living is evident in light of the fact that the ancestors were responsible for laying the foundation of the community, its values, culture, and sanctions. Their demise did not represent their detachment from the society, and because they were chiefly responsible for having made the laws, antisocial behavior was an offense against them as well as against the living. Among the Asante of present-day Ghana “private offenses” (*efisem*) are those that emerge as a result of social, political, and economic relations solely among the living, while “public offenses” (*oman akyiwade*) are those that involve the entire community, including the ancestors. Regarding this second category, the living must make sure that laws are enforced and criminals are punished, to avoid incurring the wrath of the ancestors.

Criminal codes as we have them today did not exist in ancient Africa. African criminal laws were based on fundamental teachings that were deeply interwoven with several aspects of culture and custom. A criminal offense was an act that breached basic moral teachings or flouted customs. For example, the unwritten moral codes of most societies frowned upon stealing and adultery. For stealing, however, the actual loss of someone’s property to theft carried less weight than the effects of the criminal’s disobedience on the society’s morals. Adultery was a criminal offense because it involved breach of the trust between husbands and wives. The spiritual vows men and women exchanged during marriage rites made adultery a serious form of antisocial behavior.

African criminal or legal systems also included taboos. Indeed, it is difficult to differentiate between taboos and laws, because both are integral parts of Africa culture. The list of taboos is endless. There were taboos that governed when crops should be planted and harvested, when fishing should be done, what parts of the community people ought not venture into, which animals must not be killed, and so on. Among the Yoruba of present southwestern Nigeria it is sacrilegious to hunt game in ancestral forests. This type of forest is preserved for religious and cultural purposes. Forests, rivers, and mountains are the abodes of the gods. In such places activities that were not spiritual or religious in nature were thought to be a breach of cultural beliefs and sanctions.

How was crime detected in ancient Africa? In most African societies there were gods or cults associated with crime, and when a criminal act was committed without apprehension of the perpetrator, the entire community assembled at the village shrine, where oaths were taken to reveal the offender. It was believed that the gods were capable of striking and killing offenders immediately after such oath takings. Sometimes the offender died after several weeks of sickness. In cases where the criminal was apprehended without the

help of deities, the chief or ruler of a community determined the offender’s punishment.

The gravity of the offense played a significant role in determining the type of punishment meted out. Among the Akan-speaking people (Ghana) offenses such as stealing were punishable by banishment from the community. In virtually all African societies crimes like murder were punishable by death. If an offense was closely connected to disobedience of a deity, the offender might be sacrificed to appease the god. Antisocial elements could be sold into slavery. Not all offenders were killed or banished. In some communities, such as among the Masai of East Africa, adulterers were made to pay fines in the form of cattle.

Private prosecution of offenders also took place in some parts of Africa. Magico-religious methods of punishing offenders included placing charms on property that caused thieves to be paralyzed or die after stealing it. Charms (*juju*) of this nature can also prevent people from committing crimes, for instance, by making a stealable commodity less attractive to the potential thief. Husbands also placed charms on their wives to punish other men who had sex with them.

EGYPT

BY DAVID PETECHUK

Most of what is known about ancient Egyptian law, crime, and punishment comes from funerary documents and court manuscripts, as well as some other ancient writings. Drawing on these sources, historians believe that the earliest Egyptians probably had developed a sophisticated view of right and wrong within the context of crime and punishment. They had a comprehensive system of law that addressed crimes ranging from murder and theft to grave robbing and even necrophilia, erotic interest in the dead. According to most accounts, Egyptian law was first unified under King Menes (ca. 2925 B.C.E.), who united Upper and Lower Egypt.

As in most ancient cultures, the final authority on all disputes was the king—in Egypt, the pharaoh—who was considered a living god and as such was the ultimate judge and lawmaker. Intertwined with the Egyptian judicial philosophy was Maat, the goddess who represented the ideals of law, order, and truth. In an attempt to live up to the ideals embodied by Maat, the pharaohs and those to whom they delegated authority in matters of crime and punishment were expected to view everyone, except for slaves, as equal under the law. Nevertheless, as in most societies, there were differences, both subtle and overt, in how the judicial system treated people from different social classes. For example, a noble convicted of a crime requiring the death sentence might be allowed to commit suicide, whereas others were executed.

The most serious cases of crime in Egypt were decided by the pharaoh or a special delegation that he appointed. In rare cases, divine oracles made decisions, often for crimes or transgressions involving the temples and the gods. Because Egyptians viewed the objects in Egyptian tombs as sacred,

Papyrus with part of the “Tale of the Eloquent Peasant” from Egypt, around 1800 B.C.E.; a major literary text of the Middle Kingdom, this is the story of crime and its punishment in a way that questions social and divine justice. (© The Trustees of the British Museum)

they considered tomb robbery one of the most heinous crimes. Tomb robbers became so rampant and bold that they even began robbing the graves of the pharaohs during the rule of Ramses IX (ca. 1131–1112 B.C.E.). Death was generally the penalty for tomb robbing. One man, believed to be a grave robber from the Twenty-Fifth Dynasty (which began around 700 B.C.E.), is reported to have been buried alive. Most crimes against the government resulted in execution, as did most murders, whether committed by a free citizen or a slave. The death penalty was also administered for perjury, which the Egyptians viewed as irreverence toward the gods as well as a crime against society.

Nevertheless, some historians believe that Egypt made relatively little use of the death penalty, at least in comparison with other ancient cultures. Part of the reason may be that Egyptians considered disgrace and designation as a “nonperson” to be a harsher penalty to endure than death. (Sometimes brands or cuts were used as visible signs of dishonor.) Furthermore, a dead person could not serve the pharaoh or government. Considering that those disgraced could regain their honor and lost rights only by performing heroic or valiant deeds, an individual punished with disgrace could ultimately prove beneficial to society.

In addition to death and disgrace, Egyptian law meted out a variety of other punishments, with beatings being among the most common. Many punishments were barbaric by modern standards. Mutilation—especially cutting off the nose, ears, hand(s), or tongue—was a common punishment for a variety of crimes. For example, a woman caught in adultery had her nose cut off, not only as punishment but also to destroy her attractiveness and thus prevent her from committing the crime again or enticing a man into adultery. As in most ancient cultures, women often suffered more severe penalties than men. A man caught in adultery with a married woman received a beating as a penalty, usually a thousand strokes with a stick. However, if a man raped a freeborn woman, he was castrated.

Despite the harshness of many penalties, Egypt possessed some concepts of basic human rights. For example, when a pregnant woman received the death penalty, she was not executed until her child was born, because the Egyptians considered the child guilty of no crime and therefore not to

be punished for the mother’s misdeed. Pharaoh Bocchoris (ca. 717–712 B.C.E.) suppressed the use of bondage or imprisonment for debtors.

The Egyptians also had some unusual concepts of certain crimes and unique penalties for dealing with them. For example, parents convicted of murdering their child were not put to death, because they were considered to have given life to the child. Instead, they were punished by having to hold the baby’s dead body in their arms for three consecutive days and nights, a penalty designed to evoke repentance and deter them from committing the crime again. For a time the Egyptians also tried dealing with the exploding problem of common theft (excluding theft involving tombs or temples) in a unique way. They set up a system in which thieves had to register with a “captain of thieves” and report all the goods that they stole, which the robbed person could then ransom for one-fourth of the value. Despite this attempt to control theft and restitution, it is believed that other punishments for theft predominated throughout ancient Egypt’s history, including death, fines, and various corporal punishments.

While confinement was not a common form of punishment for free citizens of Egypt, prisons did exist, dating to the Middle Kingdom Twelfth and Thirteenth Dynasties (ca. 1991–1640 B.C.E.). The prison population was made up mostly of servants and foreigners; for citizens penalties such as public beatings, fines, or execution predominated. Some temple depictions of prisons show decorative rows of panels that contain the name of a conquered country or people, with the heads and shoulders of bound prisoners above the panels. Each panel is attached to a rope, and the pharaoh is depicted as holding all of the ropes. Historians believe that the Egyptian prisons were generally operated in an orderly manner and kept relatively clean.

The influence of Egyptian laws related to crime and punishment was wide ranging. For example, the Greek Solon, who became lawgiver in Athens in 594 B.C.E., visited Egypt and is believed to have adopted some Egyptian views on crime and punishment, including the idea of applying the same punishment prescribed for a crime to someone who falsely accuses another of that crime. The Greek idea of idleness as a crime may also have come from Egypt, where free citizens had to declare in writing how they made a living and could be put

to death for making a false declaration or for being in an illegitimate business.

THE MIDDLE EAST

BY DAVID PETECHUK

The world's oldest surviving legal codes and laws come from Mesopotamia. The first known legal code, the Code of Urukagina, dates to 2350 B.C.E., and the region probably had legal prescriptions for centuries prior to this code, which was developed by and named after a ruler of Lagash. Before the Code of Urukagina, laws designating crimes and their punishment were probably based on the customs of the people and prevailing ideas of right and wrong. Although customs and laws transmitted orally served their purpose, as Mesopotamian cities and kingdoms grew and literacy spread, laws were put into writing to reduce vagueness or public discord about exactly what constituted a crime and what should be the punishment.

As with most ancient cultures, punishments for crimes were often severe. For example, a document dating to around the time of the Code of Urukagina notes that both thieves and adulteresses had their names inscribed on rocks, which were then used to stone them to death. Although the Code of Urukagina is the oldest-known legal code, an actual text has never been found, and its existence is known only through references in other ancient writings. The oldest legal code recovered dates to time of Ur-Nammu, who ruled the Sumerian city of Ur from 2112 to 2095 B.C.E. Of the code's decipherable segments, approximately 40 statements focus on crimes and punishment. Monetary fines and the death penalty were the primary punishments for crimes and were established in a manner that reflected the social conventions of the times. For example, deflowering a virgin wife of another man resulted in a death sentence. However, if the woman was only a slave to a man, the penalty was only five shekels of silver. Murder was punishable by death, but physical wounds inflicted on another were punished with a monetary fine, partly because prison was seldom used as a means of long-term punishment.

The jewel of ancient Mesopotamian law is the Code of Hammurabi. Established in the 18th century B.C.E., it is the earliest surviving record of an entire code of laws proclaimed by a king to his people. What makes the code especially exciting to historians is that it includes the entire prologue explaining moral and spiritual rationalization for the laws. Hammurabi, who ruled Babylon from 1795 to 1750 B.C.E., states that his goals are to punish severely those who are evil and to protect those who are weak. Nevertheless, many of the laws were based on social status, with harsher penalties inflicted for crimes committed against the upper class while the same crime against someone from the lower class usually garnered a much less severe punishment. Hammurabi, however, kept in mind that lower social status meant lesser ability to pay fines. As a result, poor people usually had to pay low-

er fines than their rich counterparts. Overall Hammurabi's code applied various penalties to the population according to three classes: *amelu* (patrician), *muskinu* (free non-landowner), and *ardu* (slave).

The most significant aspect of Hammurabi's codes for crime and punishment is his establishment of the law of retribution, known in legal language as *lex talionis* and popularly familiar as the biblical law of "an eye for an eye." For example, historians believe that before Hammurabi, monetary fines for causing bodily injuries were deemed sufficient largely because injuries to private individuals were not considered crimes against the state or society in general. Hammurabi, however, set more severe penalties for physically harming another person, such as cutting off the hand of a son who struck his father. His rationale for these harsher penalties may have stemmed not only from the concept of *lex talionis* but also from a belief that fines and lesser punishments alone were not enough to ensure that his people obeyed the laws.

Hammurabi's comprehensive set of codes guided by *lex talionis* covered a wide range of crimes, such as bearing false witness. The penalty for someone falsely accusing another of crime was to suffer the punishment assigned to that crime. So if a man falsely accused another of murder, the accuser would be executed instead. Other examples include cutting off a surgeon's hand when his work resulted in the death or loss of a limb of a patient and the execution of a builder or his son if a building collapsed and killed its owner. Cases dealt with in this manner also included crimes involving slavery, sexual offenses, assault and bodily injuries, murder, theft, and debts.

As for the death penalty, ancient Mesopotamian laws required death for a wide range of crimes, including the illegal buying of a slave from a minor, selling or receiving stolen goods, false claim to another's possessions, disorderly conduct in a tavern, and the practice of magic. While the means of execution for these crimes was often not specified, other crimes resulted in specific types of execution. Hanging was the punishment for many crimes, among them burglary, obliterating a slave's brand, and a woman's seeking to have someone murder her husband. Other forms of execution included burning when convicted of incest with one's own mother and drowning for certain cases of adultery, rape, and bigamy.

The Code of Hammurabi greatly influenced the legal system throughout the Near East and Persia for several centuries, including the dominant rule of the Assyrians until around 500 B.C.E. As a result, the predominant form of punishment remained corporal and, other than death, included severe beatings of up to 100 blows, forced labor, and various types of mutilation, such as cutting off the tongue. Similarly, in ancient Persia, under the rule of Darius I (r. 522–486 B.C.E.), the penalty for attacking and severely injuring or killing someone was five to 200 lashes of the whip. For the most severe crimes, usually crimes against property, the state, or the king or his family, death by impalement was a typical punishment. (Little information is available concerning punishments for ordinary crimes in Persia.)

Throughout the Middle East, an ordeal was often assigned to prove guilt or innocence. For example, a popular test from the time of Hammurabi was to throw the accused into the Euphrates River. If the current brought the person to shore, he or she was not guilty. Drowning, on the other hand, proved guilt. (It appears that the art of swimming was little known at the time.)

As in most ancient societies, imprisonment was a relatively secondary form of punishment (though the Assyrians are known to have had some exceedingly large prisons for the times). Imprisonment was primarily for lesser crimes, such as debt, bribery, tax evasion, and smuggling; offenders largely remained in prison until they could pay off their debts or fines. Long-term prisoners were usually foreigners or prisoners of war who were subsequently used for forced labor.

ASIA AND THE PACIFIC

BY DAVID PETECHUK

Asia and the Pacific are endowed with a vast and varied cultural heritage, and much of the region's history concerning crime and punishment remains unknown and is not easily synopsisized outside India and China. In China, which boasts one of the oldest legal traditions, laws focusing on crime and punishment originated from ancient moral teachings that were eventually written into legal codes. Many of the first laws formulated in ancient China date to the Zhou Dynasty (ca. 1045–256 B.C.E.) and were divided into various rituals designed to punish criminals and deter others from committing crimes.

The *Shan shu* (*Book of History*), primarily composed of recorded sayings of the governors in the Shang Dynasty (ca. 1500–1045 B.C.E.) and the Zhou Dynasty, describes the earliest of China's "five penalties": tattooing, disfigurement, castration, mutilation, and death. For example, pickpockets received brands on their arms for their first two offenses, while a third offense probably resulted in a more severe punishment. Death was the penalty for armed robbery. One of the most basic laws of ancient China was that children should obey and honor their parents; thus, for example, a girl found guilty of insulting her parents was strangled. Beating with a bamboo stick was a common but, for the times, relatively mild punishment for a variety of crimes. Because of the Chinese belief that the head is the noblest part of the body, decapitation was considered particularly shameful and was used to punish murder and a number of other serious crimes. A Han Dynasty (202 B.C.E.–220 C.E.) legal code included more than 1,000 articles on capital punishment and decapitation.

The first known complete Chinese written law dates to the fifth century B.C.E. and outlined six basic areas of law. The Law of Theft focused on property crimes against the landlord class; the Law of Banditry pertained to rebellions and personal injuries; the Law of Miscellaneous Affairs was associated with state affairs; the Law of Verdict dealt with the logic and rules behind increasing or reducing punishments; the Law of

Arrest and the Law of Prisons centered on those facets of the justice system. These laws, later called the "Law Classics," covered everything from major crimes such as murder to lesser offenses such as roguery, getting over city walls, gambling, and lewdness, and they influenced how subsequent dynasties down to modern times dealt with crime and punishment.

Culturally, linguistically, and ethnically diverse, India was one of the cradles of civilization. Nevertheless, because of the lack of written records, historians know little concerning ancient India's approach to crime and punishment. According to some sources, during the sixth and seventh centuries B.C.E. criminals were seldom if ever put to death but were rather fined for various crimes. However, by the time Chandragupta Maurya (r. 321–297 B.C.E.) came to power laws were harsher, and the death penalty and mutilation were common punishments.

The Manusmriti, or Laws of Manu, the most authoritative and best-known legal text of ancient India, combines the beliefs of Hinduism with law. It first appeared sometime between 200 and 100 B.C.E. and was derived from ancient religious texts and authoritative commentaries on these texts. As such, the Manusmriti provided ethical counsel as well as commentaries on law. The laws were thought to reflect the values of India's Hindu priests and clearly distinguished between civil wrongs, which primarily related to disputes over money and wealth, and criminal offenses involving sins such as theft and murder. Some historians believe that the laws described by the Manusmriti may not have been enforced diligently but rather provided an ideal of what the laws should represent. In fact, only a few chapters focus on crime, justice, and punishment.

Overall the Manusmriti divides crimes into 18 categories, such as nonpayment of debts, sale without ownership, nonperformance of agreements, disputes between owners of cattle and their servants, boundary disputes, assault and defamation, theft, robbery and violence, and adultery. For physical assault, various punishments were applied in ancient India, based largely on the perpetrator's caste, or social class. For example, a man of low caste who assaulted a man of higher caste often had a limb cut off as punishment. (The Laws of Manu identified places on the body where punishment could be inflicted, including the sexual organs, belly, tongue, hands, and feet.) While property damages were settled through fines, acts of violence were seen as the worst crimes imaginable and were severely punished. The Laws of Manu viewed punishment as an extremely important tool for controlling people and keeping them within their castes, thus ensuring that inferior people would not take the place of their superiors.

Laws in ancient India and the handing out of punishments were administered by the kings, who in turn were advised by various ministers and learned Brahmins (members of the highest of the four Hindu *varnas*, or social divisions, which also included, in order of importance, the Kshatriyas, or warriors; the Vaisyas, or merchants; and the lowest class, Sudras or workers). Judges were appointed to determine punishments. At the village level a committee of five or more

members, called the village *panchayat*, was in charge of dealing with criminals. The Laws of Manu had a lasting influence on India and were even revived during the modern British colonial era.

Little is known about ancient principles of crime and punishment in other parts of Asia and the Pacific. For example, Japan was sparsely populated prior to 200 B.C.E., when a culture that used iron tools began to replace the hunters and gatherers who populated the island. According to ancient Chinese records, the people who lived in what is now Japan did not commit theft, and violations of the law or customs were handled by a family member. This authority figure was ultimately responsible for establishing retribution against a family for crimes committed by any of its members. In some cases the offender's entire family was executed as a strong signal to others not to commit crimes. Interaction with China and its peoples probably influenced Japan's early approaches to crime and punishment.

EUROPE

BY MICHAEL J. O'NEAL

As is commonly the case, historians have little direct evidence about crime and how it was punished in ancient Europe. The primary obstacle is the absence of written records. In some cases, archaeologists have found inscriptions on monuments that deal with matters of law, crime, and punishment, but these inscriptions tend to be fragmentary and of little help. In Scandinavia rock carvings have been found that shed faint light on ancient Scandinavian law, but historians are uncertain about their meaning.

Missing from the record of ancient Europe is any kind of systematic legal code. Through most of the ancient period crime and punishment were matters dealt with through custom rather than any prescribed body of law. While local custom differed from region to region, early European societies operated under similar principles, suggesting that the various branches of local law descended from a common Indo-European source. Some ancient European legal principles, particularly those of the Celts, probably date back to the Early Bronze Age (roughly 1800–1600 B.C.E.) and perhaps even earlier. Others date to later periods, primarily as a result of trade and cultural contact with the Greeks and, later, the early Romans.

An overarching principle of ancient European law was the preeminence of the family, with the senior male at its head. Prior to the development of nation-states and the rise of empires and ruling dynasties, legal traditions were a matter of family ties. A person's identity was taken from the clan to which he belonged. The head of the family had absolute sway over the individuals belonging to it. In this respect, a family was a bit like a corporation, with its own rules and procedures and an ongoing existence after the death of its head. Crime, then, was a breach of the rights and privileges not just of the individual victim but of the family as well. Accordingly, it was common for the family to impose its own

brand of "frontier justice" on offenders, for the concept of a legal code, police forces, jails, courts of law, procedures for conducting trials, and the like were unknown. The result was often blood feuds.

The written record becomes more complete after the spread of the Roman Republic and the Roman Empire in the centuries before the start of the Common Era. Such classical figures as Caesar, Tacitus, and Pliny wrote about aspects of law in some of the far-flung areas of the empire, including Gaul (modern-day France), Spain, and later England. Julius Caesar (100–44 B.C.E.), for example, wrote extensively about legal matters in Gaul, which he learned about firsthand because of his participation in the Gallic wars beginning in 58 B.C.E. In time, as the Romans imposed their legal system on their colonies, legal codes developed that represented a blend of Roman and local law. After the advent of the Common Era and the beginning of the spread of Christianity, ecclesiastical law became a third ingredient that influenced the legal practices of the European nations.

According to Caesar, the ancient Celts recognized such crimes as murder, robbery, and theft, as well as other, more specific laws, such as usurping the authority of a king. A principle that ran through ancient European law was the distinction between public crimes and private crimes. Public crimes were those committed against the state; the victims of private crimes were individuals. While the state prosecuted crimes against the state, individual victims, or their families, had to pursue legal remedies on their own if they were victims of a crime. The process began with a plaintiff making an appeal to whoever was responsible for enforcing the law. Among the Celts, this person would often have been a Druid, a priestlike figure who was believed to have legal wisdom. In others, it may have been a public official or a noble whose patronage the injured party enjoyed. Often it became the obligation of the injured party to "distrain," or seize, the offender. The parties then assembled to swear oaths that they would give truthful accounts of the events in question. Witnesses, kinsmen, and other supporters of each party swore similar oaths. Monetary pledges were frequently given to ensure that the parties would appear for the hearing.

At the hearing, a judgment was rendered. If the accused was found guilty, punishment was imposed. Because there were no prisons in ancient Europe, other means of punishment had to be used. One of the most common was the monetary fine. Sometimes fines were simply a form of restitution to the victim or his family. Other fines were regarded as more of an "honor price," a way of restoring the honor of the victim. The amount of these fines often differed depending on the rank of the victim. Another common form of punishment was banishment from religious sites and rituals, a punishment the ancient Celts and Germanic tribes found particularly severe. In some cases the death penalty was invoked, but death was not a common form of punishment.

The Germanic tribes of northern Europe used the ordeal as a way of determining the guilt or innocence of an accused

criminal. The ordeal was based on the religious belief that God would not allow an innocent person to be convicted nor allow a guilty party to go free. While the ordeal remained a common practice after the spread of Christianity, it had its roots in pre-Christian Germanic practice. It was used when other forms of evidence were not available and descended from the more ancient practices of the Babylonians, Jews, and other cultural groups that also used the ordeal. The practice was used among the Germanic tribes and spread with the spread of the Roman Empire into Gaul, Italy, and the British Isles—although the Romans themselves never used the ordeal.

One of the most common ordeals was the duel. Again, the belief was that God determined the outcome of the duel based on the guilt or innocence of the parties. Only free men could take part in duels, with free women required to appoint a substitute. Another practice that had its roots in ancient Germany was the ordeal by fire. In some cases the person had to carry a red-hot bar of iron in his hands; in others he had to walk over burning coals or across a row of red-hot plowshares. Success in doing so was a sign from God of innocence. A similar ordeal was to force the accused to reach into a cauldron of boiling water and withdraw a stone at the bottom; if the accused was innocent of the crime, his bandaged arm would heal in three days. Alternatively, the accused's hands and feet were bound and he was hurled into a body of cold water. If he floated, he was innocent, but if he sank, he was guilty. In addition to several other types of ordeals was the oath. The belief was that if the accused took a solemn oath of innocence but was in fact guilty, God would punish him with death for committing perjury.

GREECE

BY DAVID PETECHUK

Although no comprehensive collection of ancient Greek laws has survived to modern times, historians believe that before approximately 700 B.C.E., Greece had no official laws or punishments for crimes. Prior to this time, retribution for various crimes was often carried out by individuals. For example, when someone was murdered, the victim's family members were likely to reciprocate by killing the murderer, which often led to extended blood feuds between families. The Greek poet Homer (ca. 850 B.C.E.), author of the *Iliad* and the *Odyssey*, also indicated in his writings that it was up to individuals to settle disputes over property, possessions, and other claims. They usually did so by fighting among themselves. Homer also suggested that in some cases people could appeal to a third party over a dispute or crime—for example, to a king, leaders of the community, or ordinary people gathered together as a group for the express purpose of judging a specific case.

Established universal laws and punishments for crimes began to appear in Greece about the middle of the seventh century B.C.E., with the evaluation of crimes and punishments based primarily on oral laws. Because of the development of

Greek city-states, each of which had their own laws, historians have found it difficult to provide a comprehensive overall picture of crime and punishment in early Greece. Nevertheless, a generalized picture has been developed based on Athenian law and procedures, which included the establishment of the Council of Areopagus by the seventh century. (Areopagus means “rocky hill” and is the name of a site northwest of Athens where the council met.) The Council of Areopagus, which was made up of a group of nine elders who served as magistrates called archons, was in charge of both conducting trials for serious crimes, such as murder and tyranny, and setting the punishment based on individual cases.

The first known instance of laws being put into writing was in 621 B.C.E., when Draco, (or Drako) the lawgiver had existing oral laws transcribed onto *axones*, or wooden tables or rollers, none of which survive today. At that time Draco made distinctions between crimes such as murder and accidental homicide. Nevertheless, almost every crime was punishable by death, from the serious crimes of murder and treason to what modern society would consider minor infractions, such as stealing food. Draco also made exile from Athens a potential punishment for murder committed by citizens. It is from Draco's name that the term *draconian* originated, to signify excessively harsh rules, leadership, and punishment. Part of the reason for mandating severe punishments for even minor crimes was that Greek religious and philosophical thought considered almost all forms of misconduct to be sacrilegious, an outrageous violation of something held sacred. As a result, a crime, no matter how minor it might appear, could bring the wrath of the gods down upon the entire populace.

In 594 B.C.E. the aristocrat Solon became the appointed lawgiver in Athens. Partly in an attempt to address public dissatisfaction over laws and punishments for crimes, Solon set out to revise the laws and institute new punishments for various crimes. He not only overturned most of Draco's death penalties but also gave the common people a more substantial role in the justice system, making it possible for even the poorest citizens to serve on a panel of judges that determined the outcome of cases and meted out punishments. In addition, all male citizens could bring charges against people and appeal verdicts they believed were unjust.

Under Solon's new laws, most penalties for crimes involved monetary payments. For example, a person convicted of rape was fined 100 drachmas or, according to other sources, staters—two denominations of money in ancient Greece. Likewise, fines for adultery with a free woman that took place in her family's house (including her father's or brother's houses) was also 100 drachmas but was reduced to a fine of 50 drachmas if it took place somewhere else. Fines for theft varied according to what was stolen and its value.

Solon also established new laws that defined specific deeds as crimes, including the mistreatment of children, slander, and male prostitution. Other common crimes in ancient Greece included bribery of the magistrates, which resulted in the death penalty if the briber was convicted, and the theft

of statues and monuments erected at Olympia and Delphi in honor of major Greek figures, such as political and military leaders and Olympic athletes. Some unusual Greek crimes included causing damage to the stump of a sacred olive tree and idleness, which prevented a person from supporting himself and his family and was punishable by death before the penalty was eventually reduced to a fine by the fifth century B.C.E.

Despite the appearance of a greater judiciousness in establishing laws covering crimes and punishments, penalties often remained severe. For example, death remained a potential penalty for a statesman who misled the Athenian assembly. In a noted case, the wealthy Athenian and military commander Miltiades was charged with this crime by Xanthippos in 489 B.C.E. for his failure to fulfill his promise of victory in a military expedition against the island of Paros. Although he was convicted, Miltiades died in prison from a war wound before his sentence was carried out. Exile was also considered a severe form of punishment in ancient Greece, because citizenship within a city-state came with many privileges that the exiled person forfeited.

Several ancient sources have noted that the ancient Greeks did have prisons. Nevertheless, long imprisonment probably was not a typical form of punishment. Imprisonment for crimes probably was rare and usually temporary until a punishment, such as death, exile, or a fine, was decided upon. Historians believe that most prisoners kept for any extended time were debtors who owed money to the state. However, the prisons were not draconian in nature. According to historians, prisoners were generally allowed freedom of movement, and restraints, such as chains, were used only occasionally.

From the writings of Greek philosophers and historians, it is clear that the ancient Greeks developed a sophisticated notion of the role punishment should play for various crimes. Their concepts of justice and punishment moved beyond the idea that punishments should be applied merely for retribution and to appease the gods. Instead, the Greeks viewed punishment for crimes as an example to deter others and as a means of correction so that those who were punished became better people unlikely to repeat their misdeeds.

Roman law was officially introduced to Greece following Rome's conquest of Greece in 149 B.C.E. Nevertheless, many Greek laws concerning crime and punishment remained in effect. In fact, Greek law and custom greatly influenced the development of Roman law. For example, in both systems, theft from a temple was punishable by death, but only Roman authorities had the power to execute criminals.

ROME

BY TOM STREISSGUTH

Roman law originated in the ancient customs of the kingdom and the Roman Republic, established among the farming villages along the banks of the Tiber River. The first written Roman law—in fact, the first surviving Roman writing of any kind—is the *Lex Duodecim Tabularum*, or the Law

of the Twelve Tables, of 450–449 B.C.E. At the prompting of the plebeians, or commoners, the leaders of Rome convened a committee of 10 men—the *decemvirs*—to create this code. The intention was to reframe in a more just form the unwritten, customary laws that heavily favored the patricians, enshrine the new laws in writing in a public place, and make them a cornerstone of the Roman Republic. To that end, the laws of the Twelve Tables were set up on bronze tablets in the Roman Forum and enforced by Rome's two elected consuls, who served as the chief law-enforcers of the realm.

A MOST HUMILIATING DEATH

To the Romans, the worst form of execution was crucifixion: the killing of a condemned prisoner on a cross or stake. The Romans first encountered crucifixion as practiced by the Carthaginians of North Africa. Reminded of their own custom of tying or nailing criminals to a tree and allowing them to die without food or water, the Romans adopted crucifixion as a punishment for slaves, pirates, thieves, and mutinous rebels. (A Roman citizen of high birth guilty of serious crimes was beheaded, allowed to commit suicide, or permanently exiled.) Mass executions of the defeated were common after civil unrest or rebellion; after the slave revolt led by Spartacus in 71 B.C.E., 6,000 prisoners were crucified along the Appian Way between Rome and the town of Capua.

A prisoner to be crucified was stripped, scourged nearly to death, and forced to carry the cross to his place of execution. He was then nailed or roped to the cross, which was made of a *stipes* (upright) and *patibulum* (crosspiece). The traditional cross was built in the shape of a letter T; the Romans sometimes attached the *patibulum* beneath the top of the *stipes*, in what became known as the Latin cross. By one tradition, a sign giving the crimes or the name of the prisoner was attached to the top of the cross.

The victim of a crucifixion could die of suffocation, shock, loss of blood, or dehydration. The death could take several days; to hasten death, the Romans broke the prisoner's legs, forcing the body's collapse and a rapid death through asphyxiation. The worst dishonor of crucifixion was in the fact that the body was left on the cross after death, to be consumed by vultures or wild animals, and not afforded a proper burial. The practice of crucifixion was central to the tradition of Christianity, which held its founder to have been executed in this brutal manner. For this reason, the emperor Constantine, the first Roman leader to convert to Christianity, discontinued the practice during his reign in the early fourth century.

The Twelve Tables prescribed the death sentence for a variety of crimes. A debtor unable to repay after 60 days could be killed by his creditor. Writers of slanderous or insulting songs could be clubbed to death. Accepting a bribe or committing fraud was also a capital crime. Those bearing false witness in court were flung headfirst from the Tarpeian Rock, a cliff near the center of Rome that served as the city's place of public execution. Anyone suffering injury could exact "an eye for an eye" but could also agree with the aggressor on monetary compensation for the injuries. In all, the Twelve Tables set out eight different forms of punishment: a fine, fetters, flogging, retaliation in kind, civil disgrace, banishment, slavery, and death.

