Pulses, legumes, and similar vegetables were dried for storage. Some other vegetables, such as mushrooms, could also have been dried. Drying, salting, and possibly smoking were used in various parts of the ancient Near East to keep meat and especially fish. The bones of saltwater fish found at inland sites in Sumer show that some sort of preservation of fish for shipment was taking place by the third millennium B.C.E. Sumerian texts show that they were making a kind of fermented fish sauce as well. Although most meat was eaten right away, the types that would have been available for processing included goat, beef, mutton, venison, and pork. Poultry such as ducks and geese were also raised and their meat dried or smoked.

As urban centers and the centralized control of commodities grew, larger storage facilities were needed. Grain, which was made into bread and (since the fourth millennium B.C.E.) beer, was stored in great quantities. The Middle Bronze Age (ca. 2000–ca. 1500 B.C.E.) silos at Beth Yerah are estimated to have held as much as 40 tons of grain. Other contemporary cities in this area, however, had a different solution to the problem of grain storage. They excavated downward rather than building upward to make their granaries. By the Iron Age (ca. 1200–ca. 586 B.C.E.) cities like Jericho and Megiddo were building rectangular storehouses and storerooms with thick walls to keep the grain and foodstuffs cool and dry. Archaeologists in Israel have uncovered storehouses in which the stored items were kept in pottery bins or jars. Occasionally, commodities such as grain were stored loose in these rooms. The remains of barley and wheat show that these were the main cereals grown and stored in the granaries.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The need to provide food during lean times was met in many different ways in Asia and the Pacific, depending on the food that was available, the climate, and people's cultures. The first people in Australia found a fairly wet climate and big forests, but the continent gradually dried out, leaving only small forests in areas that remained wet. The Australians coped by spreading out in a thin population over the continent. By living in small, family-oriented groups with a great deal of space for hunting and gathering food, the ancient Australians were able to thrive when food was plentiful and still find enough food to survive when times were lean. Rather than store large caches of food, they made sure there were not too many people to use what food was available to them throughout the year.

In tropical climates storing food was difficult because the regions tended to be wet, and moisture helped to decay food. One way to preserve fish was to smoke it. This involved suspending fish over a low-burning, smoky fire that would rapidly dry the fish. Fish devoid of moisture could remain edible for weeks or even months. Cultures throughout the South Pacific and the Indian Ocean used this technique. In areas where tapers or other sources of meat were available, meat was smoked. Techniques for storing smoked meat varied but usually involved hanging the dried meat either inside the home or underground in a chamber dug for the purpose of storing smoked meats, keeping the food away from scavenging animals.

Nomads in central and northern Asia hung meat from poles or skewers to allow the wind to dry it. It was important to allow the meat to dangle and to cut it thinly enough for the wind to dry it thoroughly. The climate of central Asia was drying out during the ancient era, creating excellent conditions for drying meat rapidly. It was difficult for the nomads to store bulky foods such as the grains most often grown in their regions: millet, wheat, and barley. Thus they sometimes took to raiding farming communities to steal the harvests

when they wanted the food rather than producing and storing the food themselves.

Keeping grains dry was very important. The Harappan civilization of about 2600 to 1500 B.C.E. made the preservation of grain a science in which they engineered sometimes spectacular granaries for storing grain against hard times. The cities of Harappa and Mohenjo Daro had granaries that may have represented the apex of grain-storage technology. The granary in Mohenjo Daro was about 150 feet in length and about 75 feet wide, and it rested on a base of bricks about 20 feet high. Atop the base was a wooden, roofed structure perhaps 12 feet high. Although the city had mostly narrow streets, a large open space around the granary allowed easy access for carts bringing in grain or unloading grain for distribution. There was a loading platform along one side of the building where grain could be hoisted up or lowered down. Inside were wooden silos that held the grain. Under the floor were air ducts, channels that circulated air to keep the grain dry to prevent rotting. The granary looked like a fortress, which has inspired some archaeologists to speculate that the granary was like a bank that held the nation's wealth. The huge structure probably ensured that Harappans would have food to eat during poor harvests.

Insects and rodents were threats to stored grain. In ancient China their feasting in granaries sometimes resulted in a shortage of food. Keeping grain sealed helped keep out insects, and large ceramic jars with tight lids were used in China, India, and Japan to protect grain. Although the ancient Japanese typically built their structures with pits in the ground, they raised their granaries on posts to help keep the stored grain out of reach of mice and other pests. The shape of a granary was rectangular. Four holes in the ground were pounded until their bottoms were rock hard, then circular wooden posts were set in them. A wooden floor a few feet above the ground was installed, followed by walls attached to the posts and a roof that was probably peaked and covered with dried grass, although archaeologists disagree greatly among themselves about this detail. It seems that by 100 C.E. nearly every village in the Japanese islands had such a granary.

Another way to preserve food was to pack it in salt. The salt would keep meat from going rancid for a time, usually long enough to carry it through a season when food was scarce. Meat preserved with salt had something in common with dry grain: It needed water to make it edible. Rice is almost not chewable unless moistened. Salted meat needed to be soaked in water to wash out enough salt to make it digestible. In much of central and northern Asia water became increasingly harder to find throughout ancient times. For nomads, this left them their wind-dried meats. For farmers, this meant digging pits in which to store their foods, though this practice seems to have come late to northern China. The soldiers of the Great Wall had storage depots for food and other supplies, but the farmers of the region still needed to be taught about granaries and storage pits as late as the 100s C.E.

In India the need for water to make dry grain and salted meat edible created a dangerous problem. People from cities went to nearby rivers or to moats to fetch their water for cooking, and the rivers and moats were dreadfully polluted by 300 B.C.E. Diseases transmitted by human waste, garbage, and rodents lurked in the water, and underheated cooking water could result in outbreaks of disease that could kill thousands in crowded residential districts. The usually wet climate of most of India also made it difficult to keep foods dry. Indians got around some of their food preservation problems by tending gardens for fresh food. Even a small household usually had a garden from which fruits and herbs could be picked daily. Except for the cold and sometimes dry far north of India, it was possible to have something ripe and edible in a garden year-round. Both men and women were often master gardeners, and men who were professional gardeners took care to teach their daughters what they knew, because the girls would ultimately be responsible for caring for the food in their household gardens. It also was a good trade for a woman to know, to make money for herself and her family in the marketplace.

EUROPE

BY MICHAEL J. O'NEAL

The ancient Europeans faced the same storage and preservation problems that ancient peoples the world over faced. The enemies of food stored over a period of time include moisture, temperature, microbes (including molds), and pests. Without effective systems of food storage and preservation, the ancient Europeans would have found it difficult to fend off famine and starvation during the long, cold winters of the North. Moreover, without methods of storage and preservation, it is not possible to accumulate perishable goods, transport them, and trade them, activities that were a necessary means to the accumulation of wealth and status.

Many of the technologies that the ancient Europeans used to store and preserve food are still in use today. The only fundamental difference is that ancient Europeans did not have electricity to power the tools they used for the task. Accordingly, they relied on the tools that nature provided. One method of preserving such food as meat, fish, vegetables, and fruits was to dry them. With a low moisture content, food was not as susceptible to spoilage. To dry food, the ancient Europeans placed it in the sun and allowed warm air to circulate around it. A variant of drying is cheese making. The ancient Europeans were able to preserve milk in cheese form by coagulating it and draining out the watery whey, leaving behind the milk solids that had a much lower water content than the original milk. In cool temperatures, cheese would keep for many months. In Neolithic Britain residues of milk fats have been found on fragments of pottery that date from 4500 B.C.E.

The problem the ancient Europeans faced, though, was that for food to dry effectively, three to five days of high tem-

peratures, bright sunshine, and low humidity were needed, so drying was not always possible. Accordingly, the ancient Europeans turned to a related technique, smoking, particularly for meat and fish. Smoke contains a number of substances that bind to the surface of the cells of meat products, allowing them to resist the action of bacteria. While meat and fish would normally spoil after perhaps a week, smoked meat and fish could be consumed safely for three months or more.

Similarly, storing meat, fish, and vegetables in brine—that is, a concentrated solution of water and salt—provided similar protection against microbes. Salt was a highly valued commodity in ancient Europe, and the salt-producing region of Austria near the modern-day city of Salzburg (*salz* means “salt” in German) enjoyed a great deal of wealth by mining it. The ancient Gauls sold salted pork to the Romans. Salt was especially valuable to the Scandinavian cultures of northern Europe, whose diet included a great deal of fish that had to be stored during winter months, when bodies of water were frozen over or too stormy to allow fishing. A related technique was the use of spices to preserve food; modern scientists have shown that some spices effectively fight the formation of harmful bacteria. In ancient Europe, however, spices were extremely valuable commodities, available only from Arab traders. The average person probably would not have had access to spices, although the elite would have.

The ancient Europeans, again in common with the rest of the world, needed reliable sources of wholesome beverages that would not become stale and brackish in storage. Fermented beverages, such as beer and wine, provided them with drinkable liquids throughout the year. Of course, the Europeans by no means invented fermented beverages, but they did introduce the wooden barrel as a way of storing and transporting wine and beer.

The ancient Europeans devoted considerable resources to the storing of food. In common with other cultures of the world, they used caves where they could. Caves have the advantage of being at a constant cool temperature, with reliable humidity levels. Caves were the earliest form of root cellars and were particularly useful for the storing of root vegetables as well as fruits.

Where caves were not available, the Europeans constructed granaries and other facilities for the storage of food, particularly for grain. Throughout the Celtic lands of western Europe and the British Isles, for example, archaeologists have uncovered a large number of hill forts and, in Scotland, brochs (circular stone fortifications) that date from the Iron Age. These hill forts were settlements that housed up to several hundred people, though sometimes they were occupied seasonally or provided a place of refuge for people and their livestock in times of war. These hill forts were administrative centers for the surrounding region, and one of the major functions they served was that of food storage and preservation.

In England, for example, hill forts such as Danebury have been found with massive grain-storage capacity. Many of these hill forts were built on chalk subsoil, and in their in-

teriors were pits used for food storage, as underground grain silos. Normally, the moisture of an underground pit would cause any grain stored in them to rot. However, the Europeans may have found a solution to the problem. The grain was poured into the pit, and then the pit was covered with an airtight clay seal. The seal was then covered with dirt to keep the seal from drying and cracking. The grain in contact with the moist earth of the pit germinated, consuming all the oxygen in the pit and releasing carbon dioxide. Because the seal was airtight, no further oxygen could enter. The remainder of the grain, then, was preserved in a state of “suspended animation.” In this way it could have been preserved for months, as long as the seal remained intact.

GREECE

BY LYN GREEN

From the Minoans and Mycenaeans (2600–1100 B.C.E.) of the Bronze Age to the Hellenistic Greek world more than a thousand years later there were many similarities in food storage and preservation. No matter what the time period, the storage needs of the people did not change. For the short term, food had to be stored before eating or before it was redistributed through rations. An example of medium-term storage was putting aside an amount of food to last through the gaps between growing seasons or before it was exported or otherwise used in trade. Farmers also had to put aside enough seed each year to plant the next season’s crop, and prudent householders and city rulers put aside food in case of famine or war. These were examples of long-term storage in large volumes. Although both seed for planting and food put aside against famine were both problems in long-term and large-volume storage, there was one significant difference. When it was time for crop planting, the storage areas for seeds would be emptied until the end of season. There was no need to worry about contamination or spoilage of food that was now open to air. This may have affected the choice of container or structure for storage.

Tablets from the palaces of Crete and Greece in the Bronze Age show that palatial structures served as warehouses for goods and food items from the surrounding countryside. Olives, olive oil, grain, honey, fruit, and meat all were stored there. Grains such as wheat and barley were sometimes kept in palace courtyards in huge pottery vessels called *pithoi*. There were also other means of storing grain. The earliest forms of storage were probably pits lined with clay or stone. They would have been kept tightly sealed to keep out air and vermin, such as rats and mice. There is much disagreement among scholars about the purpose of some of the large pits excavated at places like Knossos and whether they would have been an efficient way to store grain, because it might have been difficult to keep out pests and mold-causing moisture. It is generally agreed, however, that these large pits would have been most suitable for long-term storage. Clay bins were also used for keeping grain. Sometimes, however,

Amphora, a ceramic vessel used for storing and carrying oil and wine and other commodities, from Athens (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

the grain was stored loose in a granary or in one room of a larger storage building.

Some of the earliest buildings solely dedicated to storage of grain were round, with dome-shaped roofs. These would have looked very similar to the images of granaries from Egyptian tombs from the same time period. Granaries from the later Geometric Period in Greece have an almost identical shape. Grain was poured into the granary through a window near the top of the dome and removed at the base through another gap. Thus, the older grain at the bottom of the pile would always be used first.

During the fourth and fifth centuries B.C.E. people actually made less use of large-scale and long-term storage fa-

cilities. During the Bronze Age goods had been taken to the palaces for redistribution, but in the Classical Period (480–323 B.C.E.) the system of storage and distribution was based on individuals and their farmsteads. However, even though the local farmers could not grow enough grain to feed the nearby cities, archaeologists have not been able to identify the storage places of the imported grain in urban centers or their ports. This has led some scholars to suggest that the grain was stored in the countryside.

At Knossos a building called the Unexplored Mansion contained a number of storage jars of untouched food, including legumes, figs, and several kinds of grain. Some of the grain in these jars was hulled, but a similar find of stored Bronze Age grain in Macedonia had spikelets of wheat. Centuries later, ancient authors would recommend storing grain without threshing it (removing the chaff or straw) so that if weevils did get in, they would be confined to the outer layers of the grain. In the eighth century B.C.E. the Greek writer Hesiod (fl. ca. 800 B.C.E.) stated that threshed grain should be kept in storage jars within the house.

The available methods of storing food meant that food had to be preserved by other means before being put into storage. Unfortunately, most of the ancient descriptions of food processing come from the Roman Period, and the archaeological evidence is often not of much help. The evidence seems to point to the fact that meat, which was expensive and therefore rarely eaten, was consumed right away. Fish, on the other hand, was eaten in larger quantities, both fresh and preserved. Based on the information available, it seems likely that the Greeks usually salted or smoked both meat and fish. There are, in fact, many terms for preserved fish, but all seem to describe the species of fish and the shape of the preserved pieces rather than the process. Milk from goats, sheep, or cows was preserved for short-term use by being made into butter and for longer periods by being made into cheese. Milk solids could be formed into small bricks, dried in the sun, and later rehydrated for use in cooking.

Lentils, peas, and beans of all kinds were dried for storage and were easily reconstituted with water in stews or ground up into flour. Other vegetables could have been dried or pickled in brine or vinegar. Olives and cucumbers were certainly pickled in these ways. Greens such as lettuce and cresses were difficult to keep for long periods and probably were eaten only fresh. However, it is known that the leaves of fig trees were pickled and were used by almost every cook. Fruits that had an outer rind (such as pomegranates) or were hard (like quinces) could be kept fresh by careful storage. If the fruits were placed in containers in such a way that they did not touch the sides of the container or especially each other, they would stay fresh for a longer time. Juicier, softer fruits such as figs, plums, cherries, and grapes could be dried or preserved in honey. Grapes, of course, were also preserved by being made into wine. Most fruits, in fact, could be pressed for their juice and the juice allowed to ferment and become cider or wine or to sour and become vinegar. Not only did

this process preserve the fruit itself, but the alcohol in the fermented drinks (or the acid in the vinegar) could be used to preserve other foods.

ROME

BY LYN GREEN

Throughout the history of Rome, as capital of both a republic and an empire, the city faced the daunting task of keeping its growing population fed and supplied. However, unlike some other urban centers of the ancient world, the local countryside around Rome was inadequate to feed its massive population. To complicate matters further, as Rome grew in size and wealth, so did the demand for luxuries of all kinds. The growth of the Roman Empire and the spread of the Roman bureaucracy also increased demand for the same sorts of products throughout the vast territories as officials tried to maintain the lifestyle they had enjoyed in Italy. This demand necessitated a complex web of shipping routes and the facilities and techniques necessary to store goods of all kinds.

Although Roman writers liked to recall the good old days when their ancestors lived on *pulmentarium* (stew or porridge made of grains or beans), bread was the most important item in the Roman diet. Although spelt, barley, or rye could be used to make bread, wheat made the best loaves. Unfortunately, wheat was not a crop that grew well in Italy. North Africa and especially Egypt were the major exporters of wheat throughout the ancient Mediterranean, and trade routes from the ports of the African coast to Ostia were vital to the survival of Rome. However, as the wheat would first be stored, then shipped to Rome by boat, and then stored at Rome, some method of processing grain for storage was essential.

In order to avoid spoilage, grain must be kept in a cool, dry, and dark place. These places must also be designed to keep out such vermin as mice or rats, which would eat or contaminate the food. In the drier areas of the Mediterranean, such as Spain, the grain could be stored in underground pits that were lined with straw and tightly sealed. The Roman author Varro (116–27 B.C.E.) also mentions that the farmers of Thrace stored their grain in caves. In northern Spain and southern Gaul, the grain was stored in huge terra-cotta jars called *pithoi* or in silos. Varro also suggests using above-ground granaries that were ventilated by windows and raised up on wooden supports to allow air circulation. Another ancient description of these granaries mentions that they had brick walls 3 feet thick and were accessed from above. The author of that description also states that *amurca*, the dregs of pressed olives, should be incorporated into all the tiles and plaster used to seal the granaries in order to discourage vermin.

Wherever Roman legions went, they built large granaries, sometimes intended to hold enough food to last through a yearlong siege. These were originally built of timber, but after Trajan's (r. 98–117 C.E.) time stone granaries became more common. In either case, the grain was probably stored in sacks or baskets rather than piled loosely in chambers.

The containers would have made the job of measuring out rations much easier and would have served as barrier to vermin. The biggest civil granaries were undoubtedly those at Ostia, where the grain from Africa was delivered. Two types of granaries have been excavated at Ostia: a building consisting of long, narrow rooms facing a courtyard and two rows of rooms opening off a central corridor. Some granaries show evidence of stairs leading to an upper floor. Archaeologists are confident that grain was stored on the lower floors, but grain was of course only one of the items that could be stored in these buildings.

A number of methods of preserving food were known to the ancient Romans, and the choice of which one to use depended on the local climate and the type of food being stored. Drying, salting, smoking, and pickling were the most common ways of preserving food. Some fruits, like grapes, figs and dates, naturally lent themselves to drying without loss of flavor. They could also be packed in honey or in a mixture of honey and boiled wine. Beans, peas, lentils, and pulses were also dried, while cucumbers and olives were pickled in brine. Fish and meat were often salted by being immersed in brine, although in the hot, dry areas of the empire they could also have been wind-dehydrated. Pickling food could be done using beer vinegar, fig vinegar, wine vinegar, wine, and sour milk. The increased acidity of the food discourages the growth of bacteria, as does alcohol. As the Romans did not use distilled alcohol, wine or even beer could be used to preserve foods.

Pork was the most popular meat for upper-class Romans, but it did not keep well and care had to be taken to preserve it soon after slaughtering. To salt the meat, ancient authors recommend rubbing it with coarse salt each day for 12 days. For the first three days, between rubbings, it was kept pressed under weights to squeeze out excess moisture. Sometimes this step could be followed by further drying or smoking. Pork could also be salted in jars. The deboned pieces of meat were jammed into the jars and layered with salt until the container was crammed full. Then it was sealed tightly. The same methods were used to prepare salt fish. In the 1990s some archaeologists experimented with using spices to preserve food. They discovered that cinnamon, cumin, onion, and especially garlic slowed or even stopped the growth of microorganisms that would cause food to spoil. Black pepper, on the other hand, was not very effective in stopping bacterial growth.

Although there were ice houses in the ancient world, they were not always available. Therefore, the Romans developed other methods of keeping the color, scent, and shape of preserved foods: They prevented any air from reaching the food and starting the process of decay. There are a number of different techniques described by the ancient writer Columella (first century C.E.). For example, he states that if grapes are picked with their stems on, the ends of the stems should be sealed with pitch to keep out the air. This method is also recommended by other ancient authors for apples, quinces, cherries, plums, and pears. Quinces and pomegranates could

be completely coated in a thick layer of potter's clay and left to dry. A quick wash would remove the clay from the fruits later. The Romans also understood the importance of keeping the fruits from touching one another, and fruits might also be stored in containers divided with wood into little compartments and filled with sawdust. However, all of these methods were very labor intensive and were probably most often used on the great estates that had hundreds of slave workers.

THE AMERICAS

BY AMY HACKNEY BLACKWELL

Ancient American peoples needed to store several things: wild food items that they had gathered, seeds for the next planting season, and water for daily use and in case of drought. They also needed to preserve food, both plant foods and meats, so that they would have a steady food supply throughout the year.

Drying was the most common method of food preservation throughout the Americas. People dried such grains as corn and other vegetables either by spreading them out in the sun or by placing them in a fire. How long grains would remain edible depended on local humidity; corn would last three years in the dry climate of the North American Southwest, but it lasted only one year in the humidity of the Yucatán peninsula. People preserved meat and fish by drying them as well. Women would cut meat into strips and lay it across open racks to dry in the sun. Meat and fish could be smoked by placing them in the smoke of a slow fire for several days. Dried and smoked meats would keep for many months, depending on humidity and temperature. Native Americans sometimes embellished their basic dried meats with different ingredients. For example, sometimes they would dip the meat in ground corn before drying it and then roll up the dried strips for ease of transport during travel. Pemmican was made by cutting fresh meat into chunks, mixing it with dried berries and rendered fat, and spreading it out to dry into bars.

Native Americans who lived in cold climates took advantage of natural freezing temperatures to preserve meat. They would kill animals early in the winter, cut them into pieces of meat, and allow the meat to freeze. They could then defrost it in a fire when they were ready to eat it. The people who lived in the Arctic commonly employed this technique with seal meat. People who lived in the Andes used freeze-drying to preserve some of their food, particularly potatoes. They would lay out their potatoes on the mountainside, where the potatoes would freeze; the water would then gradually sublimate out of them, resulting in very lightweight potatoes that lasted a long time. Although people ate dried foods as they were, they might also reconstitute them by soaking or cooking them in water.

Throughout the Americas people stored food in woven baskets. People throughout the two continents began making baskets about 6000 B.C.E. Both sexes wove baskets. People

would sometimes weave baskets very quickly on the spot if they suddenly found a trove of food and wanted to carry it home. Basket styles and materials varied by region. People in the north made baskets of birch bark, ash, or sweetgrass. Native Americans in California used yucca, willow, or sumac. On the northwest coast weavers used spruce root, cedar bark, and swamp grass. People in the southeastern regions used pine needles. Basketry became more highly developed when people adopted the sedentary agricultural lifestyle, around 1 C.E. in North America and perhaps around 4000 B.C.E. in Central America.

Native Americans used baskets for a variety of purposes. They attached shoulder straps to conical baskets to make carrying baskets. Some baskets had an open weave; these baskets were lighter, good for carrying loads of firewood or large food items. Open-weave baskets were useful for catching and carrying fish or clams because they allowed the water to drain out of the basket. More tightly woven baskets could carry small items, such as seeds. When people harvested crops, they sometimes carried small baskets on their hips to hold the grain they picked, periodically emptying these small baskets into larger baskets on their backs. Different shapes of baskets were used for different food items. Baskets intended to hold fresh berries, for example, were shaped like cones to prevent the weight of the topmost berries from crushing the ones on the bottom. Baskets could be waterproofed with such substances as pine resin to make them suitable for carrying or storing water.

Native Americans throughout North America stored food in clay pots. Archaeologists have found pots throughout the continent, dating to the time when humans first lived in the area; numerous ancient pots date to between 25,000 and 8000 B.C.E. Plain mud can be formed into vessels that will dry hard, but unless they are fired, they will dissolve in water and crumble easily when dry. Baking clay in a hot fire makes it hard and more water resistant, though without some sort of glaze to seal the surface even fired clay will leak water. Archaeologists have found many unfired pots used by ancient Americans; these could have been used to store dry items, such as nuts and seeds.

Historians believe that the practice of firing clay pots was an outgrowth of basketry and food drying. One technique Native Americans developed to dry such food as corn was to place the grain in a basket lined with clay and then put it in or over a fire. The basket would burn, leaving behind a baked clay shell. As evidence for this practice, historians cite the many ancient pots with exterior textures that look as if they were formed in baskets.

Although Native Americans had used pots to store food for millennia before the advent of farming, it was when they settled down in agricultural settlements that potters gained real expertise with their art and different nations developed different designs for their vessels based on their storage needs. Women (who made most pottery) made water jars with bases designed to rest comfortably on the top of a human head in

order to carry water from streams to homes. They built large pots with tight-fitting lids that could hold grain and protect it from insects, rodents, and moisture. They constructed large water pots with glazed interiors that would not leak. They also invented pots to store seeds for planting, using different designs to identify different types of seeds.

The Maya of the southern Yucatán peninsula in Mexico stored water in reservoirs in the ground. They dug holes in the ground and then plastered the bottoms to prevent water from running out the porous limestone bottoms. These reservoirs could hold enough water to last about 18 months with no rain.

► textiles and needlework

INTRODUCTION

Archaeologists assume that the earliest clothing worn by humans were animal skins. With textiles, people were able to make clothing from hair such as wool and plants such as flax, the source of linen. Silk, which is made from cocoons of the silk worm, was an almost miraculous discovery made by people near the Yellow River in China in about 1900 B.C.E. One disadvantage all textiles had was that they each needed to be produced in the appropriate climate. Sheep, the source of most wool, needed open grasslands for their herds. Cotton required long hot seasons. Thus, the most common textiles of early times were those that traveled well—that is, ones that prospered in a wider variety of climates than most. This meant that hemp, in particular, was the common source of fabric used by the poor, because it was durable and would grow even in nutrient-poor soils.

Textiles did not pop up everywhere at once. Indeed, a newly appointed Chinese governor to far northern China in the 100s C.E. was dismayed to find that the people of the region wore few textiles and tried to keep warm by wearing grasses. Flax, which produced one of the most durable and comfortable of textiles, spread only slowly across the Old World, probably still not having reached Japan by the 300s C.E.

For ancient people in cold climates or places with cold winters, textiles were valued for their ability to hold in warmth. Thus, among the nomadic peoples of Asia, wool was especially valued. It might be itchier than cotton or linen, but where warmth mattered most, wool was preferred.

In warm climates, and even some with harsh winters but warm summers, people often did without textiles, because staying warm was not their highest priority for survival. In Sumer people often wore only wool skirts; in southeastern Asia and Japan, many people wore only loincloths, typically made of animal skin. In India the notion of wearing clothing for modesty did not arrive until the Muslim invasion. Still, in these places where textiles were not a necessity, they were valued for their decorative possibilities. Someone in India who might wear little in everyday life would nonetheless wish to wear colorful fabrics when attending a wedding or other important social event.

The earliest colors for textiles were paint and dyes. Painted textiles appeared in dry areas, such as the lands northwest of China. More common than painted textiles were dyed textiles, probably because dyes were preferred over paint. Whether dyeing textiles was an idea that originated in one place and then spread or was an idea that began in many different places is not clear, although the use of dyes by ancient Americans suggests that dyeing was an idea with different origins in different places.

The use of dyes says much about human beings and their needs. Although ancient textiles are hard to find, those that are extant are rarely plain brown or white. Usually the textiles are colored. Whether worn by the rich or the poor, they almost always have decoration, indicating that people wanted beauty in their lives even with simple textiles. Even embroidery, often associated with richly decorated robes for special occasions, would be used to brighten hems or add attractive images to textiles for everyday use.

AFRICA

BY SUSAN COOKSEY

Textiles produced on the continent of Africa in the period between 10,000 B.C.E. and 400 C.E. were made from both plant and animal fibers, including bark, reed, grass, cotton, and wool. Among textiles' many purposes were as clothing, sheets, blankets, bags, carpets, tents, and burial shrouds. Moreover, textiles were important items for trade, adornment, and markers of social, political, and economic status. Textile production in Africa and elsewhere indicates a sedentary society with skills in agriculture and husbandry; technologies used for dyeing, spinning, and various types of construction, such as weaving; and artistic ability to produce cloth that is both functional and aesthetically pleasing. Simply woven cloth probably served for everyday use, while more elaborately woven and patterned cloth was reserved for leaders and elite members of society.

In North Africa textile production was greatly affected by the influx of technologies and materials developed and distributed throughout the Mediterranean. The Phoenicians were some of the greatest purveyors of textiles, materials for textile productions, and textile technologies. After settling along the Tunisian coast, the Phoenicians introduced the eastern vertical loom to the urban Berbers, the indigenous people, around the 12th century B.C.E. In Carthage and other Phoenician towns local craftsmen wove linen and woolen rugs. In the rural areas of Tunisia textiles made of rush, reed, and alfa were produced and used for constructing tentlike dwellings for local inhabitants. Important people in rural societies may have owned woven wool textiles.

The Phoenicians are known to have traded in dyed wool by 1700 B.C.E. A purple dye derived from extracts from the murex, a shellfish, became increasingly popular in the Mediterranean world during the first millennium B.C.E. As the Phoenicians expanded trade in murex dye and murex-dyed textiles, they sought the shellfish from as far away as Africa's Atlantic coast. Evidence of textiles with murex-dyed fabric has been found in excavations of ancient Meroitic sites in Sudan, dating from 332 to 30 B.C.E. The Romans razed Carthage in 146 B.C.E. and, in the course of their occupation, taught the urban Berbers how to use a Latin loom to produce various textiles.

Cotton threads found in Dhuweila, in present-day Jordan, dated to 4450–3000 B.C.E. may have been imported across the Red Sea from India or from the area that is now the states of Sudan and Ethiopia, where a different variety of cotton was known at the time. Evidence of cotton cultivation and cotton fabrics dates back to the early fifth century B.C.E. in Meroë, located in the Nile Valley in the present-day state of Sudan.

Many Nile Valley textiles have been found in tombs. One collection from the areas of Ballana and Qustul includes burial cloths from three Nubian eras, beginning in 332 B.C.E. Textiles found in the tombs were made of various fibers, in-

cluding wool from sheep, camels, and perhaps goats as well as silk, linen, and cotton. The silk samples were imported and from a later era. A few burial cloths were made of horsehair or coarse grass or reed. However, most of the textiles were made of animal fibers. Both animal fibers and cotton were available in the area much earlier than the fourth century B.C.E. It is estimated that sheep were in the Nile Valley for thousands of years before that and were among the first domesticated animals in the region. The sheep brought to Nubia were probably a breed domesticated in Egypt. Goats and camels were imported to Egypt later and eventually brought to Nubia.

Cotton was introduced into Nubia later than animal fibers, though a type of cotton may have grown locally as early as 3100 B.C.E. The earliest samples of cotton cloth date from the fourth century B.C.E., but it is possible that cotton cloth was produced at an earlier time in Nubia. Early accounts of cotton—such as that of the Roman historian Pliny the Elder (ca. 23–79 C.E.), who referred to the “wool-bearing

Ugandan woman wearing a bark cloth dress; bark cloth began to be produced in Africa before 4000 B.C.E. (© Board of Regents of the University of Wisconsin System)

trees” of Upper Egypt and Ethiopia, and that of the ruler Ezana of Axum, who spoke of destroying crops of corn and cotton in the Nile Valley in 350 C.E.—prove the existence of cotton plants at this time. Linen textiles found in the tombs may have come from Egypt, where the flax plant was cultivated; linen weaving had been known much earlier; and, by the fourth century C.E., the trade in linen cloth was thriving. Egyptian texts of the New Kingdom (1550–1070 B.C.E.) refer to flax fields in Nubia, suggesting that at least flax may have been produced in Nubia, and perhaps linen was made there as well.

Many of the cloths used as burial shrouds were adapted for this use but were originally made for other purposes, such as clothing or sheets. Textile bags and carpets were also found in the tombs. Among them the plain-weave fabrics were locally made, whereas others were imported. It is also clear that in the earlier periods, plant fibers were used before animal fibers became prevalent. Later, in the Common Era, the use of plant fibers returned. Many of the textiles were decorated or dyed. Dyeing was done before the fibers were woven. Locally made textiles were dyed with local dyestuffs, yielding colors of brown, yellow, blue, and red. Yellow and blue were combined to produce green. The imported textiles, including carpets, were more elaborately colored with purple, yellow, and orange dyes.

Fibers were spun into yarn using various spindles and techniques. Three types of spindle were used for cotton and one for wool. Most yarn was spun so that the fibers twisted together in an S configuration. The art of weaving was well developed by the Meroitic period. Looms had been in use in Egypt since at least the Middle Kingdom (2040–1640 B.C.E.). The earliest representations of looms in Egyptian art show women using horizontal types. The more complex vertical looms used by men were introduced later. Textiles found in Nubia show evidence of both simple and complex looms. Several types of techniques of weaving were used, including plain weave, twill, and pile weave. In some cases, textiles were woven into specific shapes of garments on the loom. Finely woven mats of reed and grass may have been made on a loom as well. The Nubian textiles were decorated with geometric motifs, foliate motifs (patterns representing trees or grain, for example), and stripes rendered in various colors. One surviving cloth has purple murex-dyed stripes and was obviously imported. Some textiles had tasseled edges. Decorative elements were created using various weaving techniques or needlework. Stitching was used to decorate the cloth and to bind cloth strips on the selvages.

Bark cloth production began before 4000 B.C.E. and is still produced in Africa in the Ituri rain forest. Bark cloth is typically made of the inner bark of mulberry or ficus, which has been stripped and retted. The glutinous sludge resulting from the retting is beaten into large, thin sheets that could be colored by pigments such as ochreous earths and tannins. The finished sheets could then be fashioned into garments, coverings, or other items.

EGYPT

BY ERIN FAIRBURN

Egypt is unique among ancient cultures in that the desert location of funerary sites has preserved many objects of perishable nature that are infrequently, if ever, to be found at other ancient sites. Textiles are especially important among these rare artifacts. They shed light on how ancient peoples adapted to and utilized their environs, and their analysis can provide interesting insights into ancient technology. Egyptian textiles were used for garments, bedding, animal equipment, and lamp wicks, among other things, and were often recycled as mummy wrappings.

Almost all ancient Egyptian textiles were made of flax (*Linum usitatissimum*). Depending on when the flax was cut, the resulting threads and cloth would be a light or a golden brown color; however, the linen could be whitened by using a substance, such as natron, or by sun bleaching, as was often done to “royal” linen. The flax fibers were obtained through a process of beating and soaking the stalks until the soft interior was separated out. The fibers were then combed and dried.

Once the fibers had been thus prepared, they were ready to be spun. The spinning process began by roving, or rolling, the fibers on the thigh until they were loosely twisted. This rove would be rolled around a reel and placed in ceramic vessel or basket with a hole on the top. The fibers would be drawn from these vessels during the spinning process. They were spun onto a spindle of wood with a whorl (pulley) on top made of wood, stone, or ceramic.

Three types of spinning were used in ancient Egypt. The first technique produced thread by feeding the fibers onto the spindle with the fingers and rolling the spindle on the thigh to twist them. The second required a forked stick or ring through which to draw the thread while twisting the spindle between both hands. The third technique, the suspended spindle method, involved grasping the fibers with one hand while letting the rotating spindle swing free, thereby twisting the fibers. Counterclockwise spinning was the most common type in ancient Egypt; that is, the fibers were S-spun.

At this point, the spun fibers could be dyed. Dying does not appear to have been prevalent in ancient Egypt, but textile producers clearly knew how to produce a range of colors. Egyptian textiles contained threads dyed red, blue, yellow, brown, green, and purple. These colors were all created with vegetal (plant-based) colorants; brown, green, and purple were produced by overdyeing. While weavers did on occasion dye an entire piece of completed weaving, it was more common for them to embellish an undyed linen garment with colored threads.

Once the threads were prepared, they could be woven. Egyptians used two kinds of looms for textile weaving: a horizontal loom that was used throughout the Dynastic Period and a vertical loom that was used beginning in the New Kingdom (ca. 1550–ca. 1070 B.C.E.). Horizontal looms lay parallel to the ground with the beams pegged into place. Vertical looms

Tapestry made of multicolored wool on linen, from Egypt, fourth century C.E., showing Artemis and Actaeon (© The Trustees of the British Museum)

were perpendicular to the ground, with the warp strung onto beams attached to a frame.

Longitudinal threads, or warp threads, were attached directly to the loom. Every other thread was separated, forming two separate groups. Another thread, the weft, was strung between the two groups, or shed. Lifting a rod called the heddle switched the group to the fore, creating a counter-shed. Running the weft thread successively between the shed and counter-shed created an interlocking weave around the warp.

Several different weaving techniques were used to create textiles in ancient Egypt. The most common weave, and the simplest, was the tabby weave, where a single weft thread passes over and under individual warp threads. A variation on this is the basket weave, where the warp and weft threads are paired. Both of these methods were fairly easy to achieve on a horizontal loom. Warp- and weft-faced weaves, which

produced a two-to-one pattern that nearly hid the single threads, were also used in Egypt. Two tapestry weaves are also known, one that used the weft for the pattern and another that used the warp.

Weavers accommodated for broken or short threads by interweaving threads with either a long or a short splice. Short splices twisted together the ends of two threads and then twisted this back onto the main thread. Long splices were simply several inches of the two threads twisted together. Many preserved textiles have splices in them; finer linens seem to have mainly short splices, and coarser textiles often exhibit long splices.

A number of decorative and functional features were woven into Egyptian textiles. The most common was a fringe on the left selvedge (edge) of a textile. This was accomplished by extending the weft thread several inches beyond the last

warp and seems to have been performed only on horizontal loom-made textiles. It may have served to prevent the weft from gathering in the warp, reducing the overall width of the textile. Decorative fringes were often added to the edges of a textile as well. These were usually created by letting the ends of the warp threads hang beyond the edge of the weft. These ends were loose or tied off. Occasionally, additional thread was woven into the edges and selvages to increase the amount of fringe on the piece. Weft looping was also occasionally practiced. This process of letting the weft extend above the fabric surface at intervals created a sort of pile that probably increased the warmth of the resulting garment.

Weaving colors into textiles was a decorative technique commonly practiced. This usually extended only to weaving stripes into the edges of the textile. These stripes were usually in some combination of red, blue, and buff. Occasionally, what seem to be maker's marks were also woven into the textile at some point. Evidence for embroidery is slight in Dynastic Egypt, and most of what has been called embroidery by researchers was actually woven into the cloth. Tapestry weaving appears in the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.), beginning with pieces found in the tomb of Thutmose IV (r. 1401–1391 B.C.E.). In this technique the weaver used different color wefts in just the part of the design that demanded the particular color. These textiles were packed down to reduce the visibility of the warp.

Sewing was used to a minimal extent in Egypt, mostly for crafting garments. Seams and hems were usually rolled and stitched into place. However, textiles of all types were frequently mended, indicating their worth. Mending is found on common textiles as well as on the finer pieces found in royal contexts. The mending was accomplished by working new warp threads into the damaged area and then stitching across them. Patches were uncommon. As mentioned, embroidery was rarely used, and it was most commonly used to outline woven-in decoration.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Few examples of ancient Near Eastern textiles exist. Because cloth decays quickly, most do not remain in the archaeological record. Likewise, few positively identified weaving and spinning implements survive, but archaeologists have found numerous drawings and paintings depicting spindles and looms and women working with them. Some ancient Mesopotamian sculptures convey the texture of the cloth worn by the subjects, but it is impossible to reconstruct colors or patterns. To guess what ancient cloth must have looked like, historians can only read contemporary descriptions of textiles and view examples of textiles from slightly later periods. Weaving and spinning techniques have not changed greatly over the centuries, so anthropologists can gain insight into ancient textile manufacturer by studying the weaving techniques of less developed societies.

Near Eastern people began making textiles as early as 25,000 B.C.E., braiding, twisting, spinning, and weaving strips of bark and plant fibers to make primitive cloth. When people domesticated sheep and goats around 8000 B.C.E., they began making cloth out of wool and goat hair. Wool was the most common fiber in the region. People started growing flax for linen about 8,000 years ago; linen was a luxury cloth used for expensive garments. In Mesopotamia textile manufacturing became a major business. Most cloth production was done in individual homes as a cottage industry rather than in large factories, but many households participated in the trade. Weaving factories at Ur and Lagash around 2100 B.C.E. employed thousands of women and children, producing cloth in five grades of quality. Most of the cloth was given out as rations to dependents of the great temple households, and only a small amount was ever traded abroad. In ancient Anatolia groups of women ran cloth-making businesses. After 1500 B.C.E. commercial weaving operations throughout the region employed men, but women continued to do most of the spinning and weaving for their homes and families.

The Assyrians brought cotton plants to the Near East from Egypt around 700 B.C.E., although Near Eastern people apparently were importing cotton cloth from other lands as early as 1000 B.C.E., as cotton fragments from Bahrain, in the Persian Gulf (ancient Dilmun), attest. Silk appeared in Mesopotamia and the Near East during Roman times, brought from China through Persia via the Silk Road.

Making fibers into cloth was a labor-intensive process. After the fiber was collected from the field or the animals, it had to be cleaned and untangled by combs. The fibers were then spun into thread on spindles—wooden spikes weighted on the bottom and used to twist and wind the fibers. Women throughout the Middle East used a kind of spindle called a drop spindle.

Archaeologists can tell where some textiles were made based on spinning patterns. Cotton fibers naturally wind to the right, and flax fibers naturally wind to the left. Spinners usually wound their threads according to the fiber's natural pattern. Wool, on the other hand, does not naturally twist in either direction, so it can be spun either to the left or to the right. In an area in which linen was common, spinners often spun wool thread to the left, using the same techniques on wool as they used on linen. In an area where cotton was common, wool thread was often spun to the right. Archaeologists who find wool thread spun in a direction opposite that most common in the area can assume the thread was made elsewhere. Archaeologists can also use microscopes to examine wool fibers to determine the type of sheep the wool came from and the textile's likely place of origin.

After spinning, thread was sometimes dyed. Archaeologists have found evidence that Middle Eastern people were dyeing cloth by 3000 B.C.E. and perhaps earlier. Dyers used roots, tree bark, leaves, nuts, lichens, and berries to achieve various colors. The indigo plant was used to dye cloth blue. The most expensive dye in the region was a purple color made from the

Wool textile fragment from Persepolis, Persia (modern-day Iran) (Courtesy of the Oriental Institute of the University of Chicago)

murex shell, found off the coasts of Lebanon and Syria. This region became known as Phoenicia, or “purple land,” and its towns grew rich selling murex dye to Greeks, Romans, and other wealthy individuals; the town of Tyre was especially known for this color, which was often called Tyrian purple. To create the dye, fishermen collected thousands of the snails, cracked their shells, and dug out the veins that contained a purple mucus. It took nearly 9,000 snails to create one ounce of Tyrian purple dye, which cost more than its weight in gold.

After dyeing, the next step was to weave the thread into cloth on a loom. Early Middle Eastern looms were vertical frames on which weavers would stretch parallel threads to form the warp of the cloth. The weavers would then weave other threads through the warp, creating the horizontal fibers called the weft. The first looms had no mechanism for separating individual warp threads to create a space for the weaver to place the weft, but very quickly people discovered that it was easier to weave cloth if they used a rod to lift half the fibers at a time. Weavers wrapped the weft threads around a wooden block called the shuttle, which they could pass from hand to hand through the warp, and they used another rod to push the weft firmly together after each pass. By varying thread colors, weavers could create elaborate patterns in their cloth.

Ancient people throughout the Middle East decorated their cloth with embroidery. Persia, Babylonia, Phoenicia, Syria, and Israel were especially known for their embroidery. Embroiderers adorned cloth with traditional motifs; Persian decorations were known for being particularly ornate.

Groups developed their own unique embroidery patterns, many of which had ritual significance such as warding off evil or bringing good luck to a bride.

Carpet weaving is believed to have originated as early as 7000 B.C.E. in central Asia, where nomads wove carpets to create warm, soft, easily portable floors for their tents. Carpet making spread from central Asia into Anatolia and Persia. Anatolians were among the first Near Eastern people to weave carpets. They invented a double-knotted style of carpet weaving between the fourth and first centuries B.C.E. Village women carded and dyed their own wool and invented patterns that told stories as well as being decorative. Each group had distinctive designs. Mothers taught daughters how to weave carpets so that the young women could include them in their dowries and then produce more as married women. Carpet weaving was also important in Persia. People living on the Iranian plateau were knotting wool carpets by 500 B.C.E., though the art may have begun much earlier. Persian carpets depicted mythical events, objects from nature, or geometric patterns.

ASIA AND THE PACIFIC

BY JUSTIN CORFIELD AND MICHAEL J. O’NEAL

A wide range of textiles was used throughout ancient Asia and the Pacific, from elaborate silk and brocade (fabric with raised patterns) to coarse hemp. Very little material from this period survives, but much of it that does survive is silk and other more expensive cloths found in tombs dating from the Han Dynasty (202 B.C.E.–220 C.E.) and also outside China. However, much can be surmised from drawings, carvings, and statues of the period as well as from the small fragments of other materials that have been found by archaeologists.

The material used in China and nearby places for clothes was associated with three traditional styles of dress: the *pien-fu*, the *ch’ang-p’ao*, and the *shen-i*. The *pien-fu* was a two-piece ceremonial costume with a tunic, and underneath a skirt or trousers. The *ch’ang-p’ao* was a garment made up from one piece that covered the body from head to toe, and the *shen-i* essentially was a blend of the other two styles, usually with a *pien-fu* sewed together.

In China the most prized material was silk, which seems to have been used from about 3000 B.C.E. It was produced not only for use within China but also for export to other places, giving rise to the “Silk Road,” as the major land trade route from China to Europe became known in ancient times. Silk served as a medium of exchange for the Chinese, and it appears that a large silk industry emerged in Persia and Syria, where dyeing and weaving took place. Some silk fabrics from the Han Dynasty have been found in tombs in Palmyra, Syria, dating from 83 to 273 C.E., where they were known as “damasks in Han weave.” Similar material has been found in parts of central Asia, the Crimea, and other places along the Silk Road, indicating a flourishing trade. Besides being traded, silk was also given as presents to tribal chiefs loyal to China

and was often taken by traders to cover their expenses. Indeed, in the later Han Dynasty it is known that some people paid their fines in silk.

The production of silk was heavily protected in China, and the export of silkworms was an offense punishable by death. Therefore, it was not until the sixth century C.E. that some silkworms were smuggled to Byzantium. This restriction on silk production kept the price of silk high, and as a result, many garments, even for wealthy people in China, were made with silk and also linings in other material, such as nettle cloth.

Poorer people in China and the areas around China used not only nettle cloth but also hemp and wool; many Chinese did not like wearing woolen garments although they were favored by many of the local tribal peoples. For patterns, traditionally cloth was dyed a particular color, such as blue, red, green or yellow, but by the Zhou Dynasty (ca. 1045–256 B.C.E.), some checked patterns began to be favored. All the “terra-cotta figures” from the tomb of Qin Shi Huang (r. 221–210 B.C.E.) were originally painted, with many fragments of different colored paints being found. By the Han Dynasty wealthier Chinese preferred geometric shapes, such as checks or diamonds, with the pattern repeated continuously; poorer people tended to have their garments made from cloth of a single color. Cotton does not appear to have been used in China until the 10th and 11th centuries C.E.