Patricians still benefited from prejudice in the law, as the punishment of crimes often depended on the offender's social standing. Under the Roman Empire, established by Augustus in 27 B.C.E., *honestiores* were distinguished from *humiliores*. The former were aristocrats, soldiers, and those holding public office; the latter were everyone else. For the *honestiores*, the usual sentence for serious crimes was exile and the confiscation of property; for the *humiliores*, death or slavery was the more common consequence of a guilty verdict. Only *humiliores* could be crucified, tortured, or publicly whipped.

The Romans also distinguished between public and private crimes. Public crimes were those committed against the state, including perjury, bribery, espionage, and treason. Such crimes were more severely punished than private ones throughout Rome's history. Private crimes were those against individuals, including indebtedness, theft, murder, and assault. A robber surprised in the act could be legally killed by the injured party. A Roman who committed assault, however, could simply pay a fine, and aristocrats sometimes amused themselves by openly breaking a "private" law and blithely paying a few coins to those they had injured or insulted. In this case the victim had no recourse to the justice system.

In the fourth century B.C.E., the judicial duties of the consuls passed to the praetor. The praetor was the head of the judicial branch of government and responsible for the state's legal decisions. He appointed judges to hear cases; he also had the power to pronounce sentence and to fix the amount of damages in cases involving theft or fraud. By custom the praetor announced new laws and procedures at the beginning of his term, a practice that supposedly prompted him to enforce the laws impartially. Criers wandered the city and the Forum to announce the edicts of the praetor, whose laws were also inscribed on public tablets. Although the praetor was supposed to uphold the law equally for patricians and plebeians, juries were nonetheless composed of Roman aristocrats (who, it was asserted, had the sense of honor that would guarantee fair decisions).

Capital punishment became more common under the Roman Empire than during the Roman Republic. The usual method of execution in Rome was beheading. Crucifixion was reserved for noncitizens and for crimes considered extremely dangerous to public order, such as the rebellion of a

Drawing by Michelangelo of the Crucifixion of Christ and two thieves; crucifixion was a punishment for crimes against public order and for noncitizens. (© The Trustees of the British Museum)

slave or anyone's inspiring a revolt against Roman authority in the provinces. The bodies of executed criminals were commonly left exposed in public for the education of the citizens. A special sentence was reserved for vestal virgins, priestesses responsible for keeping the sacred fire of Vesta burning in the center of Rome. The vestals were to abstain from sexual conduct of any kind; if found guilty of impurity, the offender was buried alive.

Some criminals were sentenced to take part in gladiatorial contests, where they were left to their own devices to face skilled combatants; others were left bound in the wild and at the mercy of the elements and animal predators. Sentences of perpetual labor in the Roman quarries or slavery on a seafaring galley were also very common. Roman prisons were never the convicted criminal's final destination; they were used only to detain criminal suspects and those sentenced to death.

The praetor could commute a death sentence, order the demolition of a home, or impose permanent exile on those found guilty of a crime. In these cases the state also confiscated the guilty party's property. By ancient custom the accused were presumed innocent until proved guilty, but anyone who

committed suicide to avoid a public trial and a sentence was believed to be confessing his guilt, and his property was immediately forfeited.

Within the family, the father had the authority of judge, police, and executioner. He could put a rebellious son to death or sell his children into slavery. He could punish a son or daughter who married someone the father opposed. A Roman family also had the right to put a deformed child to death if at least five neighbors agreed.

During the empire dozens of new laws were set down by the emperors, who had the power to decree anything with the force of law at their own whim. Under Constantine (r. 306–337 C.E.), Rome officially adopted Christianity, and subtle changes began in the criminal laws. Adultery and homosexuality were made punishable by death, which was carried out by beheading, drowning, or burning. All imperial pronouncements from the time of the emperor Hadrian to that of the emperor Justinian, as well as the edicts of the praetors,

were collected by Justinian in the *Corpus Juris Civilis*, promulgated in the sixth century C.E. This law code was revived in the 11th century and became the basis of law and jurisprudence on the European continent down to the present time.

THE AMERICAS

BY ARDEN DECKER

There is little to no written or other evidence to suggest how societies dealt with crime and punishment in the ancient Americas. Because of this lack of information, nothing definitive can be gathered about the region's ancient legal or court systems.

The Middle East

~ The Code of the Assura (Assyrians), ca. 1075 B.C.E., excerpts ~

I.7. If a woman bring her hand against a man, they shall prosecute her; 30 *manas* of lead shall she pay, 20 blows shall they inflict on her.

I.8. If a woman in a quarrel injure the testicle of a man, one of her fingers they shall cut off. And if a physician bind it up and the other testicle which is beside it be infected thereby, or take harm; or in a quarrel she injure the other testicle, they shall destroy both of her eyes.

I.9. If a man bring his hand against the wife of a man, treating her like a little child, and they prove it against him, and convict him, one of his fingers they shall cut off. If he kiss her, his lower lip with the blade of an axe they shall draw down and they shall cut off. . . .

I.12. If the wife of a man be walking on the highway, and a man seize her, say to her "I will surely have intercourse with you," if she be not willing and defend herself, and he seize her by force and rape her, whether they catch him upon the wife of a man, or whether at the word of the woman whom he has raped, the elders shall prosecute him, they shall put him to death. There is no punishment for the woman.

I.13. If the wife of a man go out from her house and visit a man where he lives, and he have intercourse with her, knowing that she is a man's wife, the man and also the woman they shall put to death. . . .

I.15. If a man catch a man with his wife, both of them shall they put to death. If the husband of the woman put his wife to death, he shall also put the man to death. If he cut off the nose of his wife, he shall turn the man into a eunuch, and they shall disfigure the whole of his face.

I.16. If a man have relations with the wife of a man at her wish, there is no penalty for that man. The man shall lay upon the woman, his wife, the penalty he wishes.

I.18. If a man say to his companion, "They have had intercourse with they wife; I will prove it," and he be not able to prove it, and do not prove it, on that man they shall inflict forty blows, a month of days he shall perform the king's work, they shall mutilate him, and one talent of lead he shall pay.

I.20. If a man have intercourse with his brother-in-arms, they shall turn him into a eunuch.

I.21. If a man strike the daughter of a man and cause her to drop what is in her, they shall prosecute him, they shall convict him, two talents and thirty *manas* of lead shall he pay, fifty blows they shall inflict on him, one month shall he toil. . . .

I.32. If a woman be dwelling in the house of father, but has been given to her husband, whether she has been taken to the house of her husband or not, all debts, misdemeanors,

(continued)

(continues)

and crimes of her husband shall she bear as if she too committed them. Likewise if she be dwelling with her husband, all crimes of his shall she bear as well. . . .

I.40. If the wives of a man, or the daughters of a man go out into the street, their heads are to be veiled. The prostitute is not to be veiled. Maidservants are not to veil themselves. Veiled harlots and maidservants shall have their garments seized and 50 blows inflicted on them and bitumen poured on their heads. . . .

I.47. If a man or a woman practice sorcery, and they be caught with it in their hands, they shall prosecute them, they shall convict them. The practicer of magic they shall put to death.

I.50. If a man strike the wife of a man, in her first stage of pregnancy, and cause her to drop that which is in her, it is a crime; two talents of lead he shall pay.

I.51. If a man strike a harlot and cause her to drop that which is in her, blows for blows they shall lay upon him; he shall make restitution for a life.

I.52. If a woman of her own accord drop that which is in her, they shall prosecute her, they shall convict her, they shall crucify her, they shall not bury her. If she die from dropping that which is in her, they shall crucify her, they shall not bury her.

I.55. If a virgin of her own accord give herself to a man, the man shall take oath, against his wife they shall not draw nigh. Threefold the price of a virgin the ravisher shall pay. The father shall do with his daughter what he pleases.

I.57. In the case of every crime for which there is the penalty of the cutting off of ear or nose or ruining or reputation or condition, as it is written it shall be carried out.

I.58. Unless it is forbidden in the tablets, a man may strike his wife, pull her hair, her ear he may bruise or pierce. He commits no misdeed thereby. . . .

Asia and the Pacific

~ *Kautilya: The Arthashastra, excerpt, ca. 250 B.C.E.* ~

BOOK IV, CHAPTER 11, DEATH WITH OR WITHOUT TORTURE

When a man murders another in a quarrel, he shall be tortured to death. . . . When a man hurts another with a weapon, he shall pay the highest amercement; when he does so under intoxication, his hand shall be cut off; and when he causes instantaneous death, he shall be put to death. When a person causes abortion in pregnancy by striking, or medicine, or by annoyance, the highest, middlemost, and first amercements shall be imposed retrospectively. Those who cause violent death either to men or women, or those who are in the habit of often going to meet prostitutes, those who inflict unjust punishment upon others, those who spread false or contemptuous rumors, who assault or obstruct travelers on their way, who commit house-breaking, or who steal or cause hurt to royal elephants, horses, or carriages shall be hanged. Whoever burns or carries away the corpses of the above offenders shall meet with similar punishment.

When a person supplies murderers or thieves with food, dress, any requisites, fire, information, any plan,

or assistance in any way, he shall be punished with the highest amercement. Sons or wives of murderers or thieves shall, if they are found not in concert, be acquitted; but they shall be seized if found to have been in concert.

Any person who aims at the kingdom, who forces entrance into the king's harem, who instigates wild tribes or enemies against the king, or who creates disaffection in forts, country parts, or in the army, shall be burnt alive from head to foot. If a Brahman does similar acts, he shall be drowned. Any person who murders his father, mother, son, brother, teacher, or an ascetic shall be put to death by burning both his head and skin; if he insults any of the above persons, his tongue shall be cut off; if he bites any limb of these persons, he shall be deprived of the corresponding limb. When a man wantonly murders another, or steals a herd of cattle, he shall be beheaded. . . . When a person breaks the dam of a tank full of water, he shall be drowned in the very tank. . . . Any man who poisons another and any woman who murders a man shall

be drowned. Any woman who murders her husband, preceptor, or offspring, sets fire to another's property, poisons a man, or cuts off any of the bodily joints of another shall be torn apart by bulls, no matter whether or not she is big with child, or has not passed a month after giving birth to a child. . . .

Any person who insults the king, betrays the king's council, makes evil attempts against the king, or disregards the sanctity of the kitchens of Brahmans

shall have his tongue cut off. When a man other than a soldier steals weapons or armor, he shall be shot down by arrows; if he is a soldier, he shall pay the highest amercement. He who castrates a man shall have his generative organ cut off. He who hurts the tongue or nose of another shall have his fingers cut off. . . .

From: Kautilya, *Kautilya's Arthashastra*, 2nd ed., trans. R. Shamasastri (Mysore: Wesleyan Mission Press, 1923).

Rome

~ The Twelve Tables, ca. 450 B.C.E., excerpt ~

TABLE VIII.

2. If one has maimed a limb and does not compromise with the injured person, let there be retaliation. If one has broken a bone of a freeman with his hand or with a cudgel, let him pay a penalty of three hundred coins. If he has broken the bone of a slave, let him have one hundred and fifty coins. If one is guilty of insult, the penalty shall be twenty-five coins.

3. If one is slain while committing theft by night, he is rightly slain.

4. If a patron shall have devised any deceit against his client, let him be accursed.

5. If one shall permit himself to be summoned as a witness, or has been a weigher, if he does not give his testimony, let him be noted as dishonest and incapable of acting again as witness.

10. Any person who destroys by burning any building or heap of corn deposited alongside a house shall be bound, scourged, and put to death by burning at the stake provided that he has committed the said misdeed with malice aforethought; but if he shall have committed it by accident, that is, by negligence, it is ordained that he repair the damage or, if he be too poor to be competent for such punishment, he shall receive a lighter punishment.

12. If the theft has been done by night, if the owner kills the thief, the thief shall be held to be lawfully killed.

13. It is unlawful for a thief to be killed by day...unless he defends himself with a weapon; even though he has come with a weapon, unless he shall use the weapon and fight back, you shall not kill him. And even if he resists, first call out so that someone may hear and come up.

23. A person who had been found guilty of giving false witness shall be hurled down from the Tarpeian Rock.

26. No person shall hold meetings by night in the city.

TABLE IX.

4. The penalty shall be capital for a judge or arbiter legally appointed who has been found guilty of receiving a bribe for giving a decision.

5. Treason: he who shall have roused up a public enemy or handed over a citizen to a public enemy must suffer capital punishment.

6. Putting to death of any man, whosoever he might be unconvicted is forbidden.

CONTRIBUTORS

Saheed Aderinto is a Ph.D. student at the Department of History, University of Texas at Austin. Some of his most recent publications include “Prostitution and Urban Social Relations” and “Policing Urban Prostitution: Prostitutes, Crime, Law and Reformers in Colonial Nigeria” in *Nigeria’s Urban History: Past and Present* (2006) and “Discrimination in an Urban Setting: The Experience of Ijebu Settlers in Colonial Ibadan, 1893–1960” in *Inter-group Relations in Nigeria during the 19th & 20th Centuries* (2006). His writings have also appeared in *IFRA Special Research Issue, Ethnic and Third World Review of Books, African and Asian Studies Journal*, and *The Encyclopedia of Prostitution and Sex Work* (2006).

Olutayo Charles Adesina, Ph.D., teaches at the Department of History, University of Ibadan, Nigeria. He is the author of “The Underground Foreign Exchange Market in Ibadan during Devaluation” in *Money Struggles and City Life: Devaluation in Ibadan and Other Urban Centres in Southern Nigeria, 1986–96* (2002) and “Teaching History in Twentieth Century Nigeria: The Challenges of Change” in *History in Africa: A Journal of Method*, vol. 33 (2006).

David Otieno Akombo, Ph.D., teaches music education and world music at Wabash College of Indiana. He is the author of *Music and Healing across Cultures* (2006).

Francis Allard, Ph.D., teaches in the Department of Anthropology at Indiana University of Pennsylvania. His research interests include the archaeology of early China and Mongolia. He has contributed articles to *Archaeology of Asia* (2005) and *Beyond the Steppe and the Sown: Proceedings of the 2002 University of Chicago Conference on Eurasian Archaeology* (2006).

Miguel Arisa is finishing his doctoral studies in art history at the Graduate Center, City University of New York. He teaches at Technical Career Institutes and is a regular lecturer at the

Cloisters and a docent at the Metropolitan Museum of Art, New York.

Mariam F. Ayad, Ph.D., teaches graduate-level classes on Egyptian language and literature at the University of Memphis, where she is the assistant director of its Institute of Egyptian Art and Archaeology. Her main research interests focus on the role of women in ancient Egyptian temple ritual and the selection and transmission of funerary texts in post-New Kingdom Egypt. Her book on the God's Wife of Amun is under contract with Routledge.

Heather D. Baker, D.Phil., is a researcher at the University of Vienna, Austria, specializing in Babylonian history, society, and culture. She has published widely on Babylonian and Assyrian history and is writing a book to be titled *The Urban Landscape of First Millennium BC Babylonia*.

Robin Barrow, Ph.D., FRSC, is professor of philosophy of education at Simon Fraser University, Canada. His most recent books include *Plato* (2007) and *An Introduction to Moral Philosophy and Moral Education* (2007). He is the author of *Athenian Democracy* (2001) and *Greek and Roman Education* (1996).

László Bartosiewicz, Ph.D., D.sc., teaches archaeozoology at the Loránd Eötvös University in Budapest (Hungary) and the University of Edinburgh (United Kingdom). He is the author of *Animals in the Urban Landscape in the Wake of the Middle Ages* (1995) and principal author of *Draught Cattle: Their Osteological Identification and History* (1997) and has published more than 200 scholarly articles.

Kirk H. Beetz, Ph.D., emeritus, has published over two dozen books and more than 900 articles. His books span topics from endangered mammal species to children's literature, including *Exploring C. S. Lewis' "The Chronicles of Narnia"* (2000). His recent writings have focused on the history and culture of ancient Japan.

Craig G. R. Benjamin, Ph.D., teaches world and ancient Eurasian history at Grand Valley State University. He is the coeditor of vols. 2 (1998), 4 (2000), and 6 (2002) in the Brepols Silk Roads Studies series and the author of *The Yuezhi: Origin, Migration and the Conquest of Northern Bactria* (2007).

Uffe Bergeton, Ph.D., is in the Ph.D. program in the Department of Asian Languages and Cultures at the University of Michigan. He is the author of *The Independence of Binding and Intensification* (Ph.D. dissertation, University of Southern California) and various articles on theoretical phonology and syntax.

Amy Hackney Blackwell has degrees in history from Duke University and Vanderbilt University and a J.D. from the Uni-

versity of Virginia. Her books include *Mythology for Dummies* (2002), *LSAT for Dummies* (2004), *The Everything Irish History and Heritage Book* (2004), and *Essential Dictionary of Law* (2004). She has contributed to the *Encyclopedia of World Nations and Cultures* (2006), *Alternative Energy* (2006), and *Chemical Compounds* (2006).

Christopher Blackwell, Ph.D., teaches classics at Furman University. He is the author of *In the Absence of Alexander: Harpalus and the Failure of Macedonian Hegemony* (1999) and various protocols and software applications for building digital libraries, and he serves as technical editor for the Center for Hellenic Studies of Harvard University.

Amy Bogaard, Ph.D., teaches prehistory and archaeobotany at the Department of Archaeology, University of Nottingham, United Kingdom. She is the author of *Neolithic Farming in Central Europe* (2004).

Peter Bogucki, Ph.D., is an archaeologist who is associate dean for undergraduate affairs of the School of Engineering and Applied Science at Princeton University. He has studied prehistoric settlements in Poland and has a particular interest in the spread of farming in Europe. He is the author of *The Origins of Human Society* (1999) and the editor (with Pam J. Crabtree) of *Ancient Europe 8000 B.C.–A.D. 1000: An Encyclopedia of the Barbarian World* (2004).

Larissa Bonfante, Ph.D., professor of classics at New York University, is the author of several books on Etruscan and early Roman culture as well as publications on ancient dress and nudity, including *The World of Roman Costume*, co-edited with Judith Sebesta (1994).

Charlotte Booth is a Ph.D. student at the University of Wales, Swansea, and teaches Egyptology for Birkbeck College and other institutions in the United Kingdom. She is the author of *People of Ancient Egypt* (2007), *The Hyksos Period in Egypt* (2005), and *The Role of Foreigners in Ancient Egypt* (2005).

Lisa R. Brody, Ph.D., teaches Greek and Roman art history at Queens College, City University of New York. Her research interests include Greek iconography and cult, ancient lamps and their decoration, children in antiquity, and representation of ethnicity in Greco-Roman art. She compiled the revised edition of David Sacks's *Encyclopedia of the Ancient Greek World* (2005) and is author of *Aphrodisias III: The Aphrodite of Aphrodisias* (2007).

David Brown, Ph.D., is researching the interactions of the pre-Islamic astral sciences of Mesopotamia, Greece, India, Egypt, Iran, the western Semitic world, and China at the Free University of Berlin. He is the author of *Mesopotamian Planetary Astronomy-Astrology* (2000) and *The Interactions of Ancient Astral Science* (forthcoming).

Deborah N. Carlson, Ph.D., teaches in the Nautical Archaeology Program of the Department of Anthropology at Texas A&M University. She also directs the Institute of Nautical Archaeology's shipwreck excavation of a Roman marble carrier off the Aegean coast of Turkey at Kizilburun and is preparing the final publication of the Classical Greek ship excavated by the Institute of Nautical Archaeology at nearby Tektas Burnu.

Jeffrey S. Carnes is associate professor of classics at Syracuse University. He is the author of *The Uses of Aiakos: Pindar and the Aiginetan Imaginary* (forthcoming) as well as articles on Greek lyric poetry, gender studies, literary theory, and Plato.

Julia Marta Clapp is pursuing her doctorate in art history at the Graduate Center, City University of New York. Her research interests include modern and pre-Columbian Latin American art.

Wendy E. Closterman, Ph.D., teaches ancient history and Greek at Bryn Athyn College. Her research focuses on Athenian burial and funerary ritual. She is the author of "Family Members and Citizens: Athenian Identity and the Peribolos Tomb Setting" in *Antigone's Answer: Essays on Death and Burial, Family and State in Classical Athens*, edited by C. Patterson (forthcoming).

Leah A. J. Cohen is an independent writer and editorial consultant with a master's degree in geography from the University of Florida. She specializes in Africa area studies and food security. She was a senior author for the *Encyclopedia of African History and Culture*, volumes 4 and 5 (2005).

John Collis is professor emeritus in the Department of Archaeology, University of Sheffield, where he taught for over 30 years. He has had a major role in the development of university and professional training in archaeology in Britain, and is secretary of the European Association of Archaeologists' Committee on Training and Education. He is author of several books and excavation monographs, including *Digging Up the Past* (2004) and *The Celts: Origins, Myths and Inventions* (2004).

Constance A. Cook, Ph.D., directs the Asian Studies program and teaches Chinese language and literature courses at Lehigh University. She is the author of *Death in Ancient China: The Tale of One Man's Journey* (2006) and coeditor of *Defining Chu: Image and Reality in Ancient China* (1999).

Susan Cooksey, Ph.D., is the curator of African art, Harn Museum of Art, University of Florida.

Justin Corfield, Ph.D., teaches history and international relations at Geelong Grammar School, Australia. He is the co-author of *Historical Dictionary of Cambodia* (2003) and

has written extensively on Asia, Australia, and European colonial history.

James A. Corrick, Ph.D., is a full-time editor and writer with 25 books to his credit. His most recent titles are *The Early Middle Ages* (2006), *The Byzantine Empire* (2006), and *The Renaissance* (2007).

Arden Decker is a Ph.D. candidate in the history of art at the Graduate Center, City University of New York. Her research interests include Mesoamerican art as well as modern and contemporary art of Mexico.

Leo Depuydt, Ph.D., teaches Egyptology at Brown University and is curious about everything relating to ancient Egypt in its Near Eastern and Mediterranean context, especially the area's languages and history. He wrote *Civil Calendar and Lunar Calendar in Ancient Egypt* (1997) and *The Other Mathematics: Language and Logic in Egyptian and in General* (2007).

Haig Der-Houssikian, Ph.D., is professor emeritus (2003), linguistics, at the University of Florida, Gainesville. His research and publication interests are in morphology, Creolization, and sub-Saharan Africa.

Christine End, M.A., works on the Giza Archives Project at the Museum of Fine Arts, Boston. Her main interests of research are Middle Kingdom funerary iconography, material culture, burial practices, and mummification. As a researcher and illustrator, her work has appeared in Egyptological publications and documentaries.

Linda Evans, Ph.D., specializes in ancient Egyptian art at Macquarie University, Sydney, Australia. She recently completed her doctoral dissertation on the representation of animal behavior in Egyptian tomb paintings and has published several papers on the role and depiction of animals in the ancient world. She has also contributed chapters to *Egyptian Art: Principles and Themes in Wall Scenes* (2000), *The Encyclopedia of Animal Behavior* (2004), *Egypt: The Land and Lives of the Pharaohs Revealed* (2005), and *Historica* (2006).

Stephen M. Fabian, Ph.D., is an anthropologist and currently teaches seminars on religion, myth, and ritual at Princeton University. He is the author of *Space-Time of the Bororo of Brazil* (1992), *Clearing Away Clouds: Nine Lessons for Life from the Martial Arts* (1999), and *Patterns in the Sky: An Introduction to Ethnoastronomy* (2001).

Erin Fairburn is a graduate student in the Department of Egyptology and Western Asian Studies at Brown University. She has contributed to *The City and Urban Life* (forthcoming).

Alessia Frassani is a Ph.D. candidate at the Graduate Center of the City University of New York. Her research interests in-

clude the art and civilizations of ancient Oaxaca and issues surrounding the cultural interaction between the Old and New Worlds.

Markham J. Geller is professor of Semitic languages at University College London, in the Department of Hebrew and Jewish Studies. He has recently published a text edition of cuneiform medical texts, *Renal and Rectal Disease Texts, Babylonisch-assyrische Medizin VII* (2005).

J. J. George is working on his Ph.D. at the Graduate Center, City University of New York. His research area is pre-Columbian art and architecture.

Wolfram Grajetzki, Ph.D., wrote his dissertation at the Humboldt University of Berlin and has taught Egyptology there. He has excavated in Egypt and Pakistan and was principal archaeologist and author for the online learning project Digital Egypt for Universities (University College London). He is preparing the catalogue of Egyptian coffins in the Fitzwilliam Museum, Cambridge. His publications include *Burial Customs in Ancient Egypt* (2003) and *The Middle Kingdom in Ancient Egypt* (2006).

Lyn Green, Ph.D., has taught at several Canadian universities and for the Royal Ontario Museum. She has contributed to several encyclopedias, including *The Oxford Encyclopedia of Ancient Egypt* (2000) and the *Encyclopedia of the Archaeology of Ancient Egypt* (1999) as well as *The Royal Women of Amarna* (1996). Currently she is devoting her time to her duties as president of the Society for the Study of Egyptian Antiquities, which has over 400 members and subscribers internationally, and to writing.

Angela Herren, Ph.D., teaches pre-Columbian art and architecture as an assistant professor in the Department of Art and Latin American Studies at the University of North Carolina at Charlotte. A specialist on painted manuscripts from central Mexico, she completed a 2005 dissertation entitled "Portraying the Mexica Past: A Comparative Study of Accounts of Origin in Codex Azcatitlan, Codex Boturni, and Codex Aubin."

David B. Hollander, Ph.D., teaches ancient history at Iowa State University. He is the author of *Money in the Late Roman Republic* (2007).

Brooke Holmes, Ph.D., is an assistant professor of classics at the University of North Carolina, Chapel Hill. She is at work on a book about the symptom in early Greek medicine and classical Greek literature.

Michael Allen Holmes is a freelance editor and writer who recently contributed to *Shakespeare for Students*, 2nd edition (2007). He has also written an unpublished novel.

John W. Humphrey, Ph.D., is professor of Greek and Roman studies at the University of Calgary. A veteran of many seasons of archaeological excavation in Turkey and Greece, he is the author of *Greek and Roman Technology: A Sourcebook* (1998, with J. P. Oleson and A. N. Sherwood) and *Ancient Technology* (2006).

Keith Jordan, M.Phil., is a Ph.D. candidate in pre-Columbian art history at the Graduate Center of the City University of New York. He is currently finishing his doctoral dissertation, entitled "Stone Trees Transplanted? Central Mexican Stelae of the Epiclassic and Early Postclassic and the Question of Maya 'Influence.'"

Amr Kamel is an Egyptologist in the Rare Books and Special Collections Library at the American University in Cairo, Egypt.

David Kelly is an instructor of English writing and literature at Oakton Community College in Illinois. He has written over 100 published literary analyses and wrote the instructor's manual for the *Exploring Poetry* computer program. His short fiction has been published in *The Rockford Review*, *Grub Street*, and *The Iconoclast*, among other places.

Panagiotis I. M. Kousoulis, Ph.D., is a lecturer in Egyptology at the Department of Mediterranean Studies of the University of the Aegean. He is the author of *Moving across Borders: Foreign Relations, Religion and Cultural Interactions in the Ancient Mediterranean* (2007) and *Ancient Egyptian Demonology: Studies on the Boundaries between the Demonic and the Divine in Egyptian Magic* (2007).

Philippa Lang teaches ancient science and related subjects, with research interests in ancient medicine and philosophy, in the Classics Department of Emory University, Atlanta. She is the editor of *Re-Inventions: Essays on Hellenistic and Early Roman Science*, *Apeiron* special issue vol. 37 (2004).

Russell M. Lawson, Ph.D., is associate professor of history and chair of the Division of General Studies at Bacone College in Oklahoma. He is the author of *Science in the Ancient World* (2004), *The Land between the Rivers: Thomas Nuttall's Ascent of the Arkansas, 1819* (2004), and *Passaconaway's Realm: John Evans and the Exploration of Mount Washington* (2002, 2004).

Anne Mahoney, Ph.D., teaches Greek and Latin linguistics and literature at Tufts University. She is the author of *Plautus: Amphitryo* (2004) and *Roman Sports and Spectacles: A Sourcebook* (2001). She is also the editor of revised editions of *Allen and Greenough's New Latin Grammar* (2001), *Morice's Stories in Attic Greek* (2005), and *Bennett's Essentials* (2007).

Susan Malin-Boyce, Ph.D., serves as deputy director of the Regime Crimes Liaison Office, Mass Graves Investigation

Team, in Baghdad, Iraq. She has contributed to *Ancient Europe 8000 B.C.–A.D. 1000: Encyclopedia of the Barbarian World* (2004) and to publications addressing Early and Late La Tène settlement in Bavaria, Germany.

Renee McGarry is a student in the Ph.D. program in art history at the City University of New York Graduate Center. Her research interests include Aztec sculpture of the natural world and religious manuscripts from the post-Conquest period.

Paul McKechnie, D.Phil., is a senior lecturer in classics and ancient history at the University of Auckland, New Zealand. He is the author of *First Christian Centuries: Perspectives on the Early Church* (2002) and *Outsiders in the Greek Cities in the Fourth Century B.C.* (1989).

John M. McMahon, Ph.D., teaches at Le Moyne College in Syracuse, New York, where he directs the classics program. He is author of *Cave Paralysis: Impotence, Perception and Text in the Satyricon of Petronius* (1998) and numerous articles on the intersection of ancient literature and natural history. His most recent work includes nine entries in the forthcoming *Biographical Encyclopedia of Astronomers* (2006).

Jianjun Mei, Ph.D., teaches the history of science and technology at the University of Science and Technology Beijing. He is the author of *Copper and Bronze Metallurgy in Late Prehistoric Xinjiang: Its Cultural Context and Relationship with Neighbouring Regions* (2000).

James E. Meier, Ph.D., is assistant professor in the Department of Humanities and Social Sciences at Central Florida Community College. He is a contributor to the *Encyclopedia of African History and Culture* (2005).

Francesco Menotti, Ph.D., is a lecturer in European prehistory at the Institute of Prehistory and Archaeological Science, Basel University, Switzerland. He is the author of *Living on the Lake in Prehistoric Europe* (2004).

Melissa Moore Morison is associate professor of classics and classical archaeology at Grand Valley State University. She has extensive experience in archaeological fieldwork in Greece, Turkey, and the United States. Her research interests include Roman provincial archaeology, Greek and Roman pottery, and ceramic technology.

Penny Morrill, Ph.D., teaches pre-Columbian and early colonial Mesoamerican art at Hood College, Frederick, Maryland. She has an essay, "The Queen of Heaven Reigns in New Spain: The Triumph of Eternity in the Casa del Deán Murals," in a Brill anthology, *Woman and Art in Early Modern Latin America* (2006). She has authored several books on modern Mexican silver: *Mexican Silver: 20th Century Hand-*

wrought Silver Jewelry and Metalwork (4th ed., 2007), *Silver Masters of Mexico: Héctor Aguilar and the Taller Borda* (1996), and *Maestros de Plata: William Spratling and the Mexican Silver Renaissance*, a catalog for a traveling exhibit (2002–2004).

Julian M. Murchison, Ph.D., teaches in the Department of Sociology and Anthropology at Millsaps College. His work in cultural anthropology examines the intersections of medicine and religion in East Africa. He recently published a chapter examining stories about a cure for HIV/AIDS in *Borders and Healers* (2005).

Caryn E. Neumann, Ph.D., teaches history in Ohio Wesleyan University's Black World Studies Department. She is a former managing editor of the *Journal of Women's History*.

Emily Jane O'Dell, is a Ph.D. candidate at Brown University and has taught at Brown University in both the Department of Egyptology and Ancient Western Asian Studies and the Department of Literary Arts. She has been the chief epigrapher of the Cairo-Brown University Abu Bakr Epigraphic Survey in the western cemetery of the Great Pyramids in Giza, Egypt, for the past five years.

Simon O'Dwyer is founder and researcher for Prehistoric Music Ireland, author of *Prehistoric Music of Ireland* and prehistoricmusic.com, and contributor to *The Encyclopedia of Music in Ireland* and *The Encyclopedia of Ireland*. He has published four papers for the International Study Group on Music Archaeology.

Penelope Ojeda de Huala is a Ph.D. candidate in art history at the Graduate Center of the City University of New York, where she studies pre-Columbian to contemporary art of Latin America. Her research focus is Guatemala and Peru, particularly the enduring thoughts and practices of indigenous cultures as manifested in art.

Michael J. O'Neal, Ph.D., is a writer who lives in Moscow, Idaho. He is a frequent contributor to reference and educational books, including *Lives and Works: Young Adult Authors* (1999), *The Crusades* (2005), and *America in the 1920s* (2006).