In addition to their use for clothes, many textiles were also used for drapes and awnings as well as for tents. Elaborate embroideries existed in the houses of the wealthy, with many other buildings having areas “curtained off,” or separated using “silk screens,” although these screens were not always made of silk.

Outside China and the surrounding areas very little cloth has survived. In Southeast Asia in the Funan Empire, located in southern Cambodia and the Mekong Delta, there are a few descriptions related to clothing. A Chinese embassy from 245 C.E. recorded that the people wore nothing but eventually were persuaded to wear clothing for reasons of modesty, beginning with small loincloths. However, by the 480s and 490s C.E. many people were wearing sarongs (long pieces of cloth wrapped around the body) made from brocade, showing an important Chinese influence. It is probable that this pattern was followed in other parts of Southeast Asia.

In central Asia many of the clothes included wool from sheep and goats, with more expensive materials imported from China. The major indigenous textile industries in the region were involved in the manufacture of tents and of carpets. The former involved the use of heavy material, such as wool. The latter varied between the hard-wearing carpets used by everybody, especially the nomadic peoples, and those for decorating houses, especially for the export trade. Prior to the arrival of Islam in central Asia, many carpets showed scenes of people, hunting, and festivities, although others had geometric patterns, which became very common after the sixth century C.E. Throughout the region needles were made

from bone or horn, and few have survived, though several have been found in China, dating back to 2000 B.C.E., with some estimated to be much older.

Like China, ancient India also had a rich tradition of weaving and textile production. Archaeological excavations from the Indus Valley civilizations (ca. 3000–ca. 1600 B.C.E.) have found spindles and needles that suggest that cotton fabric was woven in homes. Mention is made in numerous ancient Indian texts, such as the Rig-Veda and the epics Ramayana and Mahabharata, of weaving, textiles, and fabrics, and ancient sculpture and murals also attest to the wide variety of textiles produced in ancient India. The ancient Indians also traded their fabrics; cotton from India has been found in ancient Egyptian tombs, and in the first centuries of the Common Era, India exported silk fabric to Rome.

The ancient Indians were particularly adept at brocade work. *Brocade* refers to any kind of fabric made with silk or silk-cotton blends with raised needlework in gold or silver (or both). The designs made with this gold or silver needlework were called *nakshas*. These fabrics were dyed with vegetable dyes, and historically color has played an important role in Indian fabrics. Thus, for example, red was regarded as the color of love, yellow the color of spring, indigo (a shade of blue) the color of Lord Krishna, and saffron (a shade of orange to orange-yellow) the color of the earth.

Because textiles and fabrics do not survive through the centuries in the same way that artifacts made of stone or metal do, less is known about textiles in ancient Japan, where traditions developed later than they did in China and were strongly influenced by those of the Chinese. It is known that by the late ancient period and into the early medieval period, the Japanese had developed a number of textile traditions. One was the use of bast fiber, which was common before the introduction of cotton. Bast was a fiber that came primarily from the gampi tree and was used principally in papermaking. It was, however, also used to produce textiles.

Another type of textile work was called *rozome*, commonly referred to as “batik” in the West. *Rozome* was a process of dyeing fabric. Wax was used to create the designs by covering those portions of the fabric that were not to be dyed. A similar technique, called *kasuri*, created designs from dyed threads. *Sashiko* was a form of decorative embroidery used primarily for functional purposes to reinforce points of stress in a piece of fabric. Also common in Japan were various methods of tie-dyeing, called *shibori*, which created designs in fabrics by folding, stitching, twisting, or binding them. While the earliest examples that have been found date to the eighth century, the traditions and techniques developed over a period of hundreds of years prior to that.

EUROPE

BY JUDITH A. RASSON

In ancient Europe cordage (thread, string, or yarn) was made by twisting fibers collected from plants or animals, most sim-

ply by rolling the fibers between one's palm and upper leg. Twisting fibers around a short rod or stick was the simplest way of spinning. The stick used to control the twisted thread was called a spindle. Cordage was used to tie things together. It was also interwoven in various ways to create cloth. Cloth was embellished by adding patterns while weaving or with embroidery. Floor and wall coverings were also made of mats, a basketry technique.

The first cordage was made in Europe during the Paleolithic Period, which coincided with the Pleistocene (up to 10,000 years ago). A piece of cordage was found in the Lascaux caves in France, famous for their Paleolithic wall paintings. The fibers were identified as bast—from a plant. No woven textiles have been found in Europe from this early period. As the climate changed at the end of the Pleistocene, people continued their nomadic lifestyles. Archaeologists call this cultural period the Mesolithic (up to 4000 B.C.E.). There is continued evidence for the use of cordage in this period. Fragments of nets made from tree bark bast have been found in waterlogged sites in Finland, Estonia, and Lithuania; the nets might have been used for fishing, but they might equally have been bags or hair coverings. No other Mesolithic textiles have been found.

As time passed, people began to rely on domesticated animals and plants, and they settled in villages. This period is called the Neolithic (up to 2000 B.C.E.). People increased their use of cordage, and this period seems to have been the time when cloth weaving was invented. People continued to use bast fibers; one example is a fishnet made of bast found in the waterlogged lake dwelling site of Zürich-Kleiner Hafner, dated from 1000 B.C.E. to 1000 C.E.

Weaving became more common during the Neolithic, and there is more evidence for both the weaving itself and the tools used. Most of the evidence for what was woven comes from impressions left in clay on pottery and elsewhere rather than the cloth itself (though a few cloth fragments have been recovered). The main fiber used was bast from flax or nettles. Plant stems, where the fibers are, had to be soaked in water and then pounded to release the fibers and combed to align them. Wool was probably not used during the Neolithic because sheep did not have fluffy coats but had many long hairs and short bristles mixed in the wool that made it difficult to spin.

Both flax and (later) wool were spun by hand on spindles. The person held the fibers in one hand or on a distaff (rod) and twisted them onto the spindle with the other hand. Spindles could be held by the thread and made to spin around to twist the fibers better. A small weight (often made of ceramic) on the spindle, called a spindle whorl, made it easier for the spindle to rotate. This method of spinning persisted into the 20th century C.E. in many parts of eastern Europe.

Weaving may have begun in Europe with belt weaving— weaving narrow bands—by fastening the end of a group of long threads (the warp) to a stable object, like a post or a tree, and maintaining the tension by fastening the other ends of

the threads to the weaver's waist. Weaving would have been done by working another thread (the weft) crosswise over and under the long threads. This method is a small version of a loom.

Neolithic looms were upright, rectangular frameworks, with two legs and a horizontal bar across the top. Warp threads were attached at the top of the bar and hung down lengthwise. A stick called a shed rod separated the warp threads. Another rod, a heddle, moved alternate warp threads forward and back so that the weaver could slide the weft thread through. This process was faster than weaving each individual thread over and under. To help hold the warp threads taut, ceramic weights were attached to groups of warp threads. This process gives its name to the warp-weighted loom. It was used throughout Europe in prehistoric times and persisted in use until the 20th century C.E. in Norway, adding to our understanding of how the loom worked. Clay loom weights are found regularly at most Neolithic sites in eastern Europe.

Cloth could be woven in different patterns, depending on the over-and-under pattern of the weft and warp. A simple interlacing of the weft over and under the warp threads is called the plain weave. A patterned weave could be created by varying the number and order of warp threads skipped in each over and under. A pattern of over-and-under alternating pairs of wefts produces a twill pattern; these patterns have names like herringbone or bird's eye. Striped and plaid cloth and also embroidery began to be used in the Neolithic. Sometimes these variations were done while the cloth was on the loom by introducing extra threads in different patterns and colors. Excellent examples come from waterlogged sites like Pfäffikon-Irgenhausen in Switzerland.

Weaving plain and complex weaves continued in the Bronze Age (ca. 2800–ca. 700 B.C.E.), after the Neolithic, when there were some innovations. Wool came into use, collected by shearing or perhaps just by pulling it out when it became long and shaggy.

The technique of sprang first appears in the Bronze Age. Sprang is a type of weaving with the warp on a square frame, without weft thread. The warp threads are attached to the crossbars at the ends of the frame and twisted around each other, starting at both ends and working toward the middle. To keep the weave from springing apart, another thread is woven across the pattern when the weaving reaches the middle. Sprang fabric is stretchy, and the technique was used where stretch was important, as in socks and sleeves. It looks like knitting, which was not invented until later. Examples of sprang caps or hairnets have been found at the Danish Bronze Age sites of Skyrdstrup and Borum Eshøj. Sprang continued to be used in the Iron Age (ca. 1000 B.C.E.–ca. 500 C.E.), and knowledge of it has survived in Scandinavia until the present.

In the Iron Age, weavers added hemp to flax and wool for their textile needs. Loom weights abound on Iron Age sites in eastern and central Europe; they are also found in Scandinavia and in England. Weavers definitely used card weaving (or tablet weaving) to form narrow edges of large pieces of cloth

Bone needles from the cave of Courbet, Penne-Tarn, France, dating to about 10,500 B.C.E. (© The Trustees of the British Museum)

to be finished on a larger loom. In card weaving a number of cards (of wood, bone, or ivory), a bit larger than standard playing cards, had a hole drilled in each corner. The warp threads each passed through one hole. The warps were moved by flipping the cards from side to side and running the weft between them. This technique might have been used earlier, but the first unequivocal use was in the Iron Age. Iron Age skills were continued into the Classical Period, when writing and the increased use of figural depictions on ceramics provide evidence beyond archaeological deposits.

GREECE

BY SPYROS SIROPOULOS

Evidence confirms that textiles were used as far back as the Neolithic Period, although no findings of actual textiles have been preserved. Bone pins (as well as copper pins from the late Neolithic period) testify to the extended use of textiles in the area of Greece. The processing of wool and linen and the manufacture of tapestries and rugs appear to have been a major part of the Minoan economy. During the acme of the Minoan society (2200–1800 B.C.E.)—also known as the palace society because the palace was the central economic and political unit—many women offered their weaving services to the palace. Preserved on clay tablets from Pylos is information about 15 specialties of weavers. This specialization is equivalent to industry by modern standards. One tablet records 10,572 animals (goats and sheep), while others describe palace weavers also working with vegetable fibers, such as linen. Linen reached the palace by annual contributions twice a year: at the end of winter and at the beginning of spring. A series of clay tablets from Cnossus relates that 10 tons of wool were distributed to 30 workshops, where 600 to 900 female weavers labored. Other tablets from Cnossus mention the processing of 45 tons of wool, which would have required an estimated 2,700 to 4,000 workers.

Raw materials were not difficult to obtain. Out of the 3,000 tablets found at Cnossus, almost 1,000 are about goats and sheep, the number of which is estimated at 100,000. The average annual production of wool from these herds, which probably belonged to the palace, is an estimated 50 tons. A bolt of textile weighed roughly 22 pounds, so 50 tons should produce about 5,000 bolts. The L-series tablets, referring to the previous year's wool process, number about 5,000 bolts, the weight of which varies between 11 and 132 kilos, whereas their total weight reaches up to 45 tons. We are also certain that the textiles were dyed both at Pylos and Cnossus, though no traces of dyeing essences have been recognized by archaeologists today.

Herodotus (fifth century B.C.E.) reported in his *Histories* that in India a wild plant produced “fleece,” obviously referring to cotton. It was Alexander the Great who introduced the cotton plant to Greece and made it part of the Greek economy. The two kinds of fibers—animal and vegetable—required different processing techniques. In the case of cotton and linen, the process went through the stages of opening the fruit, extracting the fibers, carding, combing, dyeing, and twisting them for the spinning frame. Women did most of the weaving at home, although specialized factories existed for processing wool. First the wool was washed with hot water. Then the yarns were combed and stretched. Workers stretched the wool over either their bare calves or a specialized tool called an *onos* or *epinetron*. The cylindrical clay tool covered the worker's knee and lower thigh.

Before the invention of the spinning wheel (around 500 B.C.E. in India), spinning was done by hand. Wool was bound loosely around a stick called a distaff. Many Grecian vase paintings depict women holding a distaff in one hand and using the other hand to draw the material onto a spindle—another stick with a weight at the bottom. Made to spin quickly,

Utensil used for unwinding balls of wool, called Ariadne's Clew Box (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

the spindle increased the pull on the fibers, turning them into workable threads.

The use of the loom is a topic of Homeric epics. The wise Penelope used a loom to trick her potential suitors by weaving a death robe for Odysseus's father, Laertes. She had promised to choose one of the suitors when the shroud was ready, but she undid each day's work during the night. The loom is a frame on which threads are passed over and under stable threads. With the help of a stem, a simple handheld device, women pulled the filling threads over and under the stable threads. Then, from the top of the loom, a kind of closely spaced comb was drawn, thus pressing the fibers together to form solid textiles. Of course, some techniques, such as knitting, were simpler.

In his *Republic*, Plato describes the work of the dyer. The first task was the lengthy and delicate process of preparing the dyeing materials, which were primarily barks, fruits, vegetables, animal products, or minerals. Before dipping threads into the dye, the dyer cleaned them by soaking them in potash and clay. Perhaps one of the best pictorial descriptions of the wool-working process is a painted vase dating from around 560 B.C.E. In five groups, women are shown combing wool, spinning thread, filling a basket with yarn, weighing balls of yarn, working on a vertical loom, and folding finished cloth.

Silk was also used in Greece. Through trade and colonization the Greeks had contact with people in the East who knew of the silkworm. The legislator Solon (ca. 638–559 B.C.E.) established sericulture—the farming of silkworms—to boost the economy of Athens. More than 5,000 cocoons of a silkworm are needed to produce about 2 pounds of raw silk. First the cocoons are boiled, and then their filaments are removed and twisted together into very long threads that are wound on reels.

ROME

BY LYN GREEN

Many of the surviving textiles of the Roman period are from the time of the empire and from the provinces, where, compared with Italy, the climate was often more conducive to the preservation of textiles. All the major fabrics used—cotton, linen, wool, and silk—have been found at sites in Egypt and the Near East. Of these, probably cotton was the rarest and silk the most valuable. Wool was the preeminent fabric of Roman culture. It was used for tunics, blankets, and of course, togas. It could be woven into various forms, including plain (tabby), twill, damask, and tapestry. Twill weave produced a hard-wearing fabric popular in the northern provinces. Damask weave is believed to have been developed in Egypt before the first century C.E. Tapestry weave was also used in Egypt, but often for fabrics of mixed fibers. The tapestry technique allowed wool decorations to be woven into the surrounding linen. These decorations were often colored.

One reason for the popularity of wool was that it was widely available, easily dyed, and relatively easy to prepare

for weaving, even though much of the fleece was 50 percent dirt and grease. That problem was solved to some extent by washing the sheep before shearing. The next steps, probably performed by professional wool combers, were combing and teasing the wool to prepare it for spinning. Ancient Roman wool combs have survived, but teasing the wool to separate the fibers was done with the fingers.

To spin wool into thread, the Romans used a distaff and spindle; they appear not to have had spinning wheels. One technique for making thread easier to spin was wetting it and then spinning it in the direction that the fibers have a natural tendency to twist. Thus, cotton fibers were usually spun to the right (producing a Z twist), and linen fibers were usually spun to the left (producing an S twist). Wool, however, does not have a natural twisting direction and could be spun either clockwise or counterclockwise, though spinners in some areas seem to have preferred one direction to another. For example, the threads in many samples of wool excavated in Egypt were spun to the left, reflecting the Egyptians' preference for working with linen, which has a natural S twist.

The resulting wool thread was used for sewing, weaving, or knitting, depending on the thickness of the yarn. The number of knitted socks that have survived from various parts of the Roman Empire attest to the popularity of that method of producing clothing. However, Roman knitting was different from the modern technique of looping yarn around needles. An alternate method of working wool that did not involve spinning or weaving was felting. Felt was used primarily in army gear, however.

According to the Roman historian Pliny the Elder, flax was prepared for weaving into linen by being soaked in water to remove the bark of plants. Then the inner fibers of the plant were dried and beaten successively with a wooden mallet and a flat wooden blade. The beaten fibers were drawn through a wooden combing board with teeth. Egypt was one of the major linen producers of the empire. In Greco-Roman times cotton (*gossypium*) was also introduced into Egypt to counteract the expense of importing it from India, but most of the cotton used in the empire was probably still brought from southern Asia. Silk was also brought overland from China at great expense. Once silk thread arrived in the Mediterranean, it might be rewoven with another thread, such as linen. That kind of silk was called *subserica*.

Several types of looms were in use in the vast Roman Empire: the warp-weighted loom, the two-beam vertical loom, and the horizontal loom. The warp-weighted loom was most common in Italy and the northern and western provinces of the empire. The two-beam vertical loom was used widely in the empire by the end of the first century C.E. The horizontal loom may have originated in Syria about the middle of the third century C.E.

The woven cloth was finished by fullers. In a large vat or tub filled with water, fuller's earth, urine (bought or collected from public urinals), and soapwort or other cleanser, the cloth was treaded or otherwise agitated to remove dirt.

LOOMS

A warp-weighted loom consists of two upright beams connected at the top by a bar, called the cloth bar, from which the warp threads are hung. Another beam one-third of the height of the uprights from the ground and parallel to the cloth beam is called the shed rod and helps to keep the threads separate. The warp threads are gathered and tied at the bottom to a cord strung through a warp weight. The two-beam vertical loom is very similar to the warp-weighted loom, except the warp threads are not weighted but anchored to a beam at the bottom of the loom. The horizontal loom is known to have existed only because of the types of weaving, such as damask, that were being done. No archaeological remains, pictures, or textual references to them seem to have survived. This is a complex loom suitable for professionals.

Wool was then brushed with a spiked brush to raise the nap, which was then sheared to produce a smooth cloth.

Different parts of the empire produced or imported cloth suitable to local tastes and climates. In northern provinces like Britain cloth was woven in checked patterns. Other areas, such as Egypt and Syria, favored plain garments decorated with bands or medallions of tapestry or embroidery dyed in various colors. In Italy braid was used to decorate clothing. Pliny the Elder credited the Phrygians with inventing embroidery, although it seems all they did was master the use of metallic thread.

The two most expensive dyes of the ancient world were saffron and Tyrian purple. Saffron was made from the stigmas of the saffron crocus. Tyrian purple was made from the secretions of the murex, a shellfish. Thousands of murex went into producing just a few drops of the dye; fortunately, only a drop was needed to dye a whole tunic. Also known as imperial purple, Tyrian purple has a dark reddish quality. Although the Phoenicians also produced a bluish purple from shellfish secretions, it was the redder shade that was more popular, especially in Roman times. Orchil was a kind of lichen that produced a bluish purple. Madder, woad, indigo, and safflower produced red, blue, and yellow dyes. In later Roman times the Egyptians used a technique for creating multicolored scenes by repeatedly dyeing a fabric. Each time a different color was applied, the rest of the cloth was covered in clay or wax to prevent it from absorbing color.

Tapestry hangings were a specialty of the Alexandrian weavers and often depicted landscapes or mythological scenes. Embroidery, which the Romans called “painting with the needle,” was also used to create the multicolored and often elaborate scenes. One of the masterpieces of ancient

embroidery dates to the fourth century C.E. and is part of a series depicting the seasons of the year. Its resemblance to the scenes on mosaics in other parts of the empire proves that artists of all types used pattern books, whether working in paint, stone, or thread.

THE AMERICAS

BY JULIA MARTA CLAPP

It is difficult to paint a broad picture about textile and needlework production in the ancient Americas. The inherently delicate and vulnerable construction of such materials has caused ancient textiles to disintegrate over time, leaving archaeologists with little to study. The conclusions at which they arrive can often be based upon a combination of two factors. First, archaeologists can make hypotheses based on any remaining textile artifacts that have been preserved from the ancient era. Such items are rare, much more so in certain areas than others. (For example, civilizations that existed in particularly damp climates are less likely to have preserved textiles than are civilizations in dry regions.) Second, archaeologists may examine evidence from more recent centuries and look at enduring traditions that may provide clues about the past. Any conclusions based on such observations must, however, be considered nothing more than speculation.

Among the Americas, South America arguably has the richest history of textile production. No other part of the hemisphere has left such ample or rich artifacts in this field. In general, the area that has yielded the most abundant artifacts is the northwest coast, or modern-day Peru.

The oldest textiles have been found in Huaca Prieta and are over 4,000 years old. As in North America, the majority of textiles have been excavated from gravesites that contain bodies and artifacts that are at times astonishingly well preserved. Also, similarly to the native North Americans, ancient South Americans wrapped their dead in layers of fabric, of which the inner layers have survived the best.

It is important to remember that as with some other ancient cultures, the ancient Peruvians did not have a system of writing. However, the absence of a writing system does not mean that they were unable to record thoughts or ideas. Although today we think of literacy in terms of reading and writing, some ancient cultures used other means to express themselves. In fact, weaving is an extraordinarily complex process that requires the ability to carry out intricate, advanced planning and to work with a mathematical sensibility.

We often think of textiles as being created by weaving pieces of dyed yarn together. The weaver devises in advance a color scheme, which eventually becomes a pattern. In the ancient Americas yarn was spun from either plant (for example, cotton) or animal (for example, wool) fibers. The warp consists of the strands over and under which the weft is woven. In the Chavín culture (ca. 900–ca. 200 B.C.E.), however, there is also evidence of textiles that did not have a pattern woven

Mantle border fragment made of cotton and camelid hair, first to second century C.E., Peru (Copyright the Metropolitan Museum of Art)

into them; instead, the pattern was painted on the surface. During this period ornamentation was an important part of textile production. Pieces of cloth with colorful, decorative borders and with embroidery have been found at burial sites from this era.

Stylistic developments can first be discerned in the Chavín culture. The weaving from this era represents not only abstract, geometric patterns but images of animals as well: jaguars, snakes, alligators, and birds. Many of the Chavín pieces depict the feline god, who appeared in textiles as early as 1200–700 B.C.E. The feline god was prominent in this civilization, and its presence remained throughout subsequent cultures in Peruvian history. The presence of this god indicates the strong religious significance of these pieces.

During this period the god was often represented in profile, but with its body depicted frontally. Later pieces, such as a burial cloth from around 300–100 B.C.E., represent animals in what we would consider a much more realistic or recognizable manner. This technique should not be mistaken for a development related only to the passage of time. In other words, stylistic representation did not become more realistic as time passed; later periods also occasionally used very schematic or abstract modes of representation.

In the Paracas Period (ca. 900 B.C.E.–ca. 300 C.E.) extraordinary and colorful textiles were still buried in gravesites. Both the quantity and the quality of the textiles of this period are a testament to the apparent value of this kind of production in the Paracas Period. In addition, new mythical and religious beings were introduced. As in other pantheistic societies, gods were designated to control various aspects of human life, such as agriculture or fertility. Such gods were represented on textiles, perhaps as offerings of appeasement. Such representations help us to understand the culture of this period as well; for example, the presence of an agriculture god in textiles indicates that agriculture was being practiced by ancient South Americans in Peru, and it was probably a significant part of their diet (relative to hunting and fishing, for example).

Certain prehistoric Native North American groups, particularly in the East and the Southeast, made for their elites elaborate burials, which are where most ancient textile re-

mains have been excavated. Many of these sites have been excavated and might offer clues regarding ancient textile production. Conclusions about tapestries and other forms of textiles must be made based on evidence available from garments. While such hypotheses may be less precise, such a study can at least provide information about what methods of textile production these civilizations used.

Artifacts from Late Archaic (ca. 3000 B.C.E.–ca. 1000 B.C.E.) excavations in what we now consider the southeastern United States have yielded small pieces of fabric. Through examination of these pieces, we have learned that early North Americans made both interlaced and woven cloth. Unfortunately, it is not possible to know what purposes these samples may have served outside of the burial context.

From the Adena culture (ca. 1000 B.C.E.–ca. 200 B.C.E.) archaeologists have found more woven textiles. These fabrics in particular have revealed that during that era the Adena people employed several different methods of weaving. Although many of these samples are items of adornment, such as headdresses, sandals, and skirts, woven cloth was also used to wrap other buried objects. These examples disprove any speculations that such early endeavors would have resulted in crude or unskilled production. On the contrary, archaeologists working in Adena sites have discovered cloth of very fine and delicate construction.

There is a disappointing lack of information from Mesoamerica during the ancient era. The earliest civilization that has been studied by archaeologists, historians, and art historians is the Olmec (ca. 1500 B.C.E.–ca. 400 B.C.E.). They inhabited the Gulf Coast region in Mexico, a particularly damp and swampy environment. Even generally durable stone artworks and architecture are rare, compared with that of other, later cultures. The Olmec civilization remains relatively unknown and has left us with more questions than answers.

However, before the Olmec, other traces of human life have been found, though information is sketchy at best. In the arid Tehuacán valley in central Mexico, archaeologists have found burial sites containing cloth samples made from cotton as well as human remains wrapped in woven blankets. Aside

from burials, no one can be sure what use these items had in everyday life.

► towns and villages

INTRODUCTION

In general, archaeologists have specific qualities in mind for defining *villages*, *towns*, and *cities*. They tend to disagree with one another about what makes a city. Some insist that a city must have a certain minimum population to make it a city; otherwise it is a town. For these archaeologists, the Sumerian city of Uruk was the world's first true city because by 2700 B.C.E. it had a population of 50,000 people. Others believe the size of a settlement compared with others of its time matters most. Thus Çatalhöyük in Turkey, with several thousand people, would be the first true city in 7200 B.C.E., because at that time nearly everyone lived in settlements of 250 people or fewer. This means that defining towns is difficult, because it is unclear when a town is large enough to be a city.

Archaeologists usually see distinct differences between towns and villages. A town, like a city, needs to have a municipal government that organizes public works projects. It is expected to have leadership positions that form a hierarchy such as the *en* and *nin*, council of elders, assembly of citizens, and public employees of Sumerian towns. The *en* and *nin* were the male and female coleaders elected by the assembly. Archaeologists and historians devote much study to the organization of leadership in towns, because they believe the organization will tell them about how ancient peoples experimented with organizing their lives.

Where towns might have paved streets, areas for carrying on the business of civic government, and neighborhoods of homes, villages did not have those traits. They had human-made structures, even if those structures were just huts of mud or grass, and the structures would be intended to be used over a period of years rather than just a few days or a season. From this view, people who lived in caves did not live in villages, and therefore the development of the village itself was an important step for human societies.

A village almost certainly had a form of leadership, but it would not be as formal as that of a town. Very often villages were composed of members of one family or clan, with leadership belonging to family elders and with many decisions about village life being made with the involvement of all adults in the community. Villages did not have to be inhabited all year. Some ancient peoples had two places to live—one for the summer and the other for winter. In these cases, their villages were defined by the permanence of the homes, which would be sturdy enough to survive until the villagers returned.

After developing national governments, some cultures tried to regulate the organization of towns and villages. For instance, Romans insisted on ritually sanctifying the land before building. In ancient India villages and towns were intended to imitate the structure of the capital city, only smaller. In addition to villages organized around clans, they had villages and towns that were organized around crafts. For example, a village population could be all blacksmiths, who

would be governed by their guild. Such villages were suburbs, because they usually existed to service a nearby city with their goods. Such details show villages and towns responding to developments of their cultures.

AFRICA

BY MICHAEL J. O'NEAL

The emergence of towns and villages in ancient Africa writes in miniature the history of human development and civilization. The earliest hominids emerged in Africa some three million years ago and evolved into humans during the period historians call the Stone Age. During the earliest phase of the Stone Age, about one to three million years before the Common Era, the human population was small and scattered across the savannas of tropical Africa. People in small bands lived entirely by hunting and gathering, crafting primitive tools out of stone. The only thing approaching a town or village was a temporary encampment.

Later, up to 200,000 B.C.E., tools became more sophisticated, and populations increased. Greater intelligence enabled people to begin living in communities where they could share knowledge and pass that knowledge down to their offspring. As tools for digging, cutting, and carving became more specialized, and as these stone tools were attached to hafts to form spears and axes, ancient Africans were able to move off the savannas and into other regions, including forests, highlands, and more arid desertlike areas. After about 20,000 B.C.E. yet more specialized tools emerged, including fishhooks, awls, and bows and arrows, along with boats and pottery. These developments enabled people to live longer and contributed to population increases; therefore, they were crucial for the emergence of towns and villages.

Historians and archaeologists use the term *sedentary* to refer to this new, settled way of life, because people no longer lived in nomadic hunter-gatherer bands and formed relatively permanent communities. This change required the emergence of agriculture, which occurred in northern Africa beginning in roughly 16,000 B.C.E. The center of these new, more sedentary communities was the Upper Nile River. (The Nile flows from south to north, so the Upper Nile is to the south.) Throughout the following millennia the region was far wetter than it was after about 3000 B.C.E., so numerous lakes formed. Historians believe that it was in the region around these lakes, along the southern borderland of the modern-day Sahara Desert, that the first African settlements were formed. The region is called the Sahel, an Arabic word that means "shore," suggesting that the region formed the shore of the Sahara Desert, likened to a sea. The development of agriculture, including both herding and the planting of crops, paralleled the development of towns and villages because people gathered to pool their efforts in feeding themselves. Further, agriculture provided surplus food that enabled communities to support people who were not involved directly in food production, including artists, crafts workers, and the like.

In 2002 archaeologists discovered what may be the oldest agricultural settlement in the Horn of Africa, and perhaps Africa as a whole, near Asmara, the capital of Eritrea. The village is believed to be about 3,000 years old. Excavations of the site reveal that the people lived in stone houses. To conserve heat on the cool highland plateau, walls were shared, and the typical house did not have doors but was entered through a hole on the roof. Other evidence shows that the people herded and ate cattle and goats and brewed their own beer. For clothing they wore animal skins. Throughout Africa archaeologists have discovered similar villages, though buildings were more commonly constructed of mud and mud brick.

Numerous historical developments contributed to town and village life in ancient Africa. Agriculture was one. A second, which went hand in hand with agriculture, was climate change. Again the Sahel provides examples. In the 1970s archaeologists began to excavate the ancient town of Jenne-jeno, located in Sudan in the upper Niger River delta. Until about 300 B.C.E. the area was uninhabitable because of the high seasonal floodwaters of the Niger. Eventually the area began to dry out, and the floodwaters were lower and shorter lived. The result was the emergence of a fertile alluvial plain, where floodwaters left behind silt well suited to agriculture. The settlement of Jenne-jeno began in about 200 B.C.E. The original village was on a patch of high ground. People lived in circular huts made of straw covered with mud. By about 450 C.E. the village had grown to about 60 acres. The village continued to be a vital settlement until about 1200.

Jenne-jeno is a good example of two further developments that influenced the emergence of towns and villages in ancient Africa. One was an increasing amount of trade. Based on archaeological finds, Jenne-jeno appears to have actively engaged in trade. Artifacts found in the area demonstrate that Jenne-jeno imported goods from Greece and Rome. In fact, the entire Sahel, which stretches in an east-west band across the middle of the African continent, constituted a trade route. Goods from the east and from the Mediterranean area passed through the Sahel on the way to points south, where they were traded for African goods such as ivory, precious metals, and the like. The ancient Carthaginians established numerous trading posts along the northern and western African coasts. These posts were points of contact between the Carthaginians and their neighbors to the south. Along any trading route, towns and villages supported caravans of traders, providing them with food and water, forage for horses (and later, camels), markets, and resting places. Goods probably changed hands at numerous points along these trade routes, giving rise to villages.

A second development that contributed to the emergence of towns and villages was metalworking. Once again, Jenne-jeno was a site where a considerable amount of metalworking took place. Most of this work consisted of goldsmithing and jewelry. Archaeological evidence shows the presence of ironworking as well, yet the area itself holds no iron ore, suggesting that trade also took place for metals. One of the

Site of ancient walled town, Cameroon, Central Africa (© Board of Regents of the University of Wisconsin System)

peculiarities of the historical development of Africa was that the continent seems to have skipped the Bronze Age, passing from stone technologies directly to the production of iron. Good examples are provided by the Nok people of West Africa and the Soninke people of ancient Ghana. Both of these cultures developed sophisticated ironworking technologies, including blast furnaces. They also learned that the addition of carbon to iron produces the much harder steel. Just as in modern life, where towns and communities grow up around an industry, in ancient Africa towns and villages grew up as people gathered to take part in the mining, smelting, forging, and molding operations surrounding metalworking.

EGYPT

BY WOLFRAM GRAJETZKI

Over the centuries, forms and types of settlement in ancient Egypt changed considerably. An Old Kingdom town around 2500 B.C.E. must have looked radically different from one in the New Kingdom (ca. 1550–ca. 1070 B.C.E.) or from one in Roman times. At the beginning of the Naqada Period (ca. 4000–ca. 3000 B.C.E.) towns and villages were quite loosely arranged around certain areas, though always close to the Nile. Houses were built of light materials, such as straw, and featured spaces designated for economic purposes such as keeping animals, storing food, and producing handicrafts like

pottery. In the north of Egypt houses were often built deep into the ground. Little evidence suggests that fortifications or town walls were constructed. These ancient settlements had a variety of functions. Bigger towns, such as Naqada or Hierakonpolis, were local centers where, in the Naqada Period, local rulers had their residences and where at least one important temple could be found. Smaller villages, meanwhile, served as residential centers for farmers. Whether these ancient villages also had temples or small shrines for local gods is not known, but in later villages, at least, such features are present.

At the end of the Naqada Period towns began to feature walls and became smaller, probably not because of a reduction in population but because the population density was higher within the town walls. Houses were now built of mud bricks, with certain parts made in wood, and were situated quite closely together, with little indication of broader planning and very narrow streets. Houses are assumed to have quite often been two stories high. Regarding the expansion of such settlements, at Elephantine and Abydos, for example, next to the original walled town a new area was attached to the existing walls and enclosed by a new wall, and land lots were given to certain individuals and families.

With the advent of the Old Kingdom (ca. 2575–ca. 2134 B.C.E.), some towns remained centers of local administration. Such a center would have at least one temple, ancestor

shrines for the local governors, and workshops supplying the populace with nonagricultural products. Local centers also featured marketplaces, which are as yet known to archaeologists only from depictions in tomb chapels. These markets were most likely located close to the Nile and to the town harbors, where incoming goods arrived. Despite such ready means of trade, scholars assume that even provincial capitals and larger towns had high proportions of the population directly involved in farming and producing food. Very close to the settlements, most often just beyond the town walls, were the town cemeteries.

Almost nothing is known about farming villages in ancient Egypt. The architecture and structure of houses and their arrangements within the villages might have been similar to those in the towns; villages may or may not have been enclosed by walls or other fortifications.

In the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) planned towns and settlements were built throughout Egypt. These towns follow rigid layouts, with the poorer populations living in small standardized houses in one section and the wealthier classes in larger houses in another section. The houses were arranged in rectangular blocks. In the larger houses the ruling elite used granaries to store grain and food, allowing them to supply the working population when needed. Many of these planned towns were erected around or next to temples; almost no other public buildings were constructed. However, in Elephantine, at least, an administrative building complex with many seal impressions could be found. Here, seemingly, food was collected and given to the populace, perhaps exclusively to those involved in locally organized state projects. In general, the settlements of the Middle Kingdom provide the impression of a highly organized and regulated society. Among the known pyramid towns from the Middle Kingdom, Lahun, located next to the pyramid of Sesostri II (r. ca. 1897–ca. 1878 B.C.E.), was quite expansive, with several thousand people living there. Lahun flourished under that king and then became a regional center.

From the New Kingdom not many towns have been excavated, and these few examples seem to be exceptional cases rather than regular settlements. Akhet-Aton, better known as Tell el-‘Amârna, was built by Akhenaten (r. ca. 1353–ca. 1335 B.C.E.) to be the capital city. Deir el-Medineh was a workmen’s village, built near the desert on the way to the royal tombs at Thebes, where the people of this village worked. These settlements do not show the tight planning of the Middle Kingdom towns. In Deir el-Medina, houses were arranged side by side along two narrow streets, with the village surrounded by a wall. Directly outside were the tombs of the workmen and several chapels and small temples. On Elephantine, a New Kingdom town featured tightly packed houses and several temples within the settlement, with no real planning in evidence. At Tell el-‘Amârna, on the other hand, another workmen’s village featuring rectangular blocks of houses was found, similar to the Middle Kingdom towns.

The New Kingdom town of Sesebi, in the Nubian province, is another example of a planned Egyptian town, with rows of house arranged in a checkerboard pattern, a town wall, and large temples. Next to the temple were large storage installations, indicating that the temples had strong economic functions. At the sites of several New Kingdom towns, no town walls are in evidence; in this period, perhaps, people simply felt safe. The situation changed in the Third Intermediate (ca. 1070–ca. 712 B.C.E.), during which time town walls are well known to have existed from both the archaeological record and from descriptions in texts. With the population rising, towns became densely populated places. During the Roman period, Hermopolis, in Middle Egypt, had houses seven stories high.

Especially in the Ptolemaic and Roman periods, the general picture of provincial towns changed drastically, with the appearances of new types of public buildings such as bathhouses, theaters, and other Greco-Roman-style public institutions. These buildings were in fair evidence in several provincial capitals but were less common in villages such as Karanis and other well-known villages in El Fai-yûm. Many Egyptian villages from the Roman period were on the scale of medium-sized towns from other parts of the Roman Empire, by virtue of the high population density of the region.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

Towns and villages arose in the ancient Near East when people built homes near permanent sources of water and food. People kept living in towns and villages because agriculture required large amounts of communal labor and water supplies were limited, forcing people to share the same sources. The earliest towns appeared in the ancient Near East around 12,000 to 10,000 B.C.E., as people settled near reliable sources of wild foods such as natural stands of wild wheat and barley. These first settlements were small communities of about 100 to 200 people living in simple huts.

One of the first towns was Abu Hureyra in modern-day Syria. Abu Hureyra was established around 11,500 B.C.E. by hunter-gatherers who settled there to take advantage of edible plants growing near the banks of the Euphrates River. At the time the area had forests of oak, pistachio, and plum trees and was close to grasslands that provided edible seeds. Gazelles migrated through the area regularly, providing a reliable source of meat. The people who settled in the area built houses by digging shallow depressions into the ground and then sheltering them with branches and reeds placed atop wooden posts. They built additional shelters to store extra plant foods, keeping the surplus in reserve in case of drought or a poor year for nut cultivation. The women of the community used stone mills to grind grain into meal, a labor-intensive task that forced the entire group to stay in one place year after year.

By 9000 B.C.E. the town of Abu Hureyra contained several hundred inhabitants living in houses made of mud bricks. The people grew their own grain in fields surrounding the town, and the women continued to grind wheat in their houses day after day. The villagers also herded sheep and goats for milk, meat, and wool used to make cloth. The entire community existed to grow crops and raise children, generation after generation.

Over the next several millennia people continued to build towns and live according to the same pattern. By 6000 B.C.E. most residents of the Fertile Crescent lived in small villages near ready supplies of water. They were all located on or near sources of water that could be used to irrigate crops; most settlements rose along the Jordan, Tigris, Karkheh, and Euphrates rivers.

Mud was the main building material because both stone and wood were scarce. The agricultural seasons and daily necessities determined the activities of the residents. People experimented with and mastered irrigation techniques, such as canals, that allowed them to plant fields farther and farther from the rivers. When a town became too crowded to support itself, people simply moved into a free space and built new settlements.

Towns were occupied by family groups that helped one another with the labor of farming and other communal tasks, such as building. It would have been impossible for anyone to live alone; towns and villages made it possible to raise food and channel water in the harsh landscape. Living communally also made it easier to arrange marriages and raise children. Because they lived among relatives, village dwellers could always turn to someone for help. Living in towns fostered the beginnings of spiritual thought. Most towns remained in the same place for centuries, and many generations of dead were buried there. The inhabitants came to believe that dead ancestors continued to watch over the living.

Beginning around 3800 B.C.E. the towns at the mouth of the Tigris and Euphrates began to grow into cities such as Eridu, Ur, and Uruk. The climate was drier than it had been, and populations were too large for people to support themselves on family or village farms because there was not enough water or cultivable land for everyone in the area to farm for themselves. The people living in the cities developed governments to organize agriculture and distribute grain as well as to worship their gods. For the next 800 years or so, however, many people continued to live in towns and villages. Mesopotamian cities were surrounded by towns connected to the rivers by long canals extending in every direction from the cities. These towns specialized in various products, including metalwork, pottery, and fishing. They traded with merchants in the cities to get grain, and they relied on the cities for defense and religious ritual. By 3000 B.C.E., however, most of these villages had been swallowed up by the larger cities, and the residents were co-opted to work for the city's irrigation canals and farms.

By the first millennium B.C.E. towns and villages had been established throughout the Levant, Persia, and Anatolia as well

as in Mesopotamia. Towns continued to be located near water sources and cultivable land. Most towns had a central area for people to meet and trade, and most contained a communal place of worship. Towns often sprang up along trade routes, such as the Persian Royal Road that ran across the Persian Empire. Some towns were quite small and simply organized, but as time went on they acquired more local government.

During the fifth and fourth centuries B.C.E. the Greek model of town organization spread into Asia Minor. Towns of this period were carefully planned, and the land was divided in a regular pattern. Each town contained an agora—an open space where people could gather to exchange goods or conduct business. The agora might contain a stoa—a building used for various purposes, including conducting courts of law and other civic activities. Later towns often had several stoas surrounding the agora, marking the space as an official public area. This type of town design spread throughout the Near East and Persia during the Hellenistic period, as Alexander the Great traveled through the region and founded numerous cities.

The Romans imposed their own form of order on Near Eastern towns during the empire. Towns were built on a rectangular grid pattern and included a forum—an open square used for business and politics. The local government organized the building of streets, sewers, and public water supplies. Many towns had fortifications to protect the residents from enemy attacks. The government also handled matters of taxation, grain distribution, and legal administration. During the late empire Rome's central administration deteriorated, and local people throughout the Near East took on more responsibility for their local government. In Asia Minor and the Levant local religious rulers gained power over towns and took on the financial responsibility of maintaining them.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

The region of Asia and the Pacific encompasses vastly varying climates, and the towns and villages built in ancient times varied according to people's needs for shelter from the weather, for protection, and for cooperative living. As early as 9000 B.C.E., and probably much earlier, people in Siberia and central Asia were using bones and skins from animals such as mammoths to build shelters. These people were cooperative hunters who probably gathered in small villages in order to easily form hunting packs for pursuing large game. The villages also would have allowed for greater numbers of people to deal with injuries and to gather together to keep warm in the often frigid environment.

Far to the south, in Southeast Asia, people were dealing with a very different environment: one that was warm and wet and becoming wetter. The coast offered opportunities for fishing, and people clustered together in villages to work together to harvest food from the sea. Not much is known of

these ancient villages, partly because the rising ocean covered many of them with water and partly because the humid air quickly rotted the wood and leaves that were probably used for building homes.

Farther inland, in the rain forests, villages likely consisted of little more than lean-tos, shelters of branches raised on poles on one side and leaned against trees or large rocks. These villages would be found in forest clearings, perhaps beside rivers or streams. Living quarters such as lean-tos were favored in the construction of villages on the islands of the South Pacific, where warm weather made more sheltering structures unnecessary for most of the year.

Estimates for when agriculture began in the region of Asia and the Pacific vary widely among archaeologists, with some citing about 7000 B.C.E. in what is today far northern China, while others cite the more recent figure of about 4000 B.C.E. in both the Indus River valley and in far northern China. Early agricultural villages seem to have evolved out of villages constructed by hunter-gatherers who had assembled together as family groups. Along the Yellow River people who cultivated millet while still relying heavily on hunting and gathering formed villages of fewer than 40 people, probably constituting an extended family or clan. The land on both sides of the Yellow River was well suited to incipient agriculture, being easy to dig and rich in nutrients.

Who the villagers were in 4000 B.C.E. in the Indus River valley is not known, but their culture may have given rise to the Harappan civilization of 2600–1500 B.C.E. These early villagers almost certainly had contact with Sumerian cultures in the Near East, and the designs of their villages may have been influenced by those cultures. By 2600 B.C.E. these people were building numerous towns and villages, almost all along the several rivers that flowed through the Indus River valley at that time, as well as cities for up to 50,000 inhabitants. Towns and villages were usually well planned, with grids of streets and buildings made of fired brick. Granaries, for storing grain, seem to have been found in most towns and villages.

Although the Harappan civilization faded by 1500 B.C.E., the established methods of planning towns and villages did not. As Aryan invaders from central Asia spread southward into the heart of India, they imposed many of their customs on local peoples, but they were nomads without much skill in building settlements, and they seem to have adopted some of what they found among the Harappans and cultures farther south.

By about 500 B.C.E. the forms of Indian villages were generally set, with changes occurring only slowly during the rest of the ancient era. Both towns and villages were expected to be organized in the same manner as the capital cities in India's various nations. Towns and villages were often raided by bandits or other groups still living in forests, making defensive considerations important. Thus, settlements tended to have earthen walls and main gates through which people had to pass to enter. In the case of a town, the gates would

usually have buildings attached where local officials worked; these officials would collect taxes from people bringing goods into town. In the case of a village, such work was more likely performed by the village chief or his relatives. Towns would feature bigger houses than would villages, with houses in towns reaching two stories in height, whereas houses in villages consisted of one story only.

Indian villages were usually self-sufficient, as help from cities was generally slow to arrive because of the distances between locales and because the weather often made roads difficult to travel. Thus, villages were usually located near reliable sources of water and would typically have agriculture as their most important industry. Sometimes, a village consisted almost entirely of members of one profession, such as with metalworking or ceramics manufacture; children tended to enter the professions practiced by their parents, which meant that some small villages that had formed around extended families or clans became focused on a single industry. Such villages were dependent on the economies of cities for selling their products. Occasionally, a village was placed under royal protection, meaning that the villagers were not to be bothered by outside government officials.

In China living conditions in villages were poor during most of the ancient era. Villagers in the Yellow River region lived in circular homes, often wood and dried mud surrounding a pit. The roofs were probably made of thatch, with a peak in the center. The houses formed irregular patterns in villages. The villages themselves tended to be built wherever high ground could be found near a river. Although the villagers were farmers, so much of what they produced was taken from them in the forms of fees, taxes, and loan payments that they needed to hunt and fish to supplement their diet.

By the beginning of the Han Dynasty (202 B.C.E.–220 C.E.), towns featured houses that were significantly different from those in villages, which were usually one-room hovels; advanced Chinese construction methods were applied to town buildings, which were usually wooden with heavy posts on which walls were hung. Crucial to a town was its marketplace, where peasants brought their harvests and merchants sold their goods. A marketplace was usually located on a town's main road, where visitors were sure to pass after entering the town.

In Japan archaeologists have discovered numerous remains of circular houses, with the walls encircling pits. While the largest settlement yet discovered had about 1,500 homes, most settlements were much smaller. The larger towns were probably founded on agriculture, which allowed more people to live in one place than did hunting and gathering, but even at the end of the ancient era many Japanese were still hunter-gatherers living in villages in the vast forests that covered most of the islands of Honshu and Kyushu. Villages sometimes had protective ditches around them, and some may have had wooden walls, as warfare was common by 200 C.E.