Dianne White Oyler, Ph.D., teaches African history at Fayetteville State University. She is the author of *The History of the N'ko Alphabet and Its Role in Mande Transnational Identity: Words as Weapons* (2005) as well as articles in the refereed journals *Research in African Literature*, *the Mande Studies Journal*, and the *International Journal of African Historical Studies*.

Katie Parla is an art historian and archaeological speleologist working in Rome and Naples as a docent leading didactic seminars of archaeological sites. She consults for the History

Channel and will appear in their 2007 series *Cities of the Underworld* as an expert on underground Rome and Naples.

Marie Passanante is a doctoral candidate in the Department of Egyptology and Ancient Western Asian Studies at Brown University.

William H. Peck teaches at the College for Creative Studies, Detroit, and the University of Michigan, Dearborn. He was for many years the curator of ancient art at the Detroit Institute of Arts and is at present a member of the Brooklyn Museum excavations in Egypt at Karnak. He is the author of *Drawings from Ancient Egypt* (1987) and numerous contributions to reference books and encyclopedias on the ancient world.

David Petechuk is a freelance writer specializing in educational texts focusing on the sciences, literature, and history. The former director of publications for the health sciences at the University of Pittsburgh, he is the author of *The Respiratory System* (2004), *LSD* (2005), and *Health & Medical Issues Today: Organ Transplantation* (2006).

Mark Anthony Phelps is taking a leave after teaching continuously since 1994 (primarily at Drury University, in five different departments) to finish his dissertation at the University of Arkansas entitled "Sewage from the Orontes: Roman Elite Attitudes toward Ecstatic Religion in the 3rd and 4th centuries C.E." This degree in ancient Mediterranean history augments his graduate degrees from Harvard and Johns Hopkins in Hebrew Bible and ancient Near Eastern languages and cultures. His research interests reflected in his writings are widely eclectic, spanning Paleolithic to contemporary society and including the disciplines of archaeology, linguistics, cultural anthropology, physical geography, historical geography, classical history, ancient Near Eastern history, medieval history, modern history, religion, and biblical history.

Jen Piro is a Ph.D. candidate in anthropological archaeology at New York University. Her dissertation research focuses on the development of pastoral economies in Early Bronze Age Transcaucasia.

Karen Radner, Ph.D., is lecturer in ancient Near Eastern history at University College, London. She specializes in the Assyrian Empire and is the author of *Die neuassyrischen Texte aus Tall Seh Hamad* (2002), *Das mittelassyrische Tontafelarchiv von Giricano/Dunnu-sa-Uzibi* (2004) and *Die Macht des Namens: Altorientalische Strategien zur Selbsterhaltung* (2005).

Judith A. Rasson, Ph.D., teaches in the Department of Medieval Studies, Central European University, Budapest (a post-graduate American-accredited university). Her research interests lie in southeastern Europe (especially the countries

of the former Yugoslavia) and focus on Neolithic and historic archaeology and ethnographic material culture.

Kelly-Anne Diamond Reed, Ph.D., teaches ancient Egyptian history and archaeology at Villanova University's Department of History. She is investigating early Egyptian funerary rituals and burial customs.

Duane W. Roller is professor of Greek and Latin at Ohio State University. Trained as an archaeologist, he has over 30 years' experience in field archaeology in numerous Mediterranean countries. He is the author of *The Building Program of Herod the Great* (1998), *The World of Juba II and Kleopatra Selene* (2003), and *Through the Pillars of Herakles* (2006) as well as many other publications in history, classics, and archaeology.

Kelley L. Ross, Ph.D., teaches philosophy at Los Angeles Valley College. He specializes in Kantian epistemology, metaphysics, and ethics, with emphasis on members of the Friesian tradition—Jakob Fries, Leonard Nelson, Rudolf Otto, Sir Karl Popper, and others. Since 1996 he has been the publisher and editor of the online philosophy journal *Proceedings of the Friesian School, Fourth Series*.

Edward M. W. A. Rowlands, M.Phil., has research interests in Mycenaean political geography, trade, and religion.

Lucas G. Rubin, Ph.D., develops master of science programs for Columbia University. He was previously administrator of the university's Center for Archaeology, where he managed multiple excavations and projects. His research and scholarship have focused on fires and firefighters in ancient Rome.

Michael M. Sage, Ph.D., teaches classics and ancient history in the Classics Department at the University of Cincinnati. His main areas of study are historiography and military history. He is the author of *Cyprian: A Biography* (1975) and *Warfare in Ancient Greece: A Sourcebook* (1996).

Rick Schulting, Ph.D., is a lecturer in scientific and prehistoric archaeology at the University of Oxford. His current research interests lie in understanding the Mesolithic-Neolithic transition in western Europe, emphasizing the use of radiometric dating and stable isotope analysis, and in skeletal evidence for interpersonal violence in earlier prehistoric Europe.

David R. Sear, a fellow of the Royal Numismatic Society in London and the American Numismatic Society in New York, has authored an extensive range of numismatic books over the past four decades, aimed at collectors and students of ancient Greek, Roman and Byzantine coinage. He has been a resident of Los Angeles for the past 25 years and operates a research service authenticating ancient coinage. His

numerous publications include *Roman Coins and Their Values* (1964; rev. ed., 2000–2005), *Byzantine Coins and Their Values* (1974, rev. ed., 1987), *Greek Coins and Their Values* (1978–1979), and *The History and Coinage of the Roman Emperors, 49–27 B.C.* (1998).

Robert Shanafelt, Ph.D., teaches courses in anthropology, religion, and Africana studies at Georgia Southern University. He has published a number of articles on different aspects of life in southern Africa, among them, “Crime, Power, and Policing in South Africa” in *Democratic Policing in Transitional and Developing Countries* (2006).

Alison Sheridan, Ph.D., is head of early prehistory in the National Museums Scotland, Edinburgh, specializing in the British and Irish Neolithic and Bronze Age. Exhibition work includes *Heaven and Hell—and Other Worlds of the Dead* (2000), for which she was lead curator and book editor. Other books include *From Sickles to Circles* (with A. M. Gibson, 2004) and *Vessels for the Ancestors* (with N. M. Sharples, 1992).

Spyros Siropoulos is senior lecturer of Greek philology and history at the Department of Mediterranean Studies, University of the Aegean, Greece. He has published various articles in three books: *Unlike a Woman: Gender and the Social Function of the Athenian Tragedy* (2003), *The Goat’s Skin: The Other Side of Alexander the Great’s Power* (2003; in Greek with English summary), and *The Things after Alexander: The Centrifugal Potencies of the Hellenistic Kingdoms* (2005, in Greek).

Bradley Skeen, M.A., has taught at the University of Minnesota, Webster University, and Washington University. He is a specialist in magic, religion, and philosophy in late antiquity and has contributed to research in that field in *Die Zeitschrift für Papyrologie und Epigraphik*, among other journals.

Christopher Smith, D.Phil., is professor of ancient history at the University of Saint Andrews in Scotland. He is the author of *Early Rome and Latium: Economy and Society c 100–500 B.C.* (1996) and *The Roman Clan: From Ancient Ideology to Modern Anthropology* (2006) as well as editor of several collections of essays, including *Trade, Traders and the Ancient City* (with Helen Parkins, 1998); *Sicily from Aeneas to Augustus* (with John Serrati, 2000), and *Religion in Archaic and Republican Rome and Italy: Evidence and Experience* (with Edward Bispham, 2000). He is engaged in work on Roman historiography and oratory.

Nancy Shatzman Steinhardt is professor of East Asian art and curator of Chinese art at the University of Pennsylvania. She is author of *Chinese Traditional Architecture* (1984), *Chinese Imperial City Planning* (1990), *Liao Architecture* (1997), and *Chinese Architecture* (2002) and more than 60 scholarly articles.

Tom Streissguth is a freelance author, editor, and journalist who has published more than 70 nonfiction and reference books. His most recent titles include *Clay v. United States*, *Genghis Khan’s Mongol Empire*, *Library in a Book: Hate Crimes*, *Eyewitness History: The Roaring Twenties*, and the *Greenhaven Encyclopedia of the Middle Ages*.

Ananda Cohen Suarez is a Ph.D. student at the Graduate Center of the City University of New York, specializing in pre-Columbian and colonial Latin American art history. She is particularly interested in cross-cultural encounters, vernacular religious art, and manuscript production in the early colonial Americas.

Frank J. Swetz, D.Ed., is professor emeritus of mathematics and education, Pennsylvania State University. His research interests focus on cultural and societal impact on mathematics learning and teaching. Among his recent books are *Legacy of the Luoshu: The 4000 Year Search for the Meaning of the Magic Square of Order Three* (2002) and *Teaching Mathematics to Children* (2003).

John Thorburn, Ph.D., is associate professor of classics at Baylor University, where he teaches a variety of subjects dealing with the classical world. He has published on Greek tragedy, Greek comedy, Greek and Roman history, and a variety of ancient subjects. He is the author of *The Alcestis of Euripides* (2002) and the *Facts on File Companion to Classical Drama* (2005).

Alain Touwaide, Ph.D., is a historian of sciences in the Department of Botany of the National Museum of Natural History at the Smithsonian Institution (Washington, D.C.). He has extensively published on the history of medicine in the Mediterranean world from antiquity to the Renaissance. Recently, he coedited the volume *Visualizing Medieval Medicine and Natural History, 1200–1550* (2006).

Francesca C. Tronchin, Ph.D., teaches Greek and Roman art and archaeology at Ohio State University. Her primary area of research is Roman domestic decor and issues of eclecticism in ancient sculptural displays.

David K. Underwood, Ph.D., teaches Western humanities, art history, philosophy, and Latin American studies at the University of South Florida in Tampa and at Saint Petersburg College in Clearwater, Florida. He is the author of two books and several articles and essays on Iberian and Latin American art and architecture.

David Vallilee is an independent scholar.

Frans van Koppen, M.A., teaches Akkadian at the School of Oriental and African Studies, London. He contributed to *The*

Ancient Near East: Historical Sources in Translation (2006) and *The Babylonian World* (forthcoming).

Lawrence Waldron, M.F.A., is an associate professor and doctoral candidate at the City University of New York, specializing in non-Western fields of art history and culture. He has presented and published various articles on the art and culture of the pre-Columbian Caribbean and Southeast Asia.

Ezekiel A. Walker, Ph.D., teaches African and world history at the University of Central Florida. His forthcoming book is entitled *Growth, Crisis and Transformation in the Cocoa-Farming Economy of Southwestern Nigeria* (2007).

Peter S. Wells is professor of anthropology at the University of Minnesota. His publications include *The Barbarians Speak: How the Conquered Peoples Shaped Roman Europe* (1999), *Beyond Celts, Germans and Scythians: Archaeology and Identity in Iron Age Europe* (2001), and *The Battle That Stopped Rome: Emperor Augustus, Arminius, and the Slaughter of the Legions in the Teutoburg Forest* (2003).

Jacqui Wood is an archaeologist and authority on prehistoric cooking and the lifestyles of prehistoric Europeans. She runs her own excavation in Cornwall, England.

Ronald Young, Ph.D., teaches in the Social Sciences Department at Canterbury School in Fort Myers, Florida. His teaching and research interests are in the area of Latin American Studies. In addition to numerous reference articles, he is presently working on a general history of Colombia to be published by Greenwood Press.

Katharina Zinn, M.A., is writing her Ph.D. dissertation on ancient Egyptian libraries and archives at the University of Leipzig, Germany. She works in a project on scarabs in the Fitzwilliam Museum, Cambridge (United Kingdom) and a project on Middle Kingdom Reliefs from Lisht in the Princeton University Art Museum. She has published articles on the organization of collective wisdom as well as multilingualism in ancient Egypt.

List of Illustrations

VOLUME I

Glass kohl tube in the form of a palm column, from Egypt	5	Marble statue of the Greek goddess of fertility, Demeter	37
Gold lion, used as a fabric ornament and found at Persepolis, Persia (modern-day Iran)	7	Section of the facade of a Roman aisled, barnlike building on a villa estate in the parish of Meonstoke, Hampshire, England	44
Jade ornament of four discs carved from a single jade pebble, from China	8	Facade of the Great Temple of Abu Simbel, Egypt	59
Toiletry implements from Roman Britain	10	The ruins of Persepolis (in modern-day Iran), the seat of the Achaemenian Empire of Darius I	63
Greek marble head, showing headdress of snail-shell curls	11	Panoramic view of West Lake in Lin'an (modern Hangzhou), China	66
Gold coin of the Roman emperor Marcus Aurelius, set in a gold ring	12	The theater at Epidaurus, Greece	76
Jade pectoral of the Olmec culture (Mexico), showing large holes in the earlobes, where earplugs would be placed	13	Engraving of the Roman Colosseum by Antoine Lafréry	80
View of rice fields in the Malagasy Republic of southern Africa	17	Petroglyph of animals and people at Tassili, Algeria, in North Africa	90
Wooden model of a man plowing with oxen, from Egypt	21	Banquet scene, fragment of wall painting from the tomb of Nebamun, Thebes, Egypt	95
Cuneiform tablet recording barley rations given to workers and their families at the temple of the goddess Bau, from Tello (ancient Girsu), southern Iraq	25	Human-headed winged bull from the palace of King Sargon II at the Assyrian capital Dur-Sharrukin (modern-day Khorsabad, Iraq)	99
Ritual spear blade from Japan	31	Schist head of the fasting Buddha, from Rawalpindi District, Gandhara, Pakistan	101
Iron Age farming tools, from Stantonbury Hill, Somerset, England	35		

Bird bone engraved with animal heads from the cave of Courbet, Penne-Tarn, France	106	Terra-cotta statuette of a lady in a swing, from Agia Triada, Herakleion	182
Hermes with the Infant Dionysus, by the Greek sculptor Praxiteles	111	Amphora from Pompeii, Italy	184
Roman terra-cotta relief showing an Egyptian scene set on the Nile	117	Feline-head ceramic bottle from Peru	185
Inner coffin of the priest Hornedjitef, Thebes, Egypt	125	Boys kept in seclusion in an initiation camp in Angola, southern Africa	188
Cuneiform tablet with observations of Venus, Nineveh, northern Iraq	126	Game of Senet from Egypt	190
Chinese covered jar	128	Terra-cotta figurine of a woman with a child, Cyprus	191
The Semna dispatches, administrative documents from an Egyptian outpost, from Thebes, Egypt	141	Profile of a Greek boy	195
Babylonian boundary marker, Sippar, southern Iraq	143	Roman rag doll made of linen, rags, and papyrus	196
Dedication by Alexander the Great to Athena Polias, from Priene, Asia Minor	146	Olmec figure of a baby (ceramic, cinnabar, and red ochre), Mexico	197
Wattle framework being filled with red mud, a construction technique used in ancient times, from Zambia	151	Ancient Egyptian city of Sesebi	206
Clay foundation peg from Bad-tibira, southern Iraq	154	Panels with striding lions, Neo-Babylonian, during the reign of Nebuchadnezzar II	211
Dolphin fresco in the queen's megaron (reception hall) at Knossos, the capital of Minoan Crete	159	Jade ritual reaping knife, from Henan, northern China	215
Iron window grill, Roman Britain	160	Roman silver coins depicting the founding twins of the city of Rome, Romulus and Remus	227
View of the royal tombs at Meroë, ancient city of northeastern Africa in present-day Sudan	164	Pottery vessel of the storm god, Teotihuacán, Mexico	232
Fragment of a basalt water clock, from Tell el-Yahudiya, Egypt	166	Grass, sand, and volcanic formation in the Sahara, southern Algeria	236
Kerma ware pottery beaker, from Kerma, Sudan	175	The Great Temple at Abu Simbel on the banks of the Nile	243
Painted pottery group of cattle, from el-Amra, Egypt	177	Ax made from reindeer antler found at Earls Barton, Northamptonshire, England	254
Ceramic bowl with abstract decoration, from Tall-i-Bakun in modern-day Iran	178	Petroglyph of a human figure wearing a loincloth, from the Sahara Desert at Tassili, Algeria, North Africa	273
Pottery jar with dragon handles, from China	180	Pair of child's leather sandals from Thebes, Egypt	275
Bucchero ware water jug, from Chiusi, Tuscany, Italy	181	Two Assyrian court officials from the reign of Sargon II	276
		Caryatids from the Porch of the Maidens at Erechtheion, a temple on the north side of the Acropolis at Athens	280

Pottery figures of a drummer and a woman and child, Tala-Tonalá style, Jalisco, Mexico	283	Roman gold bars with assayers' stamps	368
Group of bronze tools for woodworking from Thebes, Egypt	287	Granite statue of Senmut holding Princess Neferure, the temple of Amun, Karnak, Thebes, Egypt	378
Stone bowl from Khafajeh, Iraq	288	Cuneiform tablet with schoolwork, probably from southern Iraq	379
Bird head made of stone, Papua, New Guinea	290	Yue ware water dropper in the shape of a frog drinking from a cup, from Zhejiang, southern China	381
Steatite vase from Greece	293	Fragments of painted plaster, Roman Britain, from Otford, Kent, England	385
Papyrus with part of the "Tale of the Eloquent Peasant" from Egypt	298	Colossi of Egyptian pharaoh Ramses II and his wife at entrance to Karnak Temple	395
Drawing by Michelangelo of the Crucifixion of Christ and two thieves	304	Portion of a relief in the tomb of Darius I, king of Persia, showing his throne bearers	400
VOLUME II			
Pyramid of a king, thought to be Adikhalamani Tabirqa, in Meroë, Sudan	312	Cowrie shells, the earliest form of money in China	429
A reconstructed Egyptian grave pit	314	Roman marble relief of Jason, the physician and patient	433
Jade eye plaques from China	316	Stucco head of a monk, said to be from Hadda, Gandhara	440
Iron Age pottery cinerary urn shaped like a hut, from Italy	318	<i>The Dream of Scipio</i> , by Raphael	444
Stele of Aristion, a philosopher of Athens	319	Papyrus marriage contract between the priest Pagosh and Teteimhotep, from Assiut, Egypt	449
Gold diadem, found in the Camaná valley, Peru	321	Scarab stamp seal and impressions, in lapis lazuli, depicting Ishtar, the Assyrian and Babylonian goddess of love, fertility, marriage, and childbirth	451
Bronze figure of Isis and Horus, from North Saqqara, Egypt	329	Fragment of an archaic Greek stele, with the heads of a mother and child	455
Babylonian lapis lazuli cylinder seal of Sin-ishmeanni	331	Ethiopian Orthodox priests at festival of Timkat	463
A 19th-century Indian painting depicting the climax of the epic the Ramayana	332	Roman hand of Sabazius, found at Tournai, Belgium	469
The figure of Silenus, the mentor of Dionysus, Greek god of plays	334	Pottery dog, from Colima, Mexico	471
Marble relief with two Roman theater masks	337	Fineware cup decorated with frogs and lotus flowers painted in black, from Faras, Sudan	473
The Great Harris Papyrus, from Thebes, probably Deir el-Medina, Egypt	347		
Mesopotamian stone vase depicting animals of the first city dwellers of Mesopotamia	351		
Indian bronze cast coin	355		
Mesolithic perforated part skull and antlers of red deer, from Star Carr, Vale of Pickering, North Yorkshire, England	359		

“Empress” pepper pot, from the Hoxne hoard in Suffolk, Roman Britain	478	Stone weight carved in the form of the head of an aquatic bird and thought to have been used in fishing, from Orange County, Florida	582
Terra-cotta utensil with six receptacles, thought to be an egg dish or cup holder	480	A bronze lamp found at the palace of Persepolis, Persia	586
Detail of an Ethiopian tribute bearer, from a relief in stairway of the palace at Persepolis, Persia (modern-day Iran)	486	Broken limestone lamp from the cave of Courbet, Penne-Tarn, France	589
Greek terra-cotta statuettes: woman holding pancake and woman kneading dough	500	Roman lamp showing a chariot race	591
Spout and bridge vessel in the shape of a woman, holding what is thought to be a spindle wrapped in cloth, from the Nasca culture of Peru	503	Paleolithic stone hand ax from Olduvai Gorge, Tanzania	593
Olmec jade perforator, from Mexico	536	Papyrus from the Book of the Dead of Nakht with agricultural scenes, from Thebes, Egypt	595
Coffin with skeleton of a child, from Speos Artemidos, Egypt	547	An administrative text in cuneiform (the world’s earliest form of writing), recording food supplies, probably from southern Iraq	597
Terra-cotta votive womb, Italy	551	Pair of fragments of silk, from Cave 17, Mogao, near Dunhuang, China	599
Hellenistic ivory figure of a hunchback thought to show signs of Pott’s disease	553	Roman aqueduct in Tunis	602
Altar from Roman Britain dedicated to the goddess Fortuna, the healing god Aesculapius, and Salus, goddess of health	554		
Paleolithic stone chopping tools from Olduvai Gorge, Tanzania	562	VOLUME III	
A folding wooden headrest, from Akhmin, Egypt	563	Sandstone offering table with Meroitic cursive inscription around the edges, from Faras, Sudan	610
Stone bowl and pitcher from Greece	567	Clay tablet with Elamite inscription found in the treasury of the palace at Persepolis, Persia (modern-day Iran)	613
Roman jug, two-handled cup (the handles now missing), strainer, ladle, and stirrer, from Arcisate, near Como, northern Italy	569	Jade disc inscribed with a poem by the Qianlong emperor, from China	614
Archery case painted with a hunting scene, from Thebes, Egypt	574	Linear A tablets, from Agia Triada, Heraklion	617
Impressions of cylinder seals on clay, depicting hunting scenes and found in the treasury of the palace at Persepolis	575	The Rosetta Stone, from Fort St. Julien, el-Rashid (Rosetta), Egypt	623
Harpoon tips made of antler from the cave of Courbet, Penne-Tarn, France	578	Jade cicada, China	626
Fragments of a fresco from Tiryns, Greece, showing hunter and dog	579	Page from the Book of the Dead of Hunefer, Thebes, Egypt	644
		Sculpted panel depicting Vishnu Trivikrama, eastern India	650
		Frieze of three Greek muses	657

Copper vessel with silver wire, from Ur, southern Iraq	680	Whistling vessel in the form of a macaw, Peru, Moche culture	773
Gold cup of the Bronze Age, beaten out of a single lump of gold and found in Rillaton, Cornwall, England	683	Rock inscription at Seheil, Egypt, recording a seven-year famine	777
Gold mask from Mycenae	684	Roman wall painting showing a coastal landscape, from Boscoreale, Campania, Italy	782
Hammered gold standing figure, Colombia or Ecuador	687	Petroglyph showing herders and cows, from Sahara Desert at Tassili, Algeria, North Africa	787
Granite statue of Senwosret III, from Deir el-Bahari, Thebes, Egypt	694	The Rhind Mathematical Papyrus, showing mathematical problems and solutions, from Thebes, Egypt	799
Albert Bierstadt, The Rocky Mountains, Lander's Peak	719	Painted Greek stele with metrical inscription	804
Detail of a Persian soldier from the stairway of the palace of Darius, king of Persia, at Persepolis (modern-day Iran)	728	Granite statue of Ankhwa, the shipbuilder, possibly from Saqqara, Egypt	810
The fortifications of Eleutherae, a city in the northern part of Attica, bordering the country of Boeotia	733	Spinning and weaving tools from Iron Age England	814
Roman marble statue of a youth on horseback and wearing a military cloak	735	Frieze of <i>hydriaphoroi</i> (water carriers) from the Greek Parthenon	815
Linen bag of salt for mummification, from Deir el-Bahari, Egypt, New Kingdom	743	Traditional healer in anti-smallpox costume, Nigeria, West Africa	820
Stone panel from the palace of Sennacherib, Nineveh, northern Iraq	744	Mesopotamian terra-cotta figure of an animal thought to be a dog	822
Lead pig (ingot), Roman Britain, from Hints Common, Staffordshire	749	Greek marble block from the frieze of the Temple of Apollo Epikourio (Apollo, the Helper), Bassae, Arcadia	826
The el-Amarna Hoard, from el-Amarna, Egypt	754	Limestone stela with images of the goddess Tanit, from Carthage (modern-day Tunisia)	834
Silver coins of various cultures found at Persepolis, Persia (modern-day Iran)	756	Limestone relief panel depicting the departure of Prince Siddhartha from his palace, to start on the spiritual journey that brings him to Buddhahood	846
Fragments of a stone mould and bronze knife money, from northeastern China	757	Iron Age horned helmet, from the River Thames at Waterloo Bridge, London, England	851
Cast ingots of bronze used as money in Rome before the invention of silver coinage	761	Frieze of the gods Greek gods Poseidon and Apollo and the goddess Artemis from the Parthenon	854
Babylonian relief plaque of harpist	766		
Red sandstone railing pillar in the form of a flute player, Mathura, northern India	767		
The Greek god Apollo with kithara, a stringed instrument similar to a lyre	770		

Jade votive ax of a figure combining human and animal traits and thought to represent a supernatural being, Olmec, from Mexico	863	Painted wooden model of a boat, from Meir, Egypt	977
Head of the Greek philosopher Socrates	878	Terra-cotta model of a merchant ship, Amathus, Cyprus	978
Ivory panel commemorating Quintus Aurelius Symmachus, an orator and figure in Roman government and a prominent pagan	881	Wall painting of Ulysses and the Sirens, Roman, from Pompeii	983
Section of the Neolithic Sweet Track, the oldest prehistoric timber trackway in Britain, from Somerset, England	888	A Scythian slave and the satyr Marsyas	992
Iron hipposandal, Roman Britain, found in London	891	Image of Psyche on a lead coffin lid, Roman, made in Lebanon	994
VOLUME IV			
Deep gorge in the Atlas Mountains of Africa	898	Sarcophagus of Nectanebo II, the last native ruler of Egypt, from Alexandria	1001
Limestone stela of Heqaib, from Abydos, Egypt	900	Basalt relief of a gazelle, Neo-Hittite, from Carchemish, southeastern Anatolia (modern Turkey)	1002
Iron Age Lindow Man, found in Lindow Moss, Cheshire, England	903	A Neolithic burial jade carved with faces, from southern China, Liangzhu culture	1004
View of Mount Olympus, in Attica	905	Coins from the Hoxne hoard, Roman Britain, found in Hoxne, Suffolk	1007
Gold ring bought by a pilgrim and showing the Roman Temple of Aphrodite at Palaepaphos	906	Servants carrying food for the king's tables, palace of Xerxes, Persepolis, Persia (modern-day Iran)	1019
Neo-Assyrian stone panel from the palace of Sennacherib, Nineveh, northern Iraq	912	Pottery, Japan	1026
Base-silver radiate of Carausius, with the emperors Diocletian and Maximian, Roman Britain	914	Double spout and bridge vessel with pelican and fish, Nasca culture of Peru	1041
Unwrapped mummy of a woman, perhaps from Thebes, Egypt, Late Period	926	Game of 58 Holes, made of ivory inlaid with gold and blue paste, from Megiddo, Palestine	1050
Bust of Pseudo-Seneca by Peter Paul Rubens	942	Ceramic Liubo players, from China	1052
Altar to the sea god Neptune, an offering from the Roman admiral of the British fleet, from Lympne, Kent, England	959	Bronze group of a bull and acrobat, Minoan, from Crete	1053
Aerial view of the Niger River and surrounding savanna during the rainy season	963	Hockey game, found in the Themistoclean wall, Athens	1054
Relief fragment showing Assyrian soldiers towing a boat through shallow water	967	Roman terra-cotta sculpture of two gladiators fighting	1056
		Stone <i>hacha</i> (ax), Veracruz, Mexico	1057
		Painted wooden model of a granary, from Aswan, Egypt	1063
		Amphora, a ceramic vessel used for storing and carrying oil and wine and other commodities, from Athens	1068
		Ugandan woman wearing a bark cloth dress	1074

Tapestry made of multicolored wool on linen showing Artemis and Actaeon, Egypt	1076	Bust of a Greek warrior known as Leonidas	1145
Wool textile fragment from Persepolis, Persia (modern-day Iran)	1078	Bronze statuette of the Mars, Roman god of war, Earith, Cambridgeshire, England	1151
Bone needles from the cave of Courbet, Penne-Tarn, France	1081	Stone ball found in Olduvai Gorge, Tanzania	1162
Greek utensil used for unwinding balls of wool, called Ariadne's clew box	1081	Short sword of steel, bronze, and gold from eastern Central Asia	1165
Mantle border fragment made of cotton and camelid hair, Peru	1084	Spear thrower carved in the shape of a mammoth, from the rock shelter of Montastruc, Tarn-et-Garonne, France	1167
Site of ancient walled town, Cameroon, Central Africa	1087	Vase from Mycenae portraying warriors in battle gear	1168
Gold bracelet or diadem, from the Phoenician trading center of Tharros, Sardinia	1099	Sixteenth-century shield depicting Roman battle scene	1170
Steatite seals from the Indus Valley	1100	Bronze duck weight, found in the treasury at Persepolis, Persia (modern-day Iran)	1175
Iron Age luxury imports from Italy, Rome, and the Near East, found at Hertfordshire, England	1102	Bronze steelyard with lead weights from Roman Britain	1178
The Crawford Cup, Roman, found on the border between Syria and Turkey	1105	Red porphyry one talent weight, from Knossos	1179
Petroglyph of camel and horse, from the Sahara Desert at Tassili, Algeria, North Africa	1111	Roman cup or bowl depicting a man carving the number 7 on a nilometer, a device used to measure the water level of the Nile's annual flood	1181
Achaemenid Persian gold model chariot from the region of Takht-i Kuwad, Tadjikistan	1114	Abu Simbel—hymn in praise of the Egyptian pharaoh Ramses II	1185
Horse harness fittings from Iron Age Britain	1116	Clay tablet with Babylonian inscription, found in the treasury of Persepolis, Persia (modern-day Iran)	1186
Chariot with horse and rider, from a sarcophagus at Heraklion	1119	Pillar edict of the emperor Asoka from Uttar Pradesh, India	1188
Frieze in the temple of the Egyptian pharaoh Ramses II, showing a listing of captured cities in Nubia	1127	Painted pebbles from cave of Mas d'Azil, Ariège, France	1188
Clay prism of King Sennacherib	1132	Bilingual milestone marker	1190
Stone figure of the war god Skanda, from eastern India	1139	Pottery inkwell from Roman Britain, inscribed with its owner's name, Iucundus	1191

Entries D to I

► death and burial practices

INTRODUCTION

Death in the ancient world had many similarities to death in any other era. While bodies were burned, buried, or left in the open, survivors grappled with ideas about what it meant to be human. The history of death involves not only the disposal of remains but also the emotion of grief and the breaking of bonds between people.

Ancient cultures lacked the means to preserve intact bodies. Especially in warm climates, decomposition set in quickly, with the body emitting a stench by the fourth day. Accordingly, quick disposal of remains was needed for sanitary as well as aesthetic reasons. Ways of physically removing the dead from the living have changed very little during the course of human history, with earth burial and cremation preferred in ancient times as the basic form of funeral. In Asia followers of Zoroastrianism believed that preliminary exposure to flesh-eating animals in an open space was the only acceptable way of disposing of a body. No other means of disposal avoided desecrating the revered elements of fire, earth, and water. Subsequent collection of the bones was recommended but not required. Most other people sought to avoid animal intrusion. Near Eastern people were known to place bodies in a cave and close the opening with rocks to keep out carrion-eating animals. For Christians dismembering of bones ran counter to the hope of the resurrection of the flesh. Muslims outlawed the pre-Islamic Arabian practice of animal sacrifice at the gravesite and preferred level graves.

Some cultures extensively prepared bodies and delayed burial until their cultural rituals were complete. Many cultures washed and dressed the body, and women were typically responsible for this duty. Mummification was the preferred way of handling elite human remains in Egypt and all remains in some American cultures. The Chinchorro people of present-day Chile placed stylized masks on mummified remains of all members of their society, including babies. They kept the dead among the living for a period of time, perhaps as a comfort for the bereaved.

Death among the pagan ancients in the Mediterranean apparently did not involve any metaphysical agony. In the scant pieces of literature that have survived the ages, there is no evidence of tortured thought or psychological malaise. Salvation was associated with the deliverance of the soul from the bindings of the body, the acquisition of ordinary and supernatural benefits, and sometimes with the securing of a better fate in the hereafter. Even tragic situations, such as the death of a child, did not necessarily bring humans closer to the divine. Many Greeks and Romans either sank into despair or appear to have accepted the limits of human existence. In sharp contrast, early Christians radically departed from pagan beliefs by sanctifying human remains and building monuments over the dead. They ignored the pagan taboo against burying the victims of plagues and the corpses of strangers, which came out of a fear of catching the disease that had killed these people. Meanwhile, Muslims avoided funerary monuments as a vain custom. Death is the one constant in every culture in every period. Ancient death and burial practices showed concern for both sanitation and cultural taboos.

AFRICA

BY ROBERT SHANAFELT

Africa provides evidence of some of the world's oldest burials and mortuary rituals. At a site containing some of the oldest human remains, near Herto, Ethiopia, the skull of a child from 160,000 years ago was found to be so polished that it must have been repeatedly handled, probably in a ritual-like way. At the other end of the continent, at Border Cave, between South Africa and Swaziland, excavations uncovered what may be one of the earliest intentional burials that also dates back tens of thousands of years. There the remains of an infant were found together with a shell ornament; some of the child's bones had been stained with the red ocher. Archaeological evidence suggests that individuals continued to be buried in caves and rock shelters throughout South African prehistory.

Ocher (a powdery form of iron-rich earth or clay that can be used as a pigment) and other materials such as shells have served as mortuary goods and for other ceremonial purposes

for thousands of years in much of Africa, continuing up into contemporary times. Red ocher is of great ritual significance both in life and in death. Typically mixed with fats and then smeared on the face or body—whether of a living person or a corpse—it results in a glossy, bright red sheen. Because of the association of the color red with blood, the pigment is often linked with life and fertility.

In all of Africa, Egypt is most famous for its ancient pyramids and the tombs where mummies are found, but it is not the only place on the continent where there are elaborate pyramids and burial monuments. The rulers of Egypt's 25th Dynasty were Nubians who hailed from what is Sudan today, and they built their pyramid gravesites in their homeland. The Nubians continued these practices even after losing control of the Egyptian part of their empire. For example, at the city of Meroë, capital of the kingdom of Kush (ca. 800–ca. 350 B.C.E.), members of the ruling families were buried beneath stone or brick pyramids in tombs hewn from solid rock. At an even earlier period the royal tombs of Kerma, topped with

Pyramid of a king, thought to be Adikhalamani Tabirqa, in Meroë, Sudan. (Courtesy of the Oriental Institute of the University of Chicago)

great mounds, some as much as 100 feet wide and 45 feet high, showed the power and prestige of the rulers.

During the fourth and fifth centuries B.C.E. in Axum, a city and kingdom in highland Ethiopia, gravesites of rulers were marked with some of the world's tallest obelisks, monolithic pillars up to 100 feet high. During this time the practice of erecting obelisks and granite tombs for leaders held sway in numerous settlements extending from the Ethiopian highlands to the Red Sea coast.

Other parts of Africa have thus far shown less evidence of great tombs for the deceased in antiquity. One reason may be that social stratification and kingship developed later in these other areas, and consequently there was less focus on building costly structures to provide special honors for elites. Elaborate monuments and precious grave goods are rarely associated with the ordinary members of society. Rather, they are associated with nobility, kingship, and accumulated wealth. However, new discoveries continue to be made in Africa. For example, archaeologists have recently documented dramatic burial sites in Niger. Located primarily in the northern part of the country, these finds include stone chambers beneath massive conical mounds, some of them standing more than 45 feet tall.

Cremation is another possible way of dealing with the dead, and there is early evidence of this practice in Africa. For example, along the Rift Valley in western Kenya the famous archaeologists Mary and Louis Leakey excavated a Late Stone Age cave site known as the Njoro River Cave that dates to around 1200 B.C.E. There they found a number of cremated remains as well as funeral offerings that had also been partially burned, including elaborately decorated wooden vessels, baskets, beads, shells, and semiprecious stones that were probably strung together and worn as jewelry. The Njoro find is exceptional, however; for reasons that are unclear and that probably vary greatly from one culture to another, cremation appears never to have been very common in Africa.

Much remains to be discovered about the death and burial practices of prehistoric Africa, especially among non-elite levels of society. From what is known from more recent practices and religious beliefs, however, it is very unlikely that the dead of typical families in antiquity were disposed of without ceremony or community involvement. Throughout Africa the burial of the dead is a community matter, and there is great concern with honoring and maintaining a proper relationship with the spirit of one's ancestors.

EGYPT

BY KELLY-ANNE DIAMOND REED

Much of our information about the death and burial customs of the ancient Egyptians comes from surviving illustrations of their tomb scenes. No tomb shows all the episodes of a complete burial, but from an assortment of them we can reconstruct the typical funeral. The elaborateness of individual ceremonies and the quantity and richness of the tomb fur-

nishings of course varied with the wealth of the deceased's family.

Upon the death of an ancient Egyptian the body was taken from the home and transported to the tent of purification (*ibw*) for a ritual cleansing and then to the embalming workshop (*wabet*) for mummification. Both were probably located in the cemetery, either near or attached to the tomb. The purpose of the *ibw* was to purify the body before the rituals that inducted the deceased into the world beyond. Everything used in these ceremonies had to be ritually pure, and certain ceremonies were done behind closed doors with only the initiated allowed to attend.

Before the invention of artificial mummification, the ancient Egyptians buried their dead in the ground. Egypt's hot dry climate evaporated the moisture in the body and left it dry. In the Predynastic Period (ca. 5000–3100 B.C.E.) the body was wrapped in an animal skin or linen and placed in a shallow grave. By the end of the Early Dynastic Period (ca. 2920–2575 B.C.E.) royal graves were deeper and lined with materials such as sun-dried mud bricks or wood. Often there was also a superstructure. The coffin gave further protection. All of these protective measures prevented the body from drying and eventually led to a new method of preservation, owing to the need for an eternal body according to Egyptian religious beliefs. Thus mummification was invented, aimed at preserving the body in a dry condition mainly by using a chemical salt known as natron. The details of the mummification process varied over time. By the New Kingdom (ca. 1550–1070 B.C.E.) the procedure took 70 days. The ritual of preservation was later interpreted as imitation of the god Osiris, who died and came back to life.

From the embalming workshop the body embarked on a ritualistic voyage or pilgrimage. In the Old Kingdom (ca. 2575–2134 B.C.E.) the ceremonial voyage went to cult centers in the Nile Delta, but in the Middle Kingdom (ca. 2040–1640 B.C.E.) and New Kingdom the destination was Abydos, the most sacred place of the Osiris cult, which had become popular near the end of the Old Kingdom and influenced the funerary rituals. Once the cortege arrived on the west bank of the Nile (west being associated by the Egyptians with death), the body was hauled to the tomb on a sledge pulled by either men or oxen. The sledge also carried the so-called canopic chest containing the four canopic jars, which held the deceased's liver, stomach, lungs, and intestines.

The funeral procession consisted of relatives and other mourners, servants who carried the burial goods, and priests. Sometimes two women impersonated the goddesses Isis and Nephthys, who mourned their brother Osiris in the myth. In the older tradition the *mww*-dancers, who may have represented the ancestors of the ruler (there are many theories about the identity of the *mww*-dancers, would have met the procession at the cemetery. Boxes, baskets, furniture, jewelry, sandals, writing boards, and other items were buried with the deceased. Additional rituals took place before the body was deposited into the tomb. A special lector priest read funerary

A reconstructed Predynastic Egyptian grave pit from about 3400 B.C.E. at a time before mummification, when bodies were placed directly in shallow desert graves, where they did not decay. (© The Trustees of the British Museum)

texts from a papyrus, the Opening of the Mouth ceremony took place (supposedly restoring the faculties of the deceased so that he could be reborn in the hereafter), and offerings were made. Once the body was placed in the tomb, the footprints were swept away. An ancient Egyptian narrative, “The Story of Sinuhe” (ca. 1800 B.C.E.), provides a detailed account of an ancient Egyptian funeral: “A funeral procession is made for you on the day of burial; the mummy case is of gold, its head of lapis lazuli. The sky is above you as you lie in the hearse, oxen drawing you, musicians going before you. The dance of the *mww*-dancers is done at the door of your tomb; the offering-list is read to you; sacrifice is made before your offering-stone.”

Tomb architecture developed over time. The first superstructure was a mastaba, a stone shell (in Arabic the word *mastaba* means “stone bench”), rectangular in shape, its walls sloping so that the area of the roof was less than that of the base. The first step pyramid was built for King Djoser (r. ca. 2630–2611 B.C.E.) at Saqqara by the architect Imhotep in the Third Dynasty (ca. 2649–2575 B.C.E.). It appears that the step pyramid originated as a mastaba. It eventually developed into a true pyramid by the addition of an outer facing, as can be seen in the pyramid at Medūm built either by Huni (r. ca. 2599–2575 B.C.E.), the last king of the Third Dynasty, or by his son Snefru (r. ca. 2575–2551 B.C.E.), the first king of the Fourth Dynasty (ca. 2575–2465 B.C.E.). The most famous pyramid site is Giza, where Khufu (r. ca. 2551–2528 B.C.E.), Khafre (r. ca. 2520–2494 B.C.E.), and Menkure (r. ca. 2490–2472 B.C.E.), the son, grandson, and great-grandson of

Snefru, respectively, built their pyramid complexes. Khufu’s monument is known as the “Great Pyramid” because it is the largest one surviving.

It was at this time that the formal pyramid complex emerged, consisting of the pyramid itself, a mortuary temple, a valley temple, and a causeway down to the Nile. Sometimes there were subsidiary burials of queens or important officials, or boat burials. Most of the pyramids of the Fifth Dynasty (ca. 2465–2323 B.C.E.) are at Abusir; they are much smaller than those of the Fourth Dynasty. Pyramids were constructed until the Thirteenth Dynasty, and there are a few Seventeenth Dynasty examples from Thebes as well. Beginning in the New Kingdom a hidden valley on the west bank of Luxor, called the Valley of the Kings, was chosen as the burial spot for the kings. There they carved their tombs out of the mountain.

Royal tombs were built of stone to survive for eternity; for this reason scholars have more information about them than about the tombs of the lower classes. Private people of high rank were buried in mastabas in the Old Kingdom and later in rock-cut tombs. Simple pit graves continued to suffice for the poorest classes throughout Egyptian history.

THE MIDDLE EAST

BY KAREN RADNER

The ancient Mesopotamians usually buried their dead, either beneath their houses or in graveyards. The bodies were often laid to rest in stone or clay sarcophagi (coffins) or, most frequently, in one or two large pots. Above-ground grave mark-

ers were rare; memorial monuments inside temples have been found but had no physical connection to the burial. Cremation was uncommon, not because of a perceived need to preserve the body intact but because of the forbidding costs of building large fires in a virtually woodless environment. The Achaemenid kings of Persia were laid to rest in free-standing tombs and rock tombs cut into the imposing cliffs near the royal palaces of Persepolis. In contrast to the hidden Mesopotamian graves, these burials were highly visible and hint at a rather different role of death and funerary care in Persian society.

Spectacular recent finds of the royal tombs from the Middle Bronze Age (ca. 2000–1600 B.C.E.) palace at Qatna in Syria and the tombs of several Assyrian queens of the ninth and eighth centuries B.C.E. beneath the royal palace of Nimrud in northern Iraq have caused sensations in the archaeological world, but the most famous ancient Near Eastern burial ground remains the cemetery of Ur in southern Babylonia, excavated in the 1920s. This site, adjoining the central temple, was used for more than half a millennium, from about 2600 to 2000 B.C.E., for thousands of burials. The vast majority of the bodies were interred in simple pits—although often with very rich grave goods—but 16 burials from the mid-third millennium B.C.E. occupy multichambered stone tombs at the bottom of shaft graves. This group of graves is known as the Royal Cemetery of Ur. Its best-known resident is Queen Puabi, whose identity was revealed by an inscribed cylinder seal found with her body. Puabi and the other main occupants of the shaft graves were not buried alone but with many other bodies, male and female, evidently as part of opulent sacrifices that also included vehicles with their draft animals, luxury objects such as musical instruments and furniture, and food and drink. One such mass burial contained the bodies of 74 men and women.

Today most scholars agree that in life these people were the attendants of the main occupiers of the graves. They died during ceremonies conducted at the funerals of members of the ruling elite. As drinking bowls were found close to their bodies, it is thought that they took poison. While no writings that could shed light on this practice survive from that time, literary texts from the beginning of the second millennium B.C.E. describe the burials of Mesopotamian rulers. Most important, a Sumerian composition today known as “The Death of Gilgamesh” mentions how the favorite wife, junior wife, singer, cup bearer, barber, and attendants of this mythical hero-king of Uruk lay down with him in death. The grave goods are described as meeting gifts and presents for the gods of the netherworld, and this idea is also prominent in other textual sources.

Ancient Mesopotamian texts allow considerable insight into the mythology of death. Death was seen as the inevitable fate of all humans. The Epic of Gilgamesh, the best known of these texts, exemplifies the impossibility of escaping physical death even for a man like Gilgamesh, who is two parts divine and only one part human. The funeral ceremony enabled the

dead person’s spirit to voyage properly into the netherworld. Without it a spirit would wander the world of the living, lost and increasingly dangerous. Consequently, the loss of a dead body—for example, to the enemy on a battlefield as in the case of Sargon II, king of Assyria (r. 721–705 B.C.E.)—was a catastrophe that demanded rituals to calm the restless and malicious spirit. The responsibility for the funeral rested with the family of the deceased, as did the ensuing care for the dead, consisting offerings of food and drink to the ancestors and the evocation of their names. Although cemeteries existed, the most common form of burial was in tombs underneath the family home and accessible to it.

Contacts between the living and their dead were not limited to funerary duties but could also provide insight into the future. The netherworld was where the sun god, on his daily cycle through the universe, spent the night. Hence it was the source of the new day and, implicitly, of all forthcoming events. The inhabitants of the netherworld were therefore privy to future knowledge, and contacting them by necromancy (conjuring of the spirits of the dead in order to communicate with them) could offer that knowledge to the living.

The netherworld mirrored the world of the living and was imagined as a city surrounded by fortified and gated walls. This “Land without Return,” as it was called, was ruled by a queen, Ereshkigal, and her consort, Nergal, the god of pestilence and destruction. They were assisted by the vizier Namtar and the judges of the netherworld, among them Gilgamesh and his friend Enkidu as well as the historical king Ur-Nammu, who ruled Ur at the turn of the second millennium B.C.E. The story of how Ishtar/Inanna, the goddess of sexuality and fertility, unsuccessfully tried to wrest control over the netherworld from her sister Ereshkigal survives in two different versions, one with very close parallels in the Greek myth of Persephone: Ishtar/Inanna goes to the netherworld in order to rescue her dead lover Dumuzi, the god of vegetation. Captured by Ereshkigal, she succeeds only in striking a compromise: Dumuzi is allowed back among the living for part of the year but must return to the netherworld for the rest of it, thus defining vegetation’s cycle of demise and renewal. In the other version of the story Ishtar/Inanna has another motivation, the ambition to rule over the innumerable dead, but like death itself, the queen of the dead cannot be defeated.

The concept of the dying god who returns to life featured prominently in the Near Eastern mythology of death. This ultimate sacrifice of a deity was presented as an integral part in the creation of humankind, as the dead god’s essence was added to the clay from which humans were formed to be servants to the gods. Originally, therefore, humans were immortal, and mortality came about only through a later decision of the gods: As humankind became numerous and their constant hubbub a nuisance, the divine creators sent a flood to destroy them. Appreciating the value of the few survivors, the gods then conceived mortality as a countermeasure to

unchecked human propagation. Thus death from old age and disease came into existence.

ASIA AND THE PACIFIC

BY CONSTANCE A. COOK

The earliest human burials in Asia are found in caves occupied as much as 25,000 years ago in Southeast Asia, such as in peninsular Thailand. The very early burials are random and unclear in nature, but beginning in about 8000 B.C.E. people here began burying their dead in circular pits, their bones sometimes marked with red ocher. Regular burial grounds with grave goods, often in caves used earlier as habitations, became common in this region around 3000 B.C.E. and log coffins just before the start of the Common Era. Cremation first appeared in the northern Indus valley in 1900 B.C.E., after the decline of the predominant Harappa cultures (ca. 2500–2000 B.C.E.), whose dead were buried in wooden or brick coffins and surrounded with pottery vessels.

The 45,000-year-old Niah cave complex in Sarawak, Borneo, represents the most ancient burial style, although the period of greatest activity dates to around 4,000 years ago. In the earliest chronological layer of these cave burials, rain-forest foragers buried their dead inside logs, in wooden coffins, or simply wrapped in a shroud—a basic burial style perpetuated throughout much of Asia. Later, in Sarawak and elsewhere in island Southeast Asia and the Pacific, bodies were sometimes partially burned and placed in ceramic or bamboo containers. At Sarawak and many other sites the bodies show evidence of being processed after their primary burial and then interred again in what are known as secondary burials. Secondary burials here and elsewhere, such as among early farming communities in China, consist of group burials. One major difference is that the secondary burials in the Niah caves were in jars. Jar burials were common for children in early northern Chinese cultures, but the primary and secondary burials of adults were in pits. The Polynesian Lapita culture of 3,000 years ago removed the skulls of their dead after decomposition and sealed them in pots. The headless skeletons and the teeth were buried in pits.

Early Neolithic (7500–6000 B.C.E.) cave sites in southern China contain burials similar to those found farther south: flexed, some with perforated skulls, and bones covered in red ocher. Bodies found in Thailand from 2000 to 1400 B.C.E. were likewise covered with red ocher but wrapped in cloth and placed supine in wooden structures with pottery and shell jewelry. There is evidence of lineage burials (burials in grounds set aside for a single lineage) and ritual feasting. Burials from 3,000 to 5,000 years ago in the Red River valley in Vietnam also have bodies wrapped in ramie shrouds and buried with pottery and beads but placed in canoes, oddly reminiscent of the Ba people's canoe burials in the cliffs near the upper Yangtze River valley of China around the same period.

Beginning in the cemeteries of the Early Neolithic farming communities in China, burials were aligned in a single

Jade eye plaques from China during the Han Dynasty (206 B.C.E. to 220 C.E.), used to cover the eyes of the dead to protect the body from decomposition. (© The Trustees of the British Museum)

direction, such as north–south or east–west. A number of communities practiced secondary burials in which the bones were reorganized into kin burial sites. Grave goods included such items as stone mortars and pestles, stone axes, and pottery tripods and bowls. Occasionally, a primary burial was marked as that of a person of importance by inclusion of ritual implements such as musical instruments—for example, flutes carved of crane bones or rattles made of tortoise shells. Many cemeteries include ash pits filled with animal and human bones, vessels, and tools suggesting sacrifice to the dead and the beginning of ancestor cults. The burial of humans as sacrifice occurred especially in building projects, such as of a tomb, house, or city wall. This practice reached its peak during the Shang Dynasty (1500–1045 B.C.E.) when large royal tombs contained hundreds of victims and the cemeteries thousands.

By the end of the Middle Neolithic in northern China (5000–3000 B.C.E.) the majority of cemeteries clearly gave preference to males. Some primary burials began to have a “second-level ledge” for the display of mortuary feasting ves-

sels around the bodies, which might be covered with bone or stone beads. Some jade objects and tomb decor suggest the use of astrological or cosmic symbols in rituals to contact the supernatural through spirit mediums. In Manchuria burials from the Hongshan culture (4500–3000 B.C.E.) used rock cairns (mounds of piled stones) with a central tomb surrounded by a cluster of similar but smaller tombs. Large tombs at one Hongshan site seem to have been associated with a temple filled with statues of pig-dragons and of women naked and pregnant.

Cemeteries during the Late Neolithic (3000–2500 B.C.E.) and the highly socially stratified Erlitou culture (1900–1500 B.C.E.) in the middle Yellow River valley bear many traits that would remain common in Chinese burials for millennia. The mortuary feast display became increasingly ostentatious for the elite and included exotic and highly crafted goods such as fine painted or thin-walled pottery, jade, alligator and pottery drums, stone chimes, painted wooden vessels, and accumulated stores of meat, such as whole pigs. Bodies were placed in wooden painted and lacquered coffins over a “waist pit,” a pit dug into the cinnabar-covered floor of the tomb chamber under the waist area of the body and filled with dog, deer, or human sacrifices. In some tombs grave goods were placed in painted wooden chests at the foot and sides of the wooden coffin or in an outer coffin containing the inner coffin, with different categories of goods placed in each.

The Shang Dynasty saw the creation of royal mausoleums such as the complex near present-day Anyang, in Henan Province. It consisted of numerous large cruciform (in the shape of a cross) tombs originally filled with display bronzes and jades. Sacrificial victims of all ages and both genders, some intact, some headless or otherwise mutilated, were buried in all areas of the tomb and in thousands of sacrificial pits, along with an array of domestic and exotic animals. The burial of horses and chariots began during this period. Such magnificence was not seen again until the burial of the first Qin Dynasty emperor in 220 B.C.E., though by then the horses, chariots, and humans were made in miniature or cast out of clay.

After the Shang the second-level platform and waist pit became less common, but jades, jewelry, weapons, and clothing continued to be buried in or around the inner coffin. The outer coffin (a wooden chamber inside the tomb and outside the “inner” coffin or coffins) came to display, at first, a rich array of bronze cooking, eating, serving, and ritual ablution (or purification) vessels and some ritual jades, and then, by the fourth century B.C.E., fine painted lacquer vessels and statues. The statues protected the tomb from demons and aided the journey of the deceased into the afterlife. By this time, too, bamboo texts were placed in the tomb. Some listed mortuary gifts used in the funeral, and some of these gifts were buried with the dead. Other texts, including accounts of healing rituals, almanacs, administrative documents, and philosophical tracts, suggest that the occupant wanted to have these items to maintain some aspect of his mortal identity in the afterlife

or perhaps to prove his rank in the world of the ancestors. Wooden, clay, or stone figurines were buried with equipment for hunting, travel, ritual ceremonies, and musical feasts.

The ancient practice of jar burials continued in Japan with the Yayoi culture (300 B.C.E.–300 C.E.), whose burials consisted of stamped-earth mounds over a coffin consisting of two large painted jars placed end to end. In some cases other jar burials radiated outward from the central burial or were placed in clusters or lines. Besides bronze daggers, mirrors, glass beads, and other items found in the jars, burial mounds hold a variety of pottery vessels and serving dishes. The earlier Jōmon people buried their dead in rows of pits in communal cemeteries marked off with stone circles or ramparts.

EUROPE

BY PETER BOGUCKI

Death was an important part of life in late prehistoric Europe. The death of a member of Neolithic, Bronze Age, or Iron Age society was often the occasion for elaborate ritual and mortuary ceremonies and the display of status and wealth, and the dead continued to be present in the everyday lives of the living. There was a remarkable range in the ways that corpses were treated and eventually buried. Archaeologists consider many characteristics of mortuary practices, or practices relating to the burial of the dead. The most fundamental is the treatment of the body itself: How was the corpse prepared for burial, and how was it buried? The two principal options for dealing with a corpse are either burial as an anatomical entity of flesh and bone or transformation into ashes through cremation. Prehistoric European societies practiced both at various times and places. In addition, some societies left bodies to decay in a ceremonial location and then gathered the defleshed bones for burial, a practice known as “excarination.”

The principal choices for burial of a body in ancient Europe were either to lay it in the grave in an extended position, with legs straight and arms at the sides or crossed over the torso, or to place it in a contracted position, lying on one side with legs drawn up to the chest and arms bent. Seated burials are also known, and occasionally bodies were placed in a grave pit without apparent consideration for how they were lying. Bodies were sometimes enclosed in coffins. Virtually nothing is known of embalming or other techniques of preparing the corpse that leave little trace on the bones and therefore no long-lasting evidence.

Graves were individual, multiple, or collective. Individual burial was most common in ancient Europe, one corpse per grave; some graves contain several or many corpses, especially if members of the same family died at about the same time. Collective burials, in which graves contain many bodies, are found from time to time, commonly at the gravesites of societies that practiced excarnation. The bones were gathered into crypts containing dozens of people; in instances of violence many bodies were buried quickly in a mass grave.

Often buried with the bodies were offerings that archaeologists call “grave goods.” Sometimes these goods are lavish, in the form of finely crafted objects made from expensive materials, and sometimes they are meager or absent. Archaeologists debate the significance of grave goods. The items certainly reflect the ability of the deceased person’s family and community to acquire objects and to dispose of them by burying with the corpse. The question is whether they reflect the status and rank of the deceased person or are a symbolic display by the survivors that has ritual or spiritual meaning.

Another key feature of mortuary practice in ancient Europe was the construction of mounds (also called “barrows,” “tumuli,” or “kurgans”), cairns (mounds of small stones), megalithic tombs (built of large stones forming chambers), or wooden structures over the grave or as crypts. Careful attention was paid to the locations of these structures in the landscape. They were often positioned where they could be viewed from afar or, in some cases, only when approached from a particular direction. Over time burial monuments accumulated in specific localities to create “ritual landscapes” of mounds and other features.

Archaeologists also debate the time at which human beings began to bury their dead in a formal, careful way. The practice dates well back into the Paleolithic Period (8,000 B.C.E. and earlier). A triple burial from Dolní Věstonice in the Czech Republic dates to 25,660 B.C.E., while at Sungir’ in northern Russia, several individuals were buried around 22,000 B.C.E., some ornamented with thousands of beads. Cemeteries, specific localities devoted to repeated burials over a long time, appear during the Mesolithic Period in about 7,000–5,000 B.C.E. At Skateholm in southern Sweden about 90 people (and several dogs) were buried in a variety of positions, often with deer antlers and other artifacts, while at

Téviec and Hoëdic in Brittany (France), single, double, and multiple graves, some in stone cists and containing antlers, were associated with large ritual hearths.

During the Neolithic Period, burials became elaborate and diverse. Sometimes they were in cemeteries separate from settlements, as in central Europe between 5500 and 5000 B.C.E., and at other times they are found within settlements, as at sites like Brześć Kujawski and Ośłonki in Poland a millennium later. Elongated mounds called “long barrows” were constructed over graves in several parts of Europe, including Poland, Denmark, Britain, and France. Some of the best-known Neolithic burials are the megalithic tombs of western Europe and Scandinavia, constructed between 4000 and 2000 B.C.E. Large stone slabs were set upright to form chambers and passages, while other large stones formed roofs; the whole construction was covered with earth or small stones. Thousands of megalithic tombs were built, usually as collective graves into which whole bodies or defleshed or cremated bones were placed on many occasions. A tomb at La Chaussée-Tirancourt in France contained the remains of more than 360 people, many of which had been rearranged during subsequent openings of the chamber. At Newgrange and other Irish megalithic tombs, cremated bones were placed in small chambers that opened off the main passage.

During the Neolithic we also see glimpses of sudden and violent death. A mass grave at Talheim in Germany contains the bodies of at least 34 men, women, and children. Many had suffered blows to their skulls from stone axes. In 1991 hikers found the frozen body of a man known as “Ötzi,” or the “Ice-man,” in the Alps, where he had died 5,300 years earlier. His body showed evidence of a hard life, including injuries and an arrow wound, although the cause of his death is unknown.

Late in the Neolithic and into the Bronze Age, between about 3000 and 1200 B.C.E., single burials under mounds became common across much of Europe. Examples are the famous barrows of the Wessex culture, associated with Stonehenge in southern England, which contained artifacts of gold and other exotic materials. At Leubingen in central Germany, a barrow covered a timber mortuary house in which an elite person was interred around 2000 B.C.E. In Denmark around 1250 B.C.E., oak trunks were hollowed out as coffins, which preserved hair, textiles, and grave goods superbly.

Around 1200 B.C.E. the burial rite over many parts of Europe shifted to cremation, with the ashes buried in urns. Some cremation cemeteries, such as Kietrz in southern Poland, contain thousands of graves. Elsewhere bodies continued to be buried, as in the very rich so-called prince’s graves in southwest Germany and eastern France, around 500 B.C.E., at sites like Hochdorf and Vix. Later in the Iron Age (1000 B.C.E.–500 C.E.) some corpses were thrown into bogs and ponds across northern Europe, where they remained remarkably preserved. These “bog bodies” were either human sacrifices or executed criminals. During the early part of the first millennium of the Common Era, the burial rites throughout

Pottery cinerary urn shaped like a hut, early Italian iron age 900–800 B.C.E. (© The Trustees of the British Museum)

Europe were different from region to region, with skeletal burial common in some areas and cremation in others.

Ancient European mortuary practices varied dramatically over the millennia after people began to regard burial as a way of expressing a relationship between the dead and the living. Archaeologists pay very close attention to burial rites and graves, because they reflect social organization, status, and symbolism better than almost any other form of archaeological remains.

GREECE

BY WENDY E. CLOSTERMAN

Funerals were family affairs in ancient Greece. When someone died, family members took the lead in conducting all stages of the funeral; no religious official seems to have been involved. The funeral began with the *prothesis*, a ceremony in which the corpse was laid out for mourning at home. The women of the family washed the body, dressed it in special funerary clothes, and placed it on a bed, around which the family members gathered and mourned. Athenian vases portray women and children closest to the head of the corpse at this stage of the ritual, tearing at their hair, singing dirges, and crying out in distress, while the men stand near the feet raising their hands in more subdued gestures of mourning.

The next stage of the funeral, the *ekphora*, consisted of a procession transporting the corpse from the house to the gravesite. Here the men walked in front while the women followed, continuing to mourn. Exactly what rituals took place during burial is uncertain. Probably someone made a libation, a ritual pouring of wine or other liquid onto the ground. Archaeological digs near graves reveal long trenches or smaller areas of burnt soil containing animal bones and pottery normally used for dining, suggesting that a ritual meal was offered to the deceased. Whether the survivors participated in this meal is unknown, but it is clear that after the funeral the family gathered at a home for a communal meal.

Aristocratic families, especially in the Archaic Period (600–480 B.C.E.), often took advantage of the opportunities funerals offered for ostentatious display of wealth and position. It was probably for this reason that various cities passed laws curtailing some aspects of funerary display. For example, at the beginning of the sixth century B.C.E. the Athenian lawmaker Solon limited the length of the *prothesis* to one day and its location to within the house and required that the *ekphora* take place before daybreak.

The Greeks practiced both burial and cremation. Burial might be directly in the ground, in stone-lined graves, or in wooden or stone coffins. With cremation, the ashes of the deceased were placed in a vessel that was then buried in the ground. The Greeks also deposited objects in graves during burial. In addition to jewelry or other items worn by the deceased during the funeral, grave offerings might include pottery, mirrors, figurines, weapons, and toys. The amount and expense of grave gifts varied in different periods and regions.

Stele of Aristion, a philosopher of Athens who died in 86 B.C.E. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

Because the Greeks usually buried beside roads, especially those leading in and out of a town, the gravestones were visible to many people. The form of gravestones and the imagery on them differed with time and place. In Athens large vessels painted with *prothesis* and *ekphora* scenes, 3 feet or more in height, marked graves during the eighth century B.C.E. Later Athenian funerary markers no longer focused primarily on ritual but instead presented generalized and idealized images of the deceased. In the Archaic Period tombstones took the form of statues or stelae (stone slabs or pillars) carved in relief, most commonly depicting near-life-size men in their prime, sometimes as soldiers or athletes. Sculpted grave markers fell out of use in Athens for much of the fifth century B.C.E. When they returned to favor from about 430 to the late 300s B.C.E., they included depictions of women and of family gatherings.

Ritual obligations to the dead continued beyond the funeral. Athenians visited the gravesite for third-day, ninth-day, and 30th-day rites, the last of which officially marked the end of the mourning period. They continued to visit periodically afterward, including during the *Genesia*, an annual religious

festival for the dead. Fifth-century Athenian vase paintings depict women tending graves by decorating the tombstones with ribbons or bringing offerings such as food or vases that held oil or perfume.

In addition to family-run funerals the city of Athens in the Classical Period (480–323 B.C.E.) commemorated those who died in battle each year with annual public funerals. A prominent politician gave a speech honoring the sacrifice of the fallen soldiers, and their bones were buried together by tribe.

The Greeks believed that the mythical boatman Charon ferried the deceased to the afterlife. The god Hermes, in his capacity as guide of souls, could also play a role in leading the dead. Several different views of the afterlife circulated in the Greek world. The earliest description is found in Homer's epic poem the *Odyssey* (eighth century B.C.E.). Here the dead dwell in Hades, a dark realm beneath the earth ruled by the god Hades and his bride Persephone. The dead are shadowy beings leading a tedious existence without the physical strength or mental acuity they had on earth. Everyone, whether good or evil in life, shares the same fate in Hades.