EUROPE

BY KIRK H. BEETZ

The earliest Stone Age populations of Europe were mobile hunter-gatherers who lived in camps for short periods and then moved in search of game. Not until agriculture began in southeastern Europe around 7000 B.C.E. were settlements established with the permanence and character of farming villages. Archaeologists refer to people who live in permanent settlements throughout the year as sedentary. The practice of agriculture demands that people stay in one place to tend their crops and have a place to store the foodstuffs after the harvest. Eventually some hunter-gatherers who lived in rich environments displayed a few sedentary characteristics. An example from Europe is the communities of the Ertebølle culture that occupied the coasts of Denmark and Sweden between 6000 and 4000 B.C.E.

By 5000 B.C.E. farming had spread across central and southern Europe, and by 4000 B.C.E. it had reached the British Isles and Scandinavia. The earliest European farmers lived in various types of settlements. In the Balkans the houses made from mud were generally clustered into settlements that suggest true villages, whereas in central Europe the earliest farmers lived in farmsteads with timber houses that formed loose groupings along small streams. It is unclear whether these settlements had the organization of villages or whether each farming household functioned relatively independently. Whatever the structure of the settlement, its inhabitants were linked to other similar settlements through a network of trails and streams. Fields and pastures surrounded the houses.

By 3000 B.C.E. ancient Europeans managed to build villages even in the extreme climates of the far north. Perhaps the most famous of these villages is Skara Brae in the Orkney Islands, northeast of Scotland, where it is very cold and very windy. Skara Brae was one of many small villages made of stone near the northern seas. It was not the oldest stone village, because an older, well-developed village was found underneath it. However, Skara Brae was well preserved, allowing its remains to tell much about ancient village life. It was deliberately built in a midden, an ancient trash heap. Its walls were made of stone slabs, and there were passageways with stone walls between the village's houses, allowing people to walk from house to house without being exposed to the wind. The roofs of the houses were dirt with grass cultivated on them to hold them firmly together. Building the houses in the midden and covering both roofs and midden with soil in which grass was grown helped keep the village warm. Each house had a room set aside for a toilet, and beneath that room ran a channel that carried away the waste.

Skara Brae comprised only six houses. The climate was not good for most crops, but judging by the numerous bones found among the remnants of the village, grass grew well enough for the inhabitants to raise sheep and cattle. Villagers were likely related to one another. Some archaeologists believe that each house was closely associated with a particu-

lar family. Bodies of elderly women were found within the walls of houses, possibly an indication of villagers' belief that by revering their ancestors they could protect their houses. The village was occupied from about 3100 to 2480 B.C.E. and may have been abandoned slowly and voluntarily. Each house seems to have been ritually filled in with varying layers of debris. A common item found in the abandoned houses was antlers, which may have marked a house so closely associated with the family that no one else would have been allowed to live in it.

Other famous settlements of the early European farmers are the lake villages in central Europe, built in the foothills of the Alps between 4000 and 1200 B.C.E. At one time archaeologists thought these villages were constructed over lake waters, but it is now known that they were actually built over marshes near lakes. The levels of the lakes had risen to and sometimes over the dwellings after the villages were built, misleading early archaeologists. Piles were driven deep into the lakeside marshes until they hit a solid subsurface. Set on these piles were wooden houses with sharply peaked roofs to shed rain and snow.

Settlements that unequivocally have the character of towns began to appear during the final millennium B.C.E. One of the best known of these settlements is Biskupin in Poland, located about 143 miles to the west of Warsaw on a marshy peninsula along a lake. The town was a planned community from the start. Instead of the irregular arrangement of houses commonly seen in earlier villages, Biskupin had houses in several neat rows. They were built end to end as one long house divided by walls into many one-room dwellings. Because of the marshy character of the peninsula, the streets had to be paved with wood. In Biskupin the wooden streets stretched under the houses from one side of the town to the other, leaving no open spaces.

Around Biskupin was a wall of wood and dirt 20 feet high and 6 feet wide. Its sides and top were wooden, and the inside was filled with dirt. Within the wall were about 100 dwellings, housing roughly 700 people by about 720 B.C.E. Within the village all the crafts work took place, including metalworking. Fires either from blacksmiths or hearths burned part of Biskupin seven times. Whom the lake villagers feared is not known, though archaeologists in general speculate that raiders from the Baltic region or from the East pressed people into fortified villages like Biskupin.

By 600 B.C.E. the Celts were spreading through Europe. Along the Atlantic seaboard their villages tended to be made of stone, but inland they favored wood. Some Celtic towns were set on top of hills and were surrounded by wooden fences, but many villages were small and scattered through lowlands, usually near water but nearly always where farming was possible. Industrial centers with population densities and probably structures similar to towns were established in central Europe, where it was possible to carry out activities like ironworking and salt mining. Two of the most important centers of industry were Hallstatt in Austria, where salt was

mined, and Stična in Slovenia, where iron was smelted and forged. To the west, wealthy and powerful chiefs and their retainers lived in hilltop settlements known as hill forts, such as those at Maiden Castle in England, Mont Lassois in France, and the Heuneburg in Germany.

By the time of the Roman invasion in the first century B.C.E. the inhabitants of western Europe were beginning to expand some settlements into fortified cities called *oppida*. Described by Julius Caesar in his account of his campaigns, *oppida* combined residential, industrial, commercial, and administrative functions. Some of the most famous *oppida* are found in France at sites like Alesia and Gergovia, while others in Britain eventually became the Roman towns of Camulodunum (modern Colchester) and Verulamium (modern St. Albans). The Roman towns were laid out in a grid pattern, with wooden shops and houses lining the streets. The Roman style of towns and villages dominated until the Germanic invasions of the 300s C.E. For protection nearly every village had a small fortress, and during the Common Era churches became standard in villages and towns.

GREECE

BY SPYROS SIROPOULOS

Greece is a mountainous country. Its irregular topography makes communication and trade difficult and led to the formation of many small, independent political units. Driven by social and economic necessity, some of these small communities united, which led to the formation of larger villages and towns. In *Politics* Aristotle argued that the city was the natural culmination of a series of associations and is the only environment in which the human being can reach completion. The first union, he argued, was between man and woman and then between master and slave; the result of these unions was the household or family (*oikia*). Households came to realize that to fulfill all their needs, they needed to consolidate into a village (*kome*). Eventually various villages joined together to form a city (*polis*), which ideally were self-sustaining, independent, and dedicated to meeting people's need to live the best possible life.

Thucydides was also aware that long ago the Greeks lived in wretched villages and the union of several of them led to the formation of cities. This process, known as synoicism, also occurred in Attica, when the people from the area confined by the Parnetha, Penteli, and Hymettus mountains were united in roughly 700 B.C.E. under the leadership of Theseus. The result was Athens, whose origins may explain its plural name.

A deme was the smallest political division of a city-state. Athenian demoi are the best documented, but demoi are also found in other city-states, like Eretria, Cos, and Rhodes. The Athenian politician Cleisthenes turned about 150 demoi into the basis for the arrangement of citizenry into 10 *phylai* (tribes). Archaeological excavations have shown that smaller-sized townships and secluded cottages and farms existed all

over Attica, but residence there was seasonal. Possibly small unions of villages or farms were formed, but it is unlikely that the modern equivalent of a big village, secluded in the countryside, could be found in antiquity. The deme was the ancient equivalent of the modern village or small town.

The economic character of Greece remained essentially agricultural throughout the ancient period, which means that the civic centers, irrespective of their size, depended on the farming produce of the countryside. Many Athenians had their summerhouses outside the walls of Athens, in the country or the popular suburbs of Agryle. The countryside of the Attic Peninsula abounded with disparate cottages. For a long time the noblemen of Athens had large cottages and farms in the country, which gave them the right to excel in politics because the amount of crop a man had determined his political status. The statesman Pericles, of the fifth century B.C.E., had lands and houses in Attica, too, and he had promised to bequeath them to the state unless the invading Laconians burned them. In his *Oeconomicus* Xenophon describes vividly the life of country noblemen and praises agriculture as the source of all virtue, but he also hints at the sprawl of these cottages, with people building them anywhere they fancied.

Most farmers in classical times would have lived in the urban centers for protection and easy participation in politics. Fish was never the main course of the Athenian diet; therefore, small fishing villages around Attica never grew to considerable size, unless they turned into important trade and military centers. One example is Piraeus, which grew from a modest village to the largest port city in Greece.

Many people preferred to live outside the urban centers. For instance, in his comedy *The Clouds* Aristophanes describes the play's hero, Strepsiades, as a farmer from the deme of Acharnae who curses the fact that political obligations force him to leave his village at the break of dawn. Aristophanes makes clear the distinction between the *asty* (urban center), which Strepsiades hates, and the deme, which he longs for. In Boeotia it seems that people preferred to live permanently in the countryside. According to Thucydides, before Brasidas was received at Amphipolis he "had conquered the fortunes of Amphipolis' citizens who lived scattered all over the vicinity"—a clear description of people who resided in disparate farms and cottages rather than in organized towns and villages.

Like Strepsiades, most villagers and townsmen had to commute to Athens if they wished to actively participate in the affairs of the state. Nevertheless, each deme maintained some form of independent local administration. A *demarchos* was elected as the head official and presided over a local council. The deme possessed land and had local cults. Most important, the deme maintained a list of its members, who were officially registered after being on the list 18 years. Like cities of the classical period, smaller communities pursued the ideal of self-sufficiency. However, to sell or buy products, the villagers had to go to Athens. In Argolis (in the area of the Peloponnese) scholars have observed that two of the area's

small townships evolved into great cities from the beginning of the fourth to the beginning of the third century B.C.E. The distinctive sign of this evolution is the establishment of an agora, or marketplace. The agora was such a distinctive trademark of a city that Athens allowed only two other marketplaces to operate in all its vast territory.

ROME

BY KATIE PARLA

The first towns and villages in central Italy were Iron Age settlements later expanded by various groups such as the Villanovans, Etruscans, Latins, and, ultimately, the Romans. As Rome's territory began to grow, existing buildings in acquired towns were replaced with Roman models. Accordingly, certain common features emerged in towns and cities throughout the Roman world. These similarities were the product of town planning that combined Greek, Etruscan, and Roman elements.

During the Republican and Imperial ages, Rome expanded to include territories as far as Great Britain and the Near East. By imposing town planning on old and new settlements, the Romans were able to provide a common, unifying urban experience for all. By constructing public buildings that served as communal social and commercial spaces and by providing amenities to the people living in these territories, Rome was able to offer an unparalleled quality of life even in the smallest towns and villages.

Roman towns were typically laid out in grids; the organization of a town's streets into a grid system is called orthogonal planning. This model was borrowed from Greek town planning, but the Romans used square rather than rectangular city blocks. The streets running from east to west in such a design are called *decumani*, while those running from north to south are *cardines*. Where the principal *decumanus* axis (*decumanus maximus*) intersected the principal *cardo* axis (*cardo maximus*) is where the town forum would be located.

Romans built forums in towns and villages throughout their territory to provide a communal area to be used for political, economic, religious, and legal activities. Buildings and speaker's platforms would be constructed for meetings of the town or provincial government. Warehouses, banks, and shops would provide space for commercial exchanges. Temples dedicated to gods and emperors would reinforce the town's connection to Rome and its other settlements. Law courts, called *basilicae*, would be where Roman law was enforced and punishments doled out. Forums in Roman towns were public places where visitors would absorb the messages of unity and Roman primacy that were communicated through architecture.

Another important aspect of Roman towns and villages was their constant water supply. Aqueducts were built to bring water from lakes, springs, and rivers to settlements. These aqueducts were aboveground or belowground channels that delivered water over a distance at a low-grade angle

using gravity. Some water sources were more than 50 miles away from the towns they supplied. This constant flow of water allowed for amenities like public fountains, public bath complexes, public latrines, and even running water in some residential complexes.

Waste management was another feature of Roman towns and villages. Sewers were built below street level to channel waste away from residential, commercial, and industrial sites. Also, groups of slaves would collect trash in the streets and rinse the streets regularly to keep public areas sanitary. This would help prevent the spread of disease.

Places for public spectacles were a major social component of Roman town planning. Theaters for cultural performances, as well as stadia and arenas for gladiator fights, chariot races, wild beast hunts, and public executions, could be constructed from wood or stone. Typically, these buildings were erected on the outskirts of towns, where more space was available. During the Roman Republic (509–27 B.C.E.) private individuals commissioned the buildings and the events held there. In the empire, the state financed such projects and produced structures of great scale and permanence. The sites for public spectacle found in ancient Roman towns were places where the masses, citizens and noncitizens alike, could reap the benefits of the government's generosity, since the events were free to the public.

Another Roman structure found in all towns and villages was the bathing complex. Public baths provided a common space where all members of society could relax, wash, exercise, and interact; the baths were social areas that guests would visit most afternoons for a minimal price. Like arenas and theaters, bathing structures were usually built by politicians during the republic and commissioned by emperors and the government during the empire.

One of the fundamental functions of Roman towns and villages was to provide secure areas for residential life. Since Roman towns were surrounded by defensive walls guarded by soldiers, residents would be protected from invaders. Police also patrolled the streets to protect private property within the town limits. The two main types of residential buildings were the *insula* and the *domus*. An *insula* was an apartment block with commercial spaces for lease on the ground floor and apartments on upper stories. A *domus* was a single-family home or villa that had reception and dining areas in addition to the private bedrooms and slaves' quarters. Sometimes the rooms of a *domus* facing onto a street would be used as commercial spaces. Many examples of this practice can be found in both Ostia and Pompeii.

Towns and village were located in all areas of Roman territory. Sometimes the Romans would reorganize existing settlements, adapting standing structures into the Roman layout that they would impose on conquered towns. This could result in established towns not adhering precisely to the orthogonal plan. Pompeii offers an example in which the original Oscan street plan, with its only occasional right angles, was incorporated into first the Greek, then the Roman grid system.

In other instances towns and villages were built in the absence of preexisting settlements. In such cases, religious authorities would be consulted in order to ascertain if the gods found a site acceptable. If so, the boundaries of the town would be officially established, including the *pomerium*, a ritual boundary within which magistrates could exercise power and outside of which burials, cremations, and military exercises could take place.

Aside from social and commercial functions, Roman towns and villages served certain military functions. The towns would protect Roman territory against invaders and offer bases from which military campaigns would be launched; these were the primary functions of Rome's first colonial settlements. Another military function of towns and villages was to provide a Roman presence in a distant part of Roman territory. Since many towns were conquered during military campaigns, the Romans would seek to maintain territory by populating areas with Romans. Members of the military might receive land as part of their war booty after conquest in or near newly conquered towns and villages.

As Rome grew during the late republic and the empire, a greater need for natural resources developed. By establishing settlements in a given area, local resources could be exploited, managed, and exported from the towns. This was an especially common practice in North Africa, where the majority of Rome's grain supply was grown. Commercial and agricultural development was managed and expanded from the towns and villages established throughout Roman territory.

THE AMERICAS

BY J. J. GEORGE

The establishment of village and town settlements, allowing people to live sedentary lives, is often but not always brought about by agricultural development. More than 100 species of edible plants were originally cultivated by Native Americans, the most familiar and widespread of which were maize, which came from Mexico, and potatoes, which were originally grown in the highlands of Peru. Other cultigens that were staples for many early communities included sweet potatoes, manioc, several kinds of beans, squash, tomatoes, and chili peppers. As farmers settled beside their crops, permanent villages were established. Surplus crops could be stored and traded with other communities; surpluses could also allow for certain community members to move beyond subsistence tasks and develop as craftsmen, merchants, priests, or ruling elite. Thus, many scholars argue that agriculture paved the way for social and economic stratification and for urban advances that laid the foundation for later complex cities and empires.

However, not all permanent villages developed as agriculture-based entities. For example, early large villages in regions as diverse as California, the Northwest Coast, and coastal Peru illustrate that sedentary civilization can develop in the absence of agriculture. In localities where resource-

rich environments offered dependable food supplies, such as the salmon available seasonally along the Northwest Coast and the sardines and anchovies found in coastal Peru, villages developed and thrived according to nonagrarian initiatives. Generally, then, no single pattern defined or predicted the likelihood that a settlement would develop or succeed; each case was unique and subject to a variety of local factors. Changes in climate, for instance, could have dramatic effects on local populations, forcing massive resettlements or even causing the collapse of complex urban or semi-urban environments, as is thought to have happened when an extended drought struck the Moche towns in the Moche valley of northern Peru around the sixth century C.E. Similarly, climate change and associated decreasing yields of wild resources have been suggested as the causes of the collapse of the Hopewell in North America in the first centuries of the Common Era.

In the context of ancient civilizations, a *village* can be categorized as a settlement of as many as 30 or 40 dwellings occupying an area of several acres. A village would typically feature sturdy structures that remained in place and were occupied for extended periods of time; deep deposits of refuse, called middens; and some level of community planning. Early villages often had basic social hierarchies ruled by chiefs, as with similarly defined chiefdoms. *Towns*, by comparison, include many of the largest prehistoric communities, which covered hundreds of acres and featured housing structures numbering into the hundreds. Characteristic of towns were deep middens; heavy structures that were rebuilt or strengthened over time; dwelling units arranged in definite patterns, often in relation to ceremonial units or structures; and fortifications. All of these characteristics indicate long-term occupation of single sites.

In North America the ancestors of many peoples who would later settle into villages and towns were present as early as 7,000 years ago. While the archaeology suggests that town-level organization did not happen until after 500 C.E., examples of early North American village settlements are extensive. Such settlements include Hopewell Indian sites formed in the American Midwest by roughly 300 B.C.E.; coastal villages formed in British Columbia and southeastern Alaska, with evidence of plank houses, by 200 B.C.E.; and the villages of the Adena people, as affiliated with burial mounds and earthwork, which were formed in Ohio, Kentucky, and West Virginia between 1000 B.C.E. and 200 C.E.

Village life based on agriculture featuring intensive irrigation appeared quite suddenly in the southwestern United States around 300 B.C.E., as immigrants from Mexico established a Hohokam culture settlement in the Gila River valley at Snaketown, in southern Arizona. These people grew maize, beans, and squash and watered their crops by means of extensive canals. Early Hohokam houses were almost square, measuring 10 to 15 feet per side, and were loosely grouped together. The population of Snaketown is thought to have been about 100.

Neighboring Anasazi and Mogollon cultures also seem to have shifted from hunting and gathering to more sedentary modes of living. The establishment of pit-house villages and the production of pottery marked the transition of the Cochise in southeastern Arizona to the initial phase of the Mogollon tradition around 250 C.E. Early Mogollon villages were usually established at the ends of mesa tops, sometimes as high as 600 feet above the valley floor, at least in part for defensive reasons. One early Mogollon village referred to as the SU site had 28 houses; maize and squash were being cultivated, and some of the dwellings were of a significant size. The Anasazi of the region where New Mexico, Colorado, Arizona, and Utah meet represent a long-lived cultural tradition still extant today.

Many different settlement patterns occurred throughout Mesoamerica. Numerous villages featuring thatched-roof houses, as founded on improved maize productivity, rose during the Preclassic (ca. 1800 B.C.E.–ca. 150 C.E.) in the humid Pacific littoral of Guatemala and western El Salvador. Along the coast of the Gulf of Mexico the Olmec civilization (ca. 1500–ca. 400 B.C.E.) consisted of a series of towns and affiliated villages scattered across Mesoamerica as far as Honduras. Debate continues over the demographic identification of the primary Olmec sites of Tres Zapotes, San Lorenzo, and La Venta, all of which bear evidence of both ceremonial priorities and more advanced urban characteristics; some scholars claim these settlements as early cities. The Maya territory at this point in time comprised numerous towns and villages. The region around contemporary Guatemala City was characterized by a distribution of villages in relation to a large central town called Kaminaljuyú, which was believed to feature a core of several hundred temple mounds at its apex.

In South America evidence of maize cultivation and sedentism in Colombia and Ecuador occurs as early as 3200 B.C.E., and in Peru there is evidence of permanent village occupation at least as far back as 5000 B.C.E. at a site near the valley of the Chilca River. Analyses there have confirmed the existence of a permanent village of oval pit-houses apparently not founded on agriculture but on the efficient harvesting of the wild resources of the coast. By about 3000 B.C.E. Huaca Prieta, a modest fishing village on the north coast of Peru, had taken hold, with evidence there showing extraordinarily complex development of fiber arts. By about 2000 B.C.E. at least 100 villages like Huaca Prieta had been established along the Peruvian coast. Peruvian settlements with monumental architecture and more substantial population centers, indicating town-level development, include Caral, Asia, Salinas de Chao, El Paraíso, La Galgada, and Kotosh.

► trade and exchange

INTRODUCTION

Systems of trade and exchange in the ancient world required first that civilizations had desirable goods to trade, goods that were otherwise unavailable to the trading partner. With the advent of agriculture and the rapid shift from nomadic hunting and gathering to more settled, permanent communities, most trade involved agricultural goods. Thus, as towns and cities emerged, those communities traded with outlying agricultural areas for food and other agricultural products like wool. In exchange, they provided desirable goods produced by craftspeople, including tools, leatherwork, pottery, rope, and numerous other items that would be useful in a rural agricultural community.

Later, other types of goods were commonly traded, particularly after the discovery of metals. First copper, then bronze (a copper-tin alloy), and finally iron became the basis of trade and exchange in many parts of the world. Economic activity was by no means limited to farm products and metalwork. In time, a wide range of commodities were traded, including glass and glasswork, jewelry, gold and silver objects, minerals, perfumes, dyes, silks, amber, oils such as olive oil, salt, herbs and spices, lumber, furniture, decorative objects, and many other types of goods.

Usually, the basis for trade was little different from its basis in modern life. One civilization discovered that it had resources that other civilizations wanted or that its craftsmen had developed a particular genius for producing certain types of goods. Thus, for example, Lebanon discovered that its cedar trees were in great demand because the lumber is easily worked and cedar's natural oils made the wood

resistant to insects and decay. This natural resource became the foundation of Lebanese trade with other nations around the Mediterranean Sea. Ancient India had the resources and skills necessary for textile production, so its textiles were highly prized.

In addition to desirable goods, trade and exchange required trade routes and modes of transportation. The two choices, of course, were land routes and sea routes. Trade and exchange by land became more extensive after the domestication of pack animals. Caravans carried goods long distances, particularly in regions with broad grasslands, where transport was relatively easy and there was plenty of grass for pack animals to eat. In time, the ancient Romans constructed a vast network of roads connecting the imperial capital with its colonies, and the Chinese created a road network, often referred to as the Silk Road, connecting China with India, the Near East, and eventually Rome. As shipbuilding technologies became more advanced, nations that bordered the sea were able to maintain vigorous trade relationships both with their colonies and with other nations. In this respect, the ancient Greeks led the way, followed by the Romans and Chinese.

Trade and exchange involved more than just the exchange of goods. Trade and exchange played a major role in the diffusion of knowledge and ideas, as cultures made contact with one another through their business relationships and road networks enabled people to travel. Moreover, the wealth provided by trade and exchange led directly to some of the world's great civilizations, as bustling cities developed to support economic activity from all over the known world.

AFRICA

BY MICHAEL J. O'NEAL

Many ancient African societies engaged in trade, and some thrived on it. This was particularly the case in the northern sectors of the continent, where large settled communities developed earlier than they did in the southern half of the continent, where many groups still lived as wandering hunter-gatherers or herders. As settled communities grew, the people in them produced goods—food, metalwork, leather, glasswork, and numerous other things—they could trade with other communities far and near, and a number of kingdoms became crossroads for trade and exchange. These trading networks were a source not only of goods that were unavailable locally but also of tax revenues for kingdoms and their rulers.

One of the most vigorous trading communities was the region known as Nubia, just south of the Egyptian Empire. Nubia acted as a major crossroad for people from Egypt, the Near East, southern Africa, and later Rome, India, and the Byzantine Empire. The first civilization that developed in Nubia was the kingdom of Kush, which became a major center for trade. Goods from the southern part of Africa, including gold, ebony, ivory, exotic animals, and slaves, passed through Kush on the way to points north.

Throughout its history, though, Kush was unstable; the Kushites had to move their capital city on two occasions. Eventually an invasion by the Assyrians severely weakened Kush, and in about 350 B.C.E. the kingdom of Kush came to an end, giving way to the kingdom of Axum to the east. The Axumites occupied the highlands of Ethiopia near the Red Sea, along with parts of modern-day northern Ethiopia, Eritrea, Yemen, southern Saudi Arabia, northern Somalia, Djibouti, and northern Sudan. Axum was a mixture of indigenous Kushite people and immigrants from the southern Arabian Peninsula who had migrated to the region in about 500 B.C.E.

Like Kush, Axum derived its power from trade, primarily in such commodities as silk, spices, ivory, tortoiseshell, rhinoceros horn, hippopotamus hides, monkeys, gold, silver, cloaks and other garments, obsidian, spices, agricultural products, sugarcane, emeralds, salt, and slaves. The kingdom became immensely wealthy, and with a powerful navy on the Nile River and the Red Sea was able to extend its imperial power by establishing trading colonies throughout the region in the early decades of the Common Era. To foster trade, the Axumites developed a system of roads maintained and protected by the state. Also used for transportation and trade were riverbeds during the dry seasons and reed boats for carrying goods on lakes. Axum remained a major trading power until the rise of Islam in the seventh and eighth centuries C.E.

Among imported goods, both those from other nations and those that circulated within Axum itself, were iron, bronze, glasswork, ceramics, wood, leather, and livestock. While the bulk of Axumite trade was internal, with city centers trading manufactured goods for agricultural products from the countryside, much also was international. Most imported goods appear to have been luxury items for the elite. These goods had to pass through customs posts, where taxes were paid. Sometimes these taxes were in the form of coinage, but usually they were paid in kind—that is, a portion of the goods themselves were paid as taxes. These taxes were an important source of Axumite wealth.

One of the most important trade routes of ancient Africa ran in an east–west direction just south of the Sahara. This band, called the Sahel, was home to numerous cities and settlements that made their living primarily through trade. Goods from the east and from the Mediterranean area passed through the Sahel on the way to points south, where they were traded for African goods such as ivory and precious metals. One of these settlements was Jenne-jeno in Sudan in the upper Niger River delta. Beginning in about 200 B.C.E. Jenne-jeno actively engaged in trade. Artifacts found in the area show that the city imported goods from Greece and Rome. Along any trading route, including that of the Sahel, towns and villages supported caravans of traders, providing them with food and water, forage for horses (and later camels), markets, and resting places. Goods probably changed hands at numerous points along these trade routes.

Carthage, founded on the northern coast of Africa (in modern-day Libya) in 814 B.C.E. by Phoenician traders from the city of Tyre in Lebanon, became one of the great trading civilizations of its time. The basis of Carthaginian power was its navy, which included as many as 350 warships that continuously patrolled the Mediterranean, primarily to keep trade routes open and to drive off competitors. Carthage also maintained a large fleet of merchant ships, each capable of carrying 100 tons of goods. Much of the empire's trade was based on the Iberian Peninsula (present-day Spain and Portugal), which had rich deposits of lead, silver, and tin ore. Tin was especially important because it was mixed with copper to make bronze, the key material for weapons, armor, and other vital implements. The Carthaginians also traded for tin with Britain and possibly the Canary Islands, giving Carthage a monopoly on the tin trade and therefore on bronze.

Besides Iberian silver, Carthage had access to silver mines in North Africa, providing a solid foundation for Carthaginian wealth. But perhaps the single most-valued commodity carried in Carthaginian ships was a dye called Tyrian purple. Painstakingly made in tiny amounts from the secretions of certain marine snails, this dye was so esteemed in the ancient world that a pound of it sometimes brought a price equal in value to 20 pounds of gold. Other important commodities included textiles (silk, wool, cotton), spices, perfumes, pottery, incense, glasswork, wood, bronze, alabaster, precious stones, plows, mirrors, cabinetry, household items (pillows and bedding, for example), slaves, horses, and weapons. Food commodities included fish and a range of agricultural products, such as wine, olives and olive oil, grapes, dates, nuts, and fruits. Much of Carthage's wealth came from brokering trade in these goods. Carthage's influence also spread southward with caravans sent deep into the continent to trade for ebony, ivory, salt, timber, gold, hides, and such animals as apes and peacocks. To the north they obtained amber from the Scandinavian countries. The Carthaginians' skills in storage, transportation, and buying and selling (they invented the auction) brought their empire wealth and power.

EGYPT

BY PANAGIOTIS I. M. KOUSOULIS

The broader Mediterranean region, which includes 25 nations today, witnessed the development of some of the most important and magnificent cultures of the past: ancient Egypt, Greece, and Rome. The Mediterranean Sea facilitated this development through cross-cultural exchanges, which took the form of diplomatic affairs, wars and treaties, social, religious, and artistic imports and exports, and, of course, trade.

Even in very early times Egypt had an extensive network of direct and indirect commercial and cultural contacts with foreign populations. Egyptian ships sailed across the Mediterranean probably as early as the Second Dynasty (ca. 2770–ca. 2649 B.C.E.), mainly to obtain raw materials. We can only estimate the size of such ships, although a cedar ship built

in the Fourth Dynasty (ca. 2575–ca. 2465 B.C.E.) was said to have been 100 cubits, or 172 feet, long. Excellent representations of ships from the royal expedition of Queen Hatshepsut (r. 1473–1458 B.C.E.) to the mysterious land of Punt (perhaps in modern-day Somalia) are recorded in wall carvings at Deir el-Bahri in southern Egypt.

The main Mediterranean shipping routes follow sea currents and winds that go northward and westward along the Levantine and Anatolian coasts to the Aegean and those that go southward and eastward from Crete to Libya and Egypt. Ancient navigators considered May to September the best time for sailing the Mediterranean and might put out to sea as early as March or as late as November, but in winter the risk of storms made seafaring too dangerous, and captains kept their ships in port. Trade goods included amphorae (large clay jars used in ancient times for storage and transport) and other containers, jugs, bowls, and vases in ceramic, stone, and glass, and figurines of various materials, especially including scarabs, the carved stone beetles that Egyptians regarded as talismans. Besides ordinary trade there was considerable exchange of precious materials and other valuable items as gifts between royal authorities and foreign parties for diplomatic purposes. Many clay tablets excavated at Amarna in southern Egypt preserve lists of goods sent by Near Eastern rulers to the pharaoh as gifts.

Numerous other official writings, inscriptions, and carvings testify to an extensive trade network both within Egypt and externally. Some record expeditions to desert mines and quarries; others describe journeys to barter for goods with foreigners. The Egyptian sources report all royally authorized expeditions in standardized accounts that are all more or less alike. They record the date, the mission that the king set for the leader, and the destination. The accounts usually end with a happy and successful homecoming.

For modern readers perhaps the most striking thing in these accounts is the lack of interest in trade for the sake of profit. The aim of the expedition leaders seems to have been solely to carry out the orders of their superiors or to follow the divine will of whichever deity protected their missions. Thus the description of Hatshepsut's expedition to Punt emphasizes the god Amon's desire for the products of that land. Similarly, the Twentieth Dynasty (ca. 1196–ca. 1070 B.C.E.) *Report of Wenamun* tells the story of an official who went abroad to obtain wood for building a boat to carry the sacred image of Amon. He had no interest in buying wood for any other purpose, and he had no means of making a profit through the expedition, since he had sent from Egypt only enough commodities to obtain what he needed for the boat.

Royal control over the trade economy, especially during periods of powerful pharaohs and strong central government, left no place for private merchants. Private traders appeared only in times of weak or nonexistent central government, such as during the First Intermediate Period (ca. 2134–ca. 2040 B.C.E.) and the Second Intermediate Period (ca. 1640–ca. 1532 B.C.E.) or after the New Kingdom (ca. 1550–ca. 1070 B.C.E.).

But evidence from tombs indicates that even in times of strong central control, semiorganized barter did exist, particularly along the banks of the Nile. The most commonly exchanged items in the tomb depictions are vegetables, fish, figs, drinks, and metal containers. It appears that people engaged in this kind of trade for the purpose of enriching their diet or their home furnishings, not for profit.

Another characteristic aspect of the trade economy in ancient Egypt was gift exchange. It existed in two forms: gifts from the king to the people or vice versa and diplomatic gifts or tributes from allies and other foreign parties to the pharaoh and the Egyptian state, especially during the Middle Kingdom (ca. 2040–ca. 1640 B.C.E.) and New Kingdom. Gifts from the Egyptian populace to the pharaoh were conceived as a tribute to both the divine and the political attributes of the king. The Egyptians offered the king precious objects and commodities in order to receive from him internal peace and stability. Thus, in the step pyramid of King Djoser (r. ca. 2630–ca. 2611 B.C.E.) at Saqqara—the first monumental structure constructed exclusively from stone—a large number of inscribed jars were found, attesting to the continued practice of giving gifts to the king. Similar cases of gift giving are recorded in account papyri from the mortuary temple of the king Sesostri II (r. ca. 1897–ca. 1878 B.C.E.) at el-Lahun and in historical texts from the New Kingdom.

Tomb paintings, especially from Thebes (in southern Egypt), show porters bearing tribute to the pharaoh from almost all points of the compass. Elephant tusks, logs of ebony, and leopard skins arrived from tropical Africa. Copper ingots, amphorae filled with incense and other goods, flasks, and elephant tusks were among the items of tribute brought by Syrians and sometimes by Cretans. The gift exchange was reciprocal. The king honored the offerings and repaid the donors with equally valuable items.

A diplomatic gift carried social and cultural connotations more than it did mere economic value. Foreign rulers offered diplomatic gifts to the pharaoh as proof of the continuation of existing alliances or to offer the prospect of new ones. The custom of the diplomatic gift reached its peak during the New Kingdom, when the foreign expeditions of the pharaohs led to a greater intensity of contact with foreign lands, from Libya in the west to Nubia (modern-day Ethiopia) in the south to the countries of the Near East. Foreign tribute often included precious items and commodities that could not be found in Egyptian territory, but, again, these were not economic transactions. They were diplomatic expressions that acclaimed the pharaoh as the major delineator of action on behalf of the Egyptian society and in a superior position to the foreign emissaries.

THE MIDDLE EAST

BY FRANS VAN KOPPEN

One view of the exchange of goods and services is as a primary function of a social group, but from another perspec-

tive trade is the voluntary exchange of commodities between two parties for no reason beyond the acquisition of those goods. The two basic forms of trade are regional or domestic trade and foreign or long-distance trade. Regional trade is the exchange of raw materials and finished products inside a community or within the same region, whereas foreign trade is the movement of goods between different ecological regions that is motivated by the uneven distribution of raw materials in the natural world. The mechanisms by which commodities were distributed in ancient societies depended on particular social customs, and not all modes of exchange can be described as trade. Foreign trade focuses on the material aspect of long-distance exchange and is often considered the extraction of necessities from the periphery for the benefit of the center. In the ancient world, however, foreign trade was a function of intense interregional contacts and an essential factor in the diffusion of cultural and technological innovations, without which civilization would not have been attained.

Written sources and archaeological finds shed light on the conduct of trade. Archaeology indicates that trade predates the invention of writing by many millennia, revealing, for example, that in the Neolithic Period (ca. 8000 B.C.E.) obsidian, a volcanic glass suitable for sharp tools, was used many hundreds of miles away from its Anatolian source. Not all commodities of trade, however, are accessible in the archaeological record, and the interpretation of what has survived is often ambiguous because factors other than long-distance trade (for example, booty or tribute) also can explain the presence of artifacts of foreign material or manufacture. Ancient texts offer more conclusive evidence—in particular, cuneiform records from Mesopotamia, an area that depended on foreign imports for many essential resources, such as metals, stone, or wood, and where innumerable archival records pertaining to trade and commerce have been preserved. The existence of these records places Mesopotamia at the center of the study of ancient trade.

Ancient Mesopotamia, Persia, and other ancient Near Eastern regions were characterized by high levels of functional diversification among the population and clearly defined urban and rural sectors. These complex societies required efficient exchange mechanisms to link producers with consumers. Movements of food, craft products, and raw materials in early societies can be classified as reciprocal, redistributive, and commercial forms of exchange. Reciprocal exchange typically occurred between producers and consumers within a community and was based on long-term relationships and patterns of reciprocal obligations. Redistribution describes the collection of goods by a central authority and their disbursement to others on the basis of social status or kinship. Redistributive patterns occurred within the household and lay behind the functioning of Mesopotamian institutions that amassed agricultural produce to allocate them in the form of rations to dependents. The collection of vital resources as tribute in the Assyrian and Persian empires of the

first millennium B.C.E. also has redistributive features and had a negative effect on commercial long-distance trade.

Finally, domestic trade conformed to a commercial type of exchange, with strangers trading goods or services on a market in accordance with freely varying prices. Economic value was expressed in quantities of certain goods, particularly silver, a commodity that fulfilled in antiquity many of the functions of our money. Pairs of scales and stone weights to weigh silver accurately, as well as the skill of converting into foreign weight systems, belonged to the toolkit of every ancient trader. Buying and selling, however, were often done by barter, with several items agreed on as the countervalue in a transaction, an ensemble that may include amounts of silver. Prices and commodity values fluctuated and were subject to supply and demand, but they usually adhered to customary rates attributable to social norms rather than government interference or market price fixing. Commercial, redistributive, and reciprocal modes of exchange existed alongside one another, depending on social context or transaction type, but their relative importance varied from place to place and through time.

Sellers on the domestic market were the producers themselves. Potters, for example, produced for clients but also sold their stock in marketplaces or from their workshops. Another example is people who made their living from retail. This group includes shopkeepers and vendors, occasionally specializing in products like salt or victuals. On a different scale, a class of wealthy merchants organized bulk transports of goods and relied on commercial networks for acquisition and distribution of merchandise. Those enterprises usually were undertaken on behalf of the state, with merchants collecting and selling agricultural taxes due to the state and repaying the state in silver or other commodities. Merchants held various positions; often they were entrepreneurs who entered into contractual agreements to undertake these tasks, but at other times and places they were more like government employees.

Some of these merchants also participated in long-distance commerce, but others dedicated themselves exclusively

to trade expeditions to faraway destinations, exporting products of Mesopotamian manufacture, like textiles, vegetable oils, and foodstuffs, and importing resources, such as metals, stone, wood, aromatics, and slaves. City-states like Old Assyrian Assur (ca. 1900 B.C.E.) prospered as a result of long-distance trade, and merchants typically yielded much more political influence than did merchants in territorial states. Foreign commerce was based on family firms, with the younger male members traveling abroad or residing in foreign trade colonies like Kanesh, the central Anatolian settlement of Old Assyrian traders who sold Iranian tin and Babylonian textiles against Anatolian silver. Foreign trade depended on favorable political relations, and arrangements for merchants often were included in diplomatic treaties. Substantial volumes of wares also traveled abroad as diplomatic gifts between allied rulers—for instance during the Amarna Age (14th century B.C.E.)—but this exchange cannot be defined as trade as such, given that upholding social relations was its main purpose. Nevertheless, commerce and diplomacy often worked well together because diplomatic envoys took care of their trade interests during missions abroad.

The natural landscape dictates how long-distance communications and trade are conducted. Rivers are easy arteries of transport, and the Euphrates has throughout the millennia been the main pathway between the Persian Gulf and the Mediterranean coast, carrying large volumes of commerce that enrich ports of trade centers along its banks. Maritime trade over the Persian Gulf was particularly important in the late third millennium B.C.E., when traders from Mesopotamia met their colleagues from the Indus Valley on the island of Bahrain (ancient Dilmun). The Syrian and Phoenician cities of the Mediterranean coast were renowned trading centers from which the famous ship found at Uluburun (off the Turkish coast) sailed in the 14th century B.C.E. and where colonies were founded, such as Carthage in the ninth century B.C.E. An important overland trade connected Mesopotamia through the Zagros Mountains with the Iranian highlands; the same route became known as the Silk Road

once trade contacts with China had been established during the Roman period.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Trade helped build nations in ancient Asia and the Pacific, carrying with it ideas and inventions and encouraging people to learn about distant lands. Among the Pacific islands, trade was carried out using wooden boats. Near the Asian mainland, manufactured goods from China, Japan, and Korea went to islands like Sumatra, Java, and Tonga in exchange for spices, exotic woods, and rare seashells.

On the Asian mainland the economic giants were China and India. For most of ancient times China tended to look inward for trade. During the Shang Dynasty (ca. 1500 to 1045 B.C.E.) the Chinese believed that the world did not extend much beyond their borders in any direction. They focused on agriculture around the Yellow River. Important factors in the expansion of the Shang view of the world were attacks from outside and the discovery and then importation of goods from areas beyond China's borders. The most significant imported goods were wood and rice from the south. Instead of striving just to build good relations with their trading partners, the Shang adopted a policy that would remain typical of China's foreign trading for thousands of years: They tried to conquer the people who had the goods the Shang desired, making those goods part of the Shang Dynasty and thus goods at the command of the Shang king.

The Shang Dynasty and the Zhou Dynasty that followed (1045 to 256 B.C.E.) absorbed through warfare the Yangtze

River region and its rich rice fields. During the Zhou Dynasty, transporting the South's agricultural products to the north, where the national capitals were to be found, became a severe problem. The great rivers of China were not entirely satisfactory for shipping food; their winding and occasional shifting courses made transportation slow and unreliable. The government started building canals by the 400s B.C.E. to aid the movement of goods across the nation, but the almost ceaseless warfare among the provinces of China disrupted those public works.

The western province of Qin gained an advantage when it built a canal connecting its major rivers. This had begun as a scam: An eloquent civil engineer had been dispatched by Qin's rivals to persuade the ruler of Qin to build the expensive canal, drawing resources from Qin's military. Even after he learned of the scam, the ruler was so convinced of the value of the canal that he continued its construction. As a result, Qin was able to transport goods faster than it could earlier, thus strengthening its economy so much that it became China's foremost economic and military power.

The Han Dynasty (202 B.C.E. to 220 C.E.) was aggressive in building up trade within its borders, and it continued the practice of invading nations that had goods it wanted, such as horses from the west. More than had previous dynasties, the Han Dynasty looked outward for trading opportunities. Most of its efforts focused on overland trade. At the cost of the lives of hundreds of thousands of Chinese soldiers, the Han pushed nomadic raiders out of the northwest and extended the Great Wall westward to protect the Silk Road—a network of routes that led to Persia and through Persia to the Mediterranean world. China exported silks, ceramics, and metals to Rome, which paid in gold. Further, the Chinese pioneered trade routes into India. Some of the Chinese explorers left written records of their travels through India. Silk made its way from China to India in exchange for gems such as diamonds as well as fragrant woods.

Not until roughly the 300s C.E. did China begin trading in earnest by sea. Before then it had traded mostly with Japan, which exported its own high grade of silk and probably animal skins and ceramics to China in exchange for Chinese metals—especially copper coins, which became Japan's medium of exchange. Otherwise, Malaysian seafarers had conducted most of the sea trade between China and other southeastern lands. The Malaysians were heavily influenced by the Indians.

The first great Indian civilization, the Harappan (2600–1500 B.C.E.), was a trading empire. Although it was focused on the rivers of the Indus River valley, it established trading posts hundreds of miles away in central Asia and Iran to import lapis lazuli, tin, and bronze, sending out copper, gems, and grain. The Sumerians dealt extensively with the Harappans, and archaeologists have found numerous Harappan artifacts at Mesopotamian sites. How much the trade influenced Harappans is a matter of much disagreement among archaeologists, but it is possible that the political organization of Harappan cities imitated that of the Sumerians.

Steatite seals from the Indus Valley, dating to 2600 to 1900 B.C.E. and thought to have been used in trading with other nations and cultures (© The Trustees of the British Museum)

Much of later Indian history focuses on the spread of Aryan nomads and their Vedic culture southward through India. These nomads were a warrior people who put great store in military honor and the conquest of rival nations, yet much of southern India developed nations because of trade, not war. The peoples of southern India conducted a lively trade with each other before, during, and after the rise and fall of the Maurya Empire of about 321–185 B.C.E. and the Gupta Empire of 320–499 C.E.

The Indians of the interior formed caravans of wagons carrying goods not only produced in their own regions but also imported from other lands, thus bearing Chinese silks westward and Roman pottery eastward. The wagons transported muslin, saffron, ivory, agate, diamonds, pearls, ebony, and teak across roads to seaports. Governments arose to regulate the trade and maintain the roads. Leaders called Shatavahanas, whom historians consider somewhat mysterious figures, arose to foster trade and lead disparate peoples who organized themselves into trading nations.

India became a great generator of wealth for the Old World, trading with Africa, Rome, Persia, China, southeastern Asia, and the Indonesian islands. They established trading centers on the Malaysian peninsula, bringing their culture with them. In Indochina, the kingdom of Funan emerged as a trading nation that may have been similar to those of India. According to Chinese records, Funan was cofounded by an Indian trader.

Along India's western and eastern coasts arose trading cities. The ancient Romans sailed through the Indian Ocean to establish trading centers on the western coast, and these centers thrived for hundreds of years. In about 170 C.E. the Roman Empire suffered a recession so severe that Indians suffered economically and the Shatavahanas withdrew their trade from the west coast. To the east trade continued to thrive, with Indians opening trade with the regions of present-day Thailand and Burma, overland and by sea.

Sri Lanka, a large island in Mare Erythraeum (the present-day Indian Ocean) off the southeastern tip of India, was a way station for explorers, travelers, and traders from Europe, Africa, the Near East, India, Malaysia, Indochina, Sumatra, Java, and China. From the 200s B.C.E. to the 1200s C.E. Sri Lanka was ruled by the Sinhalese kingdom.

The Sinhalese kingdom became rich from charging fees to the traders whose ships stopped in its ports. Government officials managed port facilities and docks efficiently. Ports teemed with trading fleets from Rome, Axum, Arabia, Persia, India, and Malaysia. The docks and city streets were a colorful mix of the national garb of dozens of different lands. The visitors mixed with pious monks and local people selling their wares. Especially popular were the bountiful agricultural products of Sri Lanka, such as coconuts, bananas, mangos, passion fruit, papayas, oranges, and tamarinds. The exotic flavors of those fruits would have been welcomed by travelers after weeks at sea. In addition to fruits, the Sinhalese sold rice, sugarcane, and cotton. Thanks to an irrigation sys-

tem of 200 miles of canals, they had three harvests of rice per year. The Sinhalese were skilled water engineers who could build irrigation canals with only 6-inch rises per mile, and they knew the world was spherical and offered expert navigation skills to trading vessels.

EUROPE

BY FRANCESCO MENOTTI

Trade and exchange systems of the past have always been an important focus of research in archaeology. Studying trade and exchange can be difficult, however, especially within preliterate societies. In fact, scholars have available only what those societies left behind and time has preserved, such as archaeological artifacts. But useful information can be extrapolated from those seemingly useless remains. For instance, the materials from which artifacts are made can play a crucial role in identifying the movement of goods and reconstructing ancient exchange networks. Numerous methods of analysis have been developed to recognize and determine the origins of specific materials (stones, shells, metals, and so on) and to reconstruct production and distribution as well as the exchange system organization. Such analysis focuses on the various mechanisms of distribution that characterized ancient trade networks, from direct access to goods to down-the-line trade and eventually to a fully developed port of trade.