Some prescribed rites with secret components, so-called mystery religions, seem to have offered the possibility of a happier afterlife to anyone who completed the initiation. Taking place in Eleusis, near Athens, the Eleusinian mysteries for Demeter, the goddess of grain, and Kore, Demeter's daughter, attracted people from all over the Greek-speaking world from at least the sixth century B.C.E. until the fourth century C.E., when the sanctuary closed. These rites were open to anyone who spoke Greek and was not a murderer.

Mythical figures might arrive at other destinations in the afterlife. Menelaus, the king of Sparta in the *Odyssey*, found a pleasant afterlife in the Elysian Fields, and according to the poet Hesiod (eighth century B.C.E.) the heroes went to the Isles of the Blessed. Other myths tell of people who disobeyed the will of Zeus, the king of the gods, and spent their afterlife in perpetual torment. For example, the hungry and thirsty Tantalos stands in a pool of water with fruit overhead, but both food and drink move out of his reach whenever he tries for them. The Greeks do not seem to have ascribed such fates, good or bad, to ordinary mortals.

Another common belief was that the dead were present at their graves. As part of their ritual grave visits, family members might bring offerings of food and drink. Some people even placed lead curse tablets into the graves of strangers to communicate with the underworld. These tablets asked the dead to carry the message to deities of the afterlife to magically harm the person designated on the tablet.

ROME

BY TOM STREISSGUTH

During the early years of the Roman Republic, established around 509 B.C.E., Romans generally buried their dead. Cremation became more common in the late republic. By the third century C.E. funeral customs were again changing from

cremation to burial. The spread of Christianity and the belief in an afterlife played an important role in this change, which was complete by the fifth century and the fall of the Western Roman Empire.

In ancient Rome many religious and social traditions were attached to the funeral ceremony, though much also depended on the status and wealth of the deceased's family. All Roman families served as guardians of their dead, dressing and otherwise preparing the body for the last rites. Personal belongings of the dead were collected for burning or burial with their owner. It was also traditional to place a coin in the mouth of the deceased in order to pay Charon, the mythical ferryman who brought the souls of the dead to the underworld. After preparation, the body was displayed so that family and friends could pay their last respects. In the case of a prominent citizen a public viewing known as a *laudatio* took place, during which a speaker recounted the deeds and virtues of the dead.

All funeral processions ended outside the city: as the bodies of the dead were believed to pollute the city's sacred precincts, cremation pyres and cemeteries always lay outside the walls. Borne on a litter, the body was followed by the family and other mourners, who often gathered at night to avoid unruly crowds. Musicians, dancers, and professional mourners sometimes took part, while members of the family, if they were well to do, might ride chariots or horses. It was customary for the members of important families to wear *imagines*, or ancestor masks, made of wax and representing members of the clan who had already passed away.

The procession ended at the cemetery and, for a cremation, at the funeral pyre. The body was then burned, along with gifts and offerings brought by mourners and the possessions of the dead. After a eulogy was given, a member of the immediate family gathered the ashes into an urn. Urns ranged from simple cloth bags or ceramic vases to more elaborate stone caskets or wood or metal chests. The urn was kept in the home, sometimes the centerpiece of a small display maintained in remembrance of the dead.

For burials the body was protected by a shroud or encased in a stone or wood coffin. To further preserve the body, it might be embalmed with gypsum. Proper burial was of utmost importance to the Romans; they believed an unburied body would be rejected by Charon and would wander forever. To allow a body to become food for birds or animals was the ultimate punishment for a criminal or traitor. Those who committed suicide by hanging themselves also sacrificed their right to a proper burial, and their bodies were left exposed to the elements.

Funeral societies known as *collegia* helped people prepare for their own funeral ceremonies. Individuals made contributions to their collegium, which then helped to arrange and pay for their funerals. If burial was used, members were entombed in a columbarium, an underground vault holding niches for the storage of funeral urns, which were marked by commemorative sculpture and plaques.

The poor were buried in mass graves, their bodies covered by simple shrouds or sacks. The wealthy used sarcophagi—coffins made of wood or stone—and often had elaborate tombs. Non-Christian Romans buried a wide variety of grave goods, including household items, jewelry, pottery, shoes, clothing, weapons, and even food and drink, intended to succor the dead on their journey to the next world. Images of the dead were painted on small wooden planks or carved into stone tombstones or memorials.

Elaborate mausoleums were constructed for aristocrats, with the emperors having striking monumental buildings raised to house their remains. The most famous is Hadrian's Tomb, later known as the Castel San Angelo, which still rises above the right bank of the Tiber River in Rome. Another monument, known as the Pyramid of Cestius, was built directly into the city wall at the southern edge of Rome and survives intact to this day. The pyramid, which contains a small burial chamber, was raised about 12 B.C.E., shortly after the Roman conquest of Egypt, when Egyptian monuments and religious cults were fashionable.

Christian Romans built underground catacombs, cities of the dead that protected the remains of thousands of people. The bodies were placed in sarcophagi and then set in niches in the walls of the narrow passageways. Each grave was marked by a stone slab carved with the deceased's name, age, and date of death.

The Romans believed that the dead sometimes wandered the underworld in a state of limbo. An unappeased or restless spirit, especially of someone who had died a violent or sudden death, could appear among the living to deliver important messages or warnings. To prevent such wanderings the Romans often cut off the head of the dead or weighted the body down with stones. All the same, "curse tables" created to invoke the powers of the dead to harm an enemy were common. During the Parentalia festival the spirits of dead parents are appeased with offerings made by their offspring. Romans also carried out rituals of appeasement to the dead during the Lemuria festival.

THE AMERICAS

BY KEITH JORDAN

The earliest evidence of ancient American burial rituals and the provision of grave goods to accompany the deceased into the afterlife dates beyond 8,000 years B.C.E., suggesting that these cultural traits came to the New World with the first peoples crossing from Asia. Burials from the Paleo-Indian Period (ca. 13,000–8000 B.C.E.) show a great variety of practices. At the Anzick site in Montana, ice age hunters buried two children accompanied by finely worked stone blades, bone tools, and red-ocher pigment believed to symbolize life, blood, and rebirth. At the Marmes site on the Washington coast people were cremating their dead by 8500 B.C.E. A man from a hunter-gatherer community was interred on the ledge of a sinkhole at Warm Mineral Springs, Florida, at around

the same time, taking with him a tool of his trade—the shell hook of a spear thrower (a rodlike implement used to provide greater impetus for throwing a spear or similar weapon). At Spirit Cave, Nevada, an early Native American was buried in a rock shelter, wrapped in reed mats and a rabbit-fur robe, some 9,400 years before the present.

This diversity of burial practices continued into the succeeding Archaic Period (8000–1000 B.C.E.). Prehistoric peoples in Florida buried their dead in wetlands some 6,000 years ago. At about the same time the fisherfolk of the Chinchorro culture of Chile preserved the bodies of the deceased, especially children, by elaborate methods of mummification, the oldest evidence for this practice anywhere. They skinned the bodies, tied the bones together to form a frame, and sometimes removed the muscles and internal organs. The corpses were then dried and stuffed with ash, the features modeled in an ash paste, and the skin was reattached and covered with a black mineral pigment or painted red with iron oxide. Apparently, like later Andean peoples such as the Incas, the Chinchorros felt a need to preserve the dead so as to keep them a part of the community and ensure their survival in the afterlife.

In most hunter-gatherer burials in the Americas up to historical times, grave goods tended to be similar for all members of the community, consistent with a lack of marked differences in social status. Conversely, an increased complexity of funerary practices and the appearance of luxury burial

Gold diadem, found in the Camaná valley, Peru, and dating to the first century C.E.; it would have been attached to a mummy. (© The Trustees of the British Museum)

goods reserved for a few individuals reflect the development of social ranking in ancient American societies.

In what is now the eastern United States, groups practicing a mix of hunting-collecting and limited agriculture participated in the Adena and Hopewell burial and ritual complexes (ca. 1000 B.C.E.–400 C.E.). These widespread traditions focused on the practice of burying selected members of the community in artificial mounds accompanied by elaborate gifts, many obtained via long-distance trade. At Adena sites in the Ohio Valley small communities built conical mounds, some as high as 70 feet, over circular or rectangular wooden structures that covered graves lined with clay or logs. The dead were buried in the flesh, as secondary burials (meaning that the bodies had been allowed to decay to bones elsewhere before burial here), or as cremations. The mounds grew in layers as burials were added over time. The honored dead, who may have achieved their status by their abilities as traders or shamans, were accompanied by slate pendants, stone smoking pipes, and copper beads, bracelets, and breastplates.

Hopewell peoples (ca. 200 B.C.E.–400 C.E.) in Ohio and Illinois erected mounds over log crypts or charnel houses that might contain a hundred or more cremations or burials. The honored dead took with them thousands of objects, including stone pipes, copper axes and ornaments, freshwater pearls,

shells traded from the Gulf of Mexico, and obsidian from the distant Rocky Mountains. At one Ohio site, the many dead interred in the mounds took with them a total of 500 copper ear ornaments for luxury adornment in the afterlife, while one individual was accompanied by 300 pounds of obsidian imported from the distant Rocky Mountains. At some Illinois sites crypts were reopened periodically for new arrivals and older remains shifted to other sections of the mound to make space.

In early agricultural villages in central Mexico of the Early Formative Period (ca. 1800–1200 B.C.E.) the dead were frequently buried under the floors of their houses, presumably to keep ancestors in contact with the living. At the same time the rise of centralized chiefdoms and states in Mesoamerica led to the creation of monumental tombs for elite figures. At the Olmec site of La Venta (1200–400 B.C.E.) on the Gulf coast of Mexico, a stone tomb covered by a clay platform contained the remains of two children, who might have been royalty or sacrificial victims—with jade jewelry and figurines, mirrors of polished iron ore, ritual bloodletting implements, and red cinnabar pigment. A crocodile-shaped stone sarcophagus at La Venta probably held an Olmec ruler, though the bones had disintegrated, leaving only the jade jewelry behind. At the Chalcatzingo site in Mexico local rulers allied to those of La Venta were laid to rest in stone crypts under their palaces

INSIDE A HOPEWELL BURIAL MOUND

Hopewell burial mounds often contain numerous burials, thousands of artifacts made from such exotic materials as Gulf coast shells, Lake Superior copper, silver, meteoric iron, freshwater pearls, and coal, along with evidence of several ceremonial constructions. For example, Mound 13 at the appropriately named site of Mound City, Ohio, a low, round pile of earth some 3 feet high and 70 feet across, was built over the remains of two successive ritual buildings. These buildings consisted of wooden poles driven into the ground and probably woven together to create an arched frame, which was then covered with sheets of bark, much like later Native American wigwams. Only the depressions left by the rotted poles survive to tell us of the buildings' shapes. The second building seems to have been a funerary shrine where the bodies of the honored dead were cremated and rituals performed. It was roughly square, measuring 40 by 42.5 feet. It contained a 4-by-6-foot crematory, identified by a depression or pit where the soil was baked by repeated fires. Four "altars"—small platforms of earth—supported groups of cremated human bones and deliberately broken objects, presumably meant to accompany the ancestors' spirits into the hereafter.

Treatment of the dead may not always have been orderly by modern Western notions. The structure also contained 13 piles of cremated remains and their associated ornaments of copper, mica, slate, and other materials, and in one central area of the floor fragmentary artifacts and cremated bones had been trampled into the earth by the feet of participants in the ceremonies. At some point before the wooden building was buried under the mound, this central space ceased to be used for rituals and its stomped-upon relics were covered with sand.

Two shallow graves had been dug into the floor, but one clearly overshadowed the other in splendor and importance. The excavators of the mound in 1920–1921, William Mills and Henry Shetrone, called the more elaborate burial the Great Mica Grave because it was completely lined with sheets of this silvery material, probably imported from the Carolinas. The 6.5-by-7-foot grave was surrounded by a raised circle of mica pieces and soil containing broken stone smoking pipes—perhaps the possessions of a Hopewell shaman—as well as ornaments of animal teeth and chunks of another silvery mineral, the lead ore galena. Within the shallow excavation the cremated remains of four people accompanied a copper ceremonial headdress. Before the whole building was entombed beneath the earth mound, a small mound was erected over the Great Mica Grave, and it, too, received a shiny covering of mica sheets.

or atop platforms, alongside similar mirrors and jade figures, beads, and ear ornaments. One ruler lay alongside the broken head of a stone statue—perhaps his portrait, ritually destroyed at his death.

Elaborate burials for ruling elites in Mesoamerica continued among the ancient Maya. At Tikal, Guatemala, kings of the Late Formative Period (ca. 400 B.C.E.–150 C.E.) were buried in vaults under stone temple platforms that served as shrines for their veneration as ancestors. Some of these tombs are decorated with wall paintings, and human sacrificial victims accompanied some rulers into the afterlife. Painted pottery (probably used for funeral feasts) and jade ornaments rested with the royal dead. (In one instance, the remains of the monarch lacked the skull and thighbones—presumably they were either taken as relics by his own people or removed as trophies by enemies on the battlefield. A stone mask might have served as a magical substitute for his missing cranium.) Later (ca. 250–550 C.E.) at Tikal the burials of kings Yax Nuun Ayin and Siyah Chan Kawil contain similar riches as well as ceramics imported from the distant city of Teotihuacán (near modern-day Mexico City). Yax Nuun Ayin, whose name means “First Crocodile,” even took a sacrificed caiman into the tomb with him—perhaps a very literal emblem of his name.

At Teotihuacán a wide range of burial practices prevailed during the city’s heyday (ca. 1 B.C.E.–650 C.E.). Deceased residents of palaces and apartment complexes often remained there in subfloor burials and cremations. Though royal tombs have not been identified with certainty, the great pyramids of the city may have covered the interments of its leaders. Over a hundred sacrificial victims, along with rich offerings of stone and shell weapons and ornaments, have been found

beneath the Pyramid of the Feathered Serpent. These people may have been killed to accompany the now-looted burial of an absolute ruler. In the Pyramid of the Moon, recently discovered high-status burials include individuals buried in a seated posture—a Maya trait—along with Maya-style jade jewelry, further evidence of links between Maya and Teotihuacán rulers.

Many early Peruvian cultures show evidence of preserving the dead so that they could be accessible for veneration and to give advice to their descendants. In Paracas arid conditions have preserved mummy bundles buried in the late first millennium B.C.E. Paracas tombs are of two types, probably partially overlapping in time. In one type the mummy bundles were stacked up in bottle-shaped tombs cut into bedrock. In the other type the bundles occupy abandoned structures, often with what appears to be a most important burial surrounded by remains of lower-ranked figures. The core of each bundle consists of a corpse seated in a fetal position on a basket. Layers of shrouds interspersed with grave goods—most frequently, beautifully woven and decorated clothing—surround the body. Single cloths can reach 85 feet in length. Gold jewelry, painted ceramics, and even the polished trophy skulls of enemies could also be included between layers of wrappings. Consequently the biggest bundles contain the richest burials and their numerous effects. Although the bodies are often well preserved and commonly called “mummies,” their condition is the result of the extremely dry environment and not of artificial embalming techniques.

Egypt

~ Herodotus: “Mummification,” from *The Histories* ~

The mode of embalming, according to the most perfect process, is the following: They take first a crooked piece of iron and with it draw out the brain through the nostrils, thus getting rid of a portion, while the skull is cleared of the rest by rinsing with drugs; next they make a cut along the flank with a sharp Ethiopian stone, and take out the whole contents of the abdomen, which they then cleanse, washing it thoroughly with palm wine, and again frequently with an infusion of pounded aromatics. After this they fill the cavity with the purest bruised myrrh, with cassia, and every other sort of spicery except frankincense, and sew up the opening. Then the body is placed in natrum for seventy days, and covered entirely over. After the expiration of that space of time, which must not be exceeded, the body is washed, and wrapped

round, from head to foot, with bandages of fine linen cloth, smeared over with gum, which is used generally by the Egyptians in the place of glue, and in this state it is given back to the relations, who enclose it in a wooden case which they have had made for the purpose, shaped into the figure of a man. Then fastening the case, they place it in a sepulchral chamber, upright against the wall. Such is the most costly way of embalming the dead.

If persons wish to avoid expense, and choose the second process, the following is the method pursued: Syringes are filled with oil made from the cedar-tree, which is then, without any incision or disemboweling, injected into the abdomen. The passage by which it might be likely to return is stopped, and the body laid in natrum

(continued)

(continues)

the prescribed number of days. At the end of the time the cedar-oil is allowed to make its escape; and such is its power that it brings with it the whole stomach and intestines in a liquid state. The natrum meanwhile has dissolved the flesh, and so nothing is left of the dead body but the skin and the bones. It is returned in this condition to the relatives, without any further trouble being bestowed upon it.

The third method of embalming, which is practiced in the case of the poorer classes, is to clear out the intestines with a clyster and let the body lie in natrum the seventy days, after which it is at once given to those who come to fetch it away.

The Middle East

~ *Descent of the Goddess Ishtar into the Lower World* ~

To the land of no return, the land of darkness,
Ishtar, the daughter of Sin directed her thought,
Directed her thought, Ishtar, the daughter of Sin,
To the house of shadows, the dwelling, of Irkalla,
To the house without exit for him who enters therein,
To the road, whence there is no turning,
To the house without light for him who enters therein,
The place where dust is their nourishment, clay their
food.

They have no light, in darkness they dwell.
Clothed like birds, with wings as garments,
Over door and bolt, dust has gathered.
Ishtar on arriving at the gate of the land of no return,
To the gatekeeper thus addressed herself:

“Gatekeeper, ho, open thy gate!
Open thy gate that I may enter!
If thou openest not the gate to let me enter,
I will break the door, I will wrench the lock,
I will smash the door-posts, I will force the doors.
I will bring up the dead to eat the living.
And the dead will outnumber the living.”

The gatekeeper opened his mouth and spoke,
Spoke to the lady Ishtar:

“Desist, O lady, do not destroy it.
I will go and announce thy name to my queen
Ereshkigal.”

The gatekeeper entered and spoke to Ereshkigal:

“Ho! here is thy sister, Ishtar . . .
Hostility of the great powers . . .”

When Ereshkigal heard this,
As when one hews down a tamarisk she trembled,
As when one cuts a reed, she shook:

“What has moved her heart [seat of the intellect] what
has stirred her liver [seat of the emotions]?”

Ho there, does this one wish to dwell with me?
To eat clay as food, to drink dust as wine?
I weep for the men who have left their wives.
I weep for the wives torn from the embrace of their
husbands;
For the little ones cut off before their time.
Go, gatekeeper, open thy gate for her,
Deal with her according to the ancient decree.”
The gatekeeper went and opened his gate to her:
“Enter, O lady, let Cuthah greet thee. . . .”

Now when Ishtar had gone down into the land of no
return,
Ereshkigal saw her and was angered at her presence.
Ishtar, without reflection, threw herself at her [in a rage].
Ereshkigal opened her mouth and spoke,
To Namtar, her messenger, she addressed herself:
“Go Namtar, imprison her in my palace.
Send against her sixty diseases, to punish Ishtar.
Eye-disease against her eyes,
Disease of the side against her side,
Foot-disease against her foot,
Heart-disease against her heart,
Head-disease against her head,
Against her whole being, against her entire body.”
After the lady Ishtar had gone down into the land of no
return,
The bull did not mount the cow, the ass approached not
the she-ass,
To the maid in the street, no man drew near
The man slept in his apartment,
The maid slept by herself.

The countenance of Papsukal, the messenger of the
great gods, fell; his face was troubled.

In mourning garb he was clothed, in soiled garments clad.
 Shamash [the sun-god] went to Sin [the moon-god], his father, weeping,
 In the presence of Ea, the King, he went with flowing tears.
 "Ishtar has descended into the earth and has not come up . . ." Ea, in the wisdom of his heart, formed a being,
 He formed Asu-shu-namir the eunuch.
 "Go, Asu-shu-namir, to the land of no return direct thy face!
 The seven gates of the land without return be opened before thee,
 May Eresbkigal at sight of thee rejoice!
 After her heart has been assuaged, her liver quieted,
 Invoke against her the name of the great gods,
 Raise thy head direct thy attention to the khalziku skin."

"Come, lady, let them give me the khalziku skin, that I may drink water out of it."
 When Ereshkigal heard this, she struck her side, bit her finger,
 "Thou hast expressed a wish that can not be granted.
 Go, Asu-sbu-iaamir, I curse thee with a great curse,
 The sweepings of the gutters of the city be thy food,
 The drains of the city be thy drink,
 The shadow of the wall be thy abode,
 The thresholds be thy dwelling-place;
 Drunkard and sot strike thy cheek!"
 Ereshkigal opened her mouth and spoke,

To Namtar, her messenger, she addressed herself.
 "Go, Namtar, knock at the strong palace,
 Strike the threshold of precious stones,
 Bring out the Anunnaki, seat them on golden thrones.
 Sprinkle Ishtar with the waters of life and take her out of my presence."
 Namtar went, knocked at the strong palace,
 Tapped on the threshold of precious stones.
 He brought out the Anunnaki and placed them on golden thrones,
 He sprinkled Ishtar with the waters of life and took hold of her.
 Through the first gate he led her out and returned to her her loin-cloth.
 Through the second gate he led her out and returned to her the spangles of her hands and feet
 Through the third gate he led her out and returned to her the girdle of her body, studded with birth-stones.
 Through the fourth gate he led her out and returned to her the ornaments of her breast.
 Through the fifth gate he led her out and returned to her her necklace.
 Through the sixth gate he led her out and returned her earrings.
 Through the seventh gate he led her out and returned to her the large crown for her head.

Asia and the Pacific

~ A Vedic Funerary Hymn from the Rig-Veda, Book 10 ~

1. Go hence, O Death, pursue thy special pathway apart from that which gods are wont to travel. To thee I say it who hast eyes and hearest: touch not our offspring, injure not our heroes.
 2. As ye have come effacing Mrityu's footstep, to farther times prolonging your existence, May ye be rich in children and possessions, cleansed, purified, and meet for sacrificing.
 3. Divided from the dead are these, the living: now is our calling on the gods successful

We have come forth for dancing and for laughter, to farther times prolonging our existence.
 4. Here I erect this rampart for the living, let none of these, none other reach this limit. May they survive a hundred lengthened autumns, and may they bury Death beneath this mountain.
 5. As the days follow days in close succession, as with the seasons duly come the seasons,

(continued)

(continues)

As each successor fails not his foregoer, so form the lives of these,

O great Ordainer

6. Live your full lives and find old age delightful, all of you striving one behind the other.

May Tvashtar, maker of fair things, be gracious, and lengthen out the days of your existence.

7. Let these unwidowed dames with noble husbands adorn themselves with fragrant faint and unguent. Decked with fair jewels, tearless, free from sorrow, first let the wives ascend unto the place .

8. Rise, come unto the world of life, O woman: come he is lifeless by whose side thou liest.

Wifehood with this thy husband was thy portion, who took thy hand and wooed thee as a lover.

9. From his dead hand I take the bow he carried , that it may be our power and might and glory
There art thou, there; and here with noble heroes may we o'ercome all hosts that fight against us.

10. Betake thee to the lap of the earth the mother, of earth far-spreading, very kind and gracious.

Young dame, wool-soft unto the guerdon-giver, may she preserve thee from Destruction's bosom.

11. Heave thyself, Earth, nor press thee downward heavily: afford him easy access, gently tending him. Earth, as a mother wraps her shirt about her child, so cover him.

12. Now let the heaving earth be free from motion: yea, let a thousand clods remain above him. Be they to him a home distilling fatness, here let them ever be his place of refuge.

13. I stay the earth from thee, while over thee I place this piece of earth. May I be free from injury. Here let the Fathers keep this pillar firm for thee, and there let Yama make thee an abiding place

14. Even as an arrow's feathers, they have laid me down at day's decline.

My parting speech have I drawn back as 'twere a courser with the rein.

Rome

~ Homer: *The Odyssey*, Book XI: 18-50 ~

Odysseus speaks:

"Thither we came and beached our ship, and took out the sheep, and ourselves went beside the stream of Oceanus until we came to the place of which Circe had told us.

"Here Perimedes and Eurylochus held the victims, while I drew my sharp sword from beside my thigh, and dug a pit of a cubit's length this way and that, and around it poured a libation to all the dead, first with milk and honey, thereafter with sweet wine, and in the third place with water, and I sprinkled thereon white barley meal. And I earnestly entreated the powerless heads of the dead, vowing that when I came to Ithaca I would sacrifice in my halls a barren heifer, the best I had, and pile the altar with goodly gifts, and to Teiresias alone would sacrifice separately a ram, wholly black, the goodliest of my flocks. But when with vows and prayers I had made supplication to the tribes of the dead, I took

the sheep and cut their throats over the pit, and the dark blood ran forth. Then there gathered from out of Erebus the spirits of those that are dead, brides, and unwedded youths, and toil-worn old men, and tender maidens with hearts yet new to sorrow, and many, too, that had been wounded with bronze-tipped spears, men slain in fight, wearing their blood-stained armor. These came thronging in crowds about the pit from every side, with a wondrous cry, and pale fear seized me. Then I called to my comrades and bade them flay and burn the sheep that lay there slain with the pitiless bronze, and to make prayers to the gods, to mighty Hades and dread Persephone. And I myself drew my sharp sword from beside my thigh and sat there, and would not suffer the powerless heads of the dead to draw near to the blood until I had enquired of Teiresias."

► drama and theater

INTRODUCTION

The impulse for people to take part in performance art runs deep into human history. While early ancient peoples left behind no drama as the term is understood in modern life, archaeological evidence shows that they engaged in ritual performances, often dance, in connection with major life events. The nature of these performances was often dictated by geography. People who survived by cultivating crops, for example, took part in ritual performances connected with planting and harvesting. Those who lived in regions where they survived as hunters took part in ritual performances in connection with successful hunts. Such ritual performances also occurred to celebrate victory in battle as well as to celebrate births and marriages, mourn the dead, or ensure fertility. These early dramatic performances, however, had no plot, character development, and the like. They tended to be spontaneous expressions of the community in response to the events that defined their lives.

Much early theater had a strong religious element. Shamans, for example, often directed ritual performances. These performances, enacted out of doors, were designed to honor or appease a god. They often illustrated the culture's cosmology, or beliefs about the origin of the universe. They became a way of preserving and transmitting the culture's values and norms as well as its history, myths, and legends. In some cases, such as India, the earliest dramatic performances depicted events recorded in sacred texts. It is no exaggeration to say that in many cultures, drama and theater were the culture's history and religious "textbooks" for youngsters and others in the community.

More formalized dramatic presentations became common in ancient India, Japan, and China. These performances, which were highly ritualized and stylized and with elaborate costumes, makeup, masks, and other conventions, were often done at court for the entertainment of royalty, and Asian theatrical performances still reflect these ancient roots. In Asia, too, the arrival of roving bands of performers was often a highly anticipated event in communities.

The development of theater as the word is understood in modern times began with the ancient Greeks and Roman. While the performances of the Greeks were still highly stylized, they incorporated many of the conventions of drama

that modern theatergoers expect, including costumes, sets, dialogue, character development, conflict, and a climax. Performances took place outdoors, but the theaters in which they took place resembled modern theaters, with a stage area, a backstage area, and rows of tiered seating for spectators. Playwrights competed for honors with cycles of plays, and theatrical festivals were major events. Many of the plays written by the ancient Greeks, including Aeschylus, Sophocles, and Euripides, are still performed on modern stages, and their texts, such as Sophocles' *Antigone* and *Oedipus Rex*, remain standards in the study of literature. The Greeks, too, began to distinguish between tragedies and comedies, with the comic plays of Aristophanes occupying a major place in the history of comedy. Such plays as satyr plays, with their depictions of drunkenness and debauchery, provided comic relief for more serious tragic performances. The ancient Romans continued the Greek tradition with formal theatrical productions. The Romans performed Greek plays, but in time they produced their own playwrights, including Plautus and Terence, whose comedies are still produced.

AFRICA

BY MICHAEL J. O'NEAL

The words *drama* and *theater* in modern life evoke specific responses. A person is likely to imagine a theater with a stage, lighting, and rows of seats for spectators. Dramatic productions in modern life—and among some ancient peoples as well—are based on a script, usually one written by someone other than the performers. Theatergoers bring certain expectations to a dramatic performance, expectations about how the story progresses onstage primarily through dialogue between characters. They expect to see a linear performance, where the story unfolds in a logical progression from beginning to end. They anticipate a resolution to the story that provides them with some measure of satisfaction.

Few of these expectations would apply to the drama and theater of ancient Africa, though in the absence of surviving written texts, it is difficult for historians to reconstruct the nature of ancient African theatrical performances. To do so, they often have to extrapolate backward from later times, finding the roots of later theater in the practices of ancient peoples. In some cases archaeological findings can shed light on drama as it was performed by ancient Africans.

The “stage” for an ancient African theatrical performance could be anywhere, including a private home. Most likely, however, theater was conducted in open-air venues where members of the community could gather. In some parts of Africa the baobab tree, a tree of great symbolic significance, continues to serve as a gathering place for the community. The only lighting was that provided by fires and torches for presentations after dark. The “script” for an ancient African theatrical presentation was probably in most cases largely improvised, though such scripts could be based on traditions, folklore, and legends that had been passed down through many generations.

In ancient Africa there was a close link between theater and storytelling. An important member of the community in most African societies was the storyteller, often referred to as a *griot*, who acted as a repository, a kind of living museum, for the origins, history, and genealogy of the community. Such a person would have learned mythic stories about the community and then passed them down orally in dramatic presentations to his audience. Such stories could include accounts of creation, the origins of the people, the lineages of kings, the origins of animals and the stars in the sky, and perhaps great victories that were won in battle by the community's ancestors. None of these stories would have been new to the audience. These stories were part of the shared cultural inheritance of a people, so they already knew the characters and outcome. But like modern theatergoers, they judged the quality of the performance on the level of drama and suspense that the storyteller was able to build. Sharing an unwritten text over many generations socialized people into their community and forged social bonds.

The “actors” of ancient African theater were not trained professionals but could include anyone from the community. Again, storytellers, who could craft stories and present them with dramatic flourishes, incantations, repetition, and inflections all designed to capture the attention of the audience, could be considered among the earliest actors. It is likely, however, that members of the community participated in the productions through singing and dancing. In this sense, theatrical productions took on characteristics of spontaneous community celebrations. Dance in particular was probably an important part of a theatrical performance. In the absence of a text, the movement of people to the rhythms of drums and other musical instruments allowed people to take part in their shared cultural heritage and celebrate events—a harvest, a successful hunt—with their community. Dance, music, and song, including “call and response” singing, allowed people to express and reenact the community's deepest cultural longings and beliefs and forge a sense of unity and togetherness.

The most important actors were probably shamans and other religious figures. While some drama in ancient Africa had secular purposes and themes, it is difficult to distinguish the secular from the religious in ancient African life, for daily activities almost always had some sort of religious significance. This religious significance was often tied to the seasons and the cycles of the natural world. Religious meaning was found in virtually everything, from a storm to the emergence of crops to a flood and so on. Thus, just as modern dramatists try to interpret the complexities of life by distilling them into a two- or three-hour presentation, so African shamans and diviners tried to interpret their world through religious rituals with strong theatrical elements.

A good example of this kind of ritualistic performance is provided by the San people, often referred to as the Bushmen. Archaeologists had long assumed that the oldest ritual site in Africa dated back to about 40,000 years ago. A re-

cent find in northwest Botswana has pushed this date back some 30,000 years. There, archaeologists discovered a kind of cave that was carved into the rock by ancient Bushmen. The cave, along with the surrounding rock face, is a remarkable artistic achievement, for it depicts a python, reflecting the ancient Bushmen's creation myth that said that humans descended from pythons and that stream and riverbeds were made as the python crawled around in search of water. The cave, then, was a religious site, but the distinction between religious observance and theater among ancient Africans was no doubt one that they would not have recognized. Archaeologists speculate that as people visited the cave, the shaman would have retired into a secret chamber, where he could see the visitors. He then could have spoken to people, making it seem as though the words came from the mouth of the python. Two small shafts would have allowed the shaman to disappear. Thus, if archaeologists are correct, the cave took on elements of performance and theater, giving visitors a visual representation of the culture's creation myth. Numerous sacred sites such as this can be found throughout Africa. While their primary purpose was religious, the enactment of that religion was distinctly a form of theater.

Seasonal festivals, too, were an occasion for theatrical and ritualistic performance. Ancient Africans' lives were dependent on the cycles and changes of the natural world. Again, because religion imbued every aspect of their lives, ancient Africans would have seen the arrival of a harvest as an important event, a sign that the gods favored them. The modern Christmas-season festival called Kwanzaa has its roots in these types of ancient celebrations. Kwanzaa, contrary to widespread belief, is not a replacement for Christmas but rather a harvest festival. The rituals of renewal that surround Kwanzaa have their roots in ancient African harvest celebrations.

EGYPT

BY EMILY JANE O'DELL

Whether ancient Egypt even had a distinct dramatic form and style has been debated for many years. Egypt provides nothing in any way comparable to the archaeological and textual evidence we possess for the drama and theater of the Greeks. There are no known theatrical structures or play scripts written with the sole intention of secular entertainment. In fact, there are no dramatic scripts at all, unless one considers certain religious rituals and religious texts as blueprints for religious drama.

Neither the literature nor the tomb reliefs of ancient Egypt make any reference to the acting or theatrical profession. Since it was customary to inscribe the title or profession of a tomb's owner, the lack of evidence for an acting profession is notable and supports its nonexistence. Ancient Egypt did, however, have a rich oral tradition, and many of the myths and much of the literature were passed down orally from generation to generation. We do not know exactly how these

performances and recitations of texts were organized, but it is probable that they involved a dramatic street performance of sorts. One Egyptian story in particular, "The Contendings of Horus and Seth," thought to have been written during the New Kingdom (1550–1070 B.C.E.), reads very much like a play because of its quick changes from scene to scene and because the many different characters speak to each other in a way that is highly reminiscent of play dialogue.

The question of ancient Egyptian drama's existence is complicated by how we define *drama*. Drama can take many different forms, and theatrical styles are determined and shaped by the culture, ritual, religion, language, and ceremonies from which they emerge. Thus it can be very difficult to say what constituted or did not constitute drama in one culture or another. For example, some scholars focus on religious ritual as performance. Ancient Egyptian culture was heavily steeped in religious ritual; mythology and religious beliefs

and practices were inseparable from daily life. Ancient Egyptian rituals were very theatrical, taking place in dark temple rooms with incense and recitations of sacred texts. Spells were read aloud, which is theatrical in a sense, but whether it qualifies as drama is debatable; there is a difference between ritual and more traditional forms of drama that presuppose a script, actors, and predetermined stage actions.

Egyptologists do, however, call certain religious texts “dramatic texts.” Known from papyri and temple walls, these texts seem to be concerned with re-creating actions of the gods from when time began. They were probably not used frequently or on a daily basis but rather at commemorative events and festivals where their purpose was to inspire the triumph of order and balance over chaos. These texts were not internally focused. They show no interest in human psychology, motivations, relationships, or emotions. These “dramatic texts” are extremely fragmentary and incomplete, which may or may not have been intentional. They would have been read and acted out by the temple priesthood both within and outside the temple buildings. One wall of the Ptolemaic Dynasty (304–330 C.E.) temple at Edfu contains such a text, known as the “Triumph of Horus.” It features a linear plotline, there seem to be stage directions, and the reliefs of the different deities that accompany the text offer evidence of what the ritual reenactment may have looked like.

There are also dramatic ritual texts that celebrate the mysteries of the god Osiris. These would have been performed at Abydos, the supposed burial site of Osiris and thus the most sacred place in Egypt. The Osirian rituals were performed at Abydos from 2500 to 550 B.C.E. One papyrus has stage directions calling for two beautiful women to kneel on the ground and bow their heads. Another gives similar stage directions for the women playing Isis and Nephthys in a ritual for the temple of Osiris Khentimentiu at Abydos. This papyrus also specifies that the women were to be virgins without any hair at all on their bodies, other than wigs, to signify purification. The papyrus shifts back and forth from first person singular to first person plural (from “I” to “we”), suggesting that sometimes one of the reciters spoke alone and other times the two spoke in unison. These virgins, holding tambourines, would read the stanzas of the text in the presence of the deities. It can be inferred that the tambourines were used to accompany this recitation.

There are other so-called dramatic texts that focus on other aspects of ancient Egyptian mythology and history. For example, the so-called Memphite Drama relates the myth of Osiris’ death and resurrection and the crowning of his son Horus as his successor. The Dramatic Ramesseum Papyrus features a ceremonial play composed to celebrate the accession to the throne of Sesostri I of the Twelfth Dynasty. The text is accompanied by illustrations at the bottom of the papyrus that show the pharaoh appearing as Horus. The Egyptian Book of the Dead might also be considered a dramatic text. It is composed of many spells the dead must recite as they move through the afterlife. Many of these ut-

terances are dramatic in form, with the gods asking questions that the dead must answer from the Book of the Dead in order to pass to the next station in the afterlife. This call-and-response format reads very much like dialogue, and one could argue that Egypt’s most theatrical drama was reserved for the dead, not the living.

THE MIDDLE EAST

BY LYN GREEN

Theater as we understand it in modern Western culture does not seem to have existed in many societies of the ancient Near East. This does not mean that performance art—and especially dance—did not play an important role in these civilizations. In fact, in ancient Phoenicia one of the gods bore the name Baal Marqod, or “Lord of the Dance,” perhaps because he was worshiped through dance. Dance was an important part of the worship of many other gods and goddesses as well. At different times and in different places it seems to have been more common for one sex to dance within the temples than the other. In Iron Age Israel, for example, there seem to be more mentions and depictions of women and girls dancing than of men.

Dances were also key parts of seasonal festivals associated with agriculture, where they reenacted important myths. Some dances could put the participants into a trancelike state in which they might receive religious visions. Dance was closely associated with what anthropologists call “life crisis” occasions such as birth, death, weddings, and coming of age. It was especially closely linked to sexuality and courting. From around the 15th and 14th centuries B.C.E. there are representations of naked dancing girls done in a style strongly influenced by contemporary Egyptian art. Dance was even used in magic or healing ceremonies, both in and out of the temple. Texts from ancient Mesopotamia describe personnel from the temple of the goddess Ishtar as being part of rituals in which dancers helped drive away the demons of illness and possession.

Performances in which dancers mimed important activities such as hunting or played the roles of gods or goddesses might be considered the ancient Near Eastern form of theater. One of the most common myths to be acted out seems to have been the “Sacred Marriage.” This myth, which tells of the marriage of a fertility goddess, symbolizes the need to ensure a good harvest and bountiful offspring for herds and flocks. Although it may have been acted out between a high priestess and high priest or between a queen and a king, musicians and dancers were always involved in the ceremony.

Dance could also be used to celebrate great occasions such as victory in battle. On the walls of the palace of Nimrud in northern Iraq the soldiers of an Assyrian king are shown dancing to harps and drums while waving the decapitated heads of their enemies. The Old Testament contains numerous mentions of dances in honor of military victory. For example, after the escape across the Red Sea Moses’ sister

Lapis lazuli cylinder seal of Sin-ishmeanni, Old Babylonian, about 19th century B.C.E., showing Sin-ishmeanni being brought into the presence of the king; the dwarf figure in the center is thought to represent a dancer in rituals or entertainments. (© The Trustees of the British Museum)

Miriam led the women in celebratory dances. Virtually all depictions of kings or other high-status persons drinking or feasting also show musicians and dancers.

Festivals and especially weddings were often the occasion for group dances. Ancient Jewish texts such as the Talmud describe men dancing before the bride at a wedding. Cylinder seals from the early third millennium B.C.E. show figures with linked hands apparently dancing in a circle, and wedding dancers in present-day Syria have been observed doing very similar dances. The arms of the figures on the cylinder seals are raised to about shoulder level, and this seems to be a common position in representations of dancers from throughout the ancient Near East. From the earliest images onward the dancers in these groups are almost always shown as being all alike in posture, stature, and dress, perhaps in order to stress the unity and equality of the performers.

One type of performer common to many ancient Near Eastern cultures was the “dancing dwarf” (a name bestowed by modern scholars). The ancient images of these performers depict male musicians who, unlike most other figures in the art of their cultures, are shown frontally. They are naked and appear very short and bowlegged. Until recently, scholars interpreted these images as depicting individuals with the genetic growth disorder known as achondroplasia, but some art historians now suggest that the bowlegs and short stature are merely artistic conventions intended to show that the men are dancing while they play their instruments. This possibility reflects the fact that there is often little distinction between musician and dancer in ancient Near Eastern art. One ivory from Bronze Age Canaan shows a woman

with a tambourine dancing energetically in front of seated man of high status. Her knees are bent and her head turned to one side as the artist tries to indicate her motions. The conventions of ancient Near Eastern art made it difficult for artists to depict rhythmic movement. Other representations from ancient Mesopotamia show male dancers poised on one leg, with the other one bent, perhaps to indicate a pirouette. Other dancers, such as those shown on an ancient Hittite terra-cotta jar, are shown leaping high in the air with bent knees.

It seems that in the ancient Near East much dance was done by professionals, performing either alone or in groups. We know that in the ancient Canaanite city of Lachish dancers belonged to a guild, and performers in other cultures probably did too. These guilds would have provided training for performers. Nonprofessionals might also dance on specific occasions. At some ceremonies held by the Hittites of ancient Anatolia even the king and queen might be called upon to perform. However, it was much more common for royalty and those of status to watch than to participate. In the art of every culture of the ancient Near East from Sumer to Persia the highest-ranking individuals are often recognizable as the audience for dance of various kinds.

Dance in these ancient cultures had little in common with modern-day notions. For example, there do not seem to have been any dances where a single man and woman would dance together as they do in modern ballroom dancing. Although dancers could express themselves through their art, the goal of ancient performance was not the expression of an individual’s personality but communicating group solidarity, religious belief, or social status.

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD

Ancient peoples throughout the Asian and Pacific region used drama and theater to re-create the past, recount history, and explain legends. Over time these enactments became formalized into great pieces of work like the Mahabharata, the Ramayana, and the life of Buddha and other important figures. Although both the Mahabharata and the Ramayana originated in India, they were adapted throughout Southeast Asia and farther afield. Similarly, Chinese stories and Buddhist epics were used to illustrate the triumph of good over evil, with subplots offering examples of love and betrayal, battles won and lost, skill and stupidity.

Drama in the Indian subcontinent was overshadowed by the two great epics: the Mahabharata and the Ramayana. The former surrounds the clash by two groups of cousins fighting for supremacy, and includes within it the Bhagavad Gita, the most important Hindu text. The latter is about the life of King Rama and his efforts to free his wife, Sita, who is captured by demons and taken to the island of Lanka (mod-

A 19th-century Indian painting depicting the climax of the epic the *Ramayana*, where the hero Rama defeats the 10-headed demon Ravana. (© The Trustees of the British Museum)

ern-day Sri Lanka). The Mahabharata, consisting of 100,000 couplets, is about seven times longer than the Greek *Iliad* and *Odyssey* combined. Although performances of the entire Mahabharata or Ramayana took place, many groups of actors performed only the more famous scenes as they traveled from one village to another. Indian dance was also highly stylized and has been traced back to the theory put forward by the ancient Indian sage Natya Shastra of Bharata Muni in about 400 B.C.E. Written in Sanskrit, this work gives, in vivid detail, the precepts for actors and also playwrights. For the latter there are nine major *rasas* ("emotional responses") which can be used: love, anger, fear, heroism, terror, comedy, pity, disgust, and awe. However, one must always dominate any given play. The costumes, the makeup, and the types of dance are also listed precisely.

In China, at the court of the emperors, the theatrical performances tended to be long and formal. The Chinese opera of today, which often covers ancient stories, had its origins in about 350 C.E. but did not attain its state of refinement until perhaps 300 years later. During the Shang Dynasty (1500–1045 B.C.E.) court entertainers not only amused the emperor and his retinue but also performed ceremonies to protect the harvest and ward off evil spirits. The Imperial Music Bureau was first established by the emperor Qin Shih Huang (r. 221–210 B.C.E.) and was expanded by the Han emperor Wu Di (r. 141–87 B.C.E.). As well as being played at court for its own sake, music often provided accompaniment for theatrical performances.

Throughout the Chinese countryside bands of entertainers wandered from village to village telling stories and getting ideas for new ones. Some tombs from the Han Dynasty (202 B.C.E.–220 C.E.) are decorated with scenes of entertainers involved in acrobatics, mime, and other drama activities. As shown in Chinese classical stories, these performers were always much awaited by villages, and the roles of actors, acrobats and professional musicians in Chinese society were always highly regarded. In the Han Dynasty capital there were special horse-drawn carriages for actors. However, on the stage many actors lost most of their individuality, wearing very heavy makeup or using masks. Actors were always male, with female parts often played by young men or teenage boys. There were also groups from China's minority peoples, especially from Central Asia, who traveled the countryside telling stories of life from their point of view and introducing their customs in towns and cities throughout China. Most drama performances were accompanied by music, and it was common for groups of musicians to travel with actors.

In Southeast Asia most early drama and theater was Indian in origin, with some local variations. In Cambodia the Naga snakes would make appearances; these were supernatural beings with the attributes of both humans and snakes. While most theatrical performances drew heavily from the two Indian classics, the Mahabharata and the Ramayana, other legends were common, such as that of the birth of Cam-

bodia through the union of the daughter of a dragon king and the Indian Brahmin Kaudinya. The Mahabharata and especially the Ramayana also proved popular in Java (in modern-day Indonesia). The Javanese variations to the story can still be seen in Bali, though the most popular theater there has long been connected with the mythological Barong, the “king of the spirits.” In Southeast Asia, Vietnam was an exception because it drew more heavily from Chinese stories. Japan had similar traditions of extensive formalized performances for the court and wandering teams giving theatrical performances in towns and villages throughout the country. The earliest surviving Japanese theatrical scripts date to the 300s C.E.

Throughout the Pacific, Polynesian theater and drama often had the same themes as some of those in Asia but tended to focus more on long sea voyages, floods, the coming of “strange” peoples, and other related historical themes. In most cases these stories have come down to the present day in oral tradition. Unlike the tales of the great cultures of Asia those of the Aborigines of Australia essentially focus on the environment and geography instead of history. The Aboriginal “dreamtime” stories, which have been passed down in tribes over 40,000 years, tend to relate to providing explanations for land features. They explain how particular mountains or rivers formed, the color of natural features, and the seasons. As the oldest surviving culture in the world, the Aborigines, with their nonhierarchical society, seem to show that the origins of drama and theater lie in something like their corroborees, festivities at which they gather, sometimes from considerable distances, to celebrate important occasions with (usually nocturnal) songs and dancing, both often having complex geographical themes.

EUROPE

BY MICHAEL J. O'NEAL

For a number of reasons very little is known about drama, theater, and performance arts in ancient Europe. One reason is the low rate of literacy among the ancient Europeans. In contrast to ancient Greece, Rome, China, and other cultures, the civilizations of ancient Europe produced few people who could read and write, with the result that literature was transmitted orally rather than in written form.

Another problem was the social disruption caused by war, conquest, and migrations. The ancient Celts, for example, migrated westward, probably from western Russia, and became the dominant culture of central Europe. The Celts, though, were conquered by the Germanic and Scandinavian peoples from the north while at the same time feeling pressure on the south from the Roman Empire, which used its power to eradicate cultures and customs in the conquered territories. (Much of what little drama and theater is known from ancient Europe existed only because of the Romans.) Under these conditions, it would be surprising if much in the way of an indigenous dramatic literature survived.

Much of what historians know, or theorize, is based on fragmentary evidence, hints, and inferences, but it is likely that performance art in ancient Europe paralleled that in other parts of the world, where the record is more complete. For example, a good deal of performance art was probably conducted as part of ritual religious observances. Among the Druids, the religion of the ancient Celts, priests and shamans controlled the ritual observances of the people and were often regarded as having magical powers. They also functioned as teachers for the community. These priests conducted ritual observances, often in conjunction with such events as the equinoxes and solstices. Like most northern cultures, the Celts saw the arrival of spring or of the shortest days of winter as important events, recognized in communal ritual celebrations (celebrations that gave rise to many modern traditions surrounding such holidays as Christmas and Halloween). It is likely that these communal celebrations took on features of a dramatic performance.

One form of performance art that probably was widely practiced was the reading or recitation of myths, legends, and epic poems. Historians know that a considerable number of such works of literature existed, though how many were written down is anybody's guess, for few texts survive and even those are mostly fragments. It is known, however, that many later European epics—from Scandinavia, the Germanic peoples, and the Celts—preserved literary traditions, characters, and story lines from centuries before. Most of these works were transmitted orally, passed down from one generation of storytellers to another. Thus it is likely that some medieval narratives were developments of narratives from the ancient world. A good example is the Edda, a group of medieval folktales from Old Norse mythology whose origins no doubt extend into the mists of the ancient past.

The role of the bard, or oral storyteller, was not acquired in a haphazard fashion. The performance of these tales, myths, and legends was conducted for the aristocracy, and the bards constituted the libraries and museums of the time, guarding the culture. Most bards underwent intensive training for their role, and over time they acquired a repertoire of tales, including tales about feasts, deaths, adventures, cattle raids, battles, and visions.

One example of a relatively complete text that may have served as the script for a dramatic performance is the *Skírnismál*, a Scandinavian love poem of uncertain date but generally believed to have been written in pre-Christian times. The poem is set in dramatic form, with dialogue between the characters. The basic plot is simple: Freyr dispatches his servant Skírnir to court for him the maiden Gerdr, the daughter of Gymir, a giant. Skírnir promises gifts, but to no avail, so he finally uses threats to persuade Gerdr to meet Freyr in the grove called Barri, where the two will be married.

Some scholars believe that the *Skírnismál* is a surviving example of a flourishing tradition of ritual Scandinavian drama from pre-Christian days. It is believed that performers created effigies of gods and goddesses for use in these pro-

ductions and that two or more actors performed the speaking parts, perhaps with a narrator delivering the narrative parts of the drama. A chorus wearing animal masks may have added to the production. These plays were probably performed in temples or other sacred places, perhaps at yearly festivals. Some scholars see the *Skírnismál* and other ritual dramas as helping communities deal with the overwhelming forces of nature. For the participants ritual drama and performance would have reinforced community taboos, helped ensure a successful harvest, provided support in the cold and snow of winter, and celebrated the return of spring. In short, such performances were a kind of religious ritual to enact humans' relationship with the gods.

Dance, too, had a theatrical function. The best way historians have of studying dance from the ancient world is through pottery and artwork that depicts people dancing. It is likely that the earliest forms of dance were spontaneous celebrations of a successful hunt or marked other important occasions in the life of the community. Later more formalized dances appeared, as pictured, for example, on pottery from Romania dating to 4000–3000 B.C.E. In most cases these depictions show line or circle dances. Interestingly, in the Balkans one village dance event was called the Hora, and it still takes place in the region on Sundays. Dance may also have helped to induce trancelike states in religious rituals.

GREECE

BY JOHN THORBURN

The ancient Greeks enjoyed several kinds of dramatic entertainment, including tragedy, comedy, and satyr plays. How, why, and when such performances began is uncertain, but by the fifth century B.C.E. they were well established. Our knowledge of Greek drama comes primarily from about four dozen plays by five Athenian playwrights: the tragedians Aeschylus, Sophocles, and Euripides and the comic poets Aristophanes and Menander. Greek dramas had a religious element and honored Dionysus, best known as the god of wine, and performing plays apparently evolved from some aspect of his worship.

Besides their religious aspect, ancient theatrical performances often occurred as part of a competition. In Athens the two festivals with dramatic competitions were the Lenaia and the far larger and more important City Dionysia. At the Lenaia two tragedians, each staging two plays, competed, and two comic poets were judged based on a single play each. At the City Dionysia three tragic poets each put on three tragedies and a satyr play, whereas five comic poets each put on a single play.

The Greeks viewed performances outdoors and during the day. In the earliest times spectators might sit on the bare ground of a hillside or on temporary wooden bleachers. By the fourth century B.C.E. theaters built of stone were commonplace. They varied in size, but the Theater of Dionysus in Athens seated well over 10,000 spectators. The action of

The figure of Silenus, the mentor of Dionysus, the god of plays; the figure was placed at the front of the stage in the Theater of Dionysus, sitting at the foot of the Acropolis in Athens. (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

the plays occurred both on a rectangular stage and in front of it within the circular orchestra (literally “place for dancing”). At the rear of the stage stood a buildinglike structure, the *skene*, with one to three doors. The *skene* might represent a house, palace, military tent, or even a cave. Because the actors performed only in front of the *skene*, playwrights usually had to use a character to describe events that were supposedly occurring inside. Occasionally, though, dramatists used a wheeled platform to bring something or someone out from within the *skene*. Sometimes characters (especially divinities) appeared on the roof of the *skene* or were suspended above the stage by means of a crane called the *mechane*. Over time stages became more elevated and deeper, and the *skene* increased from one to two stories.

Music from a pipe player accompanied dramas, and the performers—all of whom were men—took roles as individual characters or members of the chorus. The Greek word *choros* means “dance,” and besides speaking, chanting, or singing their lines, the chorus members also danced. Comedies had 24 chorus members; early tragedies and satyr plays had 12,

but that number later increased to 15. Contrasting with the relatively large number of performers needed for a chorus, Greek playwrights usually had no more than three actors to perform all the speaking roles. Because a play might have more than three speaking parts, actors often had to play more than one. One reason that actors could perform both male and female roles is that they wore masks. Evidence from ancient sculpture and pottery indicates that these masks had lifelike features and hair. Masks for comedy and satyr plays often had humorous or grotesque touches such as highly arched eyebrows or grinning mouths.

The players wore costumes appropriate for their roles (for example, as kings, queens, warriors, or mourners). Euripides became notorious for dressing his downtrodden heroes and heroines in ragged clothing. The costumes worn in comedies of the fifth century B.C.E. must have been spectacular. During this period spectators saw choruses dressed as ants, birds, clouds, wasps, and many other improbable beings or creatures.

Tragedies rarely dealt with historical subject matter—Aeschylus' *Persians* is an exception—but instead were usually derived from mythology. Tragedians dramatized events from the lives of mythical figures such as Achilles, Agamemnon, Medea, Oedipus, and Orestes but used these mythological events as a platform for examining issues that concerned their audiences, such as war, the nature of justice, relationships between the sexes, and the relationship of human beings to the gods.

At the City Dionysia playwrights concluded their dramatic offerings with a satyr play, satyrs being creatures usually depicted as part human and part goat or horse. In satyr plays the chorus typically dressed as satyrs. Because satyrs were very fond of wine and sexual activity, the plays often relied heavily on jokes about wine and drunkenness, as well as sexual references. Our knowledge of these works is limited because only one complete satyr play (Euripides' *Cyclops*) has survived. We do, however, possess about 400 lines from Sophocles' *Trackers* and short fragments from many other satyr plays.

Comedy (from the Greek word *komoidia*, "revel song") varied more than tragedy in its subject matter and content. Comic poets sometimes put a humorous spin on mythological figures or events, but in the fifth century B.C.E. the Athenian comic poets also poked fun at local politics and politicians and at the social or intellectual trends of the day. By the end of that century, however, political and topical humor began to disappear. Aristophanes' *Ecclesiazusae* and *Plutus*, staged between 393 and 388 B.C.E., contain fewer references to actual persons than his earlier plays and also have diminished choral roles. By the end of the fourth century B.C.E. the chorus's function seems to have been reduced to performing a standard set of songs serving as mere interludes between acts.

After Aristophanes, comedy focused more on life in the Greek home. Roles became stereotyped: the worried father, prodigal son, meddling slave, innocent maiden, prostitute, braggart warrior. Again, our knowledge after the fifth century B.C.E. is limited because only one or two works, from Menander, have survived in anything resembling complete

form. Still, hundreds of fragments from Menander and many other comic playwrights of the fourth century and later supplement our understanding. Additionally, we have some two dozen complete plays from the Roman comic poets Plautus and Terence, who modeled their plays on those of Menander and other poets who composed in his style.

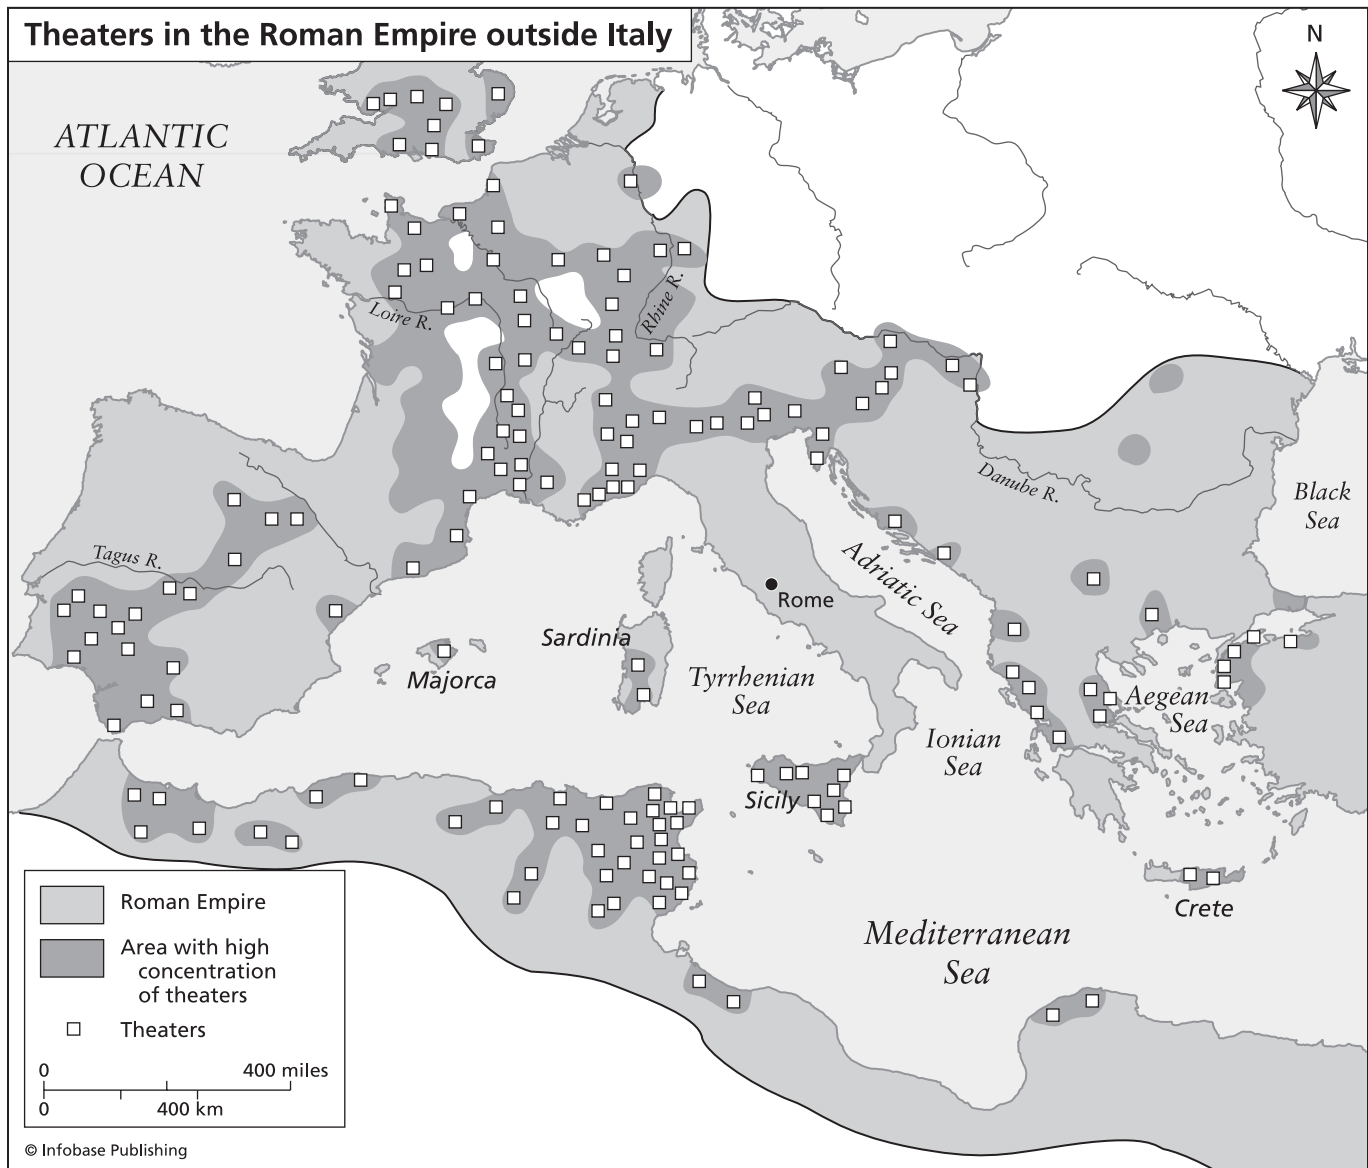

ROME

BY KIRK H. BEETZ

Much about Roman drama and theater is unknown. Most of the plays have been lost, much of Roman drama was spontaneous and not written down, and for a long time theater buildings were temporary, erected for a particular occasion and then taken down. Roman theater began as part of festivals, usually honoring gods and goddesses but sometimes celebrating military victories. Until the development of mimes, actors were only men, who wore masks that represented the characters they played; they not only spoke their lines but sang and danced as well. Even though the performances might celebrate gods, performers soon discovered that they could win audiences with comic sketches and vulgar humor.

It is not known exactly when Greek drama began to influence Roman drama, but during the 400s B.C.E. some actors put on Greek plays, with comedies being more popular than tragedies. They performed on temporary stages that were usually made of wood, though one stage used in Rome in the first century B.C.E. was recorded as having been made of marble, glass, and wood. These temporary theaters often had no seats, and audiences had to stand, but as the performances increased in popularity, builders included benches that rose in tiers like those in Greek theaters. The stage was usually broad. In front of it was the orchestra, where choruses and musicians were placed. At its back were openings that could simulate doors to buildings. By the mid-200s B.C.E. vast painted cloth backdrops were hung over the back of the stage to indicate settings for the action. Some of these backdrops were so well done that they gave the appearance of depth for background objects, while objects in the foreground seemed to thrust out over the stage. All Roman theaters were open air until 69 B.C.E., when a sponsor of theatricals, Quintus Lutatius Catulus, added a *vela*, a linen covering forming an awninglike roof for a theater.

The works of most Roman playwrights are lost, but those of Plautus (254–184 B.C.E.) have survived. He was a former actor and failed businessman who wrote plays to earn a living. Thus he catered to the desires of the paying public as much as he could. Like other Roman playwrights he borrowed plots from Greek plays and modified them for Roman audiences. His plays were often musical comedies, filled with music and lyrics he had composed. His audiences loved the variety in his plays, which included scheming slaves, braggart soldiers, pimps, prostitutes, bossy wives, and naive lovers. So successful was Plautus that his plays were performed to the end of the Roman Empire, long after stage plays had otherwise lost their popularity.

In addition to theaters on the Italian peninsula, the Roman Empire encompassed numerous theaters elsewhere in the empire.

Terence (185–159 B.C.E.) was Rome's other great writer of comedies, and all six of his plays are still complete, because monks carefully copied and preserved them throughout the Middle Ages. He came to Rome as a slave but was well educated by his owner and given his freedom. Although he was less popular than Plautus, he was admired for his understanding of human nature. Like Plautus, he borrowed from Greek sources. For Roman playwrights, using Greek settings was a matter of self-preservation. It was against the law, for example, to show Roman slaves as smarter than their masters, and the penalty for writing negatively about a living Roman citizen could be death. But with Greek sources audiences could laugh at smart slaves and other social commentary as representing Greeks, who they thought were crazy anyway.

Not much is known about Roman tragedies. Like Roman comedies they tended to be based on Greek plays, but they were more formal than the comedies. They featured actors in lavish costumes with often-grotesque masks, and they emphasized action over dialogue. The actors were held to high standards: Roman audiences often knew the plays by heart and anticipated every gesture an actor was supposed to make. They enjoyed extravagant costumes, though an entire audience reportedly fled in horror when an actor on stilts, in a long cloak, and wearing a mask of a howling face walked on stage; he conveyed terror too well.

By the time of the emperor Augustus (r. 27 B.C.E.–14 C.E.) few plays were being written, and even most of those were intended only to be read or recited, not acted. In 173 B.C.E.