Beyond the simple economic value of traded goods, the meaning of exchange systems is also important. For example, in some instances symbolic elements might be predominant over other, more logical aspects. Circulation of ideas and communication of information imbedded in people's social behavior are therefore vital in understanding social contacts. To understand trade and exchange systems in prehistoric Europe, first it is necessary to divide the geographical area into conventional archaeological periods: Mesolithic (ca. 8000–4000 B.C.E.), Neolithic (ca. 7000–ca. 2000 B.C.E.), Bronze Age (ca. 2800–ca. 700 B.C.E.), Iron Age (ca. 1000–ca. 500 B.C.E.), and Roman times (ca. 400 B.C.E.–476 C.E.). Note that the dates provided apply to only the European continent as a whole and vary according to latitude and longitude.

Although it is flimsy and localized, evidence of trade and exchange in Europe does exist from the Mesolithic. The Mesolithic is an important transitional period in Europe, during which hunter-gatherer communities underwent significant changes in technology, economy, and social organization. The constantly changing environment triggered a steady development in tool technology, passing from bone and antler tools and the microlith (blade) industry common in the early Mesolithic to the various kinds of axes (first unpolished and then polished) in the later part of the period. In fact, the scarce availability of primary sources of raw materials in some areas was the primary factor initiating mobility, social interaction, and exchange systems. Despite evidence of material circulation on vast territories (obsidian in southeastern Europe and

Luxury imports from Italy, Rome, and the Near East, found at Hertfordshire, England, and dating to the Iron Age (20 B.C.E.–50 C.E.) (© The Trustees of the British Museum)

flint in northern areas), the exchange system was probably based on simple down-the-line trade involving balanced reciprocity. An event that changed Europe forever was the beginning of agriculture toward the end of the Mesolithic.

The first phase of agriculture diffusion occurred in a southwest–northwest direction, following the core–periphery model. Agriculture certainly brought changes in subsistence and the economy, but most significant was the social transformation. Another important event that took place in the late Neolithic was the discovery of copper. All this undoubtedly influenced social interaction and exchange systems. The quantity of traded goods increased, and some of them were seen as a way to gain social status. Significant movements of goods took place in the Mediterranean (obsidian); as far north as the Balkans (*Spondylus* shell); and in central, northern, and western Europe (axes, such as the Langdale ax in Britain and the Plussulien ax in France). Although organized long-distance trade was yet to develop, goods (especially nonperishable items) were circulated over vast distances through a system referred to as down-the-line trade. Food and other perishable materials were exchanged within much smaller areas.

Toward the end of the Neolithic, prehistoric Europe once again underwent a revolution brought about by a technological advance: metal alloying. At the beginning of the Bronze Age most artifacts, tools, and weaponry were made of bronze,

a copper and tin alloy. Consequently, exchange systems became linked to the desirability and accessibility of that metal (one of the main centers of bronze production and distribution was the Carpathian Basin). Further developments in transportation, on both water and land facilitated the consolidation of established long-distance trade networks. Although trade links over long distances were already present in the Neolithic Period, it is only in the Bronze Age that archaeological records show the presence of long-distance trade routes linking north to south and east to west. All sorts of goods—including axes, swords, and pottery—were traded over these networks, but some of the longest and oldest long-distance trade routes were the amber routes in the Baltic and Mediterranean regions.

Trade routes rarely stayed the same but changed directions through space and time. Thorough analyses of archaeological records show the kinds of events (socioeconomic and political instability, migrations, wars, and so on) that caused them. Exchange mechanisms improved considerably in the Neolithic. The down-the-line system still prevailed, but the first ports of trade started to appear, especially in the Mediterranean (for example, Gadir in Spain). Coinage was not yet in use, but certain categories of artifacts definitely operated as barter tokens. The later part of the Bronze Age was characterized by a new change in social context. The appearance of hill forts, flat cemeteries, and field systems

suggest a more unstable and less ordered society, a social framework that would typify the next archaeological period: the Iron Age.

The parallel expansions of the Phoenicians and Greeks in the Mediterranean and that of the Romans in continental Europe later, undoubtedly played a crucial role in the formation of important trade networks in Iron Age Europe. Barbarian societies at the edge of the advancing powers reacted in different ways to the Mediterranean expansion, but all were fascinated by the new and exotic traded goods (wine, olive oil, and luxury items). At the same time, however, Mediterranean societies were interested in continental goods, such as metals (of which iron was becoming more and more widespread), amber, and salt. The unstable equilibrium that characterized the European Iron Age, with hill forts and competition for social status in the north and fighting for supremacy in the Mediterranean, did not hinder the trade systems. In fact, more and more ports of trade were established throughout the continent as far as Scandinavia (among them, the various amber ports of trade located in northeastern Poland and Lithuania). It is well known that the Romans conquered Europe economically well before it did so politically. Paradoxically, it was the existing pre-empire trade that facilitated the Roman conquest of Iberia (present-day Spain) and Gaul (present-day France) in the first century B.C.E.

Trade and exchange between Rome and the barbarian world continued throughout the empire. A trade buffer zone had even developed just beyond the empire's borders. That area was of great economic and political importance to both the Romans and the barbarians, with ports of trade between the two worlds located there. The barbarians would obtain prestigious and valuable items from the Romans and in return would acquire everything the empire needed, including cheap labor in the form of slaves (especially from eastern and northeastern Europe). Sadly, slaves became the "items" the barbarians most often exported to the Roman world during the empire's heyday.

The fall of Rome and the subsequent Nordic southward migrations created a period of serious instability within Europe's trading networks, but trade experienced no regression. In fact, some trade centers experienced further development and would become important emporia in early medieval times; examples are Lundeberg and Gudme in Denmark. Despite sociopolitical insecurity and massive migrations of peoples, goods continued to be moved all over Europe and beyond, linking even the most remote regions of the northeast in increasingly solid and sophisticated trade networks.

GREECE

BY EDWARD M. W. A. ROWLANDS

From prehistoric times the Greeks were able to gain access to markets beyond their shores. By the sixth century B.C.E. Greek city-states had established colonies throughout the Mediterranean and into the Black Sea; this protected access to im-

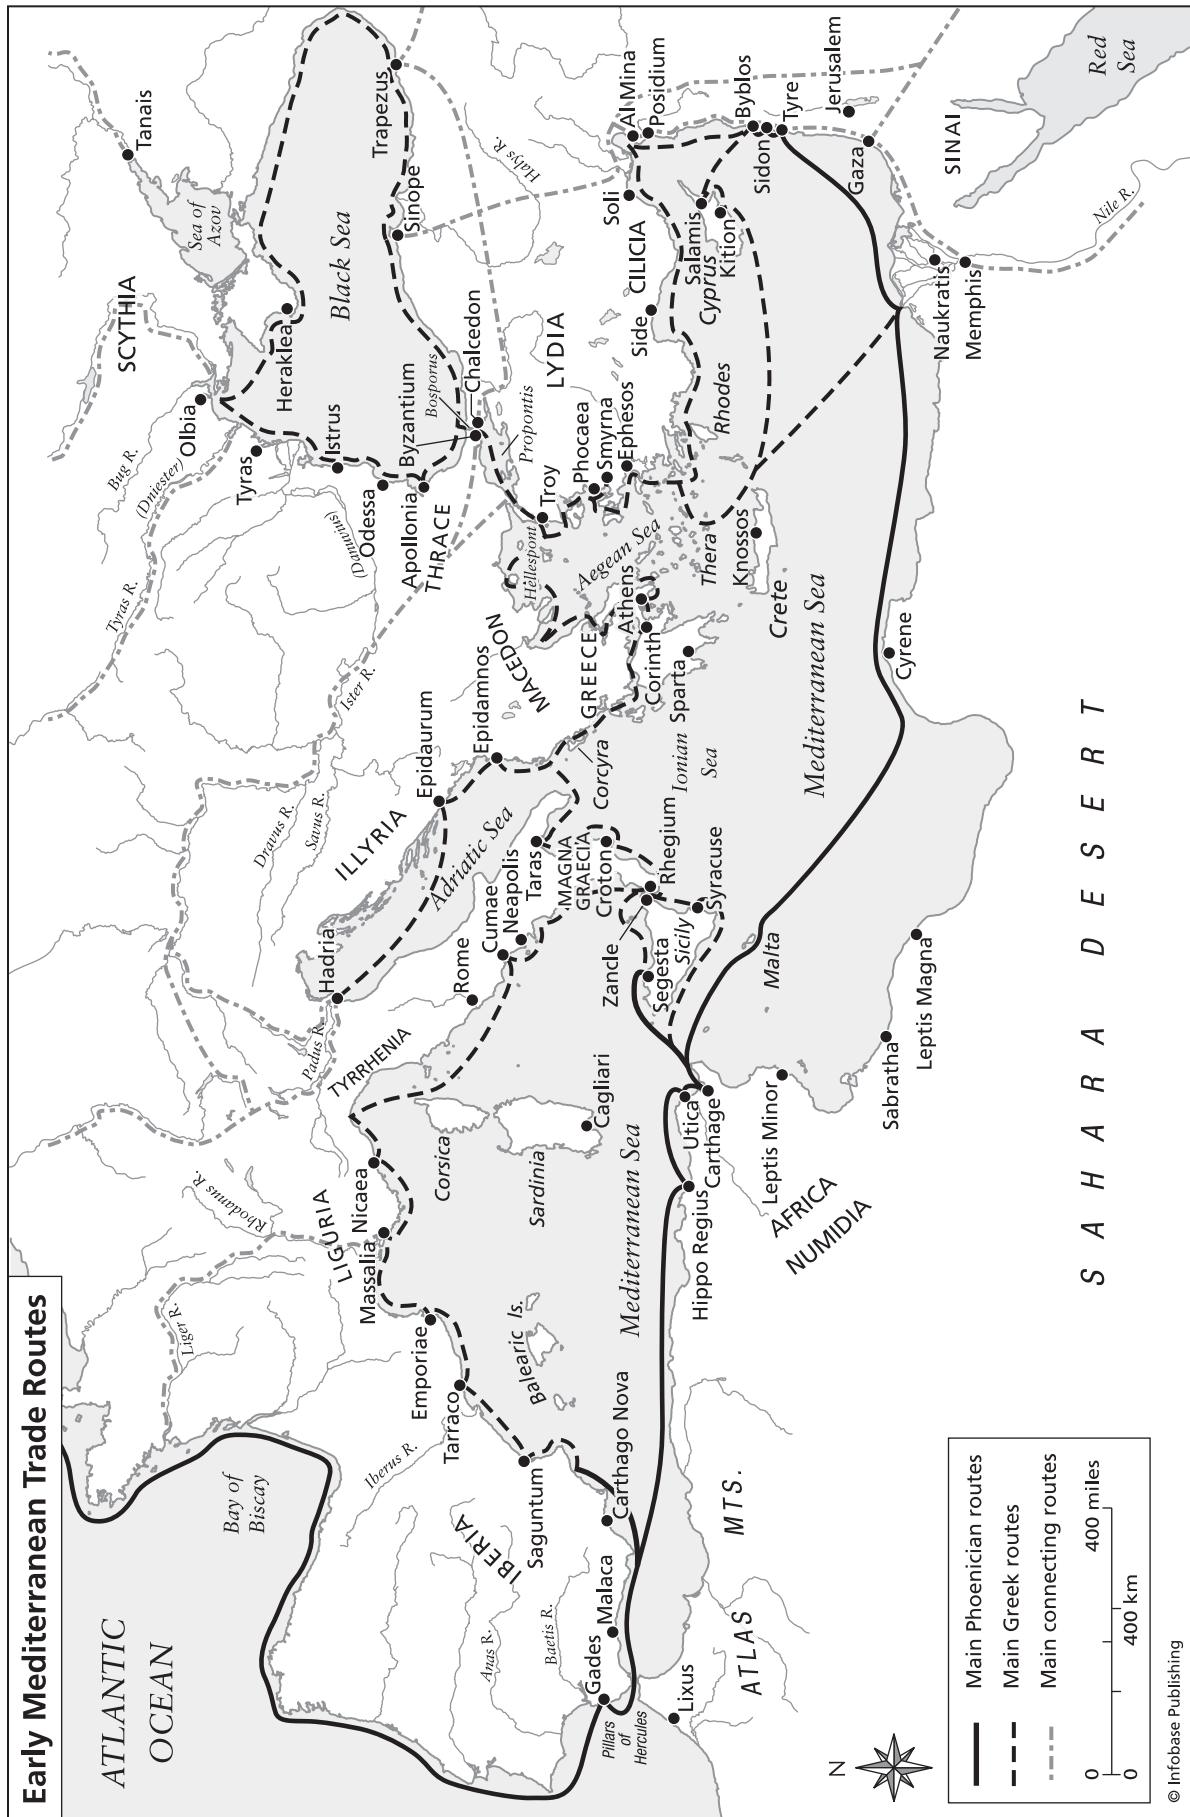

portant goods such as grain, wood, and silver. Concurrently, coins developed into a popular means of exchange. In sharp contrast was the city of Sparta, which disapproved of trade and lived on the produce of its occupied territories. By 323 B.C.E. Alexander the Great from Macedon had conquered the Persian Empire, and on his death Greece became part of one of several Hellenistic kingdoms. The Hellenistic Period, and the later Roman dominance of the Mediterranean, opened up larger markets to the Greeks, but the economic power and influence of the Greek city-states were lost forever.

At Grave Circle A—a circle of six graves in Mycenae dating to the beginning of the Late Bronze Age—finds show that by 1600 B.C.E. people in the Peloponnese could import not only golden jewelry from Crete and the Aegean but also amber from as far as the Baltic Sea. At that time Greece and the surrounding islands were tied into European and Mediterranean trade networks. As a result, the powerful militaristic peoples known as the Mycenaean were able to establish kingdoms throughout Greece, Crete, and the Aegean Islands. By controlling access to the items traded and through patronage of traded goods, the Mycenaean leadership could keep control over the elite of the kingdom.

Over the coming centuries the Greeks were to sail far and wide across the Mediterranean and into the Black Sea. Colonies were founded from the island of Sicily in the west to Crimea, in modern-day Ukraine, to the east. Through their colonies, trade centers like Athens, Thebes, Corinth, and Argos gained access to markets previously out of their reach. The Greeks imported goods such as wood, slaves, gold, silver, copper, and tin in exchange for products like wine, pottery, and olive oil. This trade increased the power of the trading centers, enabling them to monopolize production from their colonies and establishing them as powerful metropolises within their regions.

Most of the written evidence about trade and exchange that is available to modern classicists is from Athens. The city of Athens rose to serious power during the fifth century B.C.E. Western civilization has benefited from the art, drama, philosophy, and democracy developed at the height of the Athenian empire. Those developments were possible only because Athens, as a great sea power, could protect trade routes and colonies from attack. By the fifth century B.C.E. Athens had grown into a large city, and its surrounding territory of Attica could not supply enough grain to keep all Athenians alive. It was therefore imperative to maintain a route through the Bosphorus and into the Black Sea, where large amounts of grain could be accessed. According to the Athenian statesman Demosthenes, in the fourth century from the Crimea alone Athens was importing 400,000 medimnoi a year, which in modern terms is equivalent to millions of gallons of grain. Athenian legislation was also written to make sure that grain produced in Attica could not be exported and that all grain coming into the port of Piraeus had to be sold in Attica.

Coinage came to Greece in the sixth century B.C.E. from cities situated on the coast of modern-day Turkey. It

Ancient Greek trading routes extended throughout the Mediterranean.

became common for coins to be made of silver and for Greek city-states to monopolize their formation. The Athenian historian Xenophon wrote in the fourth century B.C.E. that his city was assured of trade because of its good supply of silver coins, the result of the Athenian-controlled silver mines at Laurium in Attica. Coins gave city-states a valuable way to exchange goods within Greece and for great distances beyond its shores.

Port markets (*emporía*) and marketplaces (*agora*) served as locations for trade with people from other cities. The prosperity of some of these markets, especially in Athens and Corinth, increased significantly as trade between Greek cities and overseas nations increased. In the marketplace foreigners often had to pay a tax just for purchasing goods. City-states could also collect a duty on the cargo of ships with access to their ports. Written evidence at Athens shows that it taxed the value of vessels going through the Piraeus. Although trade between short distances was possible over land, the mountainous topography of Greece usually necessitated long-distance travel by ship. Toward the end of the Peloponnesian War in 413 B.C.E., Athens further exploited trade being carried out in the Aegean by imposing a 5 percent duty on all the ports within the empire.

A noticeable contrast to Athens is apparent in the city of Sparta. In the seventh century B.C.E. Sparta conquered the territory of Messenia and enslaved the entire population, turning them into what were called helots. Messenia was a fertile territory that provided Sparta with food supplies and a workforce of helots. A deeply militaristic society, Sparta was against the accumulation of personal wealth. Its military domination of Messenia meant that it was not forced into trading with cities for grain and was able to pass laws forbidding its citizens to trade.

The activities of Alexander the Great (336–323 B.C.E.) were to have a major effect on Greek economic activity. After his death the empire he created, which stretched from Macedonia to India, was split into several Hellenistic kingdoms. The Macedonian generals of Alexander then ruled territories from Egypt, Syria, Anatolia (modern-day Turkey), and Macedonia. Greece benefited because Greek became the international language of business. The use of common currencies and the production of roads fostered economic expansion not just in Greece but throughout what became known as the Greek world. Yet Greece would not become the most important part of the greater Greek-speaking world because cities like Alexandria in Egypt were to be the main centers of manufacturing and imports.

The Roman Empire came to control Greece after the battle of Pydna in 168 B.C.E. Rome became the unquestionable trading and economic power, placing Greece in a politically united Mediterranean. In the second century C.E. the Roman author Lucian describes how he saw, in the Greek port of Piraeus, a Roman grain ship that was 180 feet long and 45 feet across, and “the crew was like an army.” Greek culture and technology influenced the beginnings of Ro-

man society, but its ports remained important for trading throughout Roman times.

ROME

BY CHRISTOPHER SMITH

Rome was superbly positioned from its beginnings to take advantage of regional trade and exchange. The city of Rome is situated on the banks of the Tiber River; as one sailed up from the Mediterranean, from the first crossing point and alongside the river ran one of the oldest roads in Italy, the Via Salaria, or “salt road,” which linked the salt pans of the coast with the interior. Salt was a vital commodity in antiquity, owing to its preservative function.

Some of the earliest archaeological evidence for the urban development of the city comes from an area adjacent to Rome’s earliest port, called the Forum Boarium, which was primarily a cattle market. As of the eighth century B.C.E. imported pottery is in evidence at this site, signifying cults that originated in the east. The most apparent is the cult of Hercules, from the Greek Herakles, which also shows Phoenician features. These artifacts demonstrate the early growth of trade links, with key connections being formed with the East. Indeed, Greek and Phoenician traders moved westward from the eighth century B.C.E. onward, bringing such unfamiliar and exotic materials as gold, silver, and ivory, which became indicators of high social status. The Romans also learned from the Greeks the formal customs of banqueting. The Etruscans, who occupied areas both north and south of Rome, were a crucial intermediary in this process of social development.

Alongside the development of such long-distance trade, vigorous and important regional trade was conducted. The hinterland of Rome, the region called Latium, was populated

The Crawford Cup, Roman, dating to the first to second century C.E. and found on the border between Syria and Turkey; this goblet was made of fluor spar, a relatively rare mineral that in the Roman period could be found only in the kingdom of Parthia (modern-day Iran). © The Trustees of the British Museum

by a number of settlements scattered across a moderately fertile plain. Exchange among these settlements and Rome was frequent and enshrined in the legal concept of *commercium*: the right of any Latin or inhabitant of Latium to own Roman land and to enter into a contract with a Roman. Every ninth day in Rome was designated as a market day (*nundina*), and these days were inscribed on the formal calendars listing the annual festivals and events, which were found distributed throughout central Italy. Other calendars simply indicate the market days and their locations. The existence of these calendars demonstrates the importance of regular local markets in the economy of central Italy.

Agriculture was at the core of most of the commercial activity in the ancient world, in terms of the short-range movement of produce; long-range transhumance—or the movement of animals, typically sheep, from summer upland pastures to winter lowland pastures—and the exploitation of animals as resources, especially in terms of meat and wool; and the long-range movement of some staples, notably grain, wine, and olive oil, across the Mediterranean. As the Roman Empire grew, Rome became involved in existing trade patterns and began to influence their development. To the east, the long-established Greek cities and the Hellenistic empires already boasted sophisticated networks of trade and exchange. To the west and north, key centers such as Marseilles, in modern-day France, and Carthage, in modern-day Tunis, were already present, but the Romans may have had a similar impact on Spain, Gaul, and Britain in the first century B.C.E. as the Greeks and Phoenicians had on Rome in the eighth century B.C.E., stimulating social and economic development. One characteristic feature of this development was urbanization, which altered economic relationships by creating centers of consumption that drew from hinterlands.

With regard to modes of transport, the sea was a crucial conduit, and Rome expended significant effort, most notably through the campaigns of Pompey in 67 B.C.E., to clear the sea of pirates. The physical evidence for maritime trade consists most notably of shipwrecks, which give important information about cargoes. Also, Rome constructed roads to facilitate the movement of armies and of goods across the empire, sometimes utilizing preexisting structures and at other times applying their engineering skills to construct new roads, such as in Britain.

In time, Rome became the greatest center of consumption of all. Rome's population rose to a million by the end of the first century B.C.E., and a substantial number expected a stable supply of food, some of which was provided by the state and subsequently by the emperor. The demand for food was increasingly satisfied by the Roman provinces; huge grain ships plied the route from Egypt to Rome, and at Ostia and Portus (first created by Claudius in 46 C.E., with substantial redevelopment by Trajan in 103 C.E.) new facilities were constructed to cope with disembarkation, storage, and distribution. Another physical sign of the relatively enormous level of consumption in Rome is Monte Testaccio, a hill close to

the Tiber some 160 feet high, entirely composed of broken oil amphorae, or containers. (Unlike wine amphorae, oil amphorae could not be reused.) Most of these amphorae came from the province of Baetica, in southwestern Spain, in the second and third centuries C.E., and the hill comprises more than 50 million amphorae, in which over 1.5 billion gallons of oil were imported into the city.

Other items in demand included building materials and metals. Quarrying was a major enterprise, and like many such enterprises was increasingly an imperial monopoly. At Mons Claudianus, in Egypt, marble was quarried for use in imperial palaces from Rome to Split, in modern-day Croatia. In addition to the masses of workers, the quarrying required an entire support network, such as to provide security over the transport route. Once imperial authority broke down at the end of the empire, quarrying ceased. The level of extraction of metal resources achieved during the empire was not matched again until the Industrial Age; the opencast Roman gold mine at Las Médulas, in Spain, was about 1.8 miles in diameter, and lead and copper pollution from the Imperial Period is detectable in the Greenland ice cap.

Metal was in demand, largely for coinage. After the introduction of coinage in Rome around 300 B.C.E. money became the dominant means of exchange with respect to taxation, wages, rent, and credit, although agricultural products also remained significant. Coinage was important at every level of the economy and grew increasingly centralized, with local mints disappearing and local currencies being phased out in favor of a central Roman currency. That currency was therefore vulnerable to debasement and consequent inflation, which became a problem in the third century C.E.

One commodity without which much of the rest of trading activity would have been impossible was human beings. Slaves were bought and sold across the empire—the Greek island of Delos had a notable slave market—and they contributed enormously through their labor to the productivity of the empire. A ratio of one slave to every three free persons has been suggested for Italy during this era. Owing to the Roman custom of freeing slaves, some could achieve substantial commercial standing themselves; this phenomenon is vividly portrayed in Petronius's fictional account, from the first century C.E., of the freedman Trimalchio, who was a substantial landowner, had diverse trading interests, and lent money to others, on the basis of which he sustained a comically excessive lifestyle. Roughly contemporary documents from Puteoli depict a family descended from a slave who for three generations engaged in loans and banking in a wide variety of enterprises, including ones run by other freedmen.

Regarding the overall nature of the Roman economy, scholars have long debated the extent of the impact of trade on the society and economy of the Roman Empire. In general, wealth derived from land carried more positive overtones than wealth derived from commerce. Some senators were engaged in trade, and a substantial wealthy elite across the empire had a diversity of commercial interests. In relation

to growth, Rome's demand for taxes from the provinces may have meant that provincial economies were obligated to grow or suffer. Regardless, growth remained gentle and regionally distinctive in the first two centuries C.E.

Toward the end of the empire, both change and continuity were represented. Inflation led to attempts at price control by the Roman emperor Diocletian, and changes were made to the taxation system, but the volume of trade remained strong. After the fall of the Western Roman Empire, goods were exchanged and peoples were transported at much lower rates, with lesser degrees of sophistication, and without the levels of central control that had characterized the Imperial Period. In the sixth century C.E. some 5,000 cargo ships sailed in the eastern Mediterranean, indicating both the continued significance of trade and exchange and the considerably greater activity during the Roman Empire across the Mediterranean.

THE AMERICAS

BY J. J. GEORGE

Trade is typically defined as a two-way exchange—the business of buying, selling, or bartering commodities—motivated by profit or need. In a true market system, trade would be at least partially divorced from social or political entanglements, and the value of the commodities would follow laws of supply and demand, unencumbered by legislation. Trading activities in the Americas, however, were varied and complex, sometimes encumbered with political and social obligations and sometimes more freewheeling.

Generally, archaeologists consider the presence of nonlocal objects at a site to be evidence of trade, although other systems of exchange existed, including reciprocity and tribute. Reciprocity implies a mutual exchange of privileges or goods, often with socially acceptable gifts exchanged on a roughly equal basis with the aim of establishing or solidifying social or political relationships. Tribute, on the other hand, was often a one-way exchange between a dominant overlord and a subject polity. The later Aztec Empire (15th and 16th centuries) provides the primary Mesoamerican model of tribute exchange: Conquered territories were forced to contribute substantial amounts of prized goods in return for assurance that they would not be decimated. Exchange in its broadest sense also included the flow of art styles, religion, ritual, ideas, and technology as part of cultural diffusion. Although this form of exchange was often unidirectional and flowed from the impulses of empire, expansion, and diffusion, it also could be a shared enterprise and a means by which disparate political and social entities were united.

Mesoamerican cultures relied almost entirely on human carriers to transport goods, limiting the range for perishable commodities and resulting in high transportation costs. The wheel was a known concept, but there is no evidence yet of its use in transportation. Transport of items such as foodstuffs was limited geographically and reinforced localized trade in those items. Longer-distance trade emphasized high-value,

low-weight luxury goods often classified as elite items. In turn, the people who controlled trade and trade routes often solidified elite status or rulership roles for themselves.

Common Mesoamerican trade items included ceramics, lithic material such as obsidian and chert, textiles, perishable tropical goods, precious stones, metals, and foodstuffs. During Mesoamerica's Formative or Preclassic Period (ca. 1800 B.C.E.–ca. 150 C.E.) chiefdoms at several sites—such as Olmec sites on the Gulf Coast, sites in the Valley of Oaxaca and Chalcatzingo in Morelos, and several sites in Chiapas—exchanged items like jadeite, obsidian tools, ceramic vessels, shell ornaments, and animal products. Obsidian is a particularly useful material to document trade systems because the absence of metal tools meant it was used extensively in tool-making and thus was highly valued. Additionally, obsidian has few sources, and its trace element composition is distinct, making chemical sourcing possible and allowing researchers to track its distribution. Major obsidian sources include Pachuca in central Mexico and El Chayal and Ixtepeque in highland Guatemala. Obsidian from these sources was found throughout Mesoamerica.

Other examples of trade items include high-quality chert from Belize, used to make tools throughout the Mayan lowlands of northern Guatemala and Mexico's Yucatán Peninsula. Basalt, andesite, and granite were used to make grinding tools such as mortars and pestles; such volcanic material was unavailable locally to people in the Mayan lowlands and was transported in from the highlands. Textiles, a highly valued but perishable item, were also traded. Although few survive, especially from the dense, tropical lowlands, the tools from which they were made, such as spindle whorls, first show up along the Gulf Coast and later throughout Mesoamerica, suggesting some system of diffusion through trade. Perishable goods like precious feathers from the quetzal bird of Guatemala and jaguar pelts—both symbols of royalty—were distributed throughout Mesoamerica. Precious stones, whose value in part derives from limited natural distribution, rarity, and symbolic importance, were used to make fine jewelry. Jadeite from Costa Rica and Guatemala and turquoise from the southwestern North America found wide distribution throughout Mesoamerica, as evidenced in various grave caches. Foodstuffs were limited locally in most periods, although empires such as Teotihuacán (ca. 100–700 C.E.), had infrastructures substantial enough to obtain grains, maize, beans, and amaranth as tribute from greater distances.

Many North American societies up to and beyond 500 C.E. were of the hunter-gatherer type, which makes data difficult to obtain. Various forms of trade were known. One example is from the first millennium C.E., which was a kind of golden age for the Arctic Eskimo, an era that saw brilliant creativity in both arts and manufacturing, and the perfection of skills and equipment required to hunt diverse northern animals. These developments originated along the shores of the Bering Sea and the Bering Strait and spread

eastward, suggesting both population diffusion and exchange systems. Because distances were often great and contact infrequent between societal territories, trade probably happened spontaneously. In other northern locations, however, trade occurred regularly between coastal and inland groups to obtain staples that their own environments did not offer. For example, during the Mesoamerican Classic Period (150–650 C.E.) sea mammal oil and blubber were traded by coastal peoples to interior peoples in exchange for furs of the caribou, fox, and wolverine. A basic form of this exchange tradition probably dates back several thousand years. A similar geographic exchange principle between interior and coast also was thought to exist in the southeastern region of North America.

In the Adena-Hopewell interaction sphere, centered in present-day Ohio with satellites spread throughout the greater Midwest, mound builders gathered periodically for funeral ceremonies and construction. Evidence suggests that some form of exchange occurred, even if it was only labor. Craft specialization, including pipes and polished stone artifacts, all highly transportable, offered prime opportunities for trade. Researchers have found a surprising concentration of Adena-style artifacts, such as stone tubes, Adena points, birdstones, gorgets, and shell and copper beads as far east as the Chesapeake Bay. Materials for Hopewell grave goods were brought in from great distances. Other traded items include obsidian from what is today Yellowstone Park in Wyoming, conch and turtle shell, shark and alligator teeth from Florida, mica and chlorite from North Carolina and Tennessee, bluish flint from Indiana, and chalcedony from North Dakota. While down-the-line, or intervillage, exchange systems may

have accounted for some of the imports, long-range trading or mining expeditions also seem to have been involved.

Evidence throughout the Andes region supports a tradition of long-distance trade. In the period of 2000–1500 B.C.E. trade between coastal Ecuador and Amazonia is supported by ceramic developments, figurine traditions, and the presence in coastal Ecuador of a type of coca indigenous to the Amazon regions. In Peru evidence of long-distance trade is found in a medicine man's outfit discovered near Lake Titicaca and dated to the fourth century B.C.E. The outfit is attributed to a type of traveling herbalist called a *callahuayas*, whose business was the long-distance transfer of goods and ideas. Remains of food, arts, and crafts at Chavín de Huántar, the center of the northern Peruvian Chavín culture (ca. 900–ca. 200 B.C.E.), indicate extensive outside relations, including a far-flung trade network presumably facilitated by llama trains. In one example, obsidian from Huancavelica, some 290 miles south, was found at Chavín de Huántar.

Greece

~ The Periplus of the Erythraean Sea: Travel and Trade in the Indian Ocean by a Merchant of the First Century, excerpt (ca. first to third centuries C.E.) ~

1. Of the designated ports on the Erythraean Sea, and the market-towns around it, the first is the Egyptian port of Mussel Harbor. To those sailing down from that place, on the right hand, after eighteen hundred stadia, there is Berenice. The harbors of both are at the boundary of Egypt, and are bays opening from the Erythraean Sea.

2. On the right-hand coast next below Berenice is the country of the Berbers. Along the shore are the Fish-Eaters, living in scattered caves in the narrow valleys. Further inland are the Berbers, and beyond them the Wild-flesh-Eaters and Calf-Eaters, each tribe governed by its chief; and behind them, further inland, in the

country towards the west, there lies a city called Meroe.

3. Below the Calf-Eaters there is a little market-town on the shore after sailing about four thousand stadia from Berenice, called Ptolemais of the Hunts, from which the hunters started for the interior under the dynasty of the Ptolemies. This market-town has the true land-tortoise in small quantity; it is white and smaller in the shells. And here also is found a little ivory like that of Adulis. But the place has no harbor and is reached only by small boats.

4. Below Ptolemais of the Hunts, at a distance of about three thousand stadia, there is Adulis, a port

established by law, lying at the inner end of a bay that runs in toward the south. Before the harbor lies the so-called Mountain Island, about two hundred stadia seaward from the very head of the bay, with the shores of the mainland close to it on both sides. Ships bound for this port now anchor here because of attacks from the land. They used formerly to anchor at the very head of the bay, by an island called Diodorus, close to the shore, which could be reached on foot from the land; by which means the barbarous natives attacked the island. Opposite Mountain Island, on the mainland twenty stadia from shore, lies Adulis, a fair-sized village, from which there is a three-days' journey to Coloe, an inland town and the first market for ivory. From that place to the city of the people called Auxumites there is a five days' journey more; to that place all the ivory is brought from the country beyond the Nile through the district called Cyeneum, and thence to Adulis. Practically the whole number of elephants and rhinoceros that are killed live in the places inland, although at rare intervals they are hunted on the seacoast even near Adulis. Before the harbor of that market-town, out at sea on the right hand, there lie a great many little sandy islands called Alalaei, yielding tortoise-shell, which is brought to market there by the Fish-Eaters.

5. And about eight hundred stadia beyond there is another very deep bay, with a great mound of sand piled up at the right of the entrance; at the bottom of which the opian stone is found, and this is the only place where it is produced. These places, from the Calf-Eaters to the other Berber country, are governed by Zoscales;

who is miserly in his ways and always striving for more, but otherwise upright, and acquainted with Greek literature.

6. There are imported into these places, undressed cloth made in Egypt for the Berbers; robes from Arsinoe; cloaks of poor quality dyed in colors; double-fringed linen mantles; many articles of flint glass, and others of murrhine, made in Diospolis; and brass, which is used for ornament and in cut pieces instead of coin; sheets of soft copper, used for cooking-utensils and cut up for bracelets and anklets for the women; iron, which is made into spears used against the elephants and other wild beasts, and in their wars. Besides these, small axes are imported, and adzes and swords; copper drinking-cups, round and large; a little coin for those coming to the market; wine of Laodicea and Italy, not much; olive oil, not much; for the king, gold and silver plate made after the fashion of the country, and for clothing, military cloaks, and thin coats of skin, of no great value. Likewise from the district of Ariaca across this sea, there are imported Indian iron, and steel, and Indian cotton cloth; the broad cloth called monache and that called sagmatogene, and girdles, and coats of skin and mallow-colored cloth, and a few muslins, and colored lac. There are exported from these places ivory, and tortoiseshell and rhinoceros-horn. The most from Egypt is brought to this market from the month of January to September, that is, from Tybi to Thoth; but seasonably they put to sea about the month of September.

Rome

≈ Petronius Arbiter (ca. 27–66 C.E.),
“*The Banquet of Trimalchio*,” excerpt from the *Satyricon* ≈

“When I came here first [as a slave] from Asia, I was only as high as yonder candlestick, and I’d be measuring my height on it every day, and greasing my lips with lamp oil to bring out a bit of hair on my snout. Well, at last, to make a long story short, as it pleased the gods, I became master in the house, and as you see, I’m a chip off the same block. He [my master] made me coheir with Caesar, and I came into a royal fortune,

but no one ever thinks he has enough. I was mad for trading, and to put it all in a nutshell, bought five ships, freighted them with wine—and wine was as good as coined money at that time—and sent them to Rome. You wouldn’t believe it, every one of those ships was wrecked. In one day Neptune swallowed up 30,000,000 sesterces on me. D’ye think I lost heart? Not much! I took no notice of it, by Hercules! I got more ships

(continued)

(continues)

made, larger, better, and luckier; that no one might say I wasn't a plucky fellow. A big ship has big strength—that's plain! Well I freighted them with wine, bacon, beans, perfumes, and slaves. Here Fortuna (my consort) showed her devotion. She sold her jewelry and all her dresses, and gave me a hundred gold pieces—that's what my fortune grew from. What the gods ordain happens quickly. For on just one voyage I scooped in 10,000,000 sesterces and immediately started to redeem all the lands that used to be my master's. I built a house, bought some cattle to sell again—whatever I laid my hand to grew like a honeycomb. When I found myself richer than all the country round about was worth, in less than no time I gave up trading, and commenced lending money at interest to the freedmen. Upon my word, I was very near giving up business altogether, only an astrologer, who happened to come into our colony, dissuaded me.

And now I may as well tell you it all—I have thirty years, four months and two days to live, moreover I'm to fall in for an estate—that's prophecy anyway. If I'm so lucky as to be able to join my domains to Apulia, I'll say I've got on pretty well. Meanwhile under Mercury's fostering, I've built this house. Just a hut once, you know—now a regular temple! It has four dining rooms, twenty bedrooms, two marble porticoes, a set of cells upstairs, my own bedroom, a sitting room for this viper (my wife!) here, a very fine porter's room, and it holds guests to any amount. There are a lot of other things too that I'll show you by and by. Take my word for it, if you have a penny you're worth a penny, you are valued for just what you have. Yesterday your friend was a frog, he's a king today—that's the way it goes."

► transportation

INTRODUCTION

Means of transportation limited empires in what they could do or expanded their horizons. The first significant empire, the Akkadian Empire (ca. 2350–ca. 2100 B.C.E.) fell apart partly because it was too large for efficient communications among its far-flung parts using the roads and transportation of its time. Good, safe transportation became a matter of importance for many civilizations.

The invention of the wheel was a crucial innovation for transportation. The earliest record for a wheeled vehicle comes from Uruk in the Near East, from about 3500 B.C.E. The wheel probably was derived from the potter's wheel and, like a potter's wheel, was originally solid. The wheel was improved and modified over centuries, with each change making the wheel capable of surviving ever-longer distances and moving faster. Speed and durability enhanced long-distance trade, enriching many cultures, and allowed ideas and technology to travel farther faster.

The first known indication of the domestication of the horse comes from Ukraine and dates to about 3000 B.C.E. The

domestication of the horse presented problems that ancient peoples did not fully overcome. Although oxen have big, prominent shoulders to press against heavy yokes, horses do not. The best solution to harnessing a horse probably came from China, where a breast strap was invented. This strip of leather stretched around the horse's chest. It restricted the horse's breathing and could compress arteries that brought blood to the horse's brain, which meant the horse was limited in the loads it could haul. This meant that while horses were great for speed, oxen remained in use, as they are still, for hauling heavy loads.

The movement of people and goods were important to ancient governments, and they often tried to regulate transportation. Some tried to do it all at once, as did the Qin Dynasty of China of (221–207 B.C.E.), regulating even the lengths of axles so that the ruts in roads would be evenly spaced and could be used by all carts. Others built up their regulations through many years of traditions, as in ancient India. Still others, like the Romans, imitated the regulations of other peoples. Each culture reflected its customs in its transportation. For instance, the Romans regarded pedestrian traffic to be essential to their way of life, and they therefore forbade produce carts in their cities during the day and built sidewalks of raised stone that forced wheeled vehicles to slow down, protecting pedestrians.

When thinking of pedestrians, it would be well to remember that although the developments in ancient transportation were exciting and sometimes led to dramatic change in the fortunes of civilizations, most people continued to walk. The ancient world was one in which people mostly carried their needs themselves. Even in the advanced culture of China's Han Dynasty (202–220 B.C.E.) road workers were expected to carry all their tools and food themselves, even to remote parts of the empire. Many people were too poor to afford to ride or even to have an animal pull their goods. In some parts of the world, the use of the wheel and beasts of burden came very late or not at all, as in much of the Americas and Pacific islands.

AFRICA

BY JUSTIN CORFIELD

Inland travel in Africa was regarded as particularly hazardous, and most early traders seem to have preferred traveling by boat. Many of the large settlements in North Africa (excluding those in Egypt) were consequently close to the coast. In sub-Saharan Africa there were also large settlements along rivers and around lakes, so it seems probable that vessels were constructed primarily for navigating rivers. Goods were clearly traded along the river Niger from an early date.

Horses were domesticated in the European steppes around 4000 B.C.E. and in Egypt by 3000 B.C.E., so it seems likely that the use of horses for transportation would have come to the rest of Africa through Egypt. The horses people initially used were much smaller than the modern domesticated horse and were better for pulling carts or chariots than carrying riders. The use of the larger cavalry horses came later, and their use quickly spread throughout North Africa

where the Carthaginians, Numidians, and others made extensive use of them for relaying messages. Horses or donkeys could be used as pack animals to carry people and important messages or to pull carriages or carts, which were made with solid wheels in Egypt and neighboring areas from at least 3000 B.C.E. Bullocks and oxen were also used for this purpose. The carts they pulled were large wooden ones; some had solid wooden wheels, while others had spoked wheels.

For long-distance travel across deserts and inhospitable terrain (as opposed to forest travel) caravan routes were fairly clearly defined. Camels were the principal beasts of burden in these conditions, and because their feet are sensitive, their escorts cleared paths through the stones that normally litter a desert. In this way routes were established. On shorter journeys where feed was available, horses and donkeys would be used. Oases, wells, and trading posts lay along these defined routes; for reasons of safety and security, these would be no more than one day's journey apart.

Crossing rivers was a task often solved by rafts guided by ropes. The Greek historian Polybius (ca. 200–ca. 118 B.C.E.) refers to the Carthaginians making rafts for their elephants to cross the river Rhône in Europe, and it seems likely that similar rafts would have been used to carry elephants, horses, wagons, people, and goods across rivers in North Africa.

Because the empires of Carthage and Rome were supported largely by slave labor, the use of manual labor for loading and unloading goods from ships would have been commonplace. For some vessels at small ports, it might also have been necessary to load things onto barges for transportation between the ship and its final destination or from the quay to the ship. Many items were transported in barrels, making it comparatively easy to roll them to their destination. Large numbers of slaves would have worked at the docks and in the mines and quarries around Carthage, and they would have carried tools, stones, and other materials by hand. The Carthaginians were well known for their use of elephants,

Petroglyph of camel and horse, from the Sahara Desert at Tassili, Algeria, North Africa (© Board of Regents of the University of Wisconsin System. Photographer: Jeanne Tabachnick)

and some could have been used for moving large amounts of stones or other items. Elephants also could have been used to help pull rafts across rivers.

An early method of transportation in the Sahara region was the chariot. Many pictures of chariots appear on wall paintings and on pots. They tend to indicate the prevalence of chariots along several established trade routes. One runs from Essaouira in Morocco through the deserts of modern-day Mauritania to Timbuktu. Another from the region around Edjele in southeastern Algeria also goes through to Mauritania and, halfway through, connects with another route that comes from the Al-Kufrah group of oases in southeastern Libya. Although these chariots are similar in all places—with horses pulling a chariot, often with semicircular sides, on which a person is standing—there have been doubts cast by historians about whether a chariot was a common method of transportation or merely a military vehicle or something for public entertainment, as in chariot racing.

Many people traveling together had to travel by foot. From the description of many North African towns of the period, it appears that people heading from one town to another would gather in the morning at a particular gate or market so they could cross the farmland or desert in a large company to inhibit assault or robbery. Bandits, violent peoples, and other problems often made traveling by foot hazardous, and it appears that there was little land contact between many of the sub-Saharan civilizations in the ancient world. This can be clearly seen through the transmission of technology such as the use of iron. The use of iron outside Egypt started in Nubia and progressed over many centuries down the east coast of Africa, missing many of the powerful inland kingdoms such as that of the Buganda in modern-day Uganda. As a result, knowledge of the technology traveled from Nubia to the coast of southern Africa far more quickly than the comparatively shorter distance to the kingdom of Buganda.

EGYPT

BY AMR KAMEL

Written and pictorial sources from as early as the Predynastic Period (ca. 5500–3100 B.C.E.) of Egypt record land and water transportation. Besides its obvious importance in everyday activities, transportation was deeply rooted in Egyptian religious ritual and beliefs, notably the solar cycle: The sun god, Ra, who was born in the east, sailed during the day across the “celestial wasters” (the sky) in his “day boat” before descending at sunset in the west into the hereafter and the womb of his mother, Nut. Then he sailed from west to east in his “night boat,” to be reborn again at dawn.

Approaching the hereafter was a favorite theme of the Egyptians, who in their tomb art often represented this final journey as a boat ride that took the mummy from the Nile’s east bank (the living world) to the west bank (the realm of the dead—the “Beautiful West,” as Egyptian texts called it), where the gate to the hereafter waited to be entered.

Three factors especially affected the development of transportation throughout the history of ancient Egypt: trade, warfare, and mining and quarrying activities. The creation of an extensive network of routes and highways spanning the whole country facilitated not only the transportation of goods but also the movement of military forces, specifically along Egypt’s southern frontier with Nubia and its northeastern one with the Near East. These routes included fortifications and way stations, which also formed part of a communications system. As for mining and quarrying, a government office established as early as the Third Dynasty (ca. 2649–ca. 2575 B.C.E.) and known as Masters of the Roads was responsible for coordinating and maintaining the land routes through the desert to quarries and mines. These roads required water stations and wells at regular intervals.

Besides these overland routes Egypt maintained a sea road into the eastern Mediterranean. From the inland port of Memphis large cargo ships descended a branch of the Nile to the sea, carrying trade goods or, in wartime, military supplies to Syria and Palestine. Because of the dominant influence of the Nile, water transportation played a much greater role in Egypt than in some other ancient civilizations. The Nile was the principal communication artery and provided the easiest and cheapest means of transportation. When population centers or other important areas lay distant from the Nile, the Egyptians linked them to the river by digging canals. Weni, a Sixth Dynasty (ca. 2323–ca. 2150 B.C.E.) administrator of the southern province (modern-day Aswān), mentioned a canal he built at the first cataract of the Nile to ease the movement of boats past these rapids. Presumably this was the same canal later cleaned by Sesostris III (r. ca. 1878–ca. 1841? B.C.E.) to facilitate his military campaign into Nubia. Necho II (r. 610–595 B.C.E.) dug a canal to connect the Nile with the Red Sea. This waterway was later maintained and deepened by the Persians and by the Ptolemaic pharaohs of the Greco-Roman Period (323 B.C.E.–395 C.E.). The Greek historian Herodotus remarked that two large ships could navigate the canal side by side.

The ancient Egyptians used boats and barges to carry people all along the Nile (or simply to ferry them across it) and to transport grain, cattle, and many other kinds of cargo. Water transportation linked the royal capital with all other cities and villages along length of the river. It aided in collecting grain or taxes from these places and transporting them to the central storehouses. River transport also figured prominently in religious festivals. During the famous Valley Feast, for example, statues of the god Amon; his consort, Mut; and their son, Knonsu, were carried in an elaborate boat procession from the Karnak temple down the river to Deir el-Bahri on the west bank to visit their ancestors. Art from private tombs at Thebes as well as textual evidence show that this festival was also an occasion for the public to cross the Nile and visit their relatives’ tombs on the west bank. An echo of this custom still exists in present-day Egypt, where people celebrate certain feast days in cemeteries in which their relatives are buried.

Although many boats on the Nile were conducting official government business, apparently there were other craft operating for private profit. Texts from the New Kingdom (ca. 1550–1070 C.E.) mention lump-sum payments given to captains of these vessels as freight fees, part of which were portioned out among the crew at the captain's discretion. Literary sources regularly portray ferrymen as greedy and their fees as exorbitant. Even the goddess Isis had to give the ferryman Nemty a golden ring to see her son Horus in his competitions with his uncle Seth. In the Book of the Dead ferrymen make all sorts of excuses to the deceased about the unreadiness of their boats to cross the celestial river, presumably to extort higher pay. The New Kingdom writer Amenemope described the character of the evil person in a telling comparison: "He acts like the ferryman in knitting words: He goes forth and comes back arguing." Most of the mummies found in Egypt from the Greco-Roman Period gripped golden coins in their hands to pay the ferrymen in the hereafter.

The primary mode of land travel throughout ancient Egypt was by foot; even high government officials and armies normally traveled that way, as a set of model figures from the tomb of Mesheti at Assiut from the Eleventh Dynasty (ca. 2040–ca. 1991 B.C.E.) reveals. Art from temples and tombs shows ancient Egyptians walking in funerals, in holy processions during festivals, and the like, in which the distance involved was relatively short, but for many centuries there was no alternative to walking for long land journeys as well.

Donkeys have been the principal beasts of burden in Egypt from prehistory to the present. Art at Deir el-Medina shows donkeys carrying water, wood, grain, straw, hay, dung, and in one case an offering to a goddess up steep paths from the riverbank. No depictions survive from ancient Egypt of people riding donkeys as their descendants do in modern-day Egypt, although one scene preserved on an Old Kingdom (ca. 2575–2134 B.C.E.) tomb at Saqqara shows the tomb's owner supervising his farm activities while riding in a litter borne by donkeys.

Several texts describe caravans of donkeys used for long-distance overland transport. The biography of Harkhuf, a Sixth Dynasty caravan leader, reports that he returned from one of his many trips to Nubia with 300 donkeys laden with all sorts of trade goods. Sabni, Harkhuf's contemporary, mentions using 100 donkeys in his mission to the south to recover the body of his father, who had been murdered there.

Wheeled vehicles apparently originated in Sumer during the early fourth millennium B.C.E. and were later adopted by the Egyptians. The earliest example, from the New Kingdom, is a gold model of a four-wheeled wagon carrying a boat. Although it is unclear whether the model is realistic or merely symbolic, heavy wagons must obviously have existed in order for it to be made at all. Scenes of Ramses II (r. ca. 1290–ca. 1224 B.C.E.) at the battle of Kadesh show an ox-drawn wagon, presumably being used to transport supplies needed on the battlefield.

Horses and the light horse-drawn chariots were introduced to Egypt from the ancient Near East around 1700 B.C.E.

as a means of transportation and quickly became invaluable military resources. New Kingdom texts and pictures indicate that kings and nobles used horses for riding and to draw chariots for travel and in hunting expeditions in the desert. However, horseback riding apparently was not greatly favored by the Egyptians.

The animal that many people automatically associate with desert transportation, the camel, was a relative latecomer to Egypt. Domesticated centuries earlier in the Near East, the single-humped camel or dromedary came into widespread use in Egypt during the Greco-Roman Period. Able to carry about five times as much as a donkey and to travel for extended periods without water, camels became invaluable for the long-distance transport of both riders and trade goods across the Egyptian deserts.

THE MIDDLE EAST

BY KIRK H. BEETZ

In the ancient Near East early roads consisted of trails pounded flat by the feet of travelers over the course of centuries. Here, as elsewhere in the prehistoric world, for many thousands of years transportation simply meant people walking, carrying on their backs such loads as they could bear. The first pack animal (meaning an animal used to carry loads on its back) in the region was the donkey, which was domesticated in Africa or the Near East sometime before 3500 B.C.E. Oxen, domesticated in the same general timeframe as donkeys, were used mainly as draft animals, pulling plows and towing carts in farm fields. Although they were very strong, oxen were too slow to be of much use for long-distance hauling. The first Near Eastern vehicles for carrying cargo were probably sledges. A sledge is essentially a framework of wood on which loads are dragged across the ground. Early sledges were soon improved by adding runners, which significantly reduced the resistance met in pulling them. It is likely that the first wheeled vehicle was a modified sledge.

The peoples of Mesopotamia were not the only inventors of wheels: Wheeled toys have been found at ancient sites in the Americas. The Mesopotamian insight was to use wheels for transportation. The old notion that the idea for the wheel came from using logs as rollers for moving heavy objects, with the logs eventually wearing thin in the middle where the weight rolled over them, leaving wider "wheels" at the sides, is probably mistaken, because wheels cut horizontally out of tree trunks quickly fall apart. Solid wheels needed to be made from planks cut vertically from tree trunks. The actual inspiration for the wheel as transportation may have been the potter's wheel.

The first known depiction of a wheeled vehicle comes from the Sumerian city of Uruk (in what is now southern Iraq) and dates to around 3500 B.C.E. It shows a sledgelike body fitted with solid wheels. The wheels were made of three boards laid side by side and held together by two boards that crossed them on the inside of the wheel. They were fixed to axles, and the axle and wheels rotated as one unit. This made

maneuvering difficult, but it still allowed two or more animals to pull together as a team and thus to haul much heavier loads than ever before. Wheeled vehicles quickly became vital to the growth of cities, to which supplies had to be carried from the countryside. By 3000 B.C.E. wheeled carts had become common.

Also around 3000 B.C.E. wheelwrights added rims to their wheels to reduce wear. At first they simply studded the outer edges of the wooden wheels with nails. This made the solid wheels more durable, but even heavier. In about 2000 B.C.E. rims made of bands of copper were introduced. At about the same time, people discovered that heated wood could be bent. This discovery led to the spoked wheel. The rim became a circle of bent wood protected by a band of copper and connected to the hub by spokes. The first spoked wheels had two wide spokes. Wheelwrights experimented with different numbers of narrow spokes, with four- and six-spoked wheels becoming common. Spoked wheels were much lighter than solid ones and thus allowed greater speed.

Transportation technology advanced still further with the making of wheels that turned independently of each other and of the axle. This innovation greatly increased maneuverability (although many simple wagons and farm carts continued to use the cruder construction of fixed wheels and axles). Among other things, the combination of light spoked wheels and independent rotation led to the development, sometime around 2500 B.C.E., of the chariot. This most famous of ancient vehicles had two wheels and eventually took a wide variety of forms. At one extreme were light, swift models used for racing or for delivering messages. At the other were heavy, armored war chariots that carried, in addition to the driver, archers and lancers.

Neither the improvements to the wheel nor the invention of the chariot would have meant much without a fast, strong animal to pull the new vehicles. That animal was the horse. Horses may have been domesticated in Ukraine in the fourth millennium B.C.E. Although the nomadic peoples of central Asia rode horses, the animals may not have appeared in the Near East until about 2500 B.C.E., when Sumerians hitched them four abreast to pull four-wheeled battlewagons. The value of horses must have been obvious throughout the region after about the 1700s B.C.E., when the Hyksos, a southwest Asian people who migrated as far as Egypt, used them to great effect in both war and peace. At about the same time, the Hittites swept down from what is now north-central Turkey aboard horse-drawn battle chariots and conquered much of northern Mesopotamia and modern-day Syria. Their enemies soon adopted this same lethal combination. When the Egyptian pharaoh Ramses II finally dealt the Hittite Empire a crushing defeat, at Kadesh, in Syria, about 1275 B.C.E., it was in one of the greatest horse-and-chariot battles of all time.

Of all the people of the ancient Near East the Persians may have made best peacetime use of the horse's potential. Persian rulers created a large network of roads to connect their empire, including the Royal Road, which spanned the Near East from the city of Susa near the Persian Gulf to the

Achaemenid Persian gold model chariot dating to the fifth to fourth century B.C.E. from the region of Takht-i Kuwad, Tadjikistan (© The Trustees of the British Museum)

city of Sardis near the Aegean, covering 1,600 miles. The Persians developed a system of way stations where horses could be cared for and exchanged, allowing messengers to cover about 180 miles a day, riding from Susa to Sardis in nine days—a rate of travel unheard of at the time. Although it was not as fast as the horse, the mule—a cross between a female horse and a male donkey—contributed greatly to transportation as both a pack animal and a draft animal. Mules tolerated heat and cold well, had tough hides, and could carry heavier loads than donkeys could. The Sumerians were using mules by the third millennium B.C.E.

For long-distance travel in the desert, however, neither horses nor mules could compete with a later arrival in the Near East, the camel, which was far better adapted to hot, dry conditions. The one-humped dromedary was probably domesticated in Arabia around 1200–1100 B.C.E., quickly revolutionizing long-distance trade. Camel caravans made it possible to transport aromatics like frankincense and myrrh from the southern Arabian kingdoms northward to Mesopotamia, Syria, and the Levant. In Iran two-humped Bactrian camels were used for similar purposes. These animals originated in the Mongolian area, but by the third millennium B.C.E. they had reached the Iranian plateau. In addition, dromedary-Bactrian hybrids were being bred by the early second millennium B.C.E. These animals became the heavy-duty trucks of antiquity, capable of carrying loads of half a ton and with far greater tolerance of extremes of heat and cold than either purebred dromedaries or Bactrians.

Inland water travel was rare in the Near East except on the Tigris and Euphrates rivers. Both rivers posed problems for people who traveled on them, because they tended to fill with silt as well as to jump their banks periodically to forge new courses to the sea. By the Early Dynastic Period (ca. 2900–ca. 2340 B.C.E.) barges moved up and down these

rivers, carrying goods and people. Sometimes oceangoing ships sailed up the rivers, transporting goods from the east. Smaller boats made of animal skins stretched over wooden frames were commonly used on the rivers to transport only a few people or for fishing.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Most ancient peoples of Asia traveled on foot. Even after the domestication of draft animals and the introduction of the wheel, transportation usually meant people walking, carrying loads on their shoulders and backs. One of the remarkable things about ancient peoples was the large amounts of goods they transported in this manner, trekking through dangerous, frequently very dry or very cold environments. The paths they wore in the earth on these journeys often became the roads of empires.

On the many large Asian islands between the Indian and Pacific oceans dense tropical forests often impeded land transportation. On such islands as Sumatra and Java water transportation was the better choice for moving goods over any but the shortest distances. People poled or paddled boats such as dugout canoes and bamboo rafts over the sinuous waters of rivers, streams, and swamps. Even on the mainland, in Indochina and much of southern Asia, dense forests inhibited travel. People walked the trails of tapirs and elephants to make their way to streams where they could use boats. On many Pacific islands, forests were thick enough to inhibit travel. The islanders often found it easier to travel by boat in the ocean around their islands than to try to travel great distances inland. For large islands, such as New Guinea, islanders made their ways to streams and used dugout canoes to carry themselves and goods. In open areas such as those in Australia, people of the Pacific continued to rely on transportation on foot through the ancient era.

The amount of goods a walker could carry was obviously limited by his or her strength. In many parts of Asia poles were set across the shoulders of two people, enabling them to carry weights greater than one person could bear. From very early times people also used sledges for heavy loads. The early sledges, little more than rough wooden frames on which goods were dragged across the ground, were soon improved by the addition of sledlike runners. This innovation may have occurred in the far north of Asia. Even after the introduction of the wheel, sledges remained the preferred mode of transportation over mud, marshes, snow, and ice. For the nomadic peoples of Siberia sledges became essential to their way of life because they frequently had to pack up and move their heavy animal-skin-and-wood tents and other goods to new places.

When the domestication of draft animals reached Asia is not known, but by 3500 B.C.E. farmers near the mouth of the Yangtze River were using oxen to pull plows. The wheel as a means of transportation was first used in Sumer, in the Near East, before 3500 B.C.E. and spread from there. The original wheels consisted of three boards held together by two

boards fitted crosswise on the inside of the wheel. These solid wheels were very heavy. The Harappans of the Indus River valley (2600–1500 B.C.E.) probably used four-wheeled wagons pulled by two oxen apiece. These heavy vehicles enabled them to transport enough grain to fill the huge granaries in their cities, providing a food reserve against hard times.

For many centuries in ancient India oxen remained the favored animals for hauling carts and wagons. They were so valuable that in some places in India it was punishable by death to kill one. Even long after the domesticated horse was introduced to India, oxen were preferred for pulling wagons. By 300 B.C.E. Indian traders formed long caravans of hundreds of wagons pulled by oxen. Ox-drawn carts of supplies followed Indian armies to war. Oxen were slower than horses but tolerated India's climate better. Thus horses served mainly to carry riders or to pull light chariots.

Two-wheeled chariots had the advantage of being faster than four-wheeled wagons. They transported elite warriors to battle and the rich through cities. Sometime after 2000 B.C.E. spoked wheels—lighter and therefore faster than solid wheels—were introduced to India. Another innovation improved maneuverability: Originally, axles and wheels formed one unit, rotating together, which made chariots, carts, and wagons difficult to turn. Eventually, wheelwrights found ways to allow wheels to turn independently of each other. The wheels could thus rotate at different speeds, allowing fast, tight turns without skidding.

By 2600 B.C.E. wheeled vehicles had appeared in China, probably introduced by nomads from central Asia who had learned this technology from Mesopotamians. Solid wheels and wheels fixed to axles presented the same problems to the Chinese as they did to the Indians, but the use of solid-wheeled carts persisted in southern China and southern Asia as they did in India, probably because of their durability and ease of construction. Although China had two great river systems, the Yangtze and Yellow River, the rivers wound through the landscape so much that the Chinese found it took longer to move on the rivers than to travel by land, which led to many road building projects to improve land transportation.

It was probably also nomads of central Asia who introduced war chariots to China. By 2000 B.C.E. people in what is now northern China were using wheels with 18 spokes. Chariots with spoked wheels, pulled by horses, were of great value to the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.). The chariot, even a heavy, lumbering one, gave Shang armies a big advantage in battle and in the transportation of military supplies against enemies who often were limited to being on foot. The advantage became even greater when Chinese wheelwrights, like those in India, discovered how to let wheels turn independently. Meanwhile, Shang four-wheeled wagons appear to have remained clumsy vehicles because the forward axle was fixed in place and could not easily shift to follow a winding road, but they were nevertheless important for transporting heavy cargoes.

The Scythians of central Asia introduced the stirrup to the Chinese. A Scythian stirrup was just a leather loop, but it

gave a rider greater stability and greater control of his mount. In about 380 B.C.E. the Chinese made a stirrup of metal rather than leather. It allowed a rider to stand up in his or her stirrups and provided enough stability that an archer could shoot accurately while riding. Until this innovation chariots had been the best mobile platform for archers. The Scythians also introduced the use of a blanket for padding under a saddle; the Chinese modified this idea by padding the saddle itself.

The Chinese were probably the inventors of the double shaft for vehicles, introducing two-wheeled carts with double shafts and one horse. The shaft of a cart or wagon is a pole extending forward, to which animals are hitched so that they can pull the vehicle. Before the introduction of the double shaft, carts had one shaft. A single shaft, however, required two draft animals, one on each side of the shaft, because a single animal would naturally pull the shaft toward the side to which it was attached. The double shaft had poles to each side of one draft animal, allowing it to pull a cart and keep it in a straight line. After 100 B.C.E. double-shafted carts became common in China.

Despite the great advances in technology, much transportation of goods was still a matter of humans carrying loads. China had many regions where the only roads were merely footpaths. Sometime around the first century C.E. an unknown Chinese inventor introduced the wheelbarrow. Essentially a small human-powered cart, this humble vehicle soon became an invaluable tool for transportation, carrying goods not only along country lanes but through the narrow streets of big cities as well, hauling tools and produce between fields and homes and moving countless tons of supplies and raw materials for the building of roads, dams, and other public projects.

EUROPE

BY MICHAEL J. O'NEAL

During the Palaeolithic, Mesolithic, and most of the Neolithic periods people in Europe traveled mainly by foot. In most cases they did not travel great distances, but sometimes they went on long treks. The frozen so-called Iceman found in the Alps in 1991 was traveling north from Italy, perhaps to escape pursuers, and was crossing the Alps when he died around 3300 B.C.E. Rivers and large lakes posed obstacles, and dugout canoes were the best means of crossing these bodies of standing water. Wetlands were crossed with wooden trackways.

In northern Europe skis were used by travelers at a very early date. They were probably invented in many different places once people began to adapt to modern climatic conditions after the ice age. Skis were found preserved in a bog in Hoting, Sweden, dating back some 4,500 years, and hundreds of others have been found throughout Scandinavia. Further, a 4,500-year-old rock carving depicting a man skiing with a hunting weapon in his hands has been found on the island of Rodoy in northern Norway, and numerous other rock carv-

ings illustrate groups of people on skis. Russian researchers found skis in the Altay region of central Asia that are at least 6,000 years old. The word for *ski* is similar in language communities as distant as Finland and Siberia, suggesting that skis were developed across most of Eurasia very long ago.

During the fourth millennium B.C.E. two developments had a profound effect on transportation in prehistoric Europe: the domestication of the horse and the invention of the wheel. Around 3500 B.C.E. the inhabitants of the steppes (vast, open grasslands) of eastern Europe and western Asia began to keep horses as livestock, initially just for food. They subsequently discovered that horses could be ridden. Archaeological evidence includes bit marks on teeth found in horse skeletons from the third millennium B.C.E., though saddles were not used until after the fall of the Roman Empire and the stirrup was a still later innovation. The domestication of the horse and the invention of horse riding had an enormous impact on the mobility of the peoples of Eurasia. It enabled them to migrate over immense distances. It transformed warfare. In particular, it contributed to the spread of the Indo-European language, the ancient common tongue from which numerous languages in Europe and parts of the Middle East and Asia descended.

Skis and the horse can transport one person, but they are of little use in transporting goods or agricultural produce. To that end, Europeans discovered that they could use animals to pull wagons, carriages, and carts. The earliest European wagons, which date to the end of the fourth millennium B.C.E., were clumsy, lumbering vehicles. They were probably first pulled

Horse harness fittings from Iron Age Britain (1–100 C.E.) © The Trustees of the British Museum

by oxen and only later by horses. The wheels were solid and heavy, typically constructed out of three joined pieces of wood. The axle was fixed so that only the wheels turned. In time the Europeans discovered ways to make wagons and carts more maneuverable. One chief innovation, dating from the second millennium B.C.E., was the use of spoked wheels rather than solid wheels. The earliest wheels were made entirely of wood, but Celtic metalworkers in central Europe learned to attach a metal band around wheels, making them far more durable on rough roads. Another innovation was the development of axles that turned, making wagons and carriages much more nimble.

Wagons pulled by oxen were used primarily by farmers in their fields and around their settlements during the Bronze Age. The archaeological record provides enough evidence for archaeologists to make good guesses as to what such carriages looked like. Among the most important finds are portions of wagons discovered in Holland. These wagons were constructed with solid wheels (that is, wheels without spokes), a forked undercarriage, a forked shaft, axles, and a large wickerwork “basket” on top for passengers or materials. Wagon technology improved during the Iron Age. The tomb at Hochdorf in Germany that dates to approximately 530 B.C.E. contained a four-wheeled wagon about 6.5 feet long, with a pole for attaching it to a team of oxen or horses extending over 6.5 more feet. Each wheel had 10 spokes. A similar wagon was found in a tomb at Vix in France.

Horses and particularly lightweight carriages were used primarily by the social elites. Among the most important carriage finds are six carriages called the Dejbjerg carriages, named for the bog in western Denmark where they were found. These carriages might have been built by the Celts in central Europe, who developed a tradition of expert carriage making. These wagons were probably used by headmen, and probably on ceremonial occasions primarily. They were much lighter than agricultural wagons and featured spoked and iron-banded wheels and bronze ornamentation. They were constructed of ash and beech, both of which are especially durable woods.

In addition to carriages and wagons the Europeans developed a type of chariot. The ancient Celts in Ireland drove a vehicle called a *carpat*, a word similar to the Latin word *carpentum* used by the ancient Romans, to refer to these vehicles. Historians long believed that these words and the vehicles they named were unrelated, but more recent research suggests that they are in fact related. The chariot was a light, two-wheeled, horse-drawn vehicle mounted on a flexible suspension. Above the suspension was a platform on which the rider stood and a seat—all protected by a fabric covering called a tent. Examples of these chariots, dating from as far back as 500 B.C.E., have also been found both in Yorkshire in England and on the Continent.

The chariot was used for purposes of warfare, but that was not its primary purpose. As a military vehicle, it served to transport soldiers and their gear, but actual fighting was done on foot. The chariot, rather like a modern-day sports car, was a mark of status. Members of the elite class used chariots to

travel about or visit their neighbors in stately fashion. They were also used by young men who wanted to display their style and daring, for the chariot was used in races and, in particular, for such feats as riding pell-mell over creeks or ditches; the flexible suspension enabled the rider, at least most of the time, to make a relatively soft landing.

The use of wheeled vehicles for long-distance transportation required the improvement of the road system of ancient Europe, which had existed for millennia as beaten tracks through the forest. Roads connected the Celtic *oppida*, or towns, which greatly facilitated trade and movement of military groups. The invading Romans made use of this road structure as well as improving it further. The Roman Empire relied on efficient transportation for administration and trade, so in addition to building roads, the Romans built some canals in Europe. In the first century of the Common Era, the Roman general Drusus built a canal that connected the Rhine River with the IJssel River in Holland. In England the Romans built the 11-mile-long Fossdyke canal near Lincoln, connecting the river Witham with the river Trent, and the 40-mile-long Caerdyke canal in the same area. Otherwise, the Romans found canal building to be impracticable in their northern colonies.

GREECE

BY CHRISTOPHER BLACKWELL

Transportation in the ancient Greek world was dominated by the sea. Overland travel was arduous and often unnecessary. The Greek mainland is mountainous and rugged, and the Greek population was concentrated in the coastal areas to the east and west of the northern Balkan Peninsula, around the edges of the southern peninsula of the Peloponnese, and scattered across the islands of the Aegean Sea and along the coast of Asia Minor.

The many separate population centers of Greece were not politically unified in any sense of the word until the late fourth century B.C.E., and even then only into a relatively loose structure of military dominance by Macedonia. Greek communities, isolated by geography and largely self-sufficient, had no need for swift overland commerce—in contrast, for example, to the Persian Empire, whose bureaucracy required and provided a network of “Royal Roads” with well-maintained stations set at intervals and supplying food, rest, and fresh animals for official travelers.

Land transportation among the ancient Greeks was largely a matter of walking. Horses were not common outside the plains of Thessaly in the northeast of Greece and were not prized as draft animals. Along the few main roads mules or oxen were the preferred beasts of burden. Oxen (cattle trained to the harness) were stronger than mules or horses but very slow. Mules (the offspring of a female horse and a male donkey) afforded the best combination of strength and speed.

Overland travel was made perilous by bandits, especially in places where roads passed far from centers of population. The myth of the Athenian king Theseus emphasizes the heroism

TURNING SEA INTO LAND AND LAND INTO SEA

When Xerxes, the great king of Persia, was planning to invade Greece in the early decades of the fifth century B.C.E., he faced a number of challenges of transport. His army numbered at least 100,000—the numbers are not known precisely, and ancient sources are notoriously unreliable in these matters—and it was supported by a vast naval fleet. Xerxes had to get his army across the Hellespont, the channel of water connecting the Black Sea with the Aegean. He also had to get his fleet safely along the coast of Thrace, the territory to the north of the Aegean, and particularly past the Chersonese, an area of peninsulas extending into the sea, regularly wracked by storms.

Xerxes' famous solution was to "turn sea into land and land into sea," as the Greek historian Herodotus reports. He built a bridge over the Hellespont, a line of barges secured by cables woven from papyrus. His first attempt succumbed to the currents of the Hellespont, whereupon he had his servants flog the body of water with whips. His second attempt succeeded. To avoid the storms around the capes of the Chersonese, he had his engineers dig a canal across the promontory of Mount Athos (today the site of a famous monastery), allowing his fleet to make the Thracian crossing without entering the Aegean proper. To Herodotus and evidently many of the Greeks, these feats of engineering represented excessive pride, an affront to the gods, and Xerxes' eventual defeat, on sea and on land, seemed only fitting.

of his choice to travel overland between Troezen in the Peloponnese and Athens (a relatively short journey). In historical times, when cargoes of any value were transported overland they tended to go in well-armed caravans, following river valleys. But there were few cargoes that needed carrying long distances by land, and so mule- or ox-drawn wagons were mainly limited to local transport, bearing produce from the countryside to urban markets or cargoes from harbors into cities. The chariot appears in poetry as a vehicle of war but was not used, in war or peace, to any significant extent by the Greeks during the historical period. Most warfare among the ancient Greeks was between neighbors and was dominated by soldiers on foot, who marched to their battles and back home again.

Trade was by sea, with bulky cargoes (most often grain) or valuable cargoes (luxury goods such as particular vintages of wine or fine pottery or textiles) moving from one end of the Mediterranean to the other and beyond. Ancient Greek trade goods have been found in England and Sweden, perhaps brought that far north by merchants looking for tin, a

metal alloyed with copper to make bronze. (Copper was common in the Greek world, but tin was not.)

Ironically, given the relative unimportance of land transport, there were occasions when ancient travelers preferred to carry their ships overland rather than sail them on the sea. Ships traveling between east and west in the Mediterranean could choose to round the southern end of the Peloponnese, risking bad weather from the open sea to the south, or to cross the Isthmus of Corinth by land. The Corinthians had constructed a dragway across the isthmus and would (for a fee) carry merchant ships across that narrow strip of land on rollers (today there is a canal).

ROME

BY KIRK H. BEETZ

The earliest remains archaeologists have found at the city of Rome are graves dating from the 800s B.C.E., but Roman tradition held that the city was founded in 753 B.C.E. By this time many of the ancient world's most important innovations in transportation had already been made, primarily in the Near East, and much of this Near Eastern technology had found its way into Italy. At the same time, Celts in Europe were making marvelous carts and chariots, experimenting and innovating in their design and uses. Still, even though the Romans acquired all the advanced transportation technology, the favored Roman method for hauling even heavy goods was humans trudging along under their burdens. Slaves were abundant, and it was easier to load them up with whatever needed to be transported, whether it was bricks or wheat, than to invest money in beasts of burden and their maintenance. Even the Roman army was apt to carry what it needed on foot. Most of its soldiers were farmers used to long hours on their feet, and the army tended to favor infantry over cavalry. Walking remained the most common mode of transport for the poor throughout the history of ancient Rome

Transporting goods by water was usually much less expensive than hauling them over land. In the time of Diocletian (r. 284–305 C.E.), it was less expensive to transport goods across the Mediterranean from Spain to Syria than to transport them over 75 miles of land. But when it came to personal travel, Romans preferred to go overland rather than travel by ship. Many did travel by ship, especially if they were in a hurry, but dry land seemed more secure to most Romans. They were also avid tourists who liked to see the sights wherever they went.

Oxen were the primary beasts of burden for pulling carts. For small farmers, oxen and a cart were essential for bringing produce to markets in towns or cities. The carts were heavy affairs, made of thick planks of wood with either two or four solid wheels. On most big Roman carts the axles were fixed to the carriage body, making turns very difficult. It required the strength of oxen to maneuver them. When taking produce to a city, the farmer walked beside the oxen rather than riding on the cart. He traveled at night, because carts carrying farm products were forbidden to be in cities during the day.

Cities were designed to favor pedestrians. There were sidewalks, and cities often had laws requiring people who owned property next to a sidewalk to provide awnings that protected pedestrians from the sun and rain. Crosswalks consisted of large flat stones laid a step apart across streets. Cart and carriage drivers had to guide the wheels of their vehicles slowly between the stones. Streets were often full of people, further slowing wheeled traffic. Wealthy people rode in palanquins, using them like battering rams to force their way through streets. The palanquin was adopted from the Near East and consisted of an enclosed carriage body on two poles. The poles were carried on the shoulders of four or more slaves or servants. In large cities it was common to see these palanquins and their bearers marching through crowds, their passengers hidden behind drawn curtains. Palanquins were often marked with the symbols of their owners and would be followed by clients of the owners, hoping for a handout whenever the palanquins stopped.

The Romans were probably the greatest road builders of the ancient world. Not only were their city streets paved and well maintained but so were the roads and highways that connected the regions of the empire. Such roads had advantages for commerce, and entrepreneurs established carriage

services for transporting passengers in cities and around the countryside. A common sight was the *raeda*, a four-wheeled cart that was large enough to hold several passengers. It was heavy, slow, and difficult to maneuver, but Roman engineers tried to lay out roads as straight as possible, which minimized the number of turns a vehicle would need to make if it stayed on a main road without making detours. There were lighter carts that also carried passengers. Lighter carriage bodies and light, spoked wheels meant that every bump in the road was felt, but with spoked wheels and teams of four horses drawing them, light carriages could cover as much as a hundred miles a day on Roman-built roads. Sometimes Romans chose to ride in a light, two-wheeled carriage called a *cisium*, which could function like a taxicab. Many Romans chose to ride horseback when traveling. Inns and even whole villages arose along major thoroughfares to provide services for all kinds of freight and passengers, with cartwrights and stables available.

The lightest cart, the *birota*, could carry about 150 pounds, and the heaviest, the *angaria*, could carry about 1,100 pounds. Neither was well suited for carrying the monumental stones that the Romans used for building. Such stones were often fitted with posts in their sides on which wheels were placed, and the whole was towed as if it were a huge cart. Liquids were transported in wooden barrels seated in wheeled frames. For pulling their carts, Romans used oxen, mules, and horses. They lacked an efficient towing harness for horses, which limited horses to light carts and chariots. Oxen were common throughout the empire, although mules seem to have been favored in dry areas because they could better tolerate hot, dry conditions. Pack mules were extensively used for carrying goods in bad weather and on narrow paths.

For moving heavy goods, Romans preferred watercraft whenever they could avail themselves of them. Although they occasionally built canals in Europe, by and large they relied on existing waterways. For instance, the city of Rome itself depended on the Tiber River. Ships laden with grain and other goods from North Africa would dock at the nearby port city of Ostia at the mouth of the Tiber, where cargo would be transferred either to barges or to land transportation. The barges were hauled upstream by slaves pulling thick, heavy ropes along the riverbank.

Horses were favored by Romans for pulling chariots and other light vehicles. Horses often worked in teams of four not only in chariot races but also in pulling transport vehicles outside cities. Individual riders rode horses for hunting as well as for travel. Romans began using spurs and riding boots in the 300s B.C.E. They also invented horseshoes. The first was the *hipposandal*, which consisted of an iron plate tied to the hoof with leather strips. They eventually developed a horseshoe made of iron that was nailed to the underside of the hoof, much like that used today. The padded saddle was introduced only late in the empire, in the 300s C.E., and was marketed to riders by Roman merchants as a way to reduce the possibility of getting hemorrhoids.

THE AMERICAS

BY MICHAEL J. O'NEAL

Horses, donkeys, and oxen were not introduced to the Americas until the time of European contact. Meanwhile, the large native animals, such as buffalo, were poorly suited to domestication either for riding or for pulling loads. Some smaller animals, such as the llamas of South America, could be trained to carry modest burdens on their backs but were too small to ride or to use as draft animals. Wheeled vehicles existed only in the form of a few toys, since there were no animals to pull the real thing. Thus, for thousands of years, when ancient Americans traveled by land, they went on foot, carrying whatever they needed with them.

Prehistoric Americans traveled along routes that were determined primarily by two factors. One was the movement of wild game, which they followed in search of food. Migratory animals such as mastodons, deer, elk, and bison created trails through forests and over plains, and ancient Americans followed these trails in search of food. They became adept at reading the signs that nature provided, including hoofprints and the droppings the animals left behind. From these signs they could tell when animals had passed and what they were eating, which provided hunters with clues about where to look for them.

The other factor that determined the footways of ancient Americans was the terrain. Throughout the Americas people were confronted with different types of terrain, from the Rocky Mountains of the American West and the Andes Mountains of South America to the tropical forests of Central America and the woodlands of the eastern half of what is today the United States. When the first Americans crossed the land bridge between Siberia and Alaska and then moved southward, their movements were channeled by a path between two glaciers. They faced changes in elevation, marshes and swamps, ravines, rivers and streams, mountains, and other natural obstacles. Naturally they sought to avoid these obstacles in their travels or, if that was not possible, at least to find the easiest way over them. Many modern roadways, as well as hiking trails in national parks, follow the same tracks left behind by ancient Americans.

During prehistoric times, when people survived by hunting and gathering, they moved about in search of food, often following similar routes each year as the seasons passed. The advent of agriculture required those who adopted this way of life to settle in more or less permanent communities, remaining in one place year-round or at least for much of the year. But circumstances often caused even settled farmers to pack up their belongings and travel, sometimes for great distances. In some cases they were motivated by the basic human need to explore. In other cases changes in climate conditions forced them to seek new farmland, or perhaps a natural disaster such as a flood, earthquake, fire, or volcanic eruption forced them to move.

In time the roadways that people had worn into the ground over generations became used for trade and cultural

contact. Roads led to the diffusion of languages and ideas and to the construction of cities that served as administrative centers and hubs for the movement of goods and people. Roads enabled rural people to transport their goods to the cities. Empires such as those of Central America needed roads for communication and in some cases military conquest. In many cases roads were needed to transport raw materials used for building cities. They also led to ceremonial centers, where people gathered for religious purposes.

As time passed, some early Americans traveled by water. Those who settled along waterways or in coastal areas used canoes and small boats, usually for hunting purposes but sometimes to transport goods for trade as well. Most of these early boats were dugout canoes; that is, they were carved out of a single log. Numerous examples of dugout canoes dating to ancient times have been found in the southeast of what is now the United States, with its long coastline and numerous rivers and lakes. Archaeologists have discovered 400 such canoes, and although some date from the later medieval period, others are thousands of years old. In Mesoamerica water became important for the transportation of goods late in the ancient period, and the peoples of the Caribbean islands relied on seacraft to travel from island to island trading goods. By about 300 C.E. the Moche of Peru in South America were using canoes to hunt mammals at sea. This growing reliance on waterways for transportation, however, was a late development in the ancient period. Transportation by foot remained the norm for many millennia.

► war and conquest

INTRODUCTION

In general, historians writing about the ancient world tend to define war as a military enterprise that required long-term preparation and planning and was carried out by one state or national government against another state or government. For the purposes of the definition, nomadic peoples united under a single leader or governing council count as a nation, which is why some historians will refer to nomadic peoples as “nations” even though they did not live in one place with defined borders.

Most anthropologists believe that people have been killing people from the beginning of modern humans. Those very ancient disputes may have begun over offended honor, a mistreated daughter, or the claiming of rights to a fertile territory. Rock paintings dating to tens of thousands of years ago, from Europe, Africa, and Asia, show people killing one another with bows and spears. Some of the combat looks organized, with figures wearing special clothes or body decorations specifically meant for battle.

Exactly when small conflicts became large ones is unknown. For a time the rise of cities in Sumer was thought to have brought about the beginning of war. As the cities grew, they needed more lands to feed their people, and they became envious of each other; for this reason they started killing each other to acquire land and to steal one another’s wealth. This would not have begun before 3500 B.C.E. Yet Çatalhüyük in modern-day Turkey dates from about 7200 B.C.E. and was built for defense against large-scale attacks. Between 10,000 and 8000 B.C.E. the residents of Jericho built massive walls

and an extraordinarily well-designed tower. Those battlements would seem to have been pointless wastes of valuable time and labor unless they were meant as defense against a large and dangerous threat, such as an army with leadership that would devote time to planning how to defeat such a stronghold. It is possible that someday the exact place and time the first war was fought will be discovered, but at present archaeologists and historians can study only the wars they know about.

War was expensive. It required a large investment of time, people, and goods to wage war. For a society to invest its energy in war, it needed to see value come from war. People had to believe that they were either gaining something valuable through aggression or keeping something valuable through defense. War had objectives that were perceived as valuable, and those objectives could be met only by sacrificing other valuables, such as human lives, money, and labor for public works. In societies in which people had to spend almost every waking moment working just to feed themselves, taking time for war was a great sacrifice. Some societies solved the problem by giving up making their own food and goods and devoting themselves to taking food and goods from other people. In northern China and northern Mesopotamia, for instance, there were nomadic peoples whose lives focused on war and whose societies’ efforts centered on annual raids for looting farming communities to the south. In China hundreds or thousands of lives, much labor, and a great deal of wealth was spent on such defenses as tall, wide walls around every city.

The constant warfare that marred much of the ancient world generated an arms race in almost every culture. The

classic example comes from ancient Sumer, where warriors used stone clubs to bash in heads, so people made metal helmets to absorb the blows, so weapons makers created metal axes to cut through metal helmets, so armorers styled larger, thicker, and more resilient metal helmets, so weapons makers developed new casting techniques that allowed them to make stronger, larger axes with curved blades that could smash through metal helmets, and so on. Many of the technological advances of ancient peoples were put to use in war, and many advances came from people trying to find better ways to fight wars.

This race in technology was paralleled by changes in military organization and strategy. Whereas the technology of the composite bow made Sargon I ruler of most of the Near East, the strategy of the phalanx helped make the Hittites the military masters of their era. The Neo-Assyrian Empire (1050–609 B.C.E.) combined its weapons and armor technologies with sophisticated deployment of highly trained units devoted to one kind of warfare, such as sappers for bringing down enemy walls, archers for long-range attacks, light infantry for responding quickly to events on the battlefield, heavy infantry to push massed enemy troops out of the way, and chariots for shock attacks to break up enemy formations.

Some historians argue that every great empire of ancient times was built through war. This may be too much of a generalization. For instance, there are the trade empires of ancient southern India to consider, but even those required some military power to keep trade routes free of bandits. What may be noteworthy is that war had its limits. Ancient Rome prospered while its armies looted newly conquered territories, but it declined when it did not continue to do so. During the Han Dynasty (202 B.C.E.–220 C.E.) of China, there was a period in the 100s B.C.E. when its army crushed opponents to the south, the west, and the north but at such a high cost of lives and wealth that its economy nearly collapsed. Even the Neo-Assyrians ended up fighting wars mostly using mercenaries and vassals because it was running out of its own men to fill its armed forces.

Perhaps it is most important in studying the wars of ancient peoples to note how people struggled to meet each day, to feed themselves and their families, and to endure the pain and sorrow that war inflicted on them. For most people most of the time war was something to be survived. Some cultures developed strict rules of warfare that minimized bloodshed, allowing for glory for the leaders and for victories while also allowing most warriors or soldiers to return home unharmed. Still, such cultures eventually either adopted the waging of war as massive bloodshed or were overwhelmed by the armies of cultures that made war a matter of slaughtering enemy troops. Those who failed to learn the lessons of advancing technology and improving military strategy tended to perish. Survival seems to have depended on vigilance, sacrifice, discipline, and sound military doctrine.

AFRICA

BY KIRK H. BEETZ

Rock paintings in southern Africa and in the Sahara show people fighting with bows and spears. The identification of these early people is not clear, but the depictions of conflict continue for thousands of years. By 9000 B.C.E. the people in southern Africa were probably the San, often known as Bushmen. It is not clear what the Bushmen fought over. As hunter-gatherers, they probably did not have much property to defend or covet, but they may have had territories they considered their own. In the often dry plains that many Bushmen inhabited, even a small family group of hunter-gatherers would have needed a wide territory in which to find food. Raids for marriageable women might have been another purpose for conflict. The combat probably involved no more than a dozen fighters at a time. At no time did the Bushmen number as many as 300,000 people, which meant they were so thinly spread over their lands that it would have been very unlikely that they could have gathered together enough people to form anything resembling an army. The same would be true for the small-statured peoples often referred to as Pygmies, who inhabited most of central Africa and much of the east and south.

For the ancient peoples of the Sahara the issue of war and conquest is more complex than for southern Africa. Their rock paintings hint at an evolution of warfare not found elsewhere in Africa. Most depictions of conflict prior to the Herdsmen Period (ca. 5095–ca. 2780 B.C.E.) show naked men in small skirmishes. During the Herdsmen Period some men in battle seem to wear robes, and there may even have been a hierarchy, indicated by a single figure wearing robes that were colored or tailored differently from those of others in his command. It seems that for the cultures depicted, the wearing of clothes may have been reserved for war or other official functions.

During the Herdsmen Period the rock paintings show a diverse ethnic population, with pale figures mixing with dark ones. The primary occupation of people seems to have been herding cattle. It is probable that conflicts focused on stealing cattle. Prestige could be won in a village or group by successfully stealing cattle from another village or group. Wars in which cattle were considered important booty continued into the medieval era. In any case, as time passed, the paintings of battles became increasingly common.

What happened to the ancient warriors of the Sahara grasslands is not entirely known. Some of the pale people and the dark people seem to have mixed, perhaps becoming the Berbers. Others retreated to Egypt. Some retreated to oases as the Sahara slowly dried and created farming communities. Around them developed nomadic groups who created their own culture of war in which they mastered horses and the use of weapons. These groups preyed on the farmers at the oases, forcing them to pay tribute or die. Sometime late during the Horse Period (ca. 2780–ca. 600 B.C.E.) the attacks on the

farmers became too much. Apparently, raiders using chariots swept out of the northern Sahara and drove the farmers out. The Greek historian Herodotus (ca. 484–between 430 and 420 B.C.E.) suggested the attackers were the Garamantes, a Berber group from the northern coastal area of North Africa. The fighting was probably very one-sided, with the attackers using not only chariots but also javelins and shields against farmers who had only bows. The farmers were probably part of an ethnic group that already occupied much of West Africa. Their descendants may have been the Bantu-speaking people who eventually spread over most of the continent.

Warfare as modern people think of it, with large numbers of warriors or soldiers united in a single cause, may have taken place in Africa in many places, but this is not known because of the lack of archaeological or written evidence. The earliest records of war tend to come from the earliest literate peoples of Africa, the Egyptians, Kushites, and Axumites of northeastern Africa.

NUBIA

Egyptian culture may have begun around 5000 B.C.E. in farming communities in Upper Egypt—the southern half of what became ancient Egypt. By 3500 B.C.E. the culture was spreading north. At the same time, a strong local culture was developing in Nubia, which was south of Egypt. The Nubians of this time were several different groups, some farmers and others pastoralists. By about 2250 B.C.E. a Nubian confederation had formed under one chief just south of Egypt in an area called Wawat. This confederation and Egypt traded with each other. Nubian warriors were noted for their ferocity, and for most of their history after 2250 B.C.E. they were in demand as mercenaries in armies as far away as Mesopotamia. Nonetheless, Wawat and much of the region around it were rich in gold, and for this prized commodity Egypt sent an army to occupy Nubia.

This was not easily done, even though the Nubians' military technology was inferior to that of the Egyptians. The Egyptians had composite bows, an import from the Near East. A composite bow had an inner lining of bone, a middle lining of wood, and an outer lining of animal skin. It sometimes was made of more than one kind of wood, each kind intended to provide strength or springiness. The composite bow was powerful, and the arrows it launched could penetrate the animal-skin shields of the Nubians. Some of the nomads among the Nubians continued to fight for decades by raiding the Egyptians, but the Egyptians built several forts in the region that eventually enabled them to defeat efforts to drive them away.

KUSH

There seems to have been much activity south of the Egyptian conquests in Nubia. A kingdom called Karmah, after one of its most important cities, became an important trading center for eastern Africa. Whatever Karmah's military problems, they were significant enough for the kingdom to

fortify its cities with walls. By 1650 B.C.E. Karmah had extended its territory almost as far north as the first cataract on the Nile. Karmah had taken advantage of a period of political chaos in Egypt, the Second Intermediate Period (ca. 1640–ca. 1532 B.C.E.). The Egyptian king Thutmose I (r. ca. 1504–ca. 1492 B.C.E.) invaded Karmah. His army sacked the city and extended Egyptian influence south of the fifth cataract of the Nile. Over the next 400 years Egypt tried to make the land it called Kush into a cultural disciple of Egypt. The children of the political elite of Kush were raised in Egypt, where they were taught to worship Egyptian gods, to follow Egyptian customs, and to speak, read, and write Egyptian. By 950 B.C.E. the Kushites had developed a strong kingdom, and its leaders regarded themselves as the true inheritors of ancient Egyptian culture.

Egypt had fallen again into chaos, having become divided among many petty kings who contended for power. The Nile Delta had several independent city-states. A strong dynasty had been founded in Kush by King Alura (r. ca. 780–ca. 760 B.C.E.). The wars in Egypt had cut the Kushites off from worship at important sites of their religion. Thus, Alura's successor, Kashta (r. ca. 760–ca. 747 B.C.E.), sent his son Piankhi (r. 751–716 B.C.E.) in 748 B.C.E. to secure Thebes.

The exact details about the army Piankhi took with him are not known, but it probably numbered more than 10,000 troops. Its principal soldiers were spearmen, still mostly equipped with spears with stone tips. They had chariots but not in great numbers. The Kush had war elephants of a species now probably extinct that was easier to train than the notoriously irritable African elephants from farther south. Piankhi himself probably rode an elephant; at least, Kushite kings are depicted in Kushite art as riding elephants. Their bows were probably still not composite. The organization of the army probably was into infantry, chariots, and elephants. Women could be military leaders in Kush, and it is likely that some of Piankhi's officers, including generals, were women. This suggests that women played other roles in the army, but evidence is scant for their participation in infantry or other units.

Regional Egyptian governors and chieftains usually submitted to Piankhi on his way to Thebes. His object was not to destroy but to preserve, so he did not loot and sack. Instead, he secured access to Thebes, where he worshipped. When he assumed the throne of Kush, he made his capital in Napata, far to the south of Egypt, along the Nile. Napata was a major site for the worship of the Egyptian god Amun, who at the time was the principal deity in Kush.

In the early 720s B.C.E. the Egyptian chief of the city of Saïs in the Nile Delta, Tefnakhte (r. ca. 724–717 B.C.E.), raised an army and navy and marched and sailed south along the Nile. King Nimlot of the city of Hermopolis surrendered to Tefnakhte. Tefnakhte then sent his fleet toward Thebes. How Piankhi actually regarded these events is unclear, but he may have viewed Tefnakhte's aggression toward Thebes as a threat to Kush's influence in Upper Egypt, of which Thebes was the capital. Piankhi sent an army into Egypt. He divided it into

two parts, one to intercept Tefnakhte's fleet before it reached Thebes and the other to take Hermopolis from Tefnakhte.