THE PERILOUS LIFE OF THE ROMAN ACTOR

Much as in Hollywood or New York in modern times most actors in ancient Rome had to struggle to earn enough to live on, but a few were fortunate, becoming the equivalent of millionaires with their successful shows. Even then, however, their popularity sometimes betrayed them. Cases in point are the actors Mnester and Paris.

Mnester was not only a skilled dancer and actor but very handsome, and the emperor Caligula (r. 37–41 C.E.) forced him into a sexual relationship that became a scandal in Rome. The relationship gave Mnester high standing in Caligula's court, and it probably irritated many patricians, who resented the upstart. Yet when Caligula was murdered, Mnester was spared, probably because his acting was held in high esteem.

When Messalina, the third wife of the emperor Claudius (r. 41–54 C.E.), demanded a sexual relationship from Mnester, he at first declined. His reward was to have his lover Poppaea Sabina forced into suicide (though her daughter of the same name went on to marry the notorious emperor Nero). Mnester himself was whipped, which left scars across his back, and eventually he submitted to an affair with Messalina. When she then conspired with a consul-elect named Gaius Silius to overthrow Claudius, she and her co-conspirators were executed. Mnester gave a great performance in pleading his innocence before Claudius, who was inclined to let him go, but the patricians demanded that a commoner not be spared when aristocrats had been executed, and Mnester lost his life.

Paris was a popular name for actors, and one such actor had a love affair with Domitia, the wife of the emperor Domitian (r. 81–96 B.C.E.). Through her he gained so much power in the imperial court that he even appointed generals. Playwrights needed his approval to put on plays. It had long been the practice of the rulers of Rome to free slaves who gave good stage performances and to elevate to the aristocracy those commoners who were good actors by giving them golden rings; Paris also did these things, even though he had no authority for it. Eventually, Domitian divorced Domitia, and after several years of wielding imperial power as if it were his own, Paris was executed.

Rome had instituted a new spring festival called Floralia; the celebrations included horse races, gladiatorial combats, and stage productions that were primarily a kind of performance called “mime”—though it was far from the silent art known by that name today. By the time Rome had its first permanent theater, built by Pompey in 55 B.C.E., mimes were its main entertainment. Mimes wore no masks, and they included both men and women. They delighted audiences with their exaggerated gestures and facial expressions, and their shows also featured dancing, magic acts, acrobatics, and singing. Performances were either unscripted or followed thin story lines arranged around jokes. Their subject matter tended to be sex (actors and actresses alike were frequently naked) or parodies of current events. Mime shows were opportunities for audiences to escape their troubles, and Romans resented anyone, including the emperor, who tried to bring seriousness to the songs, dances, and pratfalls on stage.

The permanent Roman theater was usually made of stone, often marble, with a semicircle of tiered seats. The first rows of seats belonged to the upper class, the middle rows to the middle class, and the back rows to the lower class. Often there were balconies to the side of the stage that were reserved for the emperor, his relatives, or other important figures. The large stage had a permanent backdrop of doors and colonnades with as many as three stories of open floors. The stage itself was heavily decorated with trees and other plants. At Pompey's theater those rooms away from the stage area had

fountains, artificial waterfalls and streams, and gardens where people could rest during breaks in the entertainment or go at other times to socialize and relax.

During the reign of Augustus pantomime became popular. Usually depicting tragic myths, it was often performed to music, but as with pantomime today the actors and actresses did not speak. They were much admired for their ability to tell stories with their movements, and even everyday audiences became very sophisticated in their appreciation of the art form, able to note even slight mistakes. It was possible for the best actors to become very rich, and slaves often won their freedom with skilled performances.

Mimes, dancing, and pantomimes were performed throughout the rest of the history of the Roman Empire as essential parts of festivals and other celebrations. If a wealthy Roman wanted to become popular, he or she would pay for extravagant performances. Even after the fall of the Western Roman Empire and during the reigns of Germanic kings in Italy and much of the rest of Europe, mimes and pantomimes continued to be performed until historical records for them disappear in the 600s C.E.; they probably survived on a small scale during the Middle Ages in southern Europe.

THE AMERICAS

BY ALESSIA FRASSANI

Drama and theater are essential aspects of Native American artistic expression today. Theatrical performances are a ritual activity triggered by specific events and needs and with specific desired results. Entertainment is achieved through storytelling and special effects but is not always the ultimate goal. Ensuring the community's well-being is often a main concern. Archaeological evidence suggests that public performances in the ancient Americas embodied some of these same elements.

People of high social stature (kings and religious figures) received particularly grand rituals. To some degree ceremonial performances, in ancient America and elsewhere, were political. The more complex the social organization, the stronger was the need for cohesion among different social classes. Ceremonial behavior toward higher-ranking people served this purpose.

Shamanism, a common feature of Native American religions, played a crucial role in early drama. Shamans, through innate ability and years of training, are thought to be able to do such things as transform themselves into animals or supernatural beings. During rituals a rhythmic beating of drums and shaking of rattles, repetitive chants, dancing, and the use of elaborate costumes accompany the shaman's transformation. Shamanic rituals are thus theatrical in their very nature. Conjuring up the ancestral dead was a common purpose of such performances. Assuming the identity of a supernatural being enabled the shaman to communicate with the dead in order to resolve critical political, economic, or social issues.

Excavations all over the Americas have uncovered small figurines from ancient times. In North America the funerary sites of the Adena and Hopewell civilizations (1000 B.C.E.–400 C.E.) have yielded large numbers of ritual items shaped like animals or humans. A tobacco pipe from Newark, Ohio, for example, represents a seated man wearing a bear costume. In Native American lore bears are feared and respected and are sometimes referred to as “grandfathers.” This pipe probably mourned and revered a deceased shaman-bear and testifies to the importance of animal doubles in early Amerindian rituals.

In Mesoamerica the sites of Tlatilco in central Mexico (1200–900 B.C.E.) and Colima and Nayarit in western Mexico (100 B.C.E.–200 C.E.) are famous for their abundance of small clay figurines, especially from burials, depicting dancers and musicians. The figurines, which may represent either the deceased or funerary attendants, often have richly plumed headdresses, wear jade or shell tinklers on their ankles, and hold fans or musical instruments (especially ocarinas). Typical of Colima are assemblages of warrior-dancers with helmets, weapons, and elaborate ritual armor. Effigy headdress includes crocodiles, sharks, and deities. Pacific Coast people of Mexico still wear similar costumes during annual religious celebrations.

The rich ceramic tradition of Jama-Coaque and Tumaco-La Tolita, flourishing along the Pacific coast of Ecuador and Colombia between about 600 B.C.E. and 500 C.E., produced small effigy figures that include musicians, dancers, and ritual performers. Shamans, often impersonating bats, birds of prey, or jaguars, perform fertility rituals by dancing and scattering seeds and precious stones while shaking rattles. Shells, symbols of fertility, decorate clothes and bags and may allude to the shamans' propitiatory role. The bags probably contained coca leaves, used to induce trances, or seeds to be cast ritually.

The political role of performance became more apparent in Mesoamerica and South America around the first millennium B.C.E. The Olmec civilization, flourishing between 1200 and 400 B.C.E. on the Gulf coast of Mexico, produced the earliest monumental architecture and stone sculpture in Mesoamerica. A rising elite instituted large and ambitious programs and used rituals and public spaces to legitimize their political and economic privileges.

At the Olmec site of La Venta, pyramids and platforms around large plazas created stages for open-air ceremonies that included music, singing, and dance. Stelae—vertical stone slabs carved, inscribed, and sometimes painted with commemorative information—were first created during the Late Formative Period (400 B.C.E.–150 C.E.). Often portraying rulers in full attire, they provide interesting information about the theatrical devices employed to convey the supernatural powers of these individuals. Stela 2 at La Venta, for example, shows a royal figure wearing a giant headdress with decorations probably referring to the maize (corn) plant, Me-

soamerica's staple food crop, first grown on an intensive scale by the Olmec.

The Maya of southern Mexico, Guatemala, Belize, and Honduras continued the Olmec tradition of empowering rulership through public ritual performance. The emergence of elaborate public centers during the first century B.C.E. reflects the development of a more complex social hierarchical structure that had at its top the *ahaw*, a ruler able to contact the ancestors during ritual activities. Such ceremonies were a form of public memory and a means of fostering social cohesion.

At the site of Cerros, Belize, a large step pyramid rises near the Atlantic shore. Four masks in two rows flank its central stairway. Scholars believe the masks symbolize the primary forces of the cosmos, relating to cardinal directions and celestial bodies. The temple's facade was a backdrop for ritual display of the ruler's power to control natural forces. Representations of rulers in ritual attire, holding such ritual objects as spears and serpents, symbols of visionary abilities, appear on all Mayan stelae. The frontal stance, alignment of the feet, and position of the hands suggest ritual dance.

Although no stelae survive from Teotihuacán (near modern Mexico City), the most influential center in ancient Mesoamerica, murals found inside residential compounds depict fertility rituals, suggesting that here too figures with political and religious powers existed. Walls exhibit painted images of priests walking in procession. The figures, with large goggle eyes typical of rain and fertility gods, are shown scattering seeds, precious stones, and shells. Wiggly or curly shapes indicating words and chanting come from their mouths. In some cases green-plumed headdresses transform the priests into feathered serpents, while black paint around the eyes indicates visionary abilities.

Chavín de Huántar in the northern Peruvian Andes is one of the oldest and largest archaeological sites of ancient South America. Founded around 900 B.C.E., Chavín was until 500 B.C.E. the major religious center of South America, attracting pilgrims from all over the Andean and coastal regions. Its most important place for open-air ritual activity is a large U-shaped mound. Immediately in front of the entrance to this sacred place is a circular sunken plaza, accessible only via two facing stairways. Carvings on the plaza's wall provide one of the oldest depictions of theatrical performance in the Americas. Two rows of carvings show processions of feline and humanlike creatures. Curled serpents issue from their heads and waists. The men-animals blow *pututus*, traditional Andean wind instruments made from large seashells, and hold San Pedro cacti, a desert plant with hallucinogenic

qualities. This last element makes clear the shamanic nature of the performance at Chavín. Together with music, dance, and songs, psychoactive substances were used to induce a trance that enabled the shaman's transformation.

► economy

INTRODUCTION

An economy requires that people cooperate in deciding what they value in their society. In a subsistence economy determining what is valuable may be easy: Everyone is focused on finding or creating the barest essential of life, food. In such an economy people have little time for creating luxuries or for recreation. Even so, their relationships may still be complex, because they may need to cooperate to create enough food that nobody starves, and they may need to create a hierarchy of who gets fed first and, in case of a shortage of food, who does not get fed at all. Thus, at its base, economics can be about who lives and who dies.

An agricultural economy is one that is focused almost entirely on raising crops. Such an economy can be a subsistence economy in which everything that is harvested is used each year, without a surplus. The ancient peoples of Mesopotamia, the Yellow River region in China, and Mesoamerica found ways to create surpluses of by using irrigation canals and by learning to plant two crops and have two harvests per year for such staples as wheat. Still, advanced agricultural practices brought with them new problems, especially overpopulation. Occasionally, crops would fail, and there would be a famine. Famines have killed millions of people over thousands of years along the Yellow River, and much of Mesopotamia may have succumbed to food shortages in ancient times.

One way to protect against shortages was by having a controlled economy. In a controlled economy a central authority, usually the government, dictated what was grown

and what was manufactured. Ancient Egypt had a controlled economy and the Harappan civilization of the Indus river valley probably did too. The government could save surplus grain for distribution during periods in which crops failed. Another way to save crops against bad times was through taxes. For instance, in Mesopotamia and China farmers were usually required to give some of their harvests to the government. In Mesopotamia farmers sometimes donated part of their land to the government or to the temple of their city, buying favors for themselves and providing the government and temple with direct control over some agricultural resources. This created an early form of a mixed economy, partly free market for independent farmers and partly central controlled.

An advantage of a free market economy is that it can encourage even the poorest members of society to try to create surpluses of goods, because they can use those surpluses to trade for other goods. This was often threatening to ancient governments, whose social elites viewed the generation of wealth for those outside the elites as disrupting their traditional privileges. In China almost everyone was a peasant. Although broad-minded emperors occasionally tried to give peasants civil rights and ownership of land, most of the time peasants were slaves to the land. They could not leave the land unless they were conscripted into a warlord's army; if the land was destroyed, the peasants on it were destroyed as well. When Confucianism became the dominant philosophy of government in the late 200s B.C.E., peasants and craftspeople were allowed to benefit directly from their work, which disturbed the social elite so much that it was made against the law for an ordinary person to dress well.

Surpluses of food allowed for the development of specialization in the workplace. In most early societies, everyone needed to know how to do everything, from how to make bows and arrows to how to fashion a clay pot. Perhaps the earliest division of labor was between the genders, at its most simplistic a matter of one gender doing the hunting and farming, while the other dealt with producing baskets and other household goods. Even then, there was pressure to know how to do many tasks. For instance, in sub-Saharan Africa, most women made and fired ceramics at home, quarried the clay for building homes, tended gardens, and cared for children. With the burden of caring for crops every day lifted from some members of society, it was possible for them to master a manufacturing craft, such as metalworking or creating pottery.

Those who manufactured nonagricultural goods could trade their products for food. In southern Mesopotamia this became essential by about 1000 B.C.E. Even though Mesopotamia had at one time exported grains, its soil had been poisoned by salt from rivers, and increasing populations made it impossible to produce enough food to feed everyone. The Mesopotamians were able to feed themselves by trading goods made of metal to other people who had excess grain but lacked the Mesopotamians' expertise in metalworking. Ancient Mesopotamian goods were distributed throughout the Near East and into central Asia and as far east as the Indus River valley. Nonetheless, cultures that made fine manufactured goods that they could trade for food or other goods struggled with the barter economy, in which sellers had to find someone who had what they wanted and who wanted what they had to sell.

A solution to this was the cash economy. In a cash economy sellers do not need to find someone who has exactly what they want, because buyers will give sellers money, which the sellers can then use to buy what they want from other sellers. Historians and archaeologists often judge the maturity of an economic system by whether it developed a cash economy, which allowed trades to be made quickly and enabled people or organizations to accumulate enough money to invest in building factories, as happened in ancient China, or to invest in consumer goods such as houses, medical care, and good clothes.

The study of ancient economies has pitfalls for modern observers, because ancient peoples had their own cultural priorities that affected how they treated goods and trade. There is the example of the Chinese, who refused to wear wool because their barbarian neighbors were often shepherds. They denied themselves the benefit of a warm, sturdy fabric simply because they were prejudiced against people who happened to care for sheep. Among the Celts, minting coins did not always mean that they had a cash economy, because the coins were often symbols of a chief's power and were given to followers to symbolize their obligations to their chief. Even so, the study of ancient economies is one of the best ways to learn how ancient peoples valued their worlds.

AFRICA

BY MICHAEL J. O'NEAL

For thousands of millennia the concept of an economy, as the term is understood in modern life, would have been entirely foreign to Africans. "Wealth" consisted primarily of an abundance of food. "Capital assets" included only the few portable possessions that nomadic bands of hunter-gatherers could carry with them from one encampment to another. "Labor" consisted of the daily search for food by hunters, fishermen, and gatherers, who found nuts, berries, fruits, acorns, roots, and leafy vegetables. "Economic incentive" was a rumbling belly.

Money was nonexistent. "Banks" meant those who had surplus resources and were willing to share them with others. "Corporations" were formed by small tribal bands whose members worked cooperatively to find food, haul it back to the encampment, and prepare it for consumption as well as to perform other tasks, such as gathering firewood and water. "Stockholders" were those who accumulated a herd of livestock. The "price" of a good consisted of the time it took to find it and, perhaps in the case of hunting, the injuries and even deaths that resulted from tangling with wild animals.

THE EARLY STONE AGE

Until the Neolithic Revolution and the spread of agriculture, which began in roughly in 10,000–8000 B.C.E. or later in some parts of the world, the economic systems of Africa were simple. If economics can be defined as the science of scarcity—of time, money, resources, labor—then the ancient Africans combated scarcity with unceasing labor. The chief economic activity was the hunting and gathering of food. Secondary activities included finding or building shelters, storing food, maintaining fires, and caring for children. The basic units of both production and consumption were the family. About the only specialization of labor was along gender lines. Men did most of the hunting, while women did most of the gathering, though these gender roles were not strictly adhered to; women, for example, often functioned as hunters by combing shallow waters for such food items as shellfish, and men often assisted with the gathering of fruits, nuts, and so on.

What tools Stone Age Africans had for such tasks as digging and carving game were not produced by a separate class of craft workers. Individuals made their own stone tools, arrow points, and the like, though archaeological evidence shows that some of these items were often shared, suggesting that some individuals may have been seen as more skilled in making them. Land did not have to be allocated for production, for no one owned the land or claimed land-use rights. These small communities of people, who largely inhabited the savannas of East Africa until they spread out through the continent, were largely egalitarian, meaning that they shared all resources equally. Thus, food was taken back to the encampment for everyone; kills were not attributed to any one person, so the food was available to all. Moreover, no elite

class laid claim to the production of others. No market economy drove the demand for and supply of food. The demand was persistent but the supply sometimes less so.

THE AGRICULTURAL SYSTEM

As populations spread throughout Africa and agriculture emerged as a primary way of life, the economic system had to change. Nomadic hunter-gatherers lived in a world in which no one possessed property rights to land or territory, though it is likely that groups defended territory against outsiders. The land existed as a resource for all to exploit. Systems of agriculture, in contrast, require the allocation of land. Which land is used, who uses it and for what, and when the land is used became primary considerations.

Making these considerations more important was that the amount of arable land was limited. Much of sub-Saharan Africa was covered by either dense forests or deserts, and while the Sahara was largely grassland until about 3000 B.C.E., climatic changes caused expansion of the desert, reducing the amount of land suitable for agriculture. Thus, agricultural communities, including both farmers and herders, had to settle on land that provided good soil, moderate temperatures, pasturage for livestock, and, in particular, an abundance of water. Complicating the situation was that water was in many cases available only seasonally. That is, floodplains became inundated with water during portions of the year and then dried out. All of these considerations made questions of land use and allocation important ones.

Good examples are provided by the floodplains of the Niger and Senegal River valleys, though other river valleys would have dealt with similar conditions. Along any river there were probably three areas whose use had to be allocated. One was the uplands, the areas farthest away from the river and its flooding. Here is where herds were usually pastured and people lived in permanent dwellings. Around these dwellings were gardens where women tended patches of vegetables. The primary source of water was not the river but rainfall. At lower elevations and closer to the river were floodplains, which were covered with water during annual flooding and then used for crops after the waters receded, in a type of agriculture referred to as recession agriculture; that is, crops were planted after the recession, or receding, of the floodwaters. Finally, the lowest elevations, closest to the rivers, were the flood basins. These areas tended to remain wet and boggy during longer portions of the year, in effect storing water. This was also the area exploited by fishermen and others who gathered foodstuffs such as crabs, snails, and shellfish in river shallows and lagoons. The end result was that land was allocated for use in parallel strips that followed the course of the river.

Decisions had to be made about how these units of land were used and when. Thus, for example, certain crops such as rice were suited to the flood basins, sometimes putting rice growers in conflict with fishermen. Others, including staple crops such as grains, were more suited to the floodplains, and still others were suited to the uplands. Further,

as herds of livestock ate grasses on the uplands, they had to be moved to lower elevations for pasturage, but this had to occur at times when they would not trample growing crops. Thus, for example, a crop of sorghum might have been grown in the floodplain, but after the sorghum was harvested, livestock were herded in to graze after they had eaten down the upland grasses. This movement of the herd had two primary benefits. First, the livestock ate away the stubble left behind after the harvesting of the crop, at the same time churning up the ground with their hooves, making the next planting easier; second, the livestock fertilized the soil with their manure. Modern farmers use manure and fertilizer spreaders; the earliest manure spreaders were also the manure producers.

An additional consideration was that crops were planted in rotation, depending on rainfall and temperature conditions. All of these activities had to be scheduled. Complicating matters was that one of several clan lineages engaged primarily in one of these various activities. Thus, one lineage herded livestock, another fished, still another grew certain crops, and so forth, though fishermen tended to farm as well. The foundation of the system was the consultation of headmen of the various lineages, who made decisions based largely on the most efficient and productive use of the land; each headman would probably have defended the interests and privileges of his clan. One way that conflicts were avoided was through clan intermarriages; the headman of, say, a herding clan would, in general, be reluctant to encroach on the land-use rights of a farmer if that farmer was his son-in-law or brother-in-law.

In contrast to modern life, where social and economic relationships tend to be separated, these relationships in ancient Africa were often one and the same. Thus, property and goods exchanged hands through such institutions as inheritance, bride-prices, and dowries. In the absence of currencies, a bride-price paid by a groom's family to the bride's family to compensate them for the loss of her services or a dowry paid by the bride's family to the groom took tangible forms, such as cattle. Among Stone Age peoples, value existed in the things that provided a livelihood, so these things became the medium of exchange. Acquiring a small herd of livestock by marrying a woman whose father had surplus livestock enabled a young man to gain a foothold in the area's economic system.

Complementing this method of property exchange was a system of barter. Barter as a form of economic exchange is difficult in modern life except in isolated circumstances; a rural landowner might trade a load of firewood to a local farmer in exchange for a load of hay. But this type of exchange assumes that a person who has firewood and wants hay can find another person who has hay and wants firewood; difficulties increase if one or both of the goods is perishable or the parties live at a distance from one another. But economic needs during the late Stone Age were simpler, consisting of food, livestock, tools, textiles, pottery, and a limited number of other goods necessary to survival. Since most of these goods were available in the local economy, it was not hard for people to barter them in informal, day-to-day exchanges.

This type of bartering extended to services as well as to goods. Throughout much of Africa, patron-client relationships were common. This term means that influential and wealthier members of the community became patrons for those less influential or wealthy, their clients. The patron provided protection and economic benefits for the client, who in turn performed services for his patron. The result of all these social-economic relationships was an integrated economy, with different groups of people such as clans and tribes providing economic benefits not only for themselves but also for one another. Stability was ensured by interlocking systems of clan and patron-client relationships, all strengthened by marital alliances. In this way, over time, clans united into larger tribes, which in turn united into regional powers.

Not all floodplains and river valleys were alike. The Senegal River valley was narrow, about 12 miles wide. In contrast, the Niger River valley was much wider, some 60 miles wide. The result was that the various types of land along the Niger were much more widely dispersed; rather than parallel strips, the usable land took the form more of a patchwork. Further, this larger region was inhabited by various tribes who often did not maintain good relations with one another and may have spoken different languages. Intermarriage under these circumstances was not as common. Thus, conflicts over land use arose. The result was a far less integrated economy. Individual tribes and clans staked out land for their own purposes, resulting in a subsistence economy, with each tribe or clan living largely off its own produce. Along the Senegal River, the economy was more integrated, with the various clans sharing their productive capacity with one another in large part simply because they lived in closer proximity, intermarried, and spoke the same language.

Not all of Africa became sedentary during the Neolithic Revolution. Economic developments took place at different speeds in different places. In West Africa, for example, hunting and gathering persisted as a way of life far longer than it did in other parts of the continent, primarily because the people had abundant resources and therefore had no incentive to change their way of life. Also nomadic pastoralists (herders) continued to move their herds about seasonally in some parts of the continent. These pastoralists never developed any kind of sophisticated system of resource allocation or exchange. They were the loners, the independent spirits of the African economy. They were representative of a way of looking at economic systems in the sub-Saharan. While North Africa, including the empire of the ancient Egyptians, relied on a complex governmental system, with bureaucrats, assessors, surveyors, tax collectors, and the like, all controlled by a central authority, the sub-Saharan preferred local control and independence, with economic activity directed by headmen, clans, and lineages.

MINING, METALLURGY, AND TRADE

The kinds of problems faced by the inhabitants of the Niger River valley led to a fundamental change in the economy of

that region. While the economic organizations of the Senegal River valley fostered generalists, who sustained a mixed economy of farming, herding, and fishing, the patchwork economy of the Niger River valley fostered specialization. As populations grew, it became increasingly difficult for people to meet their needs through a single economic activity. Accordingly, the Niger River valley turned more to trade and exchange. Early in the Neolithic Period, such trade took place between the various tribes that inhabited the region. In time, this trade would radiate outward to more far-flung regions. By about the beginning of the Common Era, the region was part of a trading belt that extended across the middle of Africa and linked the Sahara and regions to the east to the southern half of the continent.

With the precedent set for specialization, mining and metallurgy became important parts of the local economy. Africa was (and is) rich in iron ore. In many places, iron ore did not even have to be dug; it was visible in rock outcroppings. Interestingly, while much of the rest of the world passed through stages in which copper and then bronze were the primary metals, Africa seemed to have skipped the Bronze Age and passed directly to iron production. Iron, and later steel, changed the makeup of ancient Africa. Tools were developed that made agricultural production more efficient. With a greater abundance of food and other resources, populations increased. For growing numbers of people to meet their needs, they turned to trade with other parts of the world.

Meanwhile, iron became the mainstay of the African economy in some regions. In the Niger River area, the city of Jenne-jeno emerged as an important center of iron production. Again, the result was increased specialization of labor. Individuals mined ore, transported it, processed it by separating the iron from the ore, and turned it into weapons, plows, and other useful objects. Other individuals were responsible for cutting and hauling the enormous amounts of wood needed to stoke the fires, which were kept burning at very high temperatures. (This cutting of wood led to extensive deforestation in some areas, forcing people to abandon their settlements.) Archaeologists have found numerous remains of smithing and other iron-producing activities around Jenne-jeno and other parts of sub-Saharan Africa.

It appears that in Jenne-jeno no social elite or hierarchy of authority directed this economic activity from the top down. Rather, the economy was organized horizontally, again with lineages exercising authority over their members. The headmen of these lineages created a complex latticework of overlapping agencies and cooperative ventures that directed iron production from mining to finished products. Jenne-jeno and communities like it initiated one of the chief features of modern, urban economies: a central hub that drew people in search of economic opportunity and that provided goods and services for outlying areas in exchange for food and other agricultural products.

One peculiarity of the African iron industry, at least by modern standards, is that it was associated with religious be-

liefs. Iron, because of its strength, was regarded as a source of power, even virility. Iron provided weapons that could be used to conquer enemies who were still fighting with rocks and sticks. Thus, one group that often ran the iron industry was the priestly class. The making of iron was regarded as magical. Large fires were built to smelt the ore, out of which emerged a substance that enabled people to conquer both the land and their enemies. The flames, the smoke and ash, the heat, and the molten metal had a distinct otherworldly aspect. Accordingly, large numbers of rituals and taboos surrounded iron making. One taboo, in particular, was that ironworks, as spiritual centers, had to be strictly separated from households—perhaps the first known instance of zoning regulations that separated manufacturing from residential districts.

Iron was not the only metal that played a role in African economic systems. Gold, too, played a part, though gold in the ancient world did not have quite the same high value the modern world places on it. Gold is a soft metal, so its uses were restricted to luxury items such as jewelry. One of the most prominent gold-producing kingdoms of ancient Africa was Ghana, which began to flourish in about 200 C.E. Ghana's major export was gold. In fact, the word *ghana* referred to the ruler who controlled the region's gold supply and gold exports.

Ghana's rulers became wealthy because of the taxes they levied, though they did not tax gold. Rather, they taxed the salt for which gold was traded. (Salt was a vital commodity in the ancient world, used primarily for food preservation.) Thus, gold was traded for salt; taxes were paid on the salt, and the ruling class became the owners of capital that was used to finance public works projects such as roads and monuments. In some parts of Africa, including Ghana, only gold dust could be legally traded. Gold nuggets were regarded as the possessions of rulers, as a way of maintaining their status.

Ghana and Jenne-jeno, of course, were not the only centers of metalworking and trade. The Nubian kingdoms to the south of the Egyptian empire were also important centers of metalworking and trade. These kingdoms, including Kush and later Axum, occupied unique positions as links between Egypt to the north and the sub-Saharan to the south. And by being linked with Egypt, they were also linked to the Near East and the wider Mediterranean Sea. Accordingly, these kingdoms gained wealth as centers of trade, with middlemen importing and exporting goods—gold, jewelry, salt, ivory, ebony, elephant tusks, leopard skins, feathers, incense, and agricultural produce—up and down the region. Often this trade was not direct; one item was traded for another, which was in turn traded for a third, and so on until goods arrived in the hands of those who wanted them. Many products from the sub-Saharan were in high demand to the north because they were luxury goods or used in the production of luxury goods. Thus, the economic base of these kingdoms was not production, even though a certain amount of iron was produced, but rather exchange. Unlike the sub-Saharan, however, the Nubian

kingdoms were ruled by powerful central authorities, modeling their Egyptian neighbors, so import-export exchanges were taxed, and the proceeds used for public works projects.

CARTHAGE

The most dominant trading empire in North Africa was that of the Carthaginians. Carthage, a name derived from the Phoenician words for “new city,” was founded in 814 B.C.E. by Phoenician traders from the city of Tyre in Lebanon. The city of Carthage, the capital of the empire, was in North Africa on the east edge of Lake Tunis, in modern-day Tunisia. Some historians believe that it was the world's second-largest city during Hellenistic times, the era when the Greek empire was at its height. It was protected by massive walls and had marketplaces, towers, a theater, a council house, an area for religious worship, a huge, elaborate cemetery, four residential areas, and, in the center, a tall citadel called the Byrsa.

The basis of Carthaginian power and empire was its massive navy and a large fleet of merchant ships. Much of the empire's trade was based on the Iberian Peninsula (Spain and Portugal), the source of large amounts of lead, silver, and tin ore. Tin ore was especially important, for numerous ancient civilizations mixed tin with copper to make bronze. Carthage's strategic location between the island of Sicily and the African coast allowed it to control the supply of tin to the east.

Nearly as important as tin were the silver mines in North Africa and Iberia. Another important commodity was a dye called Tyrian purple—a dye so valued that a pound of it was equal in value to up to 20 pounds of gold. Other important commodities included textiles (silk, wool, cotton), spices, perfumes, pottery, incense, glasswork, wood, bronze, alabaster, precious stones, plows, mirrors, cabinetry, household items (pillows and bedding, for example), slaves, and weapons. Food commodities included fish as well as a range of agricultural products.

Carthage's influence also spread southward. The empire sent caravans into the African continent, where they traded for such goods as ebony, ivory, salt, timber, gold, hides, and such animals as apes and peacocks. To the north they obtained amber from the Scandinavian countries and animal hides from Europe. In summary, the Carthaginians traded in just about every commodity that anyone wanted in the ancient world. Their efficiency in storage, transportation, and buying and selling was the source of the empire's wealth and power.

The Carthaginians introduced two important innovations on the continent. One was the auction method of exchange, and the other was the use of gold as a medium of exchange. Many of the communities that traded with Carthage feared Carthaginian sailors because of their reputation for seizing slaves. Thus, they avoided direct contact with the Carthaginian merchant fleet or caravans. Accordingly, when the Carthaginians arrived, they unloaded their goods onto, say, a beach, arranging them tidily for inspection. They then

built a smoky fire to indicate their arrival and withdrew to a safe distance. The locals came down to the beach, inspected the goods, and then left behind a quantity of gold that they thought represented a fair price. The Carthaginians returned, and if they thought the price was fair, they took the gold and left; if not, they again withdrew and the locals could leave behind a greater quantity of gold if they wished. This process continued until a price had been reached, the Carthaginians accepted the gold and left, and the locals carried off the goods.

The Carthaginian economy was a command economy, directed by the ruling dynasty in Carthage. This dynasty was an oligarchy of prominent families. Transactions were taxed, creating a royal treasury used to finance the military and numerous public works projects.

MONEY

The development of money in Africa, as well as in other parts of the world, was closely related to taxation. Money, as opposed to coins and currency, is an abstraction. Money is defined in a number of ways: a medium of exchange, a store of value, a standard of value, a unit of account, and a means of payment. In modern life people store value by opening bank accounts or contributing to retirement accounts. In this way they can store resources for the future, when they can convert savings into groceries and other commodities. But while the modern world thinks of money as coins and currency, virtually anything can serve as money, as long as others accept it as money, it cannot be easily counterfeited, it is relatively scarce, and it holds its value over time.