While he had managed to take Hermopolis, Tefnakhte had problems to his rear, because the city of Heracleopolis, south of the river delta, was holding out against a siege by Tefnakhte's forces. Piankhi's army met Tefnakhte's fleet north of Thebes. A little of the battle that followed can be reconstructed. The Kushites were accomplished sailors on the Nile, and they could transport infantry quickly on their boats. The Egyptians' principal weapon was the bow and arrow. Their other weapons, which were bronze, were mostly superior to those of the Kushites. Overall, in a fight on a river, the Egyptians should have had the upper hand. The Kushites were daring fighters, however, noted for their ferocity in combat. If their spearmen could press the Egyptians into close-quarters fighting, they could overwhelm their enemy. Even at this late date, neither side's troops wore much armor. That the Egyptian fleet was decisively defeated suggests that the Kushites managed to board the Egyptian boats and force both sailors and archers into a confrontation best suited to Kush's infantry.

Piankhi then journeyed to Thebes, where he celebrated the Festival of Opet. It may have been at this time that he proclaimed himself pharaoh, thereby establishing the Twenty-fifth Dynasty of Egypt. He then joined his army at Hermopolis, where he directed the siege that resulted in the city's surrender. The wife of Nimlot asked one of Piankhi's wives to persuade him to spare Nimlot's life, which he did. Thereafter Piankhi's army sped to Heracleopolis, which was near surrender. The advantages of Tefnakhte's forces were their superior knowledge of the terrain and their bronze technology. Piankhi's forces had elephants, some warriors equipped with bronze or copper weapons, and a clear chain of command. Tefnakhte had allies and petty princes to supervise, whereas Piankhi was the undisputed commander of his troops, with a clear hierarchy of officers.

Tefnakhte's forces were driven from the field, and Heracleopolis was saved. Its people were starving. Piankhi was said to have been furious at what he saw. The starving of the city's horses especially galled him, perhaps because the horse was his emblem. Tefnakhte and his allies made a stand at the city of Memphis. For the battle Piankhi brought both his fleet and his army to the city. Instead of laying siege, which would have been the accepted military practice for Egyptians, Piankhi led an assault on the city's defenses. Apparently, attacks from both land and river overwhelmed the defenders. Again, Piankhi arrived as a savior of Egyptian culture, not as a conqueror, and it seems that civilians were not harmed.

Piankhi continued first to Heliopolis and then to Athribis, where he defeated allies of Tefnakhte. The chiefs of the cities of the Nile Delta, including Tefnakhte, then paid him homage. Piankhi was content to allow the chiefs to continue to rule their cities as long as they paid him tribute, and he returned to Napata. This made Piankhi the ruler of one of the largest empires of the ancient world, extending more

than 1,400 miles north to south, eastward to the Red Sea, and westward to oases in the desert.

What happened militarily over the next several years is unclear. It seems that Nimlot rebelled against Piankhi. Tefnakhte declared himself ruler of Lower Egypt; he died in 717 B.C.E., but his son Bekenrenef succeeded him. Piankhi died in 712 B.C.E. and was succeeded by his brother Shabaka (r. 712–698 B.C.E.), who was a less forgiving conqueror. His army of spearmen, chariots, and elephants ruthlessly crushed the enemy army, and Bekenrenef was burned alive. Shabaka brought a shift in attitude to his rule of Egypt; whereas Piankhi viewed himself as a savior of Egypt, Shabaka viewed himself as the one and only rightful ruler of Egypt. Thus, he took power away from Egypt's chiefs and established a central government bureaucracy led by Kushites to run the empire, and he moved his seat of government about 500 miles north of Napata, to Thebes.

The pharaohs of the Twenty-fifth Dynasty seem to have seen it as their duty to return Egypt to the power and glory it had held during the New Kingdom (ca. 1550–ca. 1070 B.C.E.), a period marked by great public works and Egyptian control of much of Palestine. They rebuilt decaying monuments and temples and built many new ones, and Egypt returned to some of the prosperity it had once known, but Palestine was to be their undoing.

Shabaka and his successor, Shabataka (r. 698–690 B.C.E.), had maintained an alliance with Assyria, but in about 701 B.C.E. the kingdom of Judah, led by Hezekiah (r. ca. 715–ca. 686 B.C.E.), rebelled against Assyrian rule and asked Shabaka for aid. Shabaka responded as a New Kingdom pharaoh might have; he sent assistance. The Kushite-Egyptian army met the Assyrian army at Eltekeh in Judah. The Assyrians lived for war; their society was geared toward waging war. Their army was better equipped with armor and weapons than the Kushite-Egyptian army, and it was better organized into combat units. It was more mobile and more experienced. Even so, the Kushite-Egyptian army inflicted heavy losses on the Assyrian army before having to withdraw. Some Assyrian vassals took this as a good sign, and they rebelled. The Assyrian army became afflicted with a disease that killed more than 15,000 troops, and it was unable to finish the war.

The Assyrian rulers regarded the Kushite pharaohs as irritating upstarts, but they had their hands full quelling rebellions in Palestine, delaying their eventual attack on Egypt. In 674 B.C.E. an Assyrian army met a Kushite-Egyptian army in northern Palestine and was decisively defeated. In 671 B.C.E. King Esarhaddon (r. 680–669 B.C.E.) of Assyria led an army to Egypt using camels as pack animals to transport goods through the hot, dry Sinai. His army inflicted a series of defeats on Kushite-Egyptian forces. The decisive factor may have been Assyrian armor, which was made of resilient iron and was mass-produced so that every soldier had armor and iron weapons. The Kushite-Egyptians could not supply all their troops with metal weaponry and armor, and they were still living in a Bronze Age military world, whereas the Assyrians

had the superior military organization of troops on the battlefield that was necessary for victory in the Iron Age world, as well as much superior discipline among their troops.

Pharaoh Taharqa (r. 690–664 B.C.E.) retreated to Thebes and then to Napata. His family in Thebes was murdered by the Assyrians. The Assyrians made the cities of Egypt north of Thebes their vassals. Taharqa was succeeded by Tantamani (r. 664–657 B.C.E.), who believed himself to be the only true ruler of Egypt. In 664 B.C.E. he led a Kushite force against an alliance of Egyptian vassals and Assyrians. The key to his success seems to have been mastery of the waters of the Nile; boats may have moved his forces swiftly into position.

By this time the Kushites had probably noted the value of the iron technology of the Assyrians, and Kush had already begun to establish an iron industry. In 664 B.C.E., however, the Kushites had to rely on their ferocity to overcome their enemies, which they did in a battle at Memphis. Tantamani regained control all the way to the Mediterranean Sea, but too much had changed in the Near East. His allies in Palestine had been defeated by the Assyrians, and combat had depleted his military's resources. Despite waging a stubborn defense, his army was driven ever southward by a determined counterattack of Assyrian forces commanded by Ashurbanipal (r. 668–627 B.C.E.). Thebes was sacked, its women raped, its children slaughtered, and its men enslaved.

Although Tantamani's line would survive until about 300 C.E. and its monarchs would call themselves the rulers of both Upper and Lower Egypt, they would not again rule Egypt. There is some indication that they tried again in about 601 B.C.E., when Babylon attacked Egypt. The Kushite army fought an army composed of Greek and other mercenaries near Abu Simbel, about 250 miles south of Thebes. The battle was ferocious, but the Kushites were forced to withdraw. Although the rule of Kush over Egypt was short, it had a long-lasting effect on Egyptian society: It reinvigorated Egypt's religion, arts, and economy for hundreds of years.

This was not the end for the Kushite military. Most Kushite kings and queens proved to be capable rulers who incorporated what had been learned from the Assyrians into their army. The Kushite iron industry focused on the city of Meroë, south of Napata, just south of where the Atbara River flows into the Nile. After an Egyptian army sacked Napata, the capital of Kush was moved to Meroë. The principal duties of the army became protecting Kush's trade routes that ran deep into southern Africa, west along the Sahel steppes south of the Sahara, and east to the Red Sea. Kushite inscriptions depict numerous battles, mostly against nomadic peoples. Kush assumed the role of protector from raiders for small tribal lands to its south. Elephants seem to have faded out of use in the army, as did chariots. They were replaced by horseback-riding cavalry armed with lances and bows. Spearmen remained the core of the army.

Specific military actions for Kush reappear in the historical record in 24 B.C.E. By then Rome controlled Egypt, and the Romans had built a series of forts south of Egypt, pos-

sibly infringing on territory that Kush regarded as its own. At that time Kush was ruled by a queen, called a *candace*, which Greek writers mistook for a given name rather than a title. This was probably Queen Amanirenas, a big woman with an imposing personality. The Roman governor responsible for the forts left with most of his troops to aid in fighting in the Near East. Although Amanirenas was probably present for the attack on the fort at Aswān, her army was led by a general, perhaps a Prince Akinadad, who is linked with her in inscriptions found in Meroë. Using boats and infantry the Kushite army assaulted and seized forts at Aswān and Philae. In the marketplaces there the Romans had installed statues of the emperor Augustus (r. 27 B.C.E.–14 C.E.), which the Kushites took home. A head that may have been from one of these statues was found by archaeologists hidden in clean sand under the entrance to a building in Meroë.

When the Roman governor, Gaius Petronius, returned, he counterattacked. Although the Kushite army dominated regional African groups, it was no match for the Romans, and despite stubborn fighting the army was driven south by the Romans. Amanirenas tried to negotiate with the Romans, but the Romans persisted until they captured and sacked Meroë. Several Kushite towns were left in ruins.

How Kush fell is not known. A rival kingdom, Axum, left some hints, and archaeologists have found additional clues. In about 300 C.E. Kush lost its constant war against nomads. Among the nomads were the Red Noba, who were in control of Kush when Axum invaded in 350 C.E. The key to the nomads' victory may have been camels, which enabled them to travel farther more quickly in dry climates than could horses, and Kush was drying up as the desert of the Sahara continued its spread. Where the Kushites went is a subject historians and archaeologists like to debate, but at present what happened to the Kushites is unknown.

AXUM

Axum was located where Ethiopia is today. At its height it was one of the great powers of the Indian Ocean, where its navy transported its army to fight in distant lands. Although Axum had a distinct culture of its own by 1500 B.C.E. and developed a written language, less is known about it than about Kush.

Axum's focus was on trade, and throughout its history it was a mercantile nation. Thus its military's primary duty was to protect trade. By about 400 B.C.E. Axum's navy was large, and it sailed along the coast of eastern Africa and as far east as Sri Lanka. In the Red Sea and along Africa's east coast it protected merchant ships from pirates. By maintaining safe waters Axum attracted the sea trade to its ports. Visitors to the ports saw imposing stone forts on hilltops along Axum's coast. These forts apparently represented a military class that held much political power in Axum society.

The king of Axum was the commander in chief of the military, and he sometimes led his army into battle. The army was run by nobles who based their operations in the

hill forts. Beneath them were trained officers who oversaw a well-disciplined infantry and cavalry. It is possible that Axum's army included elephants. Part of Axum's ability to protect its people from harm was its ability to project its power overseas. Its navy could transport divisions of the army throughout the Red Sea and along the southern coast of Arabia and the Near East, and Axum used this ability to effect wars and rebellions in areas it considered important to its well-being. Often when a rebellion or war of conquest disrupted Arabia, Axum would send its army to restore order and place its friends as rulers.

On the continent of Africa, Axum shared power with Egypt, Kush, and various small groups. Beginning around the 1470s B.C.E. it maintained trade relations with Egypt, which were sometimes interrupted by wars and civil wars in Egypt. Whether it meant to or not, Kush contributed to Axum's security by protecting African trade routes from bandits and nomadic marauders. Perhaps Axum's greatest king, 'Ezānā, was in power when the kingdom of Kush expired under the effects of farmland lost to desertification and attacks from nomads of the Sahara. 'Ezānā forged peace treaties with the nomads that were meant to protect Axum's borders and its trade, but the nomads who gave up their nomadic ways to settle in the remains of Kush persisted in attacking trade caravans. The breaking point seems to have come when the Red Noba mistreated ambassadors of Axum in 350 C.E. 'Ezānā led a punitive expedition into Kush, destroying villages along the way. At Meroë his army defeated the Nobu. Losses on his side seem to have been light, but his army may have killed as many as 15,000 enemy warriors. He took home with him several thousand head of cattle, many horses, and slaves.

THE BANTU SPEAKERS

Although Axum persisted as an important power for another thousand years, a people who would reshape Africa to the present day were on the move to the west by 200 C.E. These were the Zande-speaking and Bantu-speaking peoples of West Africa, probably the descendants of the farmers of the Sahara who had fled south 1,000 or more years earlier. They had iron technologies, and their blacksmiths had learned how to carbonize iron with charcoal to make steel. This was tricky, because too much or too little carbon could result in metal that was too soft or too brittle to be of good use. They were an agricultural people, and as they pushed the Pygmies and the Bushmen out of their ancient territories, the Bantu speakers, in particular, made the land permanently their own by settling and farming it. Even though it is unlikely that the Bantu speakers could summon huge armies, they could call upon more warriors on short notice than could either the Pygmies or the Bushmen.

Among themselves, the Bantu speakers at the end of the ancient era fought wars that had well-understood rules. Warriors, rarely more than 100 on each side, would gather on open land. They carried shields made of animal skins, and their weapons were usually spears. They painted their faces

and their bodies to make themselves look frightening. Actual combat seldom took more than a few lives before one side fled. In the event that neither side fled, the side that was winning would refrain from wholesale slaughter by leaving an opening for the losers to use for running away. It was against the rules for one side to surround the other because it was understood that trapped warriors would fight to the death, increasing casualties for the winners as well as the losers. It was from these warriors that the important military powers of medieval central and southern Africa would evolve.

EGYPT

BY MARIAM F. AYAD

Perhaps no other civilization survived as long as that of the ancient Egyptians. In its long history Egypt not only invaded and annexed foreign territories but also was occasionally the subject of military conquest by invading armies. In discussing the development and organization of Egypt's armed forces and Egypt's imperialistic role in history, it is important to clarify terminology. The Egyptian word *mesha*, traditionally translated as "army," is used in reference not only to a body of soldiers but also to any kind of expeditionary force, such as a mining expedition or similar peaceful endeavor. Thus the meaning of the word is not inherently militaristic but much broader, perhaps even referring to any organized group of individuals who undertake state-sponsored excursions to achieve a state-sponsored objective, militaristic or peaceful. Avoiding use of the word *army* when describing Egypt's military force might be prudent, because the term would imply the existence of a national body of soldiers from the beginning of Egyptian history until the demise of pharaonic civilization, which was not the case.

OLD KINGDOM (CA. 2575–CA. 2134 B.C.E.)

The earliest reference to a war in ancient Egyptian evidence appears on the Narmer Pallet. On one side of the pallet is a highly stylized pictorial representation of a king grasping the hair of an enemy in one hand and holding a mace in the other upraised hand. The king is shown in the process of hitting the fallen enemy, a pose that became associated with smiting enemies throughout Egyptian history. The other side of the pallet depicts the king marching in a victory procession. The representation preserved on the pallet has been interpreted as a record of a single militaristic action that led to the forceful unification of Egypt by a king of Upper Egypt. Although most scholars subscribe to a theory of a more gradual unification process, this scene, one of the earliest preserved, records some kind of a militaristic internal struggle.

As early as the Old Kingdom, Egypt wanted to acquire the natural resources of the region immediately south of its border, Nubia. To expand their kingdom's borders southward, Egyptian forces occasionally mounted campaigns into the southern region. Egypt's southern expansion came as a

Frieze in the temple of Ramses II, listing captured cities in Nubia (Courtesy of the Oriental Institute of the University of Chicago)

natural consequence of its unique geography. Running the entire length of Egypt from its southern border to the Mediterranean shore, the Nile River was Egypt's highway. The strong river current carried the ships effortlessly north, while winds blowing from the Mediterranean enabled boats to sail south. Moreover, originating in the Ugandan mountains, the Nile facilitated easy access to the African heartland.

Evidence suggests, however, that Egypt did not have a standing army during this period. Instead, various local governors were called on not only to join military expeditions but also to recruit troops from among their local constituents. The autobiography of Weni, an official under the Sixth Dynasty king Pepi I (ca. 2289–2255 B.C.E.), details an expedition to Nubia, Egypt's southern neighbor. Preserved in his tomb at Abydos, the autobiography lists Weni's many titles, including several hereditary positions (Weni had the social rank of an *iry-paet*, a title often translated as "hereditary nobleman" or "count.") In addition, Weni held several high-ranking administrative positions: He was both a governor and a chamberlain of Upper Egypt, the warden of Nekhen (a cultic center in Upper Egypt), and the mayor of Nekheb (an equally important cultic center).

Much like Weni, the officers under his command were hereditary noblemen and members of the civil administration of Egypt; among those Weni listed in his autobiography are "counts, royal seal bearers, sole companions, chieftains and mayors of towns of Upper and Lower Egypt" as well as chief priests and chief district officials. Remarkably, neither

Weni nor his officers bore any specifically militaristic titles. The high-ranking administrators among them were required to recruit their own troops from the villages and districts they governed or administered. Farmers comprised the bulk of the Egyptian military force.

Indeed, Weni's autobiography recounts the marshaling of "tens of thousands" of troops against the "Asiatic Sandwellers," which was the Egyptian way of referring to Bedouins who subsisted along Egypt's eastern border. Troops were recruited from all the districts of Upper and Lower Egypt as well as from Nubia, the area immediately to the south of Egyptian border, and even included some Libyans. As the leader of this very diverse force, Weni was proud of the discipline of his forces, which he attributed to his own rectitude. In his autobiography he boasts that while he led the troops, "no one attached his fellow, . . . no one seized a loaf or sandals from a traveler, . . . no one stole a cloth from any town, . . . no one took a goat from anyone."

Weni roughly sketched the route of the campaign, but his autobiography focuses primarily on the victorious outcome of the campaign, ending in a poetic refrain that recounts the safe return of the troops, "having slain thousands. . . [and] having carried off many troops as captives." The successful outcome of the campaign ensured that Weni would head the military force sent to fight against the Bedouins five more times. At least once Weni traveled to the battleground aboard a ship, while half of his troops proceeded on land.

MIDDLE KINGDOM (CA. 2040–CA. 1640 B.C.E.)

Soon after the long reign of Pepi II, a period of political turmoil ensued in Egypt. Known as the First Intermediate Period (ca. 2134–ca. 2040 B.C.E.), the tumultuous period following the collapse of the Old Kingdom lasted from the Seventh Dynasty through the middle of the Eleventh Dynasty. Egyptian literature describing this period implies that it may have witnessed some form of civil war. In particular, the “Instructions to King Merikare,” a text written in Middle Egyptian and surviving in three Eighteenth Dynasty copies, describes the following conditions: “Troops will fight troops. . . Egypt fought in the graveyard.” Traces of hieroglyphs preserved in this document suggest that the text refers to King Khety, a possible conflation of Akhtoy, a name commonly held by rulers of the Ninth and Tenth dynasties.

This text belongs to a larger corpus known collectively as pessimistic literature and comprising literary works dating to the Middle Kingdom. Works belonging to this genre describe how Egypt went through a period of turmoil until order was finally restored by a savior king. The “Instructions of King Amenemhat,” founder of the Twelfth Dynasty, belong to this genre. After a lengthy account of the chaos in which he found the land, Amenemhat describes how he was able not only to restore order in the land but also to vanquish Egypt’s southern neighbors in Wawat and Medajj (two districts in Nubia). Amenemhat also claimed that he “made the Asiatics do the dog walk.”

However, even in the Middle Kingdom and despite many campaigns into Nubia, the Egyptian military force lacked the many ranks and titles characteristic of a regular standing army. Similarly absent was a formal division of the military into units and subunits. Egypt’s strategic location in north-eastern Africa, lack of a formal standing army, weakened governmental authority, and lax control of the northeastern border eventually led to the occupation of the delta region by nomadic groups of western Asiatic descent, known as the Hyksos (the name is a Hellenized version of the Egyptian term *heqa khasut*, meaning “rulers of foreign countries”). The Hyksos are credited with the introduction of several technologies and inventions, not the least important of which were the wheel and its use in the military chariot.

NEW KINGDOM (CA. 1550–CA. 1070 B.C.E.)

As founder of the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.), King Ahmose is famous for the successful campaign he launched against the Hyksos strongholds in the delta. Among the several texts recording the events leading to the expulsion of the Hyksos from Egypt is the autobiography of an officer in the Egyptian military, also named Ahmose, who started his military career as a crew commander under King Ahmose and later served in the Nubian and Syrian campaigns of Amenhotep I and Thutmose I. The autobiography, inscribed in the officer’s tomb at El-Kab, records his early career and provides a vivid account of his involvement in

the battle against the Hyksos. Ahmose portrays himself as a courageous “crew commander” who climbed the ranks of the military and was rewarded for his bravery and prowess with gold (seven times) as well with tracts of arable land. As part of his reward Ahmose the officer also received male and female slaves, some of whom he had captured himself in battle and some whom others captured.

It is clear from his autobiography that Ahmose was an infantryman who “followed the sovereign on foot when he rode in his chariot.” In one episode the soldier records going to the battlefield aboard a ship called the *Wild Bull* while he was still an unmarried young man. As an infantryman Ahmose actively participated in the siege of the town of Avaris, the delta stronghold of the Hyksos. He was then appointed to serve aboard a ship named *Rising in Memphis* and took part in some “fighting on the water.” This episode, however, should not be taken to indicate that a naval battle took place. Rather, the fighting occurred on a lake or perhaps a tributary of the Nile near Avaris. The ship merely served as a platform from which archers could aim their arrows. During the battle Ahmose captured a prisoner of war, and when the captive tried to escape, Ahmose waded into the waters and recaptured him.

It is clear from his autobiography that although Ahmose was aboard ship to reach western Asia, he was an infantryman who fought on land. Thus he could be considered a marine who mainly engaged in infantry warfare. The text also suggests that Ahmose fought using primarily short-range weapons, such as the club or mace for clubbing; the spear, straight sword, or dagger for stabbing; and the battle-ax or broadsword for slashing and cutting.

Ahmose’s vivid descriptions of the fall of the cities of Avaris and Sharuhenn indicate that he also engaged in siege warfare. Whenever forces could not infiltrate a fortified city or fortress by tunneling under, climbing over, or smashing into its walls, they would launch a siege that would continue until the inhabitants began to starve and surrendered to the attacking forces. Ahmose describes how Sharuhenn was besieged for three years.

Two other types of warfare, not mentioned by Ahmose but attested to elsewhere are naval warfare, in which battles took place on water, and chariotry warfare, in which combat occurred from horse-drawn chariots. These two types of warfare, though not as well documented in the archaeological and pictorial records, are depicted on the walls of a few temples.

Although it is emblematic of ancient Egyptian warfare in popular culture and art, the chariot was rarely used in Egyptian battles. Appearing soon after the expulsion of the Hyksos, the chariot enabled a soldier to fight aboard a wheeled vehicle. A unit of mounted troops, or chariotry, was limited in size and thus considered elite. The main function of the two-wheeled, horse-drawn chariot was to provide military intelligence and reconnaissance. Protected by its mobility, a chariot would travel along the front lines of the enemy, learn-

ing the organization of its infantry forces and bombarding them with arrows. However, the chariot's use as a mobile platform from which archers could shoot their targets was only secondary. Chariots were expensive to maintain. Each vehicle required at least four horses, which needed fodder, tending, and specialized care. Eventually, the chariot became "a status symbol, and in the case of the king . . . a surrogate throne."

A mid-Eighteenth-Dynasty title, commander of horsemen, suggests the existence of a sort of cavalry or mounted troops. This is further corroborated by scenes from the tomb of Horemhet from Saqqara, which clearly depict the cavalry as an arm of the chariotry. Further evidence suggests that the cavalry unit was used extensively in Sheshonq I's Palestinian campaign of around 925 B.C.E.

Egypt's location on the Mediterranean subjected it to repeated attacks from the Sea Peoples, first during the reign of King Merneptah (ca. 1224–ca. 1214 B.C.E.) and later under Ramses III (ca. 1194–ca. 1163 B.C.E.). These invaders were groups of migrants who swept through the Mediterranean world in the 11th century B.C.E. Although the exact reason for this massive population movement remains elusive, possible reasons include severe climatic changes in the northern and western Mediterranean.

Pictorial evidence of Ramses III's naval battle against the invading Sea Peoples survives on the walls of his mortuary temple at Medinet Habu. The evidence preserved there constitutes the only known example of an active naval engagement. The scenes indicate that during the Twentieth Dynasty of the New Kingdom the Egyptians commanded large seafaring vessels. The evidence also suggests the existence of naval ranks and titles, and military ships had specific designations. Earlier in the struggle against the Hyksos and later during Piye's 25th march into Egypt, ships were used to transport troops north. But the reliefs of Medinet Habu clearly depict troops fighting from onboard ships, although the specifics of conducting naval battles cannot be reconstructed.

Along with distinct naval ranks and titles, the evidence suggests that during the New Kingdom the Egyptian forces were finally divided into distinct units, each exhibiting a clear hierarchy of ranked officials. The units were organized according to their modes of transportation. Foot soldiers, or infantry troops, made up by far the largest units. Indeed, the evidence suggests that this was the only type of unit up to the beginning of the New Kingdom.

The accounts of two major battles (Megiddo and Kadesh) shed light on New Kingdom warfare. The two accounts are propagandistic in nature, concerned primarily with the exaltation of the king and expounding on his role as the great warrior-savior in great detail. Although their propagandistic tone makes the reliability of the numbers (of troops as well as booty) mentioned there quite unreliable, they remain our only primary source on warfare, strategy, and battle moves in ancient Egypt.

Prompted by rumors of a coalition of western Asiatic rulers, Thutmose III launched a preemptive campaign into

Syria-Palestine in his first year of sole reign (ca. 1458 B.C.E.). The confrontation between the two armies took place on the plains of Jezreel across from the Canaanite city of Megiddo. Written in literary form, numerous accounts of the battle of Megiddo were engraved on Egyptian temple walls, the most extensive preserved on the walls of the Amun temple at Karnak. As in similar works of this literary genre, the author goes to great lengths to demonstrate the king's military prowess and strategic brilliance. The propagandistic tenor of the text is clear in its introductory lines, which give the complete titles of the king: "Mighty Bull, Shining in Thebes; King of Upper and Lower Egypt, Lord of the Two Lands; Menkheperre; Son of Re." The text then relates how all the victories he enjoyed in battle were granted him by "his father Re [the sun god]."

Under the pretext of quenching perceived rebellion, Thutmose III decided to march against the Asiatics at a time when they seemed to have "fallen into disagreement," when their infighting would have made them an easy target. The account engraved at the Amun temple details the events of the battle: the troops marched "out of Egypt to Gaza, then along the coast of Canaan to the entrance of the Aruna Pass" (probably the Wadi Ara near modern Hadera). Giving this account its particular historical appeal is the seemingly accurate date provided at the beginning of the narrative. The troops set out in Thutmose III's 22nd regnal year, on the 25th day of the fourth month of *Peret* (the winter season). The text also records the date that the king arrived at his destination at the city of Yehem in western Asia: year 23, first month of *Shemu* (the summer season), on the 16th day.

On his arrival, however, Thutmose III convened a council of war and received bad advice: to take "a safer route toward Megiddo." The king ignored the advice of his courtiers, deciding instead to take the dangerous crossing of "the Carmel ridge via the Aruna Pass" and enter the Jezreel Valley just outside of the city of Megiddo. He "commanded his entire army to march on that road, which threatened to be narrow. His majesty swore, saying, "None shall go forth in the way before my majesty. . . . He went forth at the head of his army himself, showing the way by his own footsteps; horse behind horse, his majesty being at the head of his army."

At seeing the king, considered a divine being, the enemy troops fled into disarray. According to the inscription preserved on a stela in Napata (a city in Nubia, in modern Sudan), the Egyptian forces then laid siege to the city of Megiddo until its leaders surrendered. The text gives a vivid description of the surrender and details the booty carried off by the Egyptian troops, giving exact numbers for prisoners of war captured (340), enemy troops killed (83), mares taken (2,041), and stallions seized (6). The text further details the finery of a gold chariots seized and records that 200 suits of armor were taken. Significantly, it does not mention the number of Egyptian troops deployed for battle, and there is no mention of how long the march (or the battle) lasted.

The battle of Qadesh, fought in the fourth year of the reign of the pharaoh Ramses II (ca. 1274 B.C.E.) at Tell Nebi

Mend on the Orontes River, was widely publicized, with many scenes of the battle engraved on the walls of several temples in Egypt and Nubia. The scenes, which proclaim the military prowess of Ramses II, propagate a version of events that claim Egyptian victory in the battle. Like Thutmose III at the battle of Megiddo, Ramses II was misled by false intelligence. The Egyptian forces were ambushed, and although both sides fought ferociously, the Hittites did not yield the land. In fact, extant Hittite records of the battle indicate that the Egyptian troops suffered a severe defeat and fled in chaos. The ensuing peace treaty between Ramses II and the Hittite king Mutewalis preserved the status quo, with both sides suffering considerable losses.

The Egyptian account of the battle of Qadesh is most significant because it indicates that the Egyptian military was subdivided into four battalions, each named after one of the major Egyptian deities. Indeed, the Egyptian versions focus on the bravery of Ramses II who, having been deserted by his infantry and chariotry, continued to fight gallantly. The poetic version of the battle surprisingly preserves a passage in which Ramses II complains that the god Amun-Re had deserted him in battle. Despite the lack of divine support, however, Ramses II is able to single-handedly defeat thousands of enemy troops. Indeed, this seems to be the sole purpose of the numerous inscribed versions of the battle: the glorification of the reigning king and the further establishment of his bravery and divinity.

Egyptian military forces were not always on the offensive. In its long history Egypt also experienced several invasions by the armies of other Near Eastern nations: the Nubians, Assyrians, and Persians, and later the Greeks and Romans, all invaded Egypt. At the end of the New Kingdom, Egypt witnessed a period of political fragmentation known as the Third Intermediate Period (ca. 1070–ca. 712 B.C.E.). During this period several rulers simultaneously claimed the kingship of Egypt. Occasionally these rivaling dynasts fought over territorial hegemony. Sometime in the early to mid-seventh century B.C.E. Egypt's southern neighbor in Sudan, the kingdom of Napata, rose to power. One of its earliest rulers, Kashta, marched north and may have controlled all the area to the south of Egypt up to Aswān. Located at the first cataract, Aswān was Egypt's traditional southern border. Kashta's sons, Piye and Shabaka, invaded Egypt several times: Piye twice in his fourth and 20th regnal year and Shabaka in his second year. The Nubians eventually succeeded in having a firm grip on Egypt; from 715 to 671 B.C.E. they fully controlled Egypt as its Twenty-fifth Dynasty. The penultimate ruler of that dynasty, Taharqa, was a military man who had spent the early part of his career leading his predecessor's armies. Taharqa tried to expand Egypt's northeastern frontiers.

Assyria was the main military force in the ancient Near East at the time, with a strong presence in Palestine. Taharqa's ambitious military intervention in western Asia may have prompted several subsequent Assyrian invasions into Egypt (in 674, 671, and 667–666 B.C.E.). The Assyrians' invasion of

Egypt was a natural consequence of its need to secure Palestine's southern boundary. They left Egypt only after installing their Egyptian ally, Psammetichus I (664–610 B.C.E.), as a vassal king. Psammetichus I succeeded in driving Tantamani, the last Nubian ruler of Egypt, from Egypt, having chased his armies all the way to Nubia in the Sudan. Psammetichus I and his successors of the Twenty-sixth Dynasty relied heavily on the use of mercenaries. Cretans, Greeks, and Jews were among the many nationalities employed in the Egyptian military at the time.

But perhaps the most devastating of all invasions was the Persian invasion of Egypt in the spring of 525 B.C.E. Having swept through the Near East, the Persians conquered Egypt and ruled it for more than a century. An Egyptian revolt in 401 to 399 B.C.E. led to the expulsion of the Persians from Egypt. Shortly thereafter, in 343 B.C.E., the Persians reconquered Egypt. This time their rule of Egypt was short lived. After a brief decade Alexander the Great invaded Egypt in 332 B.C.E.

After Alexander's sudden death his generals divided the territories he had conquered. Egypt fell into the hands of General Ptolemy, who declared himself king of Egypt. His decedents constitute the Ptolemaic Dynasty, and the period from 305 to 30 B.C.E. is known as the Ptolemaic Period. The last Ptolemaic ruler was none other than the famous Queen Cleopatra VII. Egypt was finally annexed to the Roman Empire after Cleopatra and Marc Anthony's defeat at the naval battle of Actium in 30 B.C.E.

THE MIDDLE EAST

BY KIRK H. BEETZ

In the ancient Near East the objective of warfare was the capture or defense of a capital city. The original cities of Mesopotamia were sacred, the homes of specific gods in the religions of the peoples of the area. When a city became the urban center of a state consisting of towns and villages, it retained its central place in the hearts of its populace. To capture a capital was to capture the hearts of its people and usually to bring the end of resistance.

Until about the era of the Neo-Assyrian Empire (1050–609 B.C.E.) another objective of war was to slaughter the enemy, and prisoners of war were typically executed. Even though the Neo-Assyrians were especially bloodthirsty, they changed the practice of routinely killing prisoners, because they valued their prisoners as potential slaves and tended to ship them off to parts of their empire where labor was wanted.

The archaeology of Near Eastern warfare before about 1200 B.C.E. is sketchy, but the scant physical evidence is often all that speaks of wars. Even after writing became common, war records usually contained the statistics of victory—such as how many of the enemy were killed, how many were captured, and what sort of loot was found—rather than descriptions of tactics, military organization, or even the reasons for the wars.

BEFORE 3500 B.C.E.

Warfare seems to have been a constant preoccupation for Near Easterners, even as far back as the end of the last great ice age. One archaeological site that indicates this is Jericho. Sometime between 10,000 and 8000 B.C.E. a giant stone wall was erected around a settlement at Jericho. It seems to have been intended to protect a small population and a spring. Of special interest to military historians is a stone tower attached to the wall. The tower was about 35 feet high and built solidly, with a stone staircase up the middle. The great antiquity of the tower is significant because of the tower's sophisticated design, which suggests that its builders drew on a tradition of erecting similar towers. The reason Jericho was fortified at such an early time is unknown, as is the identity of the enemy. Speculation has tended to focus on the spring and the likelihood that Jericho was a farming community. Nomads may have coveted the harvests of Jericho, and traders traveling the ancient trade route that passed through Jericho may have coveted the water flowing from the spring.

The physical remains at Jericho offer some idea of what warfare may have been like. An important point to consider is the significant expense of fortifications. Instead of farming more land or producing more goods, valuable time and thought were devoted to building walls and at least one large tower. It is logical to suppose that if the massiveness of the walls and tower were unnecessary, the society of Jericho would have built a less imposing fortification. Thus the structures' heavy-stone construction, great height, and massiveness indicate that the enemy could bring down or penetrate walls built of wood or small stones. This suggests that at that early date, attackers already knew about using sappers to undermine walls and fire to burn walls and may have even used battering rams. The tower's height may have been for guards to watch for enemies, which would mean that attacks could come unexpectedly. On the other hand, the tower was situated so that people on it could fire arrows or hurl stones at anyone attempting to scale the walls. Altogether, the evidence indicates that people were already thinking carefully about how to wage war.

Farther north, in present-day Turkey, another city offers hints about war. Çatalhöyük, established before 7200 B.C.E., was built to resemble a beehive. The city had no roads or footpaths, and its interlocking buildings had few, if any windows and no conventional doors. People moved from place to place by climbing ladders through openings in their ceilings and walking across roofs, occasionally climbing or descending where buildings were of different heights. The dominant theory about why the city was built as it was focuses on military defense. An enemy, whether bandits or a full army, would have had no clear entrance to attack. Attacking and entering an outer building would have left the enemy with nowhere to go but up a ladder, and defenders could heap stones, arrows, and burning oil on them. Seizing the city would have required fighting to take each building. Archaeologists believe that the

lack of evidence that Çatalhöyük was ever taken by force indicates that its defensive layout was successful.

**EARLY DYNASTIC PERIOD
(CA. 3000–CA. 2350 B.C.E.)**

By 3000 B.C.E. the numerous Sumerian cities established in southern Mesopotamia were already warring against each other. For several reasons the waging of war was not a simple matter of a king deciding to take his army to battle. First, there were no standing armies. Early Sumerian armies consisted of militias of free male citizens. Second, kings were not absolute rulers and had to gain consent from a council of elders or an assembly of citizens. For instance, during the rule of Gilgamesh (r. ca. 2700 B.C.E.) the city of Uruk received a demand to surrender itself to the dominance of another city-state. Gilgamesh wished to fight for his city's freedom, but Uruk's council of elders voted to surrender. Gilgamesh called for an assembly of Uruk's free citizens, and the assembly overruled the council of elders and voted to fight to remain free.

Another difficulty was that typically citizens were expected to provide their own weapons: spears, daggers, stone maces, bows and arrows, and slingshots. Although shields were available, a warrior usually carried his weapon in both hands and had a dagger strapped to his side. Protective armor was typically no more than a hat of cloth or leather. Battles in open land consisted of barrages of arrows when armies were less than 300 feet apart, because the bow of the time was accurate only up to that distance. The barrage could be followed by a charge. The enemy would meet the charging warriors with spears and rocks hurled from slingshots. A battle between big city-states could result in 10,000 dead.

Gilgamesh was famous as a city builder. Songs and poems lauded him for the great wall he directed to be built around Uruk. It was constructed from fired clay bricks, which were expensive but durable for the time; good stone for building was hard to find in southern Mesopotamia. The wall was wide enough for two chariots to pass side by side, and it had many towers. Such defenses were necessary because military leaders were learning how to organize their troops for coordinated attacks that could overwhelm lesser defenses with the sheer number of warriors scaling the walls.

By the end of the Early Dynastic Period, an arms race had developed. Bigger walls meant bigger weapons for knocking walls down. Skulls crushed by maces led to the development of metal helmets, which in turn resulted in the invention of a battle-ax that could crash through metal. This, in turn, created the need for sturdier helmets, leading to the development of new casting techniques and then sturdier ax blades that curved, making cutting through helmets easier.

**OLD AKKADIAN EMPIRE
(CA. 2350–CA. 2100 B.C.E.)**

The king who founded the Old Akkadian Empire may have been history's first military genius. Sargon I (r. 2334–2279 B.C.E.) established what is thought to have been the first

Clay prism of King Sennacherib, ca. 689 B.C.E., upon which are recorded eight successful military campaigns against various peoples who refused to submit to Assyrian domination (Courtesy of the Oriental Institute of the University of Chicago)

standing army, consisting of 5,400 men, with whom he ate daily. The Sumerian battlegwagon was a clumsy vehicle, with four heavy wheels and pulled by onagers—wild asses from central Asia. In battle Sargon and his commanders would ride the wagons more for transportation around the battlefield than for use in combat, but from the battlegwagons archers could fire on the enemy while staying out of the way of counterattacks.

The use of formations in battle and one great advance in weaponry may have been behind Sargon's ability to crush his enemies and build the world's first great empire. The advance was the composite bow. It consisted of an inner layer of bone, a middle layer of wood, and an outer layer of leather. Sometimes more than one kind of wood was used, all to give the bow more power. The result was that Sargon's archers had a range almost 200 feet greater than that of enemy archers. By having his army fire on the enemy long before the enemy

could return fire, he forced opponents into disastrous charges against well-organized formations of warriors with spears at the ready, or opponents fled because they could not come to grips with his warriors.

Sargon's successors continued to innovate. Perhaps their most significant contribution to military history was the development of specialized units within the army. Rather than having every warrior fight with every weapon, they developed units of archers, spearmen, slingshot specialists who backed up the spearmen, and charioteers.

NEO-ASSYRIAN EMPIRE (CA. 1000–CA. 626 B.C.E.)

The foremost practitioners of war of the ancient Near East were the Assyrians. They did not begin that way. Originally they settled in a mountainous region through which several trade routes passed, making their living as traders and farmers. Both trading and farming would remain vital to the economy that funded the Assyrian military. During the Old Assyrian Period (ca. 1813–ca.1365 B.C.E.) Assyria's wars tended to be reactions to aggression. Their mountains did not afford them much protection, and their harvests attracted the greed of nomads to the north and city-states to the south.

The archer was the most important weapon in the Assyrian army. The Assyrians developed a pairing of an archer with a shield bearer. The shield was composed of reeds with an outer covering of animal skin or metal. It rose higher than the heads of the shield bearer and archer, curving up over the bearer's head. It was intended to allow the archer to focus on his job of shooting the enemy while someone else worried about keeping him alive. Both bearer and archer were usually armed with daggers for hand-to-hand fighting, but it was the Assyrian commander's intention to keep his archers away from direct contact with the enemy.

During this period the Hittite Empire (ca. 1650–ca. 1200 B.C.E.) had developed to the west, in present-day Turkey. The Hittites introduced the phalanx to warfare in the Near East. The Hittite phalanx consisted of a block of soldiers who marched toward the enemy in lockstep with spears evenly spaced. The soldiers were heavy infantry, wearing weighty uniforms draped with iron plates. The Hittites' tactics involved trapping enemies into direct encounters with the heavy infantry, whose skills and armor surpassed those of others in the Near East. Further, the Hittites used chariots as true offensive weapons. Their units of chariots moved swiftly across battlefields, pulled by horses and using spoked wheels.

In about 1200 B.C.E. the Hittite Empire collapsed. Raiders whom modern historians call the Sea Peoples cut off some of the Hittites' trade routes to the south, and the Assyrians cut off their trade routes to the east. Their capital was sacked. This left openings for lesser kingdoms to expand, and it left much of the territory to the west of Assyria open for conquest.

In 1595 B.C.E. Assyria had become a vassal of the Mitanni Kingdom, but that kingdom was absorbed by the Hit-

tites during the 1300s B.C.E., giving Assyria a chance to assert its independence, which it did under King Ashu-uballit I (r. ca. 1365–ca. 1330 B.C.E.). Thereafter, the Assyrians embarked on centuries of military adventures, not all successful. King Shalmaneser I (r. ca. 1273–ca. 1244 B.C.E.) secured Assyria's northern frontier with wars in central Asia. King Tikulti-ninurta I (r. ca. 1244–ca. 1208 B.C.E.) attacked Babylonia in 1220 B.C.E., occupying the city of Babylon until 1213 B.C.E., and he spread his conquests into the Zagros Mountains to the east before he was assassinated by one of his sons.

The Assyrian Empire thereafter fell apart, pulled itself together, and fell apart again. As the Neo-Assyrian Empire it reached its zenith and gained the military reputation that it now has. The Neo-Assyrian society was geared toward making war. Its people came to rely on war as a source of luxury goods. Their boys were trained almost all their lives to be warriors, and military service was not only expected of all young men but also considered the best thing a man could do. At the same time women were repressed. They were required to wear robes that totally covered them when they were out in public, and their principal purpose was to bear boys for the military. Newborn girls were often killed because they were considered valueless.

The Neo-Assyrian military machine was a master of propaganda. It advertised its victories, spreading accounts of the horrors it had visited on its opponents. Before attacking a major stronghold such as Jerusalem, it would attack surrounding villages and towns, slaughtering the inhabitants as a display of power to discourage the defenders of the stronghold. Typically, an Assyrian envoy would stand outside the stronghold to ask in the Assyrian language that the defenders yield to the greater might of Assyria. This would involve detailing some of the horrors visited on those who resisted Assyria. Sometimes the authorities of the stronghold would agree to surrender, and usually the Assyrians would let the residents live, though they would require a very heavy tribute and force some of the men to join their army.

Often the authorities of the stronghold refused to surrender. Then the Assyrians would speak to the defenders in their native language, telling them of how they would suffer once the Assyrians won the battle. The hope was that the common people would rebel rather than endure the misery of an Assyrian victory. Thereafter tall stakes would be driven into the ground within view of the defenders, and captured soldiers and civilians would be impaled on the stakes. This was intended to demoralize the defenders. Then prisoners would be taken in view of the defenders and tortured in ways that Assyrian scribes recorded in agonizing detail. Sometimes the victims would be put in cages on carts that were pulled in circles around a besieged city to display to as many people as possible the torture being inflicted. Such events were recorded on stone walls and monuments throughout the empire to frighten anyone who might wish to rebel.

By about 722 B.C.E. the Assyrian government had adopted a policy of avoiding fighting as many of the enemy as

possible. The extraordinary cruelties inflicted on people were intended to inspire others to surrender rather than fight. Typically, in a city that did not surrender, the Assyrians raped every woman or girl they found and killed the military-age men. Boys would be made slaves. Captive populations would be shipped to parts of the empire where the Assyrian government could watch them and where they were wanted as forced labor, because the Assyrian government was depleting its lands of workers through its relentless warfare.

The Assyrians established storehouses throughout their empire, where their army could find supplies when it moved. At the core of the army was the *qurbuti*, the royal guard. This consisted of elite troops from Assyrian nobility. Assyrian kings often led their troops in battle, and the *qurbuti* accompanied them. When the king was not present, the commanding officer was the *tartanu*, who was to be obeyed as if he were the king. The army also had cavalry, called *pethallu*. However, the principal fighting units were the infantry and the chariot regiments. The most important fighters in the infantry remained the archers, who carried 50 arrows in their quivers. Most of the rest of the infantry was supposed to protect the archers. Sometimes the Assyrians fielded an army whose infantry consisted only of archers and their shield bearers. Of greatest importance were the chariots.

The Assyrian chariot was a swift vehicle, with a metal undercarriage making it tough and durable. Its spoked wheels had metal-studded rims and blades projecting from their hubs. Assyrian chariots moved as units and were used to break up enemy infantry lines. With two horses pulling each, the chariots would charge not as a line parallel to the enemy line but as a column perpendicular to the enemy line. One after another the chariots would smash into the line and then disperse as they spread the enemy line apart, their bladed wheels chewing through enemy infantry. Assyrian tactics were intended to terrify an enemy, and the chariots were truly frightful.

The driver of an Assyrian war chariot had to press forward against the front screen of the chariot to hold himself steady. On a light chariot the only other passenger was an archer or a lancer. On a heavy chariot the car would be rectangular to hold one or two shield bearers or a warrior to defend the rear of the chariot. The lancer would be armed with spears or javelins, usually tipped with iron. Sometimes lancers were used as infantrymen.

Eventually Assyria faced a shortage of men of any age; for this reason, boys younger than military age and retired soldiers often were pressed into service. The vassal troops, rarely happy about serving far from home in wars not of their own making, were unreliable. Rebellions broke out on the fringes of the empire, the Medes to the east invaded Assyria, and the army was spread too thinly to cope with all the demands at the same time. The Babylonians and Medes raced each other to the capital of Assyria, with the Medes getting there first. Over a period of about 10 years, the surviving Assyrians were hunted down and exterminated.

PERSIAN EMPIRE (CA. 538–CA. 331 B.C.E.)

The Persian Empire is also known as the Achaemenid Empire, named for its founder Achaemenes (r. ca. 600s B.C.E.). The first great Persian military leader was Cyrus the Great (r. ca. 559–ca. 529 B.C.E.). Persian soldiers were especially skilled in the use of slings and bows and arrows, perhaps a result of their origin in mountains in Iran, where hunting with such weapons would have been important. Although the Persians borrowed much of their military organization from that of the Assyrians, horses were rarely used by them in Cyrus the Great's era, relegating chariots to minor roles, whereas the infantry was of primary importance.

As was the case with the Assyrians, archers were very important to the Persian Empire. The Persians imitated the combining of shield bearers with archers, but they massed their archers behind a line of shield bearers. The shields were made of rectangles of leather stretched over rodlike willow twigs called osiers, and then the leather was allowed to harden, creating a tough but easily lifted shield. The shield bearers would form a line, one next to the other, allowing their shields to create a long, tall wall, behind which archers, also arrayed in lines, fired their arrows in volleys. Unfortunately, the shield bearers lacked weapons other than daggers for close-quarters fighting, a problem the Persian army continually tried to solve by experimenting with different kinds of weapons such as spears and curved swords.

The core of the army was the king's spearmen, the *arstibara*. After them came the *amrtaka* ("immortals"), a division of troops that gained its name from its never being allowed to be short of troops; its strength was always at 10,000. The major unit of the army was the *hazarabam*, the regiment, which had 1,000 troops. Its commanding officer was the *hazarapatis*. The *hazarabam* was divided into 10 units of 100 troops. Each unit was a *satabam*, commanded by a *satapatis*. Each *satabam* was divided into 10 companies of 10 men each. A company was a *dathabam*. On the battlefield each *dathabam* would be lined up in a column perpendicular to the front line, with its leader, the *dathapatis*, in front. The *dathapatis* carried a 6-foot spear or a large protective shield. The other nine soldiers in his company carried either bows or falchions, which were curved swords. When all the men behind the company leaders had bows and arrows, the company leaders would form a protective line of shields.

All Persian men were expected to serve in the army. A boy lived with his mother, apart from his father, until age five and then with his father, apart from his mother, until age 20, during which time he learned skills important to combat. From 20 to 24 years of age a man served in the army. His period of enlistment could be extended, and he was subject to recall to military service until he was 50 years old.

As he conquered much of the Near East, Cyrus the Great relied on vassal troops to supplement his core of Persian infantry, especially vassal cavalry. Cyrus the Great decided that his army should have a cavalry composed of Persians. Thus

he established a new unit of the army composed of horseback riders. When horses and their supplies were captured in his campaigns, he distributed them among his nobility. Then he declared that it would be considered a disgrace for any noble to be seen walking rather than riding. The cavalry would be considered an elite unit. The most prestigious unit of all would be the 1,000 horsemen drawn from the nobility and called the *huvaka* ("king's kinsmen").

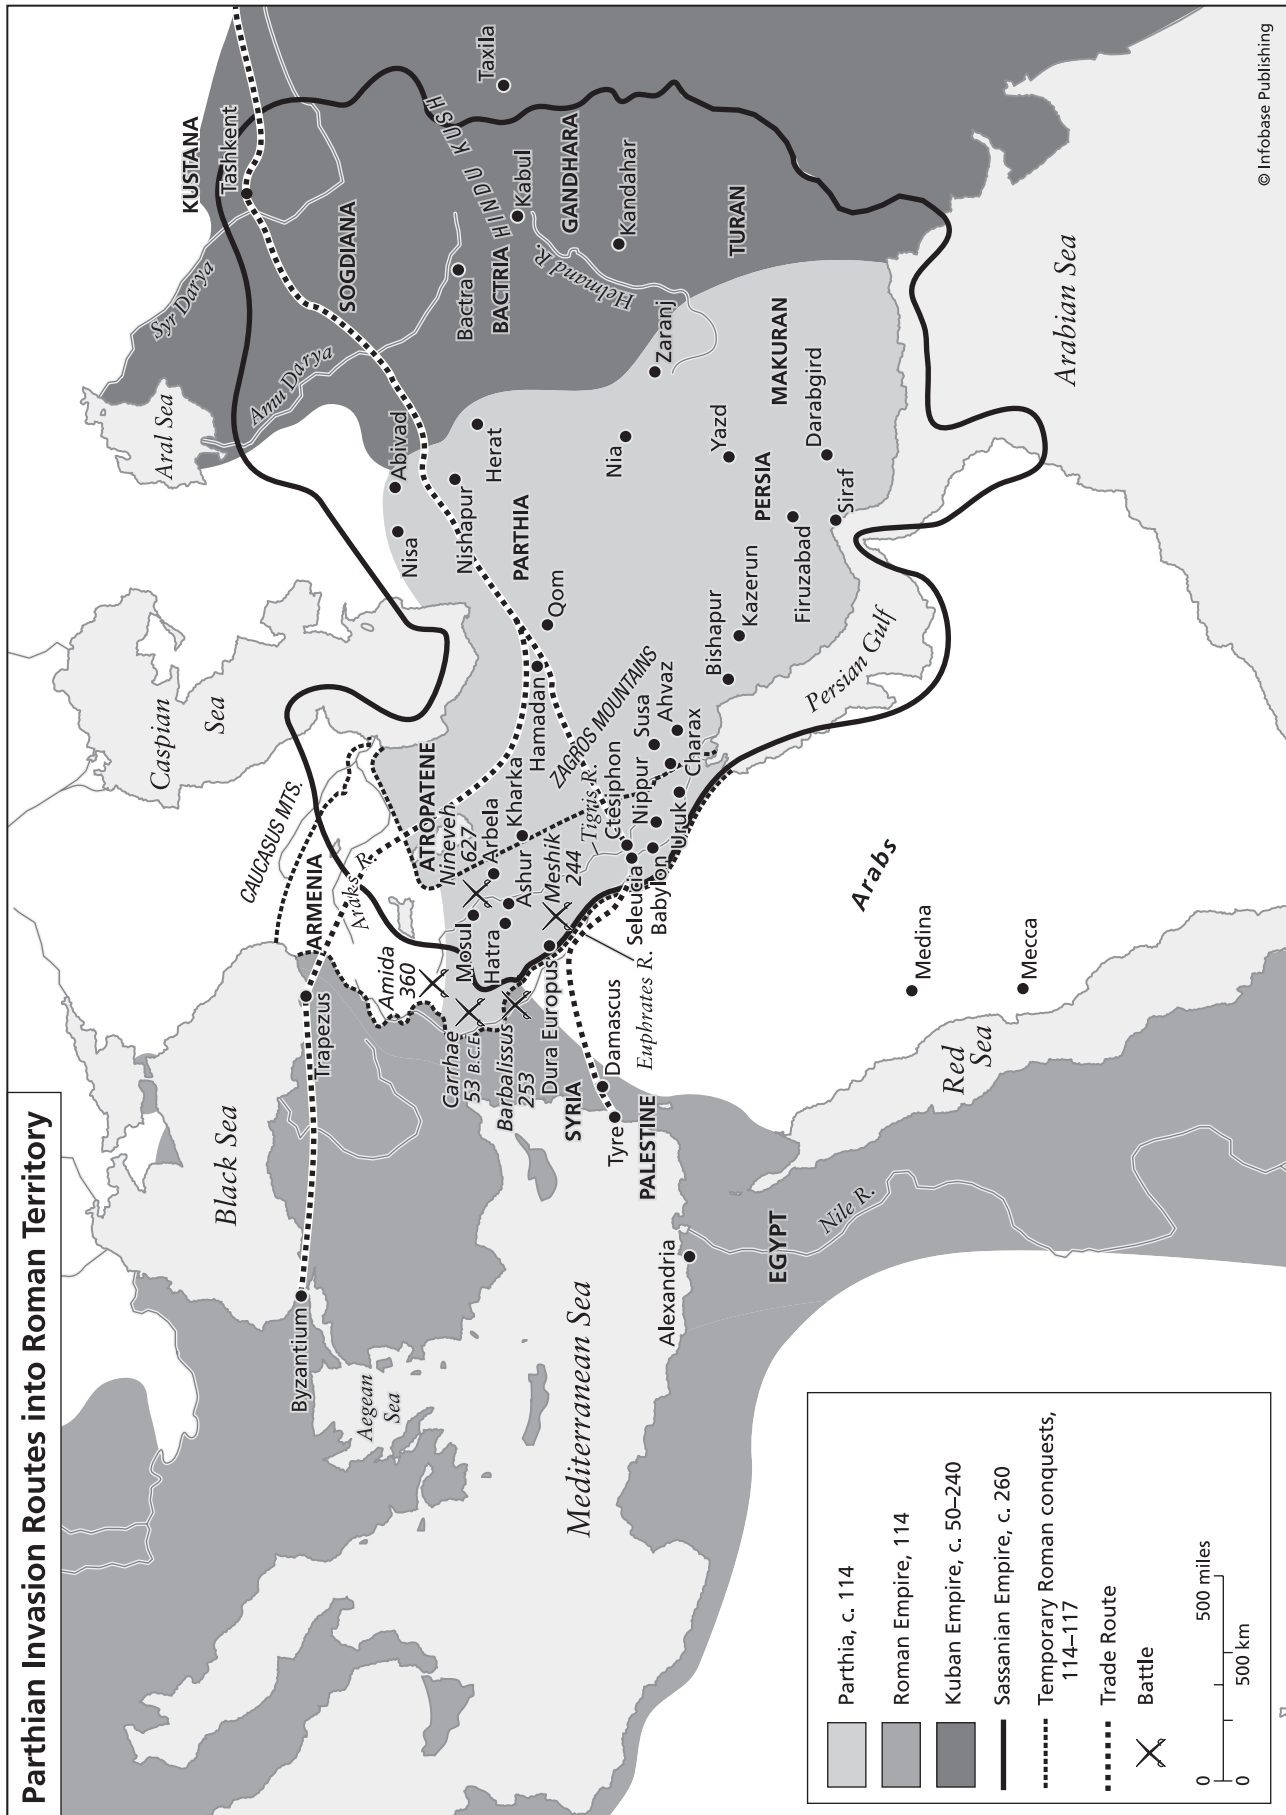

Not much is known about the organization of the Persian navy. It was developed during the reign of Cambyses (r. ca. 529–ca. 522 B.C.E.) as a response to the Egyptian navy, which had helped thwart Persian efforts to invade Egypt. It apparently borrowed ideas from the Corinthian navy, dividing its ships into units of 30 as the Corinthians did. When it was sent into battle against the Greeks in the 400s B.C.E., the Persian navy was decisively defeated. Military historians debate why this happened, but it appears that the Greek navy was more ably led and its sailors more skilled at the techniques required to disable enemy ships.

The failure of the Persian army to defeat the Greeks, first at Marathon in 490 B.C.E. and later with a massive army of between 700,000 and 1,500,000 troops, seems to have been a shock to the Near East. The perplexing methods of combat of the Scythians had been only an annoyance. The Scythians used archers on horseback, who attacked and then rode away, attacked again and rode away, and so on until the Persians stopped chasing them. In the case of the Greeks the Persians fought an enemy willing to engage in large battles of massed infantry and horsemen.

The Persian soldiers were courageous and determined fighters, but their commanders had no answer for the Greek soldier called a hoplite. The hoplites were members of heavy infantry, armed with spears and protected by shields that strapped to their forearms, allowing for a wide range of motion. Holding their shields high for protection from the Persian archers and covered by the fire of Greek archers, the hoplites were swiftly able to take advantage of changing conditions on the battlefield to close in on Persian units of archers. When the Greek style of fighting combined with the genius of Alexander the Great, the Persians often found their units outmaneuvered. From 336 to 328 B.C.E. Alexander the Great fought Persia, conquering the country just five years before his death in 323 B.C.E.

IRANIAN EMPIRES

One of Alexander the Great's generals, Seleucus I (r. ca. 311–ca. 281 B.C.E.), founded the Seleucid Kingdom (ca. 311–ca. 140 B.C.E.). The Seleucid army was most notable for its cavalry, which was probably the best in the Near East in the 100s B.C.E., but they were overcome by the Parthians, who were also famous for their cavalry. The Parthians had migrated into Iran from central Asia. The Arsacid Dynasty of Parthia was founded by Arsaces I (r. ca. 250–ca. 248 B.C.E.) and lasted from about 250 B.C.E. to 226 C.E. It was King Mithridates I (r. ca. 174–ca. 136 B.C.E.) who toppled the Seleucid Kingdom.

The Parthian and Roman armies battled each other for nearly 300 years, from the first century B.C.E. to the third century C.E.

The Parthians organized their army into 1,000-man units called dragons. The most important part of the army was its cavalry. The Parthians were master horsemen who developed the Parthian shot. A Parthian shot occurred when a horseman pretended to be fleeing and then twisted in his saddle to shoot backward at his enemy. The army combined unarmored horse archers with cataphracts—cavalry with heavy armor and arms. The light cavalry harassed the enemy while the cataphracts hammered enemy lines. Cataphracts were recruited from the retainers of Parthian nobility. Sometimes mercenaries were employed for other units.

The effectiveness of Parthian tactics and troops was shown in the Battle of Carrhae in 53 B.C.E., in present-day Turkey. A Roman army invaded Parthia, led by Marcus Licinius Crassus (115–53 B.C.E.). When he learned where the Parthian army awaited him, he had a choice of two routes. He took the route that crossed open land. The Parthians had anticipated his taking the other route, and their main army was waiting there for him. Mostly light cavalry was all the Parthian army had to fight Crassus's army in the open route. The Parthians gamely attacked, harassing the Romans with arrows. Crassus pulled his army into a square, open in the middle. The Parthian cavalry circled the Romans and fired without taking care to aim; the Roman formation was dense, and its troops were easy targets. After losing 20,000 men without ever coming to grips with the enemy, the Roman army retreated.

The Parthian Empire eventually fell to an insider rather than from invasion from the outside. Ardashir I (r. 224–241 C.E.) overthrew the last Arsacid king, founding the Sassanian Empire (226–641 C.E.). The Sassanian army had infantry, horse cavalry, and war elephants. The infantry mostly comprised spearmen who were ordered to hold their positions against attack. The cavalry were well armored and responsible for breaking up enemy formations. The elephants carried towers containing archers. Before battle the army arrayed itself into three parts. In the center, typically the largest part, were archers and the elephants. Although horses were armored, the elephants were not; they were protected instead by an escort of infantry.

ASIA AND THE PACIFIC

BY MICHAEL J. O'NEAL

Warfare in the modern world is typically waged between nation-states. For various reasons one of these states, with its own clearly defined borders, chooses to go to war with another. While civil wars continue to plague some countries, modern warfare has most often been between nations rather than within nations.

Warfare in the ancient world, including Asia, often had a different purpose. Modern nations such as China, India, Korea, and Japan did not always exist as clearly defined nation-states, with fixed borders and a central government accepted by the entire population. These regions tended to be more in the nature of collections of smaller kingdoms. Sometimes

these kingdoms united to form larger states. Just as often, though, they fought with one another as one tried to extend the reach of its authority and influence. While external enemies remained a threat, internal enemies often were the target of warfare and conquest. The result was a long, bloody process of uniting regions into larger nations.

CHINA

The dominant military power of ancient Asia was China. In the absence of any records, little is known about war and conquest—or any other topic—in prehistoric China. China as a nation began to emerge during the era called the Three Sovereigns and Five Emperors, followed by the Xia Dynasty. Most of what is known about these eras is legendary, even mythical, although archaeological finds have confirmed that at least some of what was written about them by later Chinese writers is probably based in fact. The known history of China begins with the Shang Dynasty (sometimes referred to as the Yin Dynasty), which ruled from about 1500 to about 1045 B.C.E. Much of the history of the Shang and the dynasties that followed into the Common Era is a history of internal warfare and rebellion.

The Shang Dynasty itself began in war, for historians believe that the dynasty's founder was a rebel who overthrew the earlier Xia Dynasty. Over the next several hundred years the Shang emperors fought a series of wars to defend their realm, which encompassed primarily northern China, from invaders from the steppes (vast, open grasslands) of inner Asia. At this point China as a nation was by no means fully formed. The region consisted of numerous settlements and city-states that did not coalesce into a unified nation until much later. Thus, warfare was typically a matter of conflict between neighboring city-states as they jockeyed for power and tried to extend their authority over a broader region.

The Shang Dynasty was overthrown by the Zhou Dynasty in about 1045 B.C.E. The Zhou were a people who had settled to the west of the territories ruled by the Shang, and for a long period they submitted to Shang authority. But as the Zhou population grew, its region became more powerful than that controlled by the Shang, particularly since the Shang were continually waging war with northern invaders. Thus, the Zhou defeated the Shang and established a dynasty that ruled 200 to 250 city-states until 256 B.C.E.

Their reign was not without complications, however. Barbarians from the north, particularly the Xiongnu, a nomadic people who controlled a large central Asian empire, continued to invade Chinese lands. (The Xiongnu are frequently referred to in the literature as Huns, but they are not to be confused with the Teutonic Huns of Europe.) In 771 B.C.E. they successfully overran the western portion of the Zhou lands, including its capital city. The king was killed, and his son fled to the east. Thus, the Zhou Dynasty is divided into two periods, the Western Zhou (1045–771 B.C.E.) and the Eastern Zhou (770–256 B.C.E.) The Eastern Zhou is further divided into two periods. The first, called the Spring and Autumn Period, was a time of great instability. Among the large number of Chinese city-

states, no single state had much power. Thus, they joined into a series of continuously shifting alliances as a way of defending themselves from the northern barbarians.

The name of the second phase of the Eastern Zhou, the Warring States Period, gives a clear indication of the nature of Chinese life during this time. Many of the military and political alliances that had been forged during the Spring and Autumn Period fell apart. China descended into considerable chaos as various states tried to fill the power vacuum and absorb other states, and the Zhou emperor ruled in name only. Warfare between states was nearly constant. By the end of the period, instead of hundreds of city-states, the number was eight or nine, with each vying to gain control of all of China. The nature of warfare changed dramatically during this period. Earlier, war had been conducted in feudal fashion, with aristocratic nobles each leading his own small army. During the Warring States Period armies became much larger and were made up of professional warriors.

It was during the brief, but ruthless Qin Dynasty that China's kingdoms merged for the first time into an imperial nation. The Qin emperors, who ruled from 221 to 207 B.C.E., confiscated all weapons, including those of the nobles who had fought during the Warring States Period. This step was taken to prevent uprisings. The Qin rulers also expanded China's borders by going to war against the northern barbarians. During the Warring States Period nobles had built walls and fortifications to defend their realms. The Qin emperors ordered that all these walls be linked to form China's first great wall to keep out foreign invaders. (The Great Wall of China familiar to tourists was built much later, under the Ming Dynasty.)

Despite the efforts of the Qin rulers to quell dissent and rebellion, they were unsuccessful. Near the end of the dynasty the nobles began to reassert their power. Peasants, prisoners, and soldiers rebelled. The result was the overthrow of the Qin Dynasty and the creation of the Han Dynasty, which ruled until 220 C.E. The Han Dynasty, however, began with an interregnum period from 206 to 202 B.C.E. called the period of Chu-Han Contention. During this period, in the vacuum created by the overthrow of the Qin Dynasty, two factions emerged that went to war to determine which would lead the kingdom. One faction was the Han people; the other was the Chu. These factions were led by the nobles who had been stripped of their power during the Qin Dynasty. The numerous battles these two sides fought—the battles of Julu, Pengcheng, Lingbi, and Xi River, for example—became part of the cultural identity of the Chinese and are still depicted in Chinese movies, television shows, and even board games. The power struggle was fierce; at times the warring armies were as large as half a million men. After the tide shifted back and forth several times, the Han, led by Liu Pang (r. 206–195 B.C.E.), emerged victorious and created the Han Dynasty.

The Han Dynasty tried to scale back the level of warfare. To the north the rulers paid tribute to the Xiongnu and tried to buy peace through intermarriage. The dynasty also tried to appease other neighboring nomads, which continued to be a

threat. At the same time, the Han Dynasty used its superior military force to extend its borders into the regions of present-day Vietnam and Korea. The military also functioned to keep open the Silk Road, the trading route that eventually extended westward all the way to Rome. In 154 B.C.E. the military had to put down the Rebellion of the Seven States, led by several minor princes who objected to the Han Dynasty's efforts to centralize the government. The rebellion was marked by initial ferocious fighting, but in the end it lasted only three months.

Less than three decades later the Han Dynasty concluded that its treaties with the Xiongnu were ineffective and costly. In 129 B.C.E. a force of 40,000 Chinese cavalry attacked. Warfare persisted intermittently until 119 B.C.E., when a Chinese force of 100,000 cavalry and 200,000 foot soldiers drove the Xiongnu into the Gobi Desert. The campaign, while successful, was costly; the Chinese took 140,000 horses into the desert, but fewer than 30,000 returned. The Xiongnu, however, just would not go away. In the first century of the Common Era, China dispatched one of its most famous generals, Pan Ch'ao (31–101 C.E.), to subdue them and drive them out of the Tarim Basin to China's west. In 97 C.E. he commanded an army of 70,000 men to drive them even farther west; he went as far as the Caspian Sea, where he struck an alliance with the Parthian Empire. Despite all of China's successes against the Xiongnu, in 311 C.E., 100 years after the end of the Han Dynasty, the Xiongnu sacked Luoyang, the capital of the Han.

One of the last military actions of the Han Dynasty was the suppression of the Yellow Turban Rebellion, sometimes called the Yellow Scarves Rebellion. The rebellion took place in 184 and was led by Daoist peasants who objected to the regime's decision to make China a Confucian rather than a Daoist state. Despite fielding an army of 360,000, the rebels were unsuccessful and were put down in 185. Fighting erupted again in 186, 188, and 192, when the rebellion was finally ended.

For many historians, the Yellow Turban Rebellion, so called because of the yellow headscarves the rebels wore, was the unofficial start of the Three Kingdoms Period (220–263 B.C.E.) that followed the Han Dynasty. Again, China was wracked by instability. The "three kingdoms" were those of Wei, Shu, and Wu, though they were not really kingdoms but regions whose emperors each claimed to be the legitimate heir to the Han Dynasty. The period was marked by a great deal of infighting, which eventually led to the defeat of the Shu by the Wei. The Wei, in turn, were then defeated by an alliance of the Wu and the Jin Dynasty (265–420 C.E.). The period was extremely bloody, with a large percentage of the population killed during the wars that raged from about 190 to 280. On the heels of these civil wars came the War of the Eight Princes (also called the Rebellion of the Eight Kings or Rebellion of the Eight Princes), another period of civil war from 291 to 306 C.E. The rebellion was centered in northern China. Again, it led to huge population losses, which greatly reduced the power of the Jin Dynasty. The dynasty itself was rent by divisions, leading to the creation of the Western Jin Dynasty (265–316 C.E.) and the Eastern Jin Dynasty (317–420

c.e.). One of the most important battles in ancient Chinese history was the Battle of Fei in 383 c.e., when the numerically inferior eastern Jin army defeated the surviving western Jin to claim control over the throne.

One of the results of this long history of warfare was the production of texts about military strategy. One is referred to as the “Thirty-Six Strategies.” The origin of the book is shrouded in mystery. Historians generally believe that it was compiled by a General Wang during the Warring States Period. It consists of a number of proverbs about warfare, many of which were probably traditional by that time. The number 36 is a figure of speech used to refer to “numerous” strategies, divided into six sections. To cite one example, the text advises military commanders to “deceive the sky to cross the ocean.” The text explains this precept by saying that the clever commander hides his true intentions by going about daily activities in full view of the enemy; hiding or moving about in the darkness only attracts suspicion.

The other great military text from ancient China is *The Art of War*, written, it is thought, in the sixth century by Sun-tzu. The book has 13 chapters and is still regarded by military planners as the definitive treatise on military strategy—particularly on how to win a battle or war without actually fighting but rather by outsmarting the enemy. The book continues to be required reading for officers in Asian militaries. Many of the book’s statements have become proverbial, such as the famous quote “All warfare is based on deception.” The book was rediscovered in the West in the 1980s when corporations and political candidates began using its precepts to plot business or campaign strategies and outsmart their rivals. The book has also entered the popular culture in the West, with numerous references to it in movies, plays, sports, music, board games, and television shows.

Based on these and other texts, as well as on the archaeological record, historians and archaeologists have been able to reconstruct the nature of warfare in ancient China. They know, for example, that weapons during much of ancient China’s history were made of bronze. Examples include the spear, whose point was made of bronze, and the dagger-ax, which was primary weapon of foot soldiers. A dagger-ax consisted of a dagger-shaped blade mounted perpendicularly on a wooden haft, or handle. Often the blade consisted of a dagger on one side and a scythe-shaped blade on the other. Other weapons included the sword, many quite elaborate and ornate, and the crossbow. Chinese soldiers also wore armor, which tended to be light and flexible rather than heavy and thick, trading the stopping power for speed and maneuverability. The Chinese invented gunpowder, probably in the third century c.e., but gunpowder was not used as a component of military weapons until much later.

The horse-drawn chariot was a primary instrument of war. Ancient China was a feudal society, and there emerged a warrior class that emphasized the skills of horsemanship and the handling of the chariot. Horseback riding tended to be difficult for Chinese men, who wore robes rather than trousers, but skills in military horsemanship were highly

developed among members of the aristocratic warrior class, and many troops stormed into battle on horseback. In about the fifth century c.e. the stirrup was introduced, allowing mounted warriors to retain stability and balance and so fight on horseback with swords and lances.

Early warfare tended to be ceremonial and ritualized. As time went on it became more brutal and bloody. Much emphasis was placed on deception and tricking the enemy. Also common was siege warfare, where an attacking army surrounded a city, bombarded it with missiles launched by catapults, and wore down the residents over time. In more conventional battles the norm was not to arrange regiments of troops in a fixed order of battle but rather to rely on firepower using crossbows. Large numbers of archers loaded their weapons, took aim on the order of their commander, and then fired simultaneously, in this way overwhelming the enemy by the sheer number of arrows that had to be ducked.

Naval warfare played a major part in the history of ancient China. During the Qin Dynasty, for example, China had a fleet of ships capable of transporting close to one million pounds of grain to feed troops during war. The Qin also had a fleet of *lou chuan*, or “castle ships,” with large, elevated decks. The Han continued to build warships, and its fleet reached 2,000 castle ships able to carry 200,000 seamen.

INDIA

The history of warfare and conquest in ancient India in many ways parallels that of China. Rather than being a unified nation-state, India was a collection of numerous smaller kingdoms. At times the number of kingdoms was as few as 16. Such was the case during the Iron Age in about 500 b.c.e., when the 16 kingdoms were collectively called the Mahajanadapas. At other times the number of kingdoms and principalities was much larger, as many as 100 or more. As in China, these kingdoms often competed with one another for territory and resources, so they often went to war. Warfare, though, was conducted on a smaller scale than it was in China and consisted primarily of border skirmishes.

India, however, faced more external threats than did the Chinese. Like China, India was subject to invasion by barbarians from the north. One of the greatest civilizations of the ancient world, the Indus Valley civilization, was destroyed by northern Aryan invaders in about 1600 b.c.e. Additionally, in the fifth century b.c.e. India was invaded by the Persians under the king Darius the Great (r. 522–486 b.c.e.) and was ruled by the Persian Empire for nearly 200 years until Macedonia, under the leadership of Alexander the Great (r. 336–323 b.c.e.), conquered the Persian Empire, including its holdings in India. One of the key events in this conquest was the Battle of the Hydaspes River (now called the Jhelum River) in 326 b.c.e. Alexander invaded to subdue the various Indian kings, but one, Porus (d. between 321 and 315 b.c.e.), who ruled the area around Punjab, resisted. Alexander sent a large army against him. Porus and his army put up fierce resistance, but eventually Alexander won and made the area the eastern border of his empire.

India as a unified empire did not flex its military might until the Maurya Dynasty, which maintained a standing army of three-quarters of a million troops, most belonging to a warrior caste. The empire, founded about 321 B.C.E. by Chandragupta, was based in eastern India but in time stretched across western, central, and portions of southern India. One of the greatest achievements of the Maurya was the liberation of those parts of the country that were occupied by the Macedonians. One of Chandragupta's ministers, Kautilya (fl. 300 B.C.E.), wrote a text called the *Arthashastra*, a book that examined the military arts along with politics, economics, and other subjects.

One of the most important rulers of the Maurya was Chandragupta's grandson, Asoka (r. ca. 265–238 B.C.E. or ca. 273–232 B.C.E.). Early in his reign Asoka was a talented military commander. His major achievement was to lead a large army against the Kalinga, one of the kingdoms of southern India. Although he triumphed, he lost an estimated 10,000 troops, and when he saw the devastation the war had caused both to the armies and to the civilian population, he renounced war and accepted the teachings of Buddhism. However, as many historians note, he had no further reason to go to war, for he had successfully united most of what is modern-day India.

Stone figure of the war god Skanda, from eastern India, eighth to ninth century C.E.; Skanda was a popular deity in ancient India. © The Trustees of the British Museum

In the centuries that followed the end of Maurya rule, India again fragmented. The invading Kushans established an empire that stretched across the center of India. The later Gupta Empire, which ruled from C.E. 240 to 550, again united India, primarily because of its strong military organization.

One of the most important military weapons of the Gupta Empire, as well as the empires of its predecessors, was the chariot. Indian chariots were more like troop-transport vehicles, in contrast to the light Roman and Egyptian chariots that normally come to mind. They carried at least two men—the driver and an archer—but many carried up to seven and were so heavy that four and even six horses were needed to pull them. Sometimes the chariots were simply driven at high speed into the middle of a fight, where their large wheels crushed enemy infantrymen. Meanwhile, the archers were as high as six feet off the ground, giving them a tactical advantage over enemy troops on the ground.

Another important tool used by Indian armies, which came into use in about 1500 B.C.E., was the elephant, which Indians continued to use in war until the 19th century. Elephants were a measure of wealth and prestige; Chandragupta's army had more than 21,000. Elephants were analogous to modern-day tanks. They were covered with armor and often had long daggers, sometimes poisoned, attached to their tusks. Each elephant provided protection for as many as six infantrymen, who fought with bows and arrows, lances, and javelins and then retreated behind the elephant when necessary. Elephants were also used to break down walls and enemy fortifications. One battle tactic, used by Porus at the Battle of Hydaspes, was to range the elephants in a line, providing a kind of moving fortress or wall. Like chariots, they were often driven directly into the battle, crushing enemy troops underfoot as archers mounted on the elephant's back shot at men below. Some elephants were even trained to swing weapons such as balls and chains back and forth.

Unlike China, which made extensive use of horse-mounted cavalry, Indians did not in general fight with cavalry. One exception was the Rajput Kingdom, which had an extremely skilled cavalry. Otherwise, the main force of an Indian army was its infantry, which fought primarily with bows and arrows and hundreds of different types of swords. The armies of India tended to be huge, much larger than the armies fielded by other empires at the time. Even though the kingdoms at war might have been small, it was not unusual for their armies to number in the hundreds of thousands. India maintained a navy for military purposes; during Maurya rule the navy became quite extensive. Although the navy was used to subdue islands and provinces along the coast, naval warfare was not a prominent feature of India's military history.

India was particularly noteworthy for its use of planned battle tactics and formations. Some of these battle formations were complex and included the *chakra* (wheel), *suchi* (needle), *chayana* (hawk), *mala* (garland), *garuda* (eagle), and *padma* (lotus). These terms reflected the shape of the formations. Thus, for example, in the *padma* formation archers (as well as the commanding general) were on the inside, surrounded

by cavalry and infantry in the shape of a lotus flower, protecting the archers. If enemy troops managed to force their way into the area between the “petals” of the flower, the two petals would swing together, crushing the troops between them. The *garuda* formation featured elephants and the most skilled archers at the “beak,” archers who were almost as good at the “head,” “wings” of swift cavalry and infantry troops, and a “body” of reserves behind.

KOREA

Like China and India, Korea consisted of a number of city-states, except that the number was much smaller, reflecting the small size of the Korean peninsula. During the first millennium B.C.E., the three city-states that dominated were Koguryo Paekche, and Silla, though other minor city-states existed as well. Within each of these city-states were several groups. Historically, these city-states have been called the Three Kingdoms, and the Three Kingdoms Period extended from the first century B.C.E. to 668 C.E., when Silla defeated Koguryo.

Militarily, the most powerful and dominant of the kingdoms was the Koguryo (the name from which *Korea* evolved). Beginning in 37 B.C.E. and into the first centuries of the Common Era a succession of monarchs united the kingdom, extended the kingdom's boundaries and, in particular, resisted the Chinese. During the reign of Taejo (53–146 C.E.) the Koreans mounted a number of well-conceived attacks on the Chinese garrisons at Lolang, Xiantu, and Liaodong. Their efforts were successful, and Koguryo became entirely independent. The regime also launched attacks against smaller states to absorb them. Later, under King Gwanggaeto the Great, who reigned from 391 to 412 C.E., the kingdom further expanded its territories through military conquest; in fact, the king's name means “great expander of territory.” His army conquered at least 64 walled cities and 1,400 villages against a group called the Buyeo. He subdued additional peoples, annexed portions of the peninsula, conquered Silla, and waged war against Japan. The result of his efforts and those of his son was to turn Korea into a unified country for some 50 years.

Less is known about the tactics and organization of ancient Korean armies. Although there was a measure of internal warfare, Korea did not engage in extensive armed conflict with neighbors, and weapons technology was not as highly advanced as it was among the Chinese. In general, Koreans fought using farm implements and other common objects. Among them were the *ji pang e*, a cane; the *jang bond*, or long staff; the *jung bong*, a staff of middle length; the *tahn bong*, or short stick; the *jang tan-do*, or long dagger; and the *nat*, or sickle. Koreans, though, did not carry these simple weapons into battle without training. Martial-arts training provided warriors with the skills the needed, including the *hyungs*, or patterns, to turn these objects into lethal weapons. Accompanying this was training in hand-to-hand combat. Many of these Korean martial arts continue to be taught in the modern world.

The ancient Koreans, especially those in the kingdom of Silla, maintained a strong warrior class. Boys and young

men were sent to schools that emphasized training in military tactics and the use of weapons, and the most promising ones were given further training and became members of the warrior class.

JAPAN

Warfare was infrequent during the Jōmon Period, the earliest period of Japanese history, which began about 13,000 B.C.E. and extended to about 300 B.C.E. During the fourth and third centuries B.C.E. waves of immigrants from Korea and China changed the fundamental makeup of Japan. From about 300 B.C.E. to 300 C.E. the Yayoi Period of Japanese history (named after the modern Tokyo suburb in which archaeological remains of the culture were found in the 19th century) was marked by the introduction of metal weapons and the rise of an aristocratic warrior class. Most of the warfare in which Japan took part was internal. Japan at the time was not a unified nation-state but a collection of villages and small cities. Japan was an agricultural society, and imbalances in the productivity of its numerous communities led to conflict. The basic unit of society was the clan (*uji*), and each clan, led by a noble, fielded an army to defend its interests. This emphasis on an aristocratic warrior class continued into the Yamato Period that followed the Yayoi. The Yamato emperors continued the process of subduing groups and even attacked part of Korea in 391 C.E. The pattern, then, was similar to those of China, India, and Korea, as small kingdoms warred with each other over resources and in the attempt to forge a larger kingdom.

Little is known about ancient Japanese battle tactics or military organization. It is known that some warriors fought on horseback, but most were foot soldiers. The archaeological record shows arrow points, swords, knives, and axes made of iron. Bronze weapons included halberds, swords, and spears. Because ancient Japanese society was feudal and clan based, no nation-state mounted a centralized army; rather, military forces were small, and their members consisted of the men that the feudal overlord could press into service.

OCEANIA

Social organization throughout Oceania, including Micronesia, New Guinea, and Australia, was highly fragmented in ancient times. None of these peoples built an empire or even a nation. The basic unit of organization was the tribe. Tribes were typically run by a “big man,” the tribal leader. Geographically, the unit of organization was the island or, on larger islands, the village. Sometimes primitive warfare broke out as populations grew and tribes competed for resources; at times they resorted to cannibalism. Also, population pressures often forced islanders to leave to find new lands.

EUROPE

BY KIRK H. BEETZ

Violence was a large part of life in ancient Europe. Evidence of interpersonal violence first appears in the Mesolithic Pe-

riod (ca. 8000–ca. 4000 B.C.E.), and mass burials such as those found at the Neolithic (ca. 7000–ca. 2000 B.C.E.) sites of Asparn in Austria and Talheim in Germany contain skeletons that bear signs of blows from stone axes. Traumatic injuries on bones are common features of Neolithic skeletons throughout Europe. The nature of this violence is difficult to determine, but from about 5500 B.C.E. onward banks and ditches around Neolithic settlements are common. Sites like Darion in Belgium were very clearly fortified with palisades and ditches, and movement into the sites was channeled through gates that could be defended. Since Darion was located on the frontier of Neolithic settlement at the time, it could be speculated that the site was defended against the hunter-gatherers on whose territory the farmers were encroaching.

Warfare in prehistoric Europe did not involve the conquest and control of territory because this would entail organized political units that did not yet exist. Instead, warfare primarily took the form of raids to obtain livestock or other resources, or they were factional struggles between the adherents of one chief or leader and those of another that turned violent. They probably involved techniques such as ambushes in the forest and the terrorization of the inhabitants of isolated settlements and farmsteads rather than large, organized groups of warriors. Violence may also have been directed at individuals rather than groups, as the wounds on the frozen, 5,300-year-old “Iceman” found in the Alps in 1991 suggest.

During the Bronze Age (ca. 2800–ca. 700 B.C.E.) and Iron Age (ca. 1000 B.C.E.–ca. 500 C.E.) the increased effort expended in the fortification of settlements as well as the many types of weapons that could be manufactured from bronze and iron indicate that conflict and warfare may have increased. Sites without much evidence of permanent settlement but with elaborate fortifications may have served as refuges in times of threat. The emergence of chiefs who could command their retainers to take up arms against communities loyal to their enemies shifted warfare to a new level of organization, and the chiefs themselves may have owed much of their status to their accomplishments in battle. Such values may have resulted in further escalation of warfare throughout the Bronze Age and Iron Age as individuals sought prestige and wealth.

Soon after 2000 B.C.E. the bow and arrow almost disappeared from European warfare. This was an odd development because the bow and arrow remained very important instruments of war in and near Asia. Throughout much of Europe, however, small projectile points that could have served as arrowheads almost disappeared from the archaeological record. There may be two reasons for this, one cultural and the other technological. By 2000 B.C.E. Europeans were adopting what archaeologists and historians call a heroic culture. They usually point to the epic poem the *Iliad* by the Greek poet Homer (eighth or ninth century B.C.E.) as an example of what a heroic culture was like. In a heroic culture warriors dominate. The apex of society is the individual leader who has distinguished himself or herself in combat. For Europe this may have encouraged the use of hand-to-hand weapons

that were suited to contests between two easily identifiable warriors rather than long-range weapons in which death and victory came anonymously.

The key technological development was the sword. In southern Europe and the Near East small swords and daggers were favored for combat, but in the rest of Europe swords grew increasingly longer. By 900 B.C.E. the Celtic peoples were conquering Europe, and their weapon of choice was a slashing sword. Celtic masters of metalworking found ways to make long swords tough and durable. In the Near East swords remained short partly because metalworkers could not keep a sword strong and durable after it reached the length of about 2 feet; their swords would snap when they became too long. Short swords were intended more for stabbing than slashing, and they were used only for fighting in very close quarters, as in the combat favored by the Romans.

THE CELTS

By the time the Romans and Celts came into direct conflict in the late 400s B.C.E. the Celts had developed a style of warfare that favored the long sword. When they met and slaughtered a Roman army near the city of Rome in 390 B.C.E., they were using long swords with blunted points that were intended entirely for slashing. They also used spears, which they made in three lengths. The longest spear was designed for thrusting, the medium-length spear was made for throwing, and the short one was used for close combat. There seems to have been no loss of prestige for using spears, but the sword was the weapon of preference for most Celtic warriors.

The Celts of that era had fully developed their warrior culture. The best way for someone to advance in Celtic society was through heroic victories in combat. Also prestigious was the taking of the heads of fallen heroes and bringing home loot. An interesting aspect of Celtic looting was that they often gave their best loot to gods or goddesses, frequently dumping what they brought home into lakes and rivers as gifts to the gods who had aided them in battle.

Headhunting by the Celts appalled many of the Greeks and Romans who explored Celtic Europe before Rome’s invasions of central Europe in the middle of the first century B.C.E. The heads of cowards were not taken. There was no glory in killing someone who ran away or froze in fear. Instead, Celtic warriors cut off the heads of people they had killed face to face. Although these heads were usually those of men in the male-dominated Celtic society, some were probably of women who had earned reputations as fearsome sorceresses or masters of combat. Celtic oral tradition has many tales of warriors being taught the skills of combat by women who were masters of battle, and killing them in armed combat was considered just as glorious as killing a great male warrior. The greater the warrior, the more prestige would come from having his head. The heads were hung on the walls of Celtic homes, and the family in the home would recite the many glorious achievements of the former owners of the heads, just as they would of the ancestors or living family members who had slain them.

In battle Celtic horsemen hung the heads from the necks of their horses as part of the intimidation of opponents that was always a part of Celtic warfare.

Celtic homes offer some indication of what Celtic wars were usually like. Most Celts lived in homesteads, which were houses on farms. The ground around the houses was fortified with a wooden wall. Although the defenses of a homestead would not protect residents from large armies, they were adequate for keeping out raiders. Most Celtic warfare consisted of raids, mostly for stealing cattle. Cattle were a form of booty that successful raiders could show off to others. Young men in small groups often wandered Celtic Europe looking for adventure, gaining experience in combat skills while fighting warriors at homesteads. This activity was treated more as a sport than serious warfare.

More serious were disputes over land, insults, or large numbers of stolen cattle. Protecting one's land and defending one's honor or the honor of one's group were considered imperative. Stealing a few dozen cattle was seen as excessively greedy. To settle these disputes, sometimes hundreds of warriors met for combat. The two sides would agree to meet at a place with sufficient open ground for everyone to see and to fight. Honor came from being seen to overcome a foe.

Until about the time of the Roman general Julius Caesar (100–44 B.C.E.), chariots figured prominently in Celtic warfare in continental Europe, and they lingered in Britain and Ireland for about 100 years after Caesar's era. The chariot had a driver who was a follower of the warrior who owned the chariot. He would stand out on the shaft that thrust out between the two horses from the car, maneuvering the chariot quickly to take his warrior through battle. In doing so, he won merit for his skill and for the great courage that it took for him to be vulnerable to the enemy. In the 200s B.C.E. the Celts invented the four-pommel saddle, which had two pommels in front of the thighs to hold them in place and two at the rear of the saddle. This gave the Celtic cavalryman the stability that allowed him to become a fighting machine, protected by chain-mail armor and shield while wielding an assortment of weapons that would be given to him by two mounted followers. The team was called a *trimarcisia*, which meant "three horses" in Celtic.

Sometimes these battles ended without bloodshed. A warrior might take charge of his chariot and put on a display of acrobatic daring—handstands, leaps, and tumbles—while racing in front of the enemy. Often, the warrior rode out on horseback and performed a variety of impressive stunts. Sometimes the skill of such a warrior was so great that both sides agreed to settle the dispute in favor of the side of the outstanding performer. Roman soldiers were amazed at the skill of such warriors before combat, but they had no idea the demonstrations were intended to substitute for actually killing people. On the other hand, the Romans well understood the idea of duels between champions to settle battles without additional bloodshed.

Before battle the champions would step forward from the ranks of their sides. The champions would proclaim their he-

roic deeds and the deeds of the warriors they had killed. The objective was to overawe the other side. The Celts believed that the spoken word was as powerful as the might of a well-armed warrior, and they took boasting seriously. Sometimes no one would emerge to answer the boasting of the opposing champion, and the battle was settled without bloodshed. If the boasting was answered by a champion, then each would compete in oratory, trying to make the other back down. If neither backed down, then they would fight.

During the duel the other warriors of both sides would shout and blow their *carnyxes*, which were horns with the heads of animals on one end. They made a great din of harsh sounds. Many of the warriors would have drunk alcohol before battle to make themselves reckless. Once one champion or the other won, the battle could be settled, and everyone could go home. Sometimes a new challenger emerged. One oral account tells of a warrior who killed more than 100 challengers before everyone agreed to stop fighting. Sometimes after a duel was over, the warriors of both sides would charge at each other in a frenzy of bloodlust, each hoping to be seen to be heroically felling enemies. This charge was intended to settle the battle; the Celts had no backup strategy if the charge failed. Thus, the losers in a charge often ran away. The Romans learned to take advantage of this: If they could withstand the first charge of the Celts, they could win, because the Celts had no idea what to do next.

There was another kind of war for the Celts, and this was the war of conquest. When a tribe grew too big for its territory or was driven from its lands by an invader, the members sometimes abandoned their homes and carried their property on carts. If attacked while carting across country, the men would engage the enemy in combat. If they were overcome, the women would fight next. To actually seize the carts meant having to defeat the children, who would guard them. A Greek explorer, Posidonius (ca. 135–51 B.C.E.), was awed by the size and strength of Celtic women. He and others noted that if a Celtic man fell in combat, the fighting was not always over, because his wife was skilled in hand-to-hand combat and could deliver tremendously powerful blows with her feet and her fists as well as with weapons. Children were trained in fighting almost from birth.

When Caesar invaded central Europe in 58 B.C.E. he introduced a form of warfare that was unfamiliar to the Celts. The Roman troops fought as tightly structured units. Like the Celts, their objective was usually to fight hand to hand, using their superior skill, armor, and weapons to overcome their adversaries. Further, the Roman objective was to annihilate the enemy. Over hundreds of years the Celts had developed a structure for combat that usually allowed them to avoid much bloodshed. The objective was to make one's point, dazzling friends and foes, and then go home and feast, exaggerating one's heroism while telling about the battle. The Romans rarely quit, but just kept coming. Celts often panicked and ran after their initial charge if this failed to put the Romans to flight.

When the Celts had competent leadership and worked together, they were almost more than the Romans could handle.

During the Roman conquest of Europe the Romans lost an entire legion near Belgium when a group of Celtic tribes under unified leadership fought them. The charismatic Celtic leader Vercingetorix (d. 46 B.C.E.), who had recently become chief of the Averni tribe, persuaded tribes from all over Europe to join into one army under his command. He lost battles to the Romans but kept his alliance intact, and he switched to guerilla warfare, which the Romans were ill equipped to handle.

The Celts burned their farms so the Romans would not find food, and they killed Roman units that were sent away from their main army to forage. Vercingetorix's crucial mistake was to take his army to Alesia, a fortified city in central Europe. It is likely that he did not know enough about Roman tactics to grasp that Roman engineers would build a fortification to surround Alesia to starve him out. He probably hoped that the Romans would be caught between relief forces from the north and his army in Alesia. The fractiousness of the Celts contributed to their downfall. Some refused to help and were later overwhelmed by the Romans. Others refused to send all their warriors. Three times the Celts attacked the Roman fortifications simultaneously from inside and out, twice nearly penetrating Roman lines and overwhelming the Romans. More warriors might have been enough for success, but the Celts were forced to surrender. Vercingetorix was imprisoned and later executed in 46 B.C.E.