In ancient Africa tangible goods were the primary form of money. Objects were priced relative to one another, so that a certain quantity of salt, for example, was regarded as equivalent in value to a certain amount of gold. African traders who formed the marketplace for goods were adept at determining these relative values. They served as middlemen who exchanged the commodities and collected a surplus that was their payment for brokering the transaction. Similarly, a cow could serve all the purposes of money, and objects were “priced” relative to cattle. In some cultures a person could pay for something with a cow and receive “change” in the form of a sheep or goat or perhaps some other commodity, such as a sheepskin. The English word *pecuniary*, referring to money, comes from the Latin word *pecus*, meaning “cattle,” and the English words *cattle*, *chattel* (any goods or tangible property), and *capital* (in the economic sense of assets) all have the same linguistic origin. Interestingly, the modern world has similar financial instruments. While cattle are not used much as money, certain intangible things are. In 1997 the pop music star David Bowie introduced “Bowie bonds,” a form of money that gave owners of the bonds a claim on future royalties from his music. While the form has changed, the basic concept of providing something of value in exchange for something else, rather than exchanging coins and currency, is little different from the practices of ancient Africa.

The problem was that the taxing authorities could use only so much salt or so many heads of cattle. Accordingly, systems of coinage developed primarily as a way to pay taxes and not as a way to facilitate barter, as is commonly believed. Secondly, coinage was a more convenient way to pay such obligations as fines, bride-prices, and tribute to foreign conquerors; the word *pay* comes from the Latin *pacere*, meaning to “appease” or “make peace with.” In ancient Africa coins were not minted out of precious metals for these purposes. The most common form of “coinage” was the cowrie shell, a brightly colored shell from warm-water gastropods (mollusks, for example) that had value because they were brightly colored and thus were used in luxury goods such as jewelry. At various times, though, other similar items were used as coinage, including feathers, metal tools, and ivory. The later Carthaginians minted coins and also used gold as a means of payment.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

The inner structure of the ancient Egyptian state was based on three factors: economy, religion, and political ideology. These factors were closely connected in a variety of modes and expressions. The pharaoh was regarded as the earthly manifestation of the divine and the guarantor of the fertility of the land and the fecundity of the stock. The Egyptian lands were the exclusive property of the king, who divided them into agricultural domains and placed them under the control of the temple or political administration.

Although there was no word equivalent to *economy* in the vocabulary of the ancient Egyptians and nor was there a planned economic framework, the transition from a nomadic to an economic culture, the unification of Upper (South) and Lower (North) Egypt, and the formation of the political state and administration gradually led to the development and institutionalization of a working economic system.

Economic transactions and practices are documented in a variety of sources. Even from the inauguration of Egyptian political history there is evidence, from the end of the fourth and the beginning of the third millennium B.C.E., of the tripartite nature of Egyptian society (religious, political, economic) and the role of economy in it. For example, on the mace head (a ceremonial staff) of the mythological king Scorpion (Dynasty 0, ca. 3050 B.C.E.) the central scenes depict the king's efforts to render the land agriculturally valuable through the exploitation of certain techniques (seeding, harvest, tree plantings) and ritual actions (presentations to divinities).

Sources of economic information can be categorized into two principal groups. The first group includes monumental inscriptions and pictorial representations that cover almost two millennia, from the Old Kingdom through the New Kingdom (ca. 2575–1070 B.C.E.). The evidence from the Old and Middle Kingdoms is scanty and becomes much more

plentiful during the New Kingdom. Such evidence includes offering and trading scenes among individuals or between the state authorities and the populace as well as transactions and gift exchanges between the state and foreign traders, diplomats, and rulers.

The second group of sources includes administrative documents and financial records from temples, tombs, or private individuals that attest to actual economic transactions. They are preserved mostly on papyrus rolls in a quite fragmentary nature, are written in hieratic handwriting (referring to an informal expression of Egyptian hieroglyphs), and include complicated technical terms. The best examples are the papyrus Abusir, which describes daily economic activities from the mortuary temple of Neferirkare, a Fifth Dynasty ruler (ca. 2446–2426 B.C.E.) at the region of Abusir (Lower Egypt), and papyrus Boulaq 18, which records 23 days of economic transactions at the Theban residence of the Thirteenth Dynasty ruler Sobekhotep II (ca. 1745 B.C.E.).

Individual economic transactions were recorded on ceramic or stone ostraca (fragments of pottery with inscriptions), such as those from workmen's village at Deir el-Medina, dating to the later New Kingdom. The ostraca include information about the prices of certain commodities. Because of the

scanty and personal character of the material, though, important details, such as the date and time of the transactions or description of the traded goods, were often omitted.

In spite of these omissions, useful information concerning the basic principles and values of the ancient Egyptian economic system can be deduced. In many respects, the Egyptian economy showed several differences from our modern perspective, and it was centered on the following three principles: the principle of barter and market exchange, that of redistribution, and that of reciprocity and tributes. Tying these factors together were the centralized state authority (the pharaoh) and the religious institutions.

PRICE UNITS

One major difference from our modern economic system was the lack of coinage and true money to store and transport wealth throughout the Pharaonic Period (ca. 3050–712 B.C.E.). The import and use of money were inaugurated toward the first millennium B.C.E. by foreign mercenaries in the armies of the pharaoh. At first the native Egyptians did not recognize the value of coined money, regarding the coins merely as artistic objects in gold or silver, appreciated mainly by the metalworkers.

The Great Harris Papyrus, from Thebes, probably Deir el-Medina, Egypt, during the reign of Ramses IV, around 1200 B.C.E.; the scene is of the king making a donation of goods (including 309,950 sacks of grain and a quantity of metals and semiprecious stone). (© The Trustees of the British Museum)

The Egyptians used four units of measurement to price and trade commodities, the *deben*, the *senyu*, the *hen*, and the *khar*. These units coincided with quantities of certain commodities: weights of silver and copper or bronze and units of capacity of grain and sesame oil. More specifically, the *deben* was a measure of weight used mostly for copper but also for other precious material, such as gold and silver. One *deben* of copper weighed about 3.5 ounces. Silver and gold *deben* are not mentioned in the ostraca but only in the papyrus records. The ostraca were used and distributed only among the lower-class populace, while the papyri recorded mostly transactions among the high officials and the palace.

The *senyu* was a weight in silver equal to one-half *deben*, or 1.75 ounces. Its use was inaugurated during the Nineteenth and early Twentieth Dynasties (ca. 1307–1155 B.C.E.). The *senyu* could be used to express a value in the same column of figures with the *deben*. One could find in an ostrakon the value of certain objects in *senyu* but the total of the column in *deben* of copper.

The *hen* was a measure of volume equal to half a quart or less. Its value could vary according to the substance or liquid to be measured, but generally it was regarded as equal to one *deben*. Finally, the *khar* was a measure of the volume of grain, either emmer (a type of wheat) or barley, equal to about 20 gallons, and it was valued at two *deben*. The *khar* was most commonly found as a unit of value for baskets, both because the volume of a basket was equal to its value and because baskets were inexpensive.

The ratios among the four units as well as their exact values are not fixed in the sources. For example, one document values a basket at one-quarter *senyu* for a volume of one-half *khar*. Because one *khar* is valued at two *deben*, one *senyu* is worth four copper of *deben*. In another document, though, one *senyu* of garment was worth five copper of *deben*. Weight and price, both expressed in *deben*, were hardly distinguishable from one another. In the Egyptian mind there was no difference at all, for the *deben* was not money.

Cases of inflation and price fluctuation have been recorded. Quite often, one *deben* of silver was valued as 100 *deben* of copper. This uncertainty in the value system was a strong indication that the Egyptians were not looking for monetary profit in their transactions but only the acquisition of objects. The lack of fixed prices led to the introduction and development of a unique bartering system.

BARTER

Acquiring and disposing of goods was done by bargaining on a price. Although there were no fixed prices, ancient Egyptians were fairly consistent in determining how much an item was worth. For everyday goods, like food, clothes, or sandals, the cost would have been one or two *deben*, but bigger and more valuable items, like animals or territories, would have cost more *deben*. The objects were traded for goods that were worth the same amount.

Metals were used in exchanges but not as coinage. Their values, equated with their weights, were measured on a balance against stone weights. An example of the bartering method was documented in an ostrakon from the village of Deir el-Medina. According to the inscription, one person wanted to buy a wooden coffin, nationally valued at 25 *deben* of copper. He had to exchange a set of commodities of equal value. These could have included actual copper pieces whose *deben* value was obtained by direct weighing on scales, various animals such as pigs or goats, or raw materials for coffin construction.

Before deciding whether to barter his product, the coffin maker examined the exchange goods to determine if they met his needs. According to the inscription, the coffin maker valued the exchange items as follows: the copper items for 8.5 and five *deben*, respectively; one of the offered animals (a pig) with five *deben*; the other animals (two goats) with three and two *deben*, respectively; and the two logs of sycamore tree for two *deben*. In total, the price of the exchanged goods was 25.5 *deben*, which was slightly more than the assessed value of the coffin. It seemed that this slight difference did not trouble the buyer, because he wanted the coffin and was willing to offer for it the items the seller required.

Evidence of loans has also been recorded in the Egyptian sources. Two types of loans existed: one was made with a fixed date for repayment and a penalty if that day was missed. The second type was based not on a fixed day for repayment but rather on an obligation for reciprocity between the lender and the debtor.

REDISTRIBUTION AND LABOR

The land beneficiary and redistribution system was an important component of the ancient Egyptian economy. Under this system, the soil of Egypt was the exclusive property of the king, who could concede it to temple authorities, state officials, or the populace, according to his wish. Priests and high dignitaries were granted the use of land, but the king retained direct ownership. A careful distinction was made between the ownership of the land, a royal prerogative, and the right to gain income from land.

The beneficiary system led to the increase of the temples' territories and wealth, which gradually became hereditary. Control of the land was passed through the priestly offices, which were free from all obligations to the royal administration. It is known that in the time of Ramses III (r. ca. 1194–1163 B.C.E.) the domain of the god Amun in the ancient city of Karnak (South Egypt) controlled well over 900 square miles of usable agricultural land, along with vineyards, gardens, marshlands, quarries, and mines.

Trade relations between temples and religious centers from different regions as well as between temples and their surrounding areas or various state offices are well documented in the surviving sources. A primary source of income for a temple came from renting land to the peasant population. Another source of income was the plunder and foreign

tributes the king obtained during his campaigns and delivered to the religious institutions.

Such royal benefits were used for the internal needs of the temple, redistributed in the form of rations, and given as payments for the expenses of the state and the king, in particular. The construction of major works, such as the royal tomb, cenotaph (a commemorative monument), statues, and stelae (commemorative stone pillars), was often accomplished through the wealth of the temples. This particular kind of redistributive economy flourished especially during the New Kingdom. The economic growth of the temples rendered them intermediaries between the central and local administrations. During the periods when royal power was in decline, the temples and their representatives became substitutes for the political authorities.

The redistributed economic practice was not confined to interactions between the state and the clergy. It also defined the pharaoh's working and compensational policy toward the state's workforce. The following working classes could be traced in the Egyptian socioeconomic system: scribes, administrators, officials, craftsmen, agricultural laborers, and slaves.

The first three classes were literate and formed the elite of Egyptian society. The educational institutes provided the state, temples, and administrative offices with their personnel. Scribes could also work outside large offices for high officials and state stewards. The lower level of scribes and officials may have been given a wage (in the form of various commodities, such as copper or grain) in addition to their rations, while the upper ranks lived on the rents collected from endowment lands attached to their positions. Craftsmen earned income by selling their crafts to provide tombs and mortuary temples with artifacts and artwork. Most of these items were made in small, organized workshops attached to the palaces, mortuary complexes, temples, or offices of the elite. Independent craft work was done as well; many tomb representations depict people making craft transactions in markets, an indication of the independent function of this class of labor.

The largest percentage of the Egyptian workforce was made up of farmers, usually under the directorship of a landlord and organized into households or small groups. Either they rented land from the state or priestly authorities, or land was rewarded to them through the economic principles of redistribution and reciprocation. Taxes were calculated based on their annual production. With larger estates, the owner or lessor of the land provided a large number of workers to farm the land together. These laborers were mostly soldiers or slaves who had been captured in war or during foreign campaigns abroad.

This brings us to the final working class, that of slaves. In ancient Egypt this class did not include only the stereotype of the foreigner but also everybody who was under the rulership of a superior being, divine or human. Thus, a nobleman was the slave of a lord or high official, a farmer was the slave of his landlord, and a priest was the slave of his local god. Even

the pharaoh was regarded as the slave or servant of god. Slave dealing was done on a personal level, not in public or open markets. The transactions, though, had to be performed in the presence of a royal official or the local council.

MARKETS

The temple or political offices allocated the soil production and commodities to the populace according to each individual's needs. Surplus together with local food and homemade items could be traded at local markets. These were usually built close to road intersections or on riverbanks near harbors. The most commonly traded goods were bread, beer, fresh and dried fish, meat, and vegetables. The last two were probably surplus from the offerings to the priests in the mortuary and religious temples. Luxury goods were rarely traded in the markets. Common items offered for exchange included leather sandals, pieces of furniture, and ceramics.

Prices in the market were determined by supply and demand, though prices were sometimes fixed. State representatives supervised the prices and organization of the markets. They were also responsible for preventing raw materials and goods, which were the property of the state, from being diverted to illegal trading markets ("black markets") and for protecting customers from being cheated.

TAXATION

The system of benefits and land bestowment on institutions and individuals brought to the state a great deal of income in the form of taxes, which might have included a share in the produce of the land, cattle and other products, human labor, and wealth. Temples, foreign settlements, and garrisons were major beneficiaries of tax revenues generated by the annual levy during the New Kingdom. Evidence for taxation covers the whole period of the ancient Egyptian civilization and comes from administration texts, letters, and tomb scenes.

The taxes were received in kind by the chancellor in charge of the treasuries of Upper and Lower Egypt. Taxes in grain were collected by the pharaoh's so-called overseer of the granary. Redistribution of tax revenues to their beneficiaries was handled by the palace's master of largesse. Agricultural and land taxes were estimated after the land production was measured by surveyors in the company of scribes and an inspector.

Corruption or failure in tax collection led to severe punishment. A distinctive scene in the tomb of the vizier Khentika of the Sixth Dynasty (2323–2150 B.C.E.) depicts the judgment and corporal punishment of five district governors brought before the vizier and charged with corruption in tax collection. Within the royal decrees enacted by the king Horemheb of the Eighteenth Dynasty (r. 1319–1307) is a series of laws for addressing specific abuses on the part of governmental officials and soldiers who denied their responsibility in giving taxes to the state. There were also cases of district mayors and officials who formally complained about the taxes for which they were held liable.

Foreign lands were also obliged to contribute to the annual levy if they were regarded as proper Egyptian cities after their conquest or surrender to the Egyptian authorities. They paid their taxes through gifts or tributes to the pharaoh and the state, which might consist of precious metals (gold, silver, lapis lazuli), chariots, horses, cattle, and people to labor as servants or serfs.

RECIPROCITY AND FOREIGN TRIBUTES

One characteristic aspect of the trade economy in ancient Egypt was the gift exchange. It existed in two forms: as gifts between the king and his populace and as diplomatic tributes from allies and foreign parties to the pharaoh and the Egyptian state, especially during the Middle Kingdom (ca. 2040–1640 B.C.E.) and New Kingdom (ca. 1550–1070 B.C.E.).

Donations from the Egyptian populace to the pharaoh were conceived as tributes to both the divine and political status of the king. The Egyptians offered precious objects and commodities to receive internal peace and stability from the king. This practice can be traced as far back as the Old Kingdom. For example, in the step pyramid of the king Djoser (ca. 2630–ca. 2611 B.C.E.) at Saqqara—the first monumental structure constructed exclusively from stone—several inscribed jars were found that attested to the continued practice of giving gifts to the king. Gift giving has been recorded in account papyri from the mortuary temple of the pharaoh Sesostri II (ca. 1897–ca. 1878 B.C.E.) at el-Lahun, as well as from the papyrus Abusir and historical texts from the New Kingdom.

The gift exchange was reciprocal. The king honored the offerings and repaid the donors with equally valuable gifts. For example, one Egyptian source refers to the king's gifts to his liegemen and locates the ritual at which they were distributed at the forecourt of the palace. Diplomatic gifts were offered to the pharaoh from foreign rulers as evidence of existing or prospective allies. A diplomatic gift tended to convey social connotations rather than economic value. It was received with special care by the Egyptian authorities on a specific day of the year, and the whole process was ritualized and closely connected with the celebration of the New Year's festival. The first evidence of such foreign "tribute scenes" is recorded on the walls of the funerary complex of Khnumhotep, a monarch in the region of Beni Hasan (Lower Egypt) at the beginning of the second millennium B.C.E. A caravan of Levantine men and women are shown offering to the pharaoh a special lead ore that was used by the Egyptians as eye paint.

The custom of the diplomatic gift reached its peak during the New Kingdom, when the foreign expeditions of the pharaohs led to increasing contacts with foreign lands, from Libya in the west to Nubia in the south and territories in the Near East. This aspect of economic practice is best documented in the royal correspondence between the Egyptian king and the rulers of the Near East, the so-called Amarna Letters. These are clay tablets that were found in the city of Tel el-Amarna (Upper Egypt), the ancient site of the palace

of King Amenhotep IV (better known as Akhenaten). The collection consists of about 350 letters from the mid-14th century B.C.E. between the Egyptian state of the Eighteenth Dynasty and the rulers of the ancient territories in the Near East. The clay letters were inscribed in cuneiform script—the writing system used throughout western Asia at the time—and mostly in the language of Akkadian (Babylonian), the common language of international relations. The correspondence dealt with a variety of issues: alliance, strategic cases, trade, dynastic marriage, foreign gifts and tributes, quarrels between vassals, and legal and diplomatic issues.

Foreign tributes could include precious items or commodities that could not be found in the Egyptian territory. They were not just economic transactions but had diplomatic connotations, where the pharaoh was acclaimed as the major delineator of the action on behalf of the Egyptian society and in a superior position to the foreign representatives. In many cases these foreign tributes were combined with diplomatic marriages between members of the foreign and Egyptian courts. Thus, in Amarna Letter 22, the king of the Near Eastern kingdom of Mittani, Tushratta, gave his daughter to the king of Egypt to be his wife, together with precious gifts and various commodities.

THE MIDDLE EAST

BY JAMES A. CORRICK

There was no one single economy in the ancient Near East. Still, there were several factors that were commonplace. For the most part Near Eastern societies were agricultural in nature, and thus the growing of crops and the raising of animals were important economic activities. Equally common were other economic elements such as taxation, trade, and tribute from war. Prior to the fourth millennium B.C.E., however, except for agriculture, other economic pursuits were of little importance, as small farming communities were fairly self-sufficient, with their residents providing most of what they needed themselves. With the appearance of the first cities, more complex economies emerged.

SUMER

Around 3500 B.C.E. southern Mesopotamia came under the control of the Sumerians and became the site of several independent city-states, the largest being Uruk. Each of these Sumerian states had a distributive economy, one in which a central authority collected food and other goods, stored these collections, and then redistributed them according to the people's social positions or needs. The collection of food and goods was a form of taxation. In each Sumerian city administrators—priests and bureaucrats—required that each household pay this tax. Accordingly, part of what a household (which could be either a nuclear or extended family) grew, raised, or made was turned over to the city's temple and its palace, the headquarters of the secular authorities. Sumerians paid taxes on their crops and livestock, on boats they

owned, on fish they caught, and even on burials of the dead. Merchants also paid import and export duties. Sumerians, however, did not pay their taxes with money, because currency did not exist anywhere in the ancient Near East until the invention of coinage in the sixth century B.C.E. Instead, taxpayers brought to the temple and palace animals, grain, dates, pottery, and cloth, among other items. Such payment is known as payment in kind.

The tax was a payment for the privilege of working the land, which belonged to the god or goddess of the city (each urban center being the home of specific deity). The representatives of the local god or goddess were the city's ruler, its priests, and its palace authorities. Although private ownership of land did exist, many of the fields and pastures were in the hands of the temple and the palace. Both the religious and secular authorities increased their holdings by purchasing land or by confiscating it from those who failed to pay their taxes.

By around 3000 B.C.E. an established system of distribution existed in the city-states of Sumer. As goods came into temples and palaces, they were placed in jars, baskets, or rooms, to which were affixed clay seals. Records of amounts were kept by placing clay counters or tokens into spherical clay containers, known as bullae, much as paper records today are placed in file folders. With the invention of writing at the end of the fourth millennium, a written record of the content of each bulla was incised or impressed onto its surface. Eventually, the written record, incised on a clay tablet, replaced the bullae.

Sumerian priests and palace officials oversaw the use to which the food and goods collected as tax were put. Some of the yield was stockpiled for times of famine, while some was reserved as seed for the next year's crop. A portion of the tax was used as offerings in religious ritual. Taxes also went toward financing the construction and maintenance of irrigation canals and public buildings. They paid for wars, which in turn brought back booty and tribute as additional revenues for each Sumerian city-state.

Additionally, some of the goods were used for trade, an important part of the economy of each Sumerian city-state. Food, which was sent to other, less productive regions of the Near East; pottery; and textiles were all important trade goods. In exchange, the Sumerian cities received stone and timber for building and metal for tools and weapons, as well as jewelry, perfumes, exotic animals, and other luxury items that became part of the personal wealth of religious and government officials or were given out as gifts to others to buy their support.

Finally, although many of the city's households produced enough food, clothing, and other goods to feed their members even after paying their taxes, others did not and depended on the collected tax to meet their needs. Among those dependent upon tax stores were a city-state's ruler, its priests and priestesses, and its government bureaucrats, along with their families. Others were craftspeople who produced

cloth, pottery, and metal tools and weapons. The tax freed both the Sumerian elite and the craftspeople from the necessity of providing for at least some of their own needs and thus gave them the time to perform their duties and work.

Payment in kind was not the only method of settling a tax bill in ancient Sumer. There was also a labor tax. Known in modern times as a *corvée*, the labor obligation meant that the members of a household had to work a certain number of days in the fields controlled by its temple and palace, in digging or cleaning out irrigation canals, and in constructing public buildings. Of all the taxes, the *corvée* was the most burdensome. Farmers found themselves bringing in the harvest of the temple and the palace while their own crops languished in the fields. Worse still was military service that sometimes sent men away from their farms for months at a time, sometimes never to return if they were killed in battle.

Women and children, on the other hand, were employed in large weaving factories, in addition to performing agricultural labor. Textiles were a Sumerian economic mainstay, used for gifts, religious offerings, and trade items. Thus hundreds and sometimes thousands of women and children in each city-state plucked the wool from sheep and spun it, wove it, and washed the final cloth product. Women were also responsible for brewing beer from stores of grain.

The Sumerian tax burden had the beneficial effect of improving production efficiency so that the number of items a worker could produce increased. For instance, in order to turn out more ceramic bowls and pots faster, craftspeople moved from forming pottery solely by hand to using molds and potter's wheels. The rise of centers that specialized in making particular goods, such as pottery, metals, or textiles,

contributed to increased production efficiency. Such centers, for example, appeared toward the end of the fourth millennium B.C.E. in the southern city-state of Uruk. To what extent these centers were set up and run by the priests and bureaucrats remains unknown. It is possible that the centers came into existence not because of official sponsorship but because they were located in areas that, unlike other regions, had access to the resources necessary for the items they produced.

By the middle of the third millennium B.C.E. the distributive economy of the Sumerian city-states centered on the great household, often referred to by the Greek term *oikos*. A great household could be a temple, a palace, or a large, wealthy estate. Each *oikos* controlled the production, labor, and consumption of its members, who unlike those of the traditional small household were not kinfolk. Small kin-based households still existed, but most of the economic activity was now in the hands of the *oikoi*.

The head of an *oikos* could be a man or a woman. These *oikoi* leaders were among the highest-ranking members of Sumerian society, and thus Sumerian kings and queens headed their own *oikoi*, as did prominent government officials and wealthy merchants. Each *oikos* had its own fields, pastures, herds, orchards, workshops, and storage depots. Each also had managers and a labor force. The latter were recruited from the large pool of city residents; by the third millennium B.C.E. some 80 percent of southern Mesopotamians are estimated to have lived in the cities. *Oikos* laborers were often specialists—farmhands, animal handlers, cooks, gardeners, brewers, potters, weavers, and metalworkers. With such material and human resources, an *oikos* was able to meet most of the needs of its members.

In exchange for this labor the *oikos* provided its members with certain basics—oil, beer, wool, and flour and, on special occasions, milk, fruit, salt, and fish. Age, gender, and the type of work determined how much an *oikos* member received. Generally, *oikos* members had to process these distributions further: thus they had to make the flour into bread and the wool into cloth. Each *oikos* also gave out plots of land to its highest-ranking members; the higher the rank, the larger the land grant. Among those eligible for land were political leaders, priests and priestesses, scribes, canal inspectors, managers, soldiers, and skilled artisans. In addition to these grants, an *oikos* also rented out land to nonmembers of the household for a share of the plot's crops.

THE SPREAD OF THE SUMERIAN ECONOMIC SYSTEM

The Sumerian city-states were not the only ancient Near Eastern societies to have a distributive economy, payment in kind, and a *corvée*. Indeed, by the early third millennium B.C.E. such were to be found in the growing urban centers of northern Mesopotamia and the Levant. To what extent these economic forms existing elsewhere in the region were due to other peoples having independently developed them and to what extent they were imported from Sumer is unclear. How-

ever, Sumerian traders, sometimes living in colonies next to other Near Eastern cities, had business connections throughout much of the region. It is certainly possible that these traders brought with them Sumerian economic concepts.

Another method for the export of the Sumerian economic system may have been conquest. In the early 24th century B.C.E. Sargon the Great created the Akkadian Empire, which he would rule for almost half a century. Under Sargon and his successors the empire incorporated the Sumerian city-states, northern Mesopotamia, Elam, and Armenia. The distributive economy of Sumer was already present in northern Mesopotamian cities. It may also have developed previously to conquest in such Elamite cities as Susa or been brought to the region by the Akkadians. The economy of Armenia at this time is unknown, but the later Armenia-based society of Urartu possibly had a distributive economy.

THE AKKADIANS

The Akkadian rulers did not change the local economies of their subject cities. Instead, they required the payment of tribute, with each conquered city having to send a portion of its collected food and goods to the imperial capital of Agade in northern Mesopotamia. The collection of tribute was already an old idea by the time of the Akkadian Empire. Among the Sumerians, after a successful war against an enemy city, a victorious king brought back rich loot and later received tribute from the conquered. The king added this newfound wealth to the palace treasury, sharing some of it with high-ranking military officers and bureaucrats. Some of it was also presented to the city temple. Trade, another important part of the state income, also benefited from such conquest, as traders soon arrived to claim a piece of the city's increased prosperity, and taxes on their operations also enriched the city. Where in Sumer conquest was generally modest, often with only one city dominating another, and short-lived, frequently in terms of years, the Akkadian Empire held an extensive territory for a century and a half.

In order to manage the finances of the empire, the Akkadians introduced a common accounting practice in all their conquered territories. Accounting had to be done using the same cuneiform signs and tablets having the same shape and layout. Additionally, since payment was in kind, the Akkadians standardized weights and measures by introducing the *gur*. One *gur* was equal to about 43 gallons of barley. Valuing goods by comparing them to a quantity of barley, the most common grain that was grown in Mesopotamia, had been a longtime practice of the Sumerians. The *gur* would continue to be used, at least in Mesopotamia, for the next two millennia.

The Akkadians were succeeded by other states, such as the Third Dynasty of Ur and the Old Babylonian kingdom, who each in turn ruled much of Mesopotamia, north and south. No matter the state, the old Sumerian distributive economy remained in place in each Mesopotamian city. Payment in kind likewise survived, though it was supplemented by occasional payments in silver; along with weights of barley,

weights of silver were used to determine the value of goods. The *corvée* still operated, though labor obligations were eased by the presence of slaves, who were either those captured in war or those enslaved when they failed to meet their tax payments. The *oikoi* continued to be the managers of at least local economies.

THE HITTITES

To the north of Mesopotamia were Anatolia and the Hittites, who appeared around 1800 B.C.E. and lasted until around 1200 B.C.E. Beginning in about 1650 B.C.E. the Hittite kingdom expanded from its central Anatolian homeland to conquer all of Anatolia, including Armenia in the west and part of the Levant. Unlike the Mesopotamians, the Hittites had few cities, and their domestic economy revolved around small, self-sufficient farming communities that provided most of their own needs and owned all farmland in common. Hittite agriculture, however, did not produce surpluses; indeed, the Hittites often had food shortages, which they made up either through tribute collected from those that they had conquered or through trade.

If the Hittites did not have food to trade, they did have metals. Mining of tin, silver, and iron were lucrative. Tin was important in the manufacture of bronze, and thus there was always a ready market for it. Enough silver was produced that the Hittites used it as a medium of exchange. Iron was a novelty item because it was almost as rare as gold, whose only source at this time was Egypt. Iron was also more for show than utility. Weapons and tools made from it at this period were no stronger than those made from bronze, and thus it was more often used to make jewelry and statuettes, both of which were prized trade goods.

The Hittites acquired copper for manufacturing bronze in the same way that they acquired many of their resources: They conquered those who had it, in this case Isuwa in western Anatolia. Maintaining the army was a major expense for the Hittites, but as with other military states, an army allowed the Hittite kingdom to bring in loot from successful campaigns and to ensure that those conquered paid regular tribute, either in silver or as payment in kind. Additionally, the army could protect essential Hittite trade routes from others who might try to charge Hittite merchants a toll for use of these routes. Instead, any tolls exacted were collected by the Hittite kingdom.

URARTU

The waning of the Hittites around 1200 B.C.E. saw the emergence in Armenia of the kingdom of Urartu, which reached its height during the eighth century B.C.E. Like other ancient Near Eastern societies, Urartu had an economy that depended on agricultural production, with part of the harvest from its rich farmlands going to trade. Additionally, the mining and export of copper, silver, and iron was an essential part of the Urartu economy. Besides unworked metal, Urartu traded metal tools, weapons, and jewelry, which were esteemed for

their craftsmanship as far away as northern Italy. The kingdom's economy also benefited from its geographic position, which allowed it to control the trade routes that connected northern Mesopotamia and Elam to the Mediterranean. Urartu exacted a toll in payment of kind from the traders who used these routes.

Urartu may have had a distributive economy, since its administration centers, fortresses located in a mountainous region of the kingdom, held large storage facilities for grain and wine. Conversely, rather than being redistributed, these stored goods may have been meant to feed the inhabitants of a fortress during the occasional siege by Urartu enemies. The kingdom also probably had a labor tax, since it undertook the construction of aqueducts and other large works projects using workforces, most likely made up of *corvée* draftees.

THE ASSYRIANS

The most persistent attackers of the Urartu mountain fortresses were the Assyrians, for whom loot and tribute played an extremely important role in the economy. From their northern Mesopotamian home the Assyrians conquered the remainder of Mesopotamia and much of the Near East in the 11th century B.C.E. For 400 years they would exact tribute from their subject peoples. Like previous conquerors, the Assyrians appear to have left much of the economic structure of their conquests in place, demanding an annual tribute, which was paid in silver or in kind and which was sent to the Assyrian capital. In some cases the collection of the tribute was in the hands of a native ruling family; the Assyrians then sent expeditions to bring the tribute to Assyria. In other instances, perhaps where the original ruling family proved resistant to paying the tribute, the Assyrians placed one of their own in charge. This governor then saw to the collection and delivery of the tribute.

Trade also was important to Assyria and may have dictated some of its expansion. More directly, through military control of much of the Near East, Assyria controlled almost all the trade routes and thus the flow of the majority of Near Eastern trade. It thus had ready access to copper, silver, wood, and other valuable resources as well as much of the luxury trade enjoyed by the Phoenician cities, which paid Assyria a handsome tribute. Proceeds from tribute and trade had to be large in order to make up for the Assyrian policy of exempting from taxation their home cities, such as Nineveh. The *corvée* also did not apply to the Assyrian homeland. Instead, conquered cities had to supply laborers when required as well as soldiers for the army.

THE PHOENICIANS

Among the most lucrative tributes collected by the Assyrians was that from the Phoenician city-states, such as Tyre, Sidon, Byblos, and Arvad. Of all the ancient Near Eastern economies, that of the Phoenicians was the most dominated by trade. The stretch of the Levant coast on which the Phoenicians lived was narrow, mountains rising not far inland. Thus

there was little arable land for agriculture. Importing food became a top priority of the Phoenicians in order to sustain the populations of their cities.