Another able leader undone by Celtic customs of war was Queen Boudicca (d. 60/61 C.E.). She was the widow of a king of the Iceni, a tribe in eastern Britain. The Romans governed the Britons harshly, but her tribe had managed to keep the peace. The spark that touched off a firestorm was the rape of two Iceni girls by Roman soldiers. How old Boudicca was is unclear. She was old enough to have had a 12-year-old daughter, but she could still have been in her late 20s. She is usually imagined as middle-aged. She was described as big, but Celtic women in general looked big to the Romans. Nonetheless, she was either imposingly tall or heavy or both. Her blazing red hair hung down to her waist. In battle she painted half her body green and wore a large robe. She was said to be a sorceress.

In western Britain 10,000 Roman troops were slaughtering Druid priests. Perhaps as many as 10,000 marched to suppress Boudicca's rebellion. She had drawn to her about 100,000 warriors from homesteads across Britain. Instead of their usual frontal charge, the Celts quietly surrounded the Romans in a forest and then attacked from all sides at once. They killed nearly every Roman soldier. Their attacks on Roman towns and fortifications were similarly disciplined. They seemed unconcerned with taking trophies but fought the Roman way, totally destroying the enemy. The Roman governor fled London with his troops, leaving it to Boudicca's army.

By the time Boudicca brought her army to bear on the 10,000 Roman soldiers marching from the west, having exterminated the Druids, she had more than 200,000 warriors, along with supply wagons and fierce Celtic women to defend them. The Romans were holed up in a small valley. Boudicca arrayed her forces in a line to face them. Charioteers put on

traditional Celtic shows of skill and bravery. The Romans stepped forward in a jagged line of V formations designed to break up the Celts' solid line, allowing Roman soldiers to hack at their foes from the front and the sides. The Celtic mistake was to allow themselves to be provoked. They charged as a mass, making a din so frightening that the Romans nearly panicked. Then the Celts pressed in on each other, trying to get at the Romans. Chariots overturned. Warriors suffocated. The Roman line held, and the Celts panicked. Following a longstanding tradition for Celtic war leaders, Boudicca committed suicide when it was clear the battle was lost.

THE GERMANS

By Caesar's era the Celts were beleaguered not only by the Romans from the south but also by the Germans from the north and east. In fact, Caesar began his campaign to conquer Gaul by first driving away Germanic invaders. These Germans came primarily from the north but were conquering their way through northeastern Europe and would eventually threaten Roman Europe from both north and east. Their motivations for conquest varied. Sometimes a tribe's population grew so much that the tribe chose to expand its territory to accommodate its growth. Sometimes a natural disaster or an invasion of its territory drove a tribe from its homes and into territory claimed by someone else. Often the conquest was inspired by a desire for loot. At other times a leader wanted glory.

War chiefs tended to serve only while a war lasted. Customs varied among Germanic tribes, with some choosing one leader while others chose two. One reason for choosing two might have been to prevent either one from using his power to make himself the permanent king. In early campaigns against Germanic armies the Romans noted that the Germans seemed wild and ill equipped. A German warrior was expected to supply his own weapons and armor. This meant that German armies of the first century B.C.E. often featured warriors wearing only breechcloths (loincloths), without even protection for their heads. Often they had no shields. They just carried spears and rarely axes or swords. In the close hand-to-hand combat that both Romans and Germans favored, the Romans cut the Germans to pieces.

The Germanic fighters differed from the Celtic warriors in an important way: They knew how to fight as units and were accustomed to having a long-term strategy. Like the Celts, they liked to show off their courage, toughness, and prowess. In the dead of winter men would ride naked and bareback on horses to display their contempt for discomfort. They were used to being cold, tired, and uncomfortable, and in the long run they would prove to be formidable opponents for other Europeans.

The basic Germanic fighting unit was the family. Family members stayed together during marches and battles and were responsible for each other's well-being. If a war chief failed to satisfy his troops with his leadership, families could desert, choosing to return to protect their homes rather than serve someone they did not trust. An army could disintegrate

this way. Family groups were organized into clans composed of their relatives. The clans were organized into tribes. The tribes often had their own chiefs, and a war chief needed to address their worries and their ambitions, keeping those factors in check while trying to keep everyone focused on the military campaign.

Summoning warriors family by family was a slow process, and it depended on the mutual obligations between family members and their chief. Germanic armies tended to bunch together, which made them difficult to maneuver on the battlefield and hard to organize into efficient marching. Poor scouting and a focus on internal discipline among the troops meant that German armies were often taken by surprise. When surprised, they might not flee, but they were slow to respond and poorly organized at such times; they might stubbornly fight where they stood until they were cut down. Even so, when they were assembled and units were properly sorted out by family, clan, and tribe, the Germans could form large, formidable armies.

Generals were usually men from well-known warrior families. During the first century C.E. the leaders of these families became nobles, and their status and political power continually increased as their tribes forged national identities over the next several centuries. These nobles were usually dedicated full time to preparing for and waging war. Around them grew the *comites*, full-time warriors who served a noble. During the ancient era Germanic warriors were primarily infantry. They did not have the exceptionally sophisticated cavalry gear that the Celts had, making it hard to use horses as mobile battle platforms the way the Celtic cavalry did, although those few who fought from horseback were extraordinarily skilled and not to be taken lightly.

The waging of war was the preoccupation of most Germanic peoples. Their sons were taught throughout childhood how to kill their enemies, and if the family could afford it, a son's coming-of-age ceremony included a gift of weapons, helmet, and shield. Even poor families could give a son a *framea*, a light spear. Leadership in a tribe was often determined by who was the most successful warrior. In some tribes the chiefs were elected by the warriors of the tribe, but in others a notion of kingship was developing that would evolve into the system of mutual obligations that became the feudal system of the medieval era.

After Caesar's time many German tribes became *foederati*, or tribes that were federated with Rome and helped protect Roman borders. By the year 9 C.E. the Romans were making good progress advancing their borders east and north into German lands. The Germans in Roman-held territory were beginning to speak Latin as their primary language, were wearing Roman-style clothing, and were adopting Roman customs. A Roman governor, however, abused and overtaxed the Germans in Roman territory, making it easy for German nationalists to recall days when their ancestors roamed the land, terrifying their enemies. In 9 C.E. the Germans rose in revolt.

The Romans had many Germans in their armies. One was Arminius, a member of the Cherusci tribe. He had proved so valiant in battle that he had been awarded Roman citizenship, but he was still German at heart. He hoped that through warfare he would win enough glory to become chief of the Cherusci. The Roman emperor Augustus (r. 27 B.C.E.–14 C.E.) appointed a successful diplomat, Publius Quintilius Varus (d. 9 C.E.), as commanding officer of the Roman army in Germany. In September 9 C.E. he led three Roman legions, composed of 15,000 troops, toward their winter quarters through lands that were unfamiliar to him. Although other Germans with him warned that Arminius was untrustworthy, Varus followed the guidance of Arminius.

In what followed can be seen the strengths of German tactical thinking. Arminius led the Romans through muddy grounds, weakening the soldiers' legs and making them weary. Ahead of them was a large German army. As the Romans marched between a large bog to their right and a 300-foot-tall hill to their left, about 10 miles north of the modern German town of Osnabrück, they confronted a wall of mostly sand, about 4 feet in height and several feet deep. Behind it were German warriors, coordinating their defenses through cooperation. The site was discovered in 1987. The area in front of the wall shows that the Romans tried to storm it several times. The wall was a zigzag shape that broke up the Roman line and allowed defenders to stand on the wall and use their spears to strike Romans from their sides as well as their front. The absence of debris on the German side of the wall suggests that the Romans never made it over the top.

Behind the Roman column Germans who had hidden in the woodlands to the left of the Romans tried to block a Roman retreat. Others waited to storm the column from the woods. What resulted was a well-timed, carefully coordinated ambush in which an experienced army of 15,000 troops was trapped. Varus fell on his sword to avoid being captured, as did several of his officers. This left junior officers and regular soldiers to fight without a center of authority to coordinate their actions as they faced an enemy that fought with discipline. Many Roman soldiers fought as Romans often did, determinedly holding their ground when the Germans finally charged into them. The German strategy had broken up the Roman column so the German warriors could penetrate it and take on individual soldiers. Romans were very good at one-on-one combat, and this strategy by the Germans probably resulted in unnecessary deaths for many of them. But Arminius was leading Germans, not Romans, and to keep German warriors satisfied with his leadership, he probably had to let them have their battlefield glory.

Some Romans made their way into the woods and slowly went back home. Others were captured, tortured, and taken to altars set up in the woods. When Romans visited the site six years later, they found Roman heads dangling from trees and blood-drenched altars as well as the bones of Romans piled across the battlefield. Almost all died, about 15,000. Romanization of much of Germany was halted, and the Romans

eventually withdrew back into Gaul. Arminius became chief of his tribe and a war leader of several tribes. He was assassinated by relatives in 21 C.E.

GREECE

BY MICHAEL M. SAGE

Warfare in ancient Greece, though it changed over time, always spanned the full range of possibilities from small-scale raiding to full-scale pitched battles. As the most dangerous of activities, it was marked by formal declarations, special religious rites, and a number of symbolic acts whose character changed over time, such as the erection of battlefield trophies, thanksgiving and victory sacrifices, and the use of special burial rites for the fallen.

Early Greek warfare tended to pursue restricted goals. City-state governments remained relatively simple and lacked the means to control large blocks of territory. Hoplite warfare focused on gaining control of the enemy's agricultural land, and normally that was enough to bring victory. Greek arms and tactics were not well suited to siege warfare, which was the only way to achieve complete victory. For the most part, warfare centered on boundary disputes, raids, and in certain cases, hereditary feuds.

It is difficult to gauge the frequency of organized warfare. The absence of sources makes any estimate impossible from the Mycenaean Period (ca. 1600–ca. 1150 B.C.E.) until the fifth century B.C.E. For the period from 500 to 338 B.C.E. Athens was at war two out of every three years. However, no comparable figures exist for other Greek states, and Athens was a special case. In all periods warfare on any scale is the most costly of activities, and Athens during this period had resources not available to most Greek states. Sources give the impression that warfare was common until the imposition of Roman domination in the mid-second century B.C.E. For the period after 400 B.C.E. there is scattered evidence in the form of inscriptions for frequent warfare among smaller communities in Crete and elsewhere.

ATTITUDES ABOUT WAR

The attitude of the Greeks toward warfare was, as is the case for most societies, ambivalent. On one hand, war was recognized as an evil. The historian Herodotus (ca. 484–between 430 and 420 B.C.E.) blames war for overturning the natural order of things: “In peace, sons bury their fathers. In war, fathers bury their sons.” In his *Laws*, Plato (ca. 428–348 or 347 B.C.E.) asserts that that we should pray to be spared from war and civil strife and that no man can be a true statesman unless he prepares for war only as a means to peace. Despite the misery it brought, war could also be viewed as desirable. The earliest Greek literature that we possess, the *Iliad* and the *Odyssey*, composed by Homer (ninth–eighth? century B.C.E.), suggests that excellence as a warrior is a man's most important quality. The growth of the city-state, which consisted of an urban core with its dependent towns and village,

Bust of a warrior known as Leonidas (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

and the associated stress on the importance of the community, altered this “heroic code.” The emphasis shifted to a warrior's contribution to his city in battle, but the significance attached to an individual's prowess in battle remained the same. Warfare also had more tangible attractions. The normal Greek view was that the conquered and their possessions passed into the hands of the victor and were his to dispose of as he pleased. Slaves brought the highest profit, but other items, such as personal valuables or temple treasures, also brought wealth. It was the capture of cities and temples that gave the greatest returns.

In politics war always remained an option and was pursued when it offered some advantage, especially among the more powerful states. There was a change in the fourth

century B.C.E., first visible in 371 B.C.E., when the notion of a common peace among Greek states developed; however, the idea had little practical effect and never excluded warfare against non-Greeks. Peace among the Greeks was achieved only by Roman control.

THE MYCENAEAN PERIOD

There is little available evidence for the earliest period of Greek warfare, the Mycenaean Period. It is generally assumed that the Greek mainland and islands were divided into a number of small kingdoms centered on heavily fortified citadels. Given the absence of any contemporary description of warfare, inferences have to be made on the basis of archaeological finds of weapons and contemporary pictorial representations of fighting in frescoes and reliefs. An additional source of information is provided by the Linear B tablets. These tablets are accounting documents produced by the palaces and written on clay. They highlight the importance of chariots in this period. Large numbers of tablets as well as replacement parts for them were maintained. In addition, a set of tablets from the kingdom of Pylos in the southwestern Peloponnese details the organization of a coastal watch in response to an unknown threat. It is clear that there was technological development in the period, especially in producing more effective swords, but we do not have the data to trace the interaction between changes in technology and the development of new forms of war making.

The importance of chariots in the tablets poses a problem. Mainland Greece, with its rugged topography, is not well suited to the use of the chariot, especially in the mass formations found in the contemporary Near East. It may be, given some later parallels, that chariots served as elite transport to the battlefield and that their primary function was to display the high status and importance of their owners. The weapons finds and portrayals of fighting indicate the importance of the heavy thrusting spear. Although the sword is found in all periods, the thrusting spear is found most frequently. The use of such a weapon implies some type of compact formation, though its organization eludes us.

THE DARK AGES

The end of the Mycenaean Period in about the middle of the 12th century B.C.E. witnessed profound changes on the Greek mainland and islands. The palaces were destroyed and with them the writing system used to keep their accounts. The archaeological finds paint a picture of a depopulated and fragmented society based primarily on small villages with a much reduced economy during the dark ages (ca. 1100–ca. 750 B.C.E.). Most political units centered on a local chief, who functioned with the support of local nobles. The amount of surplus wealth that such a society could devote to warfare was small, and it is probable that most of the fighting centered on raiding and small-scale conflict.

The same difficulties in reconstructing warfare in this period arise as for the previous one. We have to rely on weapons finds, and from about 850 B.C.E. there are vases that show

fighting. Evidence points to the importance of missile warfare, with javelins and an open and fluid manner of fighting. Chariots are pictured, and there have been occasional finds of chariots in graves dated to after 1000 B.C.E. These must have belonged to the elite, but their function remains unknown. Based on evidence from the Homeric poems, these armies must have consisted of relatively small war bands operating under the leadership of a local chief or prince whose primary adversaries were small armies of a similar nature. These formations were too small and lacked the organization to achieve permanent conquest. Warfare for the most part must have consisted of raiding and border warfare.

THE ARCHAIC PERIOD

The warfare of the *Iliad* and the *Odyssey* has been a particular focus of discussion. There has been debate about realism and the period in which the works are set. It seems that they reflect the period towards the end of the dark ages and the beginning of the following period, the Archaic (ca. 600–ca. 480 B.C.E.). They portray a world of small-scale states controlled by kings and the nobility, where war is the primary means of enhancing one's prestige and status. The kings and nobles, such as Achilles and Hector, dominate the combat and display superhuman strength.

Despite the presence of gods and other fantastic elements, Homer's works do present a comprehensible picture of warfare. The poems reveal a style of warfare close to that of the dark ages. The elite lead individual war bands that often function independently. Combat is normally in loose formation and mostly involves the exchange of missiles. This formation responds to circumstances. Under pressure from the enemy or in pursuit, it can compact, and battles between closely formed groups of warriors occur. These masses are important in determining the course of combat despite the focus on the actions of the elite. The elite function primarily as front fighters and often fight before the masses of their men, challenging enemy leaders. The poems portray their successes as the key to victory.

The use of chariots in Homer has evoked further controversy. They are used singly and often serve as transport for warriors who drive into battle, fight dismounted, and then use the chariots as transport to the rear. The movement of these vehicles in and out of the battle has no parallel elsewhere. Chariots were normally used elsewhere in massed formations as missile platforms or as transport to the battle but were not used to fight along with the infantry. Although the use of intermingled chariots and infantry is not impossible, it seems likely that the poet's use of chariots for his heroes is the product of an attempt to emphasize his heroes' superhuman nature.

From the second half of the eighth century B.C.E. Greece underwent a profound change. Population increased dramatically, there was extensive colonization around the Mediterranean, external trade resumed, and writing was reintroduced. Accompanying these developments was the formation of a new political organization: the city-state. In essence, the city-state consisted of an urban core based on a defensible citadel surrounded by public and religious spaces. It served as the

political, social, and economic center for the surrounding countryside and its dependent towns and villages. In conjunction with these changes, royal government disappeared and was replaced by aristocratic rule and a political structure consisting of magistrates, council, and assembly. The higher population of these communities as well as their greater wealth allowed them to mobilize far more resources for war than had been possible earlier.

These profound developments in Greek society provided the context for a momentous change in warfare. The decisive arm on Greek battlefields over the next four centuries was to become the heavily armored infantryman (hoplite) using the heavy thrusting spear as his main offensive weapon and fighting in a dense, rectangular phalanx formation. This transition was accompanied by changes in equipment. Metal helmets, corselets (armor covering the torso), and a new type of shield appear. Hoplites were drawn from the better-off farmers and landowners and served at their own expense. Mass, weight, depth, and cooperation among the members of the phalanx became the decisive elements in this simple type of warfare in which masses of heavily armed men engaged each other on flat, level plains. It was a form of warfare developed to protect a city's agricultural land on which it depended for its food supply. The short, sharp engagements and the ample defensive equipment were designed to limit warfare's destructive effects.

These developments were limited to central and southern Greece. Elsewhere older forms of warfare persisted. Whatever the connection between these developments and political change, it was only in areas where the city-state was common that hoplite warfare came to dominate. The evidence does not permit a firm date to be assigned to the development and spread of this type of warfare. Elements of the equipment that later became typical appear around 700 B.C.E. and the first portrayals on pottery of warriors in a phalanx-like formation occur in the middle of the seventh century B.C.E. A date around and after 600 B.C.E. is reasonable, though some hold that its full form emerged only around 500 B.C.E. How quickly it spread is unknown.

THE FIFTH CENTURY B.C.E.

The dominance of this form of fighting led to changes in other arms. Light-armed troops whose main offensive arm was missile weapons lost their importance, and their main functions were now to act as a screen for the deployment of the phalanx and to aid in pursuit. Contemporary with these developments in infantry fighting, the cavalry also experienced significant changes. From the seventh century B.C.E. there are portrayals of warriors on horseback, but they appear to be mounted hoplites rather than true cavalry. The transition to true cavalry, that is, troopers who fight from horseback, may be as late as the first half of the fifth century B.C.E. under the impact of the Persian invasion of Greece in 480 B.C.E. The first organized cavalry appear in Athens in the 450s B.C.E., while Sparta had none until the 420s B.C.E., and few major states remained without such formations. This cavalry was useful for flank and

rear attacks on organized infantry and for protection from enemy cavalry forces. In addition, it was employed in pursuing broken infantry and in protecting foraging parties.

The Persian War of 480 B.C.E. marked a watershed. For the first time a substantial number of Greek states served under the unified command of a single state, Sparta. Athens, building on an earlier decision to expand its navy, became the most important maritime power. The Greek victory had momentous consequences. Sparta remained focused on its supremacy in the Peloponnese, but Athens was able to create an alliance against the Persians that within a generation would develop into a naval empire of subject states. Unlike the Spartans, who demanded only military service, the Athenians demanded tribute, and the empire became a substantial contributor to the maintenance of its fleet and its citizens.

At Athens all Athenians who were between the ages of 18 and 60 and who possessed a certain level of wealth were entered in a list of those eligible for military service, with the wealthiest serving as cavalry. Athens was unique in providing pay for military service from 456 B.C.E. on. Army organization was based on units of 1,000 and 300. The larger units had their own officers, but nothing is known of the organization of the smaller ones. The cavalry had its own commander and subordinate officers, and the same must have been true of the light-armed troops, though they are not mentioned. Overall command was vested in an annually elected board of 10 generals. Normally, two or three generals exercised command on a campaign. The historian Thucydides (d. ca. 401 B.C.E.) informs us that in 431 B.C.E. the hoplite army totaled 29,000 men out of a population of about 180,000, with 13,000 serving in the field army and the youngest and the oldest defending the city.

There was no parallel to the Spartan army elsewhere in Greece. All other armies were citizen militias; only Sparta possessed a professional army. As a result of a unique social and economic system, all full Spartan citizens were freed to devote themselves to full-time military training. This was an extraordinarily rigorous training that began in childhood and continued until the end of adolescence. The army was organized on the basis of age groups and geographical districts within Sparta. This army was far better articulated than any other Greek force. The largest units of 600 men were composed of four successively larger units, each with its officers. Normally, overall command was vested in one of the two Spartan kings, though occasionally detached forces could be commanded by other officers.

Sparta's unique military system fueled a policy of expansion that resulted in the acquisition of extensive lands on the western flank. Sparta's attempt to expand its control to the north was checked by the mid-sixth century B.C.E., and a new policy of alliance in the Peloponnese was adopted. Sparta was clearly the controlling member, and the allies were bound to follow where Sparta might lead. Despite Sparta's military superiority, several large and important states in the Peloponnese, such as Argos, remained out of the league and were at times openly hostile. After its initial expansion Sparta's main military preoccupation was to ensure its local dominance.

In Boeotia and a few other areas where federalism had emerged, there were federal armies with member states contributing troops according to population, and command was held by federally elected officers. Elite units are mentioned at Thebes in Boeotia and at Argos in the fifth and fourth centuries B.C.E., but we know almost nothing of their organization. Given that most Greek armies were militias, it is probable that they were commanded by each city's magistrates.

The Peloponnesian War (431–404 B.C.E.) between Athens and Sparta and its allies precipitated a number of changes. For the first time mercenary troops from the poorer regions of Greece were employed on a large scale as well as specialist troops drawn from non-Greek sources. The dominance of the hoplite outside of decisive battles was reduced. Combined forces of light-armed troops, cavalry, and hoplites were shown to be effective in small-scale actions. The length of the war and the employment of mercenaries led to a growing professionalism, visible both at the level of the individual soldier and in positions of command. The greater professionalism and frequent warfare in the fourth century B.C.E. led to the development of new tactics and changes in hoplite equipment.

In these years Greek politics had essentially become bipolar, with most Greek states aligned with either Sparta or Athens. In addition to the war's effect on the nature of warfare, this conflict also had profound political consequences. It destabilized a number of states, leading to internal factional fighting, which was often bloody. A number of cities were destroyed and the population enslaved. It led to the Spartans' realization that the older strategy of laying waste to an opponent's agricultural land as the key to victory no longer held in Athens's case, since as long as Athens dominated the sea, it could supply itself from overseas. This realization led the Spartans to solicit Persian money to subsidize their navy and so involved them in the affairs of the Greeks of Asia Minor.

By the end of the war Sparta stood supreme. Athens was subordinated but not destroyed so that it could serve as a counterweight to the ambitions of Thebes. However, Spartan blunders created a number of coalitions of major Greek states to oppose Sparta. Sparta's supremacy lasted until 371 B.C.E. and Sparta's defeat in battle by Thebes, which now assumed Sparta's role. By 362 B.C.E. Sparta's ascendancy had ended, and no state emerged as dominant; rather, there was a series of combinations in an attempt to limit the power of any one state.

THE FOURTH CENTURY B.C.E.

The rise of Macedonia radically changed the situation. The most crucial development of the fourth century B.C.E. was the rise of a powerful and expansive monarchy in Macedonia. Its creation was the work of Philip II (r. 359–336 B.C.E.). Philip consolidated a weak state rent by faction and in the process created an army superior to any the Greek world had yet seen. Macedonia had always had effective cavalry, but it was Philip's achievement to develop a superb infantry. Its organization must be inferred from Alexander's army, whose structure is far better known. The cavalry was organized into eight

units, one being the royal cavalry of 300, which also served as a bodyguard. The other seven units were each 200 to 300 men strong. The infantry phalanx was levied by geographical areas and by the end of Philip's reign was 24,000 strong and divided into sections of 1,500. Two other infantry units are known, one of 250 and one of 16. There were also substantial numbers of light-armed troops of all types drawn from Macedonian and subject populations, who also provided specialized units. The king was normally in command and had a number of senior commanders drawn from the Macedonian nobility, who commanded units on the battlefield and in independent expeditions. The Macedonian army represented a departure from traditional Greek forces. For the first time a force was created that effectively used different modes of fighting in combination in large-scale battle.

The army that Philip's son, Alexander the Great (r. 336–323 B.C.E.), led against Persia in the spring of 334 B.C.E. was essentially the force his father had created except for a substantial presence of allied Greek contingents. It probably differed only in having a higher proportion of cavalry, since the main Persian strength was concentrated in that arm. One innovation Alexander may have made was the creation of an elite infantry guard, the hypaspists of 3,000 men who were armed in the same manner as other heavy infantry and under the direct command of the king. Attrition, distance, and Alexander's own vision led to an attempt to incorporate Oriental troops into his army. Oriental cavalry were added to the army as Alexander advanced eastward, but they were kept separate from Macedonian troops. Orientals were denied positions of command except in special circumstances.

Alexander's conquests of the Persian Empire and northwestern India created the initial conditions for a massive movement of population from Greece and Macedonia to the Near East. This movement, over by about 250 B.C.E., led to the spread of Greek culture and the extensive urbanization in the Near East. The kingdoms of Alexander's successors were controlled by Greeks and adopted Greek political practices. The military forces continued and completed a military revolution. The use of professional soldiers culminated in the professional standing armies of the Ptolemies and the Seleucids. Militia-based armies continued to exist on mainland Greece and in Macedonia, but even there professional soldiers were employed on a substantial scale. These were much more heterogeneous armies than those of the Classical Period (480–323 B.C.E.), consisting of Greeks, Macedonians, and mercenaries drawn from all over the Mediterranean as well as levies of subject peoples. War and conquest had created Greek states on a far vaster scale than earlier. Despite these advantages, none of the monarchies created in the wake of Alexander's death was capable of resisting the advance of a Roman army based on the militia system.

Alexander's death in 323 B.C.E. led to a half century of struggle, which ended in the establishment of three large successor kingdoms: the Ptolemaic based in Egypt, the Seleucid, whose territory stretched from the seacoast of Asia Minor to northwestern India at its greatest extent, and the

Antigonid, centered in the Macedonian heartland. Their armies were direct descendants of Philip's and Alexander's. There were changes in scale; armies were now much larger, and cavalry declined in importance. An innovation of the period was the institution of an elephant corps. Europeans had first met the elephant in battle in northwestern India and were quick to adopt it for their own use. Elephants were used to screen against cavalry, to attack infantry, and to break into fortifications. After 300 B.C.E. they were equipped with towers manned by troops armed with missile weapons. Little is known of how these elephants were organized. Difficulties in breeding as well as the general ineffectiveness of elephants in European warfare led to their disappearance from Western battlefields by the middle of the second century B.C.E.

The major Hellenistic armies, except for the Macedonian, which relied on its own population for its main military forces, used mercenaries. Greeks serving as mercenaries in the Near East are known as early as the seventh century B.C.E. However, in Greece the use of a militia as the main military force meant that mercenaries appear infrequently. The first large-scale use of such forces dates from the Peloponnesian War and continues into the fourth century C.E. Economic troubles caused by the war and by the growing need for specialist troops whose fighting techniques required extensive training spurred their use. Philip and Alexander employed them as well. The Hellenistic monarchies had an enormous need for manpower, and although the core of their armies consisted of Greek and Macedonian settlers, they hired large numbers of mercenaries from all over the Mediterranean. A parallel development can be seen in naval forces, where professional rowers had to be hired.

ROME

BY JAMES A. CORRICK

By tradition the doors to the temple of Janus in the Roman Forum were closed in times of peace and open during times of conflict. During the centuries of the Roman Kingdom and Roman Republic, these doors were shut only twice, and after the formation of the empire they were open far more often than they were closed. War was indeed a constant throughout Rome's history, for Rome was built on war and conquest. Its dominance of the Mediterranean world was through force of arms. Its treasury and many of its prominent citizens and leaders were periodically enriched through the loot of conquest and the governance of conquered provinces, whose inhabitants were forced to pay tribute under the threat of Roman military reprisal.

ROMAN ATTITUDES TOWARD WAR

The Romans were a militaristic people who saw war as a natural—indeed a proper—way of establishing their dominance over others. Thus for much of its history Rome spent half of its revenues on maintaining its military and on waging war. It gave its top officials—consuls, praetors, proconsuls, propraetors, and the occasional dictator—the imperium that gave

them the authority, among other things, to command troops in battle. It demanded that its elected officials not only serve in the military but also have combat experience. Further, it elevated Mars, who had been a minor agricultural god, to the second most powerful deity in the Roman pantheon, just after Jupiter, by making him the god of war.

The Roman character itself was shaped by war and the demands of war. The Romans were a people who valued discipline, endurance, and courage and who saw duty to the state as among the highest goals to be achieved. They praised those who rejected luxury for austere living and who took no notice of physical hardship. They admired the pragmatic. All of these characteristics made for good, reliable soldiers.

Yet despite their belief in the rightness of combat and battle, Romans did not take war lightly. They knew, as the Roman poet Virgil (70–19 B.C.E.) wrote in the *Aeneid*, that war was horrible. Accordingly, the centuriate assembly was to debate the justness and necessity of any proposed military action, which its delegates then had to approve through majority vote. Nor were Romans reluctant to use other means of gaining their ends. Roman officials, for instance, often negotiated with states to avoid war; sometimes they brought these states under Rome's influence through treaties, sometimes through large bribes to foreign rulers.

Still, Rome was mostly at war somewhere in the Mediterranean, the Middle East, or along its northern European border. The deliberations of the centuriate assembly were often short-circuited by aristocratic influence over delegates who voted as their patrons desired; patricians could enrich themselves only through agriculture or war and were thus often inclined to go to war. Occasionally, Roman leaders simply ignored the assembly altogether. Diplomatic efforts were often feeble or filled with demands the Romans knew would be rejected.

In the end, successful wars of conquest led Romans to see themselves and their culture as superior to others. They were convinced that Rome's destiny was to be ruler of the world. They had no hesitation in pursuing that destiny through warfare and military occupation of other lands, nor did the Romans question that they had a right to plunder and loot their fallen enemies for the enrichment of Rome.

EARLY ROME

Nothing is known about Roman warfare prior to the eighth century B.C.E. Beginning in the eighth century, according to Roman historians such as Livy (ca. 59 B.C.E.–17 C.E.), the Roman Kingdom fought a number of wars with neighboring peoples, among them the Albans, the Fidenae, and the Sabines. The latter were defeated in several battles after they attacked in response to Romans supposedly seizing Sabine women for wives. To what extent these accounts of early war are factual is difficult to know because no actual records survive from this early period. For the most part, Rome's early wars were probably minor affairs, in general being no more than skirmishes with neighbors that consisted of border disputes or raids to seize livestock, slaves, and plunder.

Little is known about the Roman army of the early kingdom. Probably small, the army was led by the king and consisted of the royal bodyguard and a few hundred citizens of the city. By the end of the seventh century B.C.E. the army, a militia of citizen soldiers, had grown, with its organization deriving from the supposed three tribes that inhabited the Roman kingdom: the Ramnes, the Tities, and the Luceres. Each tribe contributed 1,000 soldiers, who supplied their own weapons and armor and who were under the command of a tribune, or tribal officer. Further, each tribal subdivision provided 100 men to form a unit known as a century. The total 3,000-strong body was called the *legio*, or levy, better known as a legion. Attached to the legion was the cavalry, numbering some 300.

The infantry would remain the core of all Roman armies. Infantry units could move more quickly and readily than cavalry through the often mountainous Italian terrain and in later centuries were more easily transported by sea to distant conflicts. Chariots, popular in other parts of the ancient world, were impractical and rarely employed by the Romans in war because of their legacy of fighting in rugged Italy. Because of their reliance on infantry, the Romans would always favor close-quarter, or hand-to-hand, fighting. Roman cavalry would act primarily as scouts and as protection from enemy cavalry as well as for rear attacks against opposing troops.

War for early Rome was a seasonal business, with the summer being the traditional battle season for the city. Winter conditions were generally too poor for combat, and the Roman soldiers, being mostly farmers, had to plant in the spring and harvest in the fall. At the end of summer campaigning, the legion was disbanded to be reformed the following year.

A CHANGE IN STRATEGY

Beginning in the fifth century B.C.E., the first years of the republic, Rome used its army to conquer and dominate its Etruscan neighbors north of the Tiber. This initial series of conquests culminated with Rome's victory over its archrival Veii in 396 B.C.E.

This series of conquests marked a change in Roman strategy that would dictate the course of all Rome's wars until the time of the later empire. Prior to the fifth century B.C.E. Rome's strategy was primarily defensive, countering specific threats posed by neighboring peoples. However, in the fifth century B.C.E. Roman warfare became almost exclusively offensive with the Romans coming to view war as a means of subjugating others and thus expanding their territory. From the fifth century onward the Romans engaged in wars of conquest that in the end would give them control first of Italy and then of much of the Mediterranean. This expansion would offer Rome increased protection from attack by pushing its enemies farther from the city itself. Expansion in Italy also brought more farm land under Roman control. An important consequence of this larger food supply was the growth of the city of Rome.

Gaining dominance over other states required a battlefield strategy of not just defeating an enemy army on the field but also destroying the enemy force by killing as many opposing warriors as possible. Without the protection of its own army, many enemy states surrendered to the Romans. Any that continued to resist through use of their remaining soldiers or by arming noncombatants suffered bloody reprisals from the Romans, who often killed many of the surviving adults and sold the rest along with children into slavery.

Rome sometimes resorted to other means of winning a war that did not involve direct combat. Roman soldiers might burn enemy fields and thus force surrender through the threat of starvation. They might wait until an enemy army disbanded, either because the soldiers had to return to tend their fields or because they ran out of money to pay mercenary troops. On the whole, however, Romans preferred meeting and besting their enemies on the battlefield.

PHALANXES AND SIEGES

The Roman army of the early republic had grown to a legion of 6,000 infantry, to which 18 centuries of cavalry were attached. The legion was still divided into centuries, but the number of soldiers in each century varied. (Exact numbers are not now known.) Soldiers were recruited from five social classes of citizens, with those of the top class being able to afford to equip themselves with the best weapons and armor and with those of the lowest class lacking armor and armed only with slings and stones. Additionally, the Roman army was now modeled on the Greek hoplite forces, in which warriors carrying long thrusting spears and with shields overlapping marched in a succession of rows, varying in number from eight to 16, toward the enemy. These massed lines were called a phalanx, Greek for "roller," and allowed fallen soldiers in the front line quickly to be replaced from the lines behind.

Although they continued to prefer close-quarter infantry engagement during this early period of expansion, Romans learned siege craft when they attacked the Veian city of Fidenae. Unable to breach the city's defenses, the Romans laid siege. The purpose of a Roman siege, like any siege, was to cut the enemy off from supplies—food, weapons, and sometimes water—and then through repeated attacks to wear down resistance until Roman soldiers could gain entry to the besieged city. In later centuries the Romans would employ siege engines such as battering rams to bash in gates or to knock holes in defensive walls and ballista and onagers capable of hurling large rocks against enemy walls (the latter could also throw flaming pitch into an enemy city). The use of these engines helped bring a siege to a quicker end. At Fidenae the lack of such engines led to a siege lasting six or seven years.

DEFEAT AND REORGANIZATION

By the fourth century B.C.E. Rome was the strongest military power in central Italy. In terms of weapons and armor, Ro-

mans were generally no better equipped than their enemies. Rather, they owed their success in war to a stress on teamwork and esprit de corps over individual heroics. Additionally, the hard—sometimes brutal—training of Roman soldiers led to proficiency in the use of arms and to disciplined obedience. At all times on the battlefield, Roman soldiers were expected to maintain their formation and to stay sheltered behind their body-length shields, from behind which they delivered quick stabbing blows with their short swords.

Nonetheless, Romans were not invincible. Indeed, in 390 B.C.E., six years after its final victory over the Veii, Rome suffered one of its most humiliating defeats at the hands of Celts from Gaul. These Gauls first destroyed a Roman army and then went on to capture Rome and to demand an exorbitant tribute before retreating back north. The weakness that the Gauls exploited was the phalanx formation. Roman training and teamwork made the phalanx effective against other massed enemy infantry. Nevertheless, it did not allow Roman soldiers much flexibility of movement on the battlefield, while

the Gauls who fought as individuals or in small groups were more mobile and thus were able to outflank the Romans.

The Romans quickly abandoned the phalanx and adopted a new battlefield formation that divided the legion into units called maniples. A maniple, from a Latin word meaning “handful,” consisted of 160 soldiers, or two centuries of 80 each. Each maniple acted semi-independently and was arranged in three lines. The front line would engage the enemy and then, after about 15 minutes, would fall back and be replaced by the second line, which in turn would be replaced by the third. This maneuver gave the soldiers a period of rest before rejoining the fight. The single legion of the army was also replaced by first two, then three, and finally four legions. Each legion had 60 centuries or 30 maniples.

PYRRHUS AND WAR ELEPHANTS

Although the defeat by the Gauls left Rome weakened, it soon grew militarily powerful again and, with its restructured army, brought the Italian peninsula under its control over the next century. In doing so, Rome had to fight three wars with the Samnites, beginning in 343 B.C.E. It was in 312 B.C.E., during the second of these wars (326–304 B.C.E.) that the Romans, realizing that they needed a method of moving troops and supplies rapidly, built the first of their roads, the Via Appia, or Appian Way, Roman roads would be one of the keys to Rome’s success in waging successful war in the centuries to come, as they were able to rush troops relatively quickly to trouble spots in their holdings.

In 280 B.C.E. Roman expansion in Italy brought war with the Greek colony of Tarentum, to whose aid Pyrrhus, ruler of the Greek city-state Epirus, came. This war was the first time that Rome faced one of the Mediterranean superpowers and the first time that its soldiers encountered war elephants. It was these latter that gave Pyrrhus a victory in his first two battles with the Romans.

The Romans may have lost the first battles, but as would be their practice in the centuries to come they refused to concede defeat. Instead, they regrouped and continued the war. They allied themselves with the other major Mediterranean power, the Carthaginians, and they adapted their battlefield tactics to deal with enemy elephants. In 275 B.C.E. the Romans met Pyrrhus for the final time and defeated him by routing his elephant corps through the use of javelins and fire and perhaps at times by hitting the animals on the head.

THE FIRST PUNIC WAR

The defeat of Pyrrhus left the Greek colonies open to Roman conquest, and Rome quickly defeated each in battle. As the Romans were finalizing their control of Italy, they became embroiled in a war with Carthage over Sicily. Rome and Carthage would fight three wars, the first from 264 to 241 B.C.E. Known as the Punic Wars, these conflicts would leave Rome with the beginnings of its overseas empire and as the strongest state in the Mediterranean world. Carthage would be destroyed.

Bronze statuette of Mars, god of war, Roman Britain, second century C.E., from Earith, Cambridgeshire; Mars wears the armor of a general, including an elaborate helmet, sheet-metal leg guards decorated with thunderbolts, and an embossed chest plate moulded to the form of the body. (© The Trustees of the British Museum)

The outcome of this conflict was by no means assured, particularly since Carthage was the great naval power of the period and Rome had no navy at all because the city's wars had to date been conducted on the Italian mainland, generally inland. When water transport was necessary to carry troops along the Italian coast, Rome turned to its allies on the Bay of Naples for ships and crews. In order to win the First Punic War, Rome built its first fleet, modeling its ships on captured Carthaginian vessels. The Romans developed a new device to aid them in this new type of warfare. The *corvus* was a large gangplank that could be dropped onto an enemy ship. A large spike at its end drove deep into the enemy's deck. Army legionnaires then crossed over the *corvus* to take the other vessel. The device worked very well, allowing the Romans to use their greatest battle strength, close-quarter infantry fighting. With the aid of the *corvus* the Romans defeated two Carthaginian fleets and won the First Punic War.

Despite two more wars with Carthage and other sea engagements, the republic never maintained a permanent navy. When a fleet was needed, it was built, as for Pompey's expedition in 64 B.C.E. against the pirates of the Mediterranean. Even when they existed, republican fleets often came to grief. Led by commanders with no nautical experience, entire fleets were lost to storm and shipwreck. It would not be until the empire that Rome would maintain a permanent navy, and even then the seafaring service would remain secondary to the army.

THE SECOND AND THIRD PUNIC WARS

During the Second Punic War (218–202 B.C.E.) the Carthaginian general Hannibal (247–183 B.C.E.) crossed the Alps; after inflicting a series of devastating defeats on the Romans, most notably at Cannae, he and his army ravaged the Italian countryside. Hannibal made no attempt to attack the city of Rome, perhaps because its walls, built after the Gauls' capture of the city in 390 B.C.E., made Rome a difficult target. Instead of continuing in its attempt to defeat Hannibal's army, Rome tried a new tactic: It launched an attack on the city of Carthage. Hannibal was recalled to defend his home, where he was overcome by the Roman general Scipio Africanus Major (236–184 or 183 B.C.E.).

Carthage was destroyed in the Third Punic War (149–146 B.C.E.). Following their strategy of annihilating their enemies, the Romans captured the city of Carthage after a brief siege, sold into slavery those Carthaginians not killed, and razed the city to the ground. When the Romans finished, nothing remained of the Carthaginians or their culture, and Rome was the most powerful state in the Mediterranean.

The Punic Wars left Rome in control of Sicily, North Africa, and parts of the Iberian Peninsula. Over the next century they conquered and occupied the southern part of Gaul, Macedonia, Greece, and much of the Middle East. Although Rome was still technically a republic, it was by the first century B.C.E. an empire in all but name.

SOCIAL CHANGE

Roman war and the conquest brought power and wealth to Rome, but they did even more. They changed what was a small farming community, more town than city, into one of the largest and most cosmopolitan cities of the ancient world. Rome became a place where people from all over the Mediterranean lived, worked, and traded. Roman society itself was, if not softened, altered by exposure to other peoples, most notably the Greeks, whose literature, art, and philosophy were embraced by many Romans.

War also brought to Rome millions of slaves, whose cheap labor led to economic dislocation for many Roman citizens. By the first century B.C.E. the small farms of early Rome had mostly given way to large farming estates owned by wealthy individuals and worked by slaves. The small Roman farmers were left landless and without a livelihood. Occasionally, one of these estates was broken up and its land distributed to soldiers, such as those who served Pompey and Julius Caesar. However, such redistributions were not given to Roman peasants, many of whom made their way to Rome, where they lived in tenements and depended on food from the state grain supply. There was little but poverty for these Roman citizens, for as in the countryside, most work in the city was done by slaves.

POLITICAL CHANGE

War and conquest also led to political change. The political organization of the republic, designed to rule a single city, was not capable of handling the administration of such a large realm. The Roman Republic lacked any true central authority and had virtually no state employees with which to handle the day-to-day details of government. Its ruling officials, two consuls, served for only one year, a period that was often insufficient to study and then handle problems in Rome's far-flung provinces. Additionally, the consuls could overrule each other and be overruled by other elected officials, so important matters frequently were left unattended for years at a time. Although they had fewer checks on their power, Rome's provincial governors, the proconsuls and propraetors, also rarely had more than a yearlong appointment, sometimes a goodly amount of that time being eaten up preparing for the job and then traveling to the assigned region. The strain of governance was one of the contributing factors leading to the eventual disintegration of the Roman Republic and the emergence of the Roman Empire, with its single source of authority, the emperor, and its elaborate bureaucracy.

This political change was also aided by the rise at the end of the second century B.C.E. of generals whose troops were more loyal to them than to the state. These generals, among them Marius (ca. 157–86 B.C.E.), Sulla (138–78 B.C.E.), Pompey (106–48 B.C.E.), and Julius Caesar (100–44 B.C.E.), became rich from the plunder of successful campaigns and used this money to buy the favor of many Roman citizens. Caesar, for instance, for one year paid the rent of everyone living in

Rome. These generals also vied with one another for power. They fought pitched battles until in 31 B.C.E. Octavian, later Augustus Caesar (ca. 27 B.C.E.–14 C.E.), emerged victorious, soon becoming the first emperor.

MILITARY CHANGE

The army also underwent changes during the growth of Rome as an imperial power. The Punic Wars and those fought elsewhere required an increase in the number of legions to 20, along with the creation of several urban legions made up of the old and underaged, whose duty it was to protect the city of Rome. Over the final three centuries of the republic, the number of legions would fluctuate according to military demands; the number appears not to have dropped below six.

At the end of the second century B.C.E. further changes were made to the structure of the legion. These changes would remain in place until the late empire. According to tradition, under Gaius Marius each legion was divided into 10 cohorts rather than 30 maniples. A cohort was made up of 480 soldiers divided among six centuries, thus giving each legion a complement of 4,800. When combined with a new weapon, a long spear called a *pilus*, the cohort was felt to retain flexibility in combat while increasing the strength of the Roman force. At the beginning of battle each legionnaire threw his *pilus*, the point of which was designed to bend so that it could not be used against the Romans. A *pilus* was capable of piercing light armor, and if it stuck in an enemy soldier's shield, its weight would make the shield too cumbersome to carry.

Over time, each legion was also augmented by a body of troops that came from various Latium and other Italian communities. Generally, some 500 soldiers and cavalry were drafted from each town until each legion was accompanied by an auxiliary, known as an *ala sociorum* (wing of allies), which was of equivalent size to the legion itself. Attached to each legion was also an elite group of allied fighters, the *extraordinarii*. Mercenaries, particularly archers from Crete, also fought with each legion. When on campaign, then, each legion fielded a total of between 8,000 and 10,000 troops along with 750 to 1,250 cavalry.

THE NATURE OF ROMAN WAR

Over the centuries the nature of Roman warfare itself changed. The skirmishes and raids of the kingdom and the early republic—brief affairs at best—turned into long offensive campaigns of conquest that required extended marches or sea voyages just to reach the enemy. Once engaged, Roman soldiers might have to fight several battles in succession. Sometimes campaigns lasted years and involved not only battle but lengthy sieges of enemy cities and strongholds. Once a region was conquered, it had to be occupied by permanent garrisons. These extended campaigns and occupations also changed the character of the Roman army. By the end of the first century C.E., what had started as a seasonal, volunteer militia made up of part-time soldiers had transformed into a standing army with a core of career professionals.

When in the second century C.E. the empire reached its farthest extent, the nature of Roman war once more changed. Instead of large offensive campaigns, the army was engaged mostly in consolidating the frontier areas that were still in the process of becoming Roman—indeed, many never really did—and in patrolling and defending the imperial borders.

THE AMERICAS

BY MICHAEL J. O'NEAL

As communities of people migrated and spread throughout the Americas in ancient times, they inevitably came in conflict with one another. The usual source of the conflict would have been territory and resources. As one nation encroached on another's territorial hunting grounds, the earlier inhabitants very likely would have resisted, and conflict would have erupted. The problem for historians, as is often the case with the ancient world, is the lack of any kind of documentation for warfare. Accordingly, historians have to rely on other tools. One such tool consists of oral legends about warfare that were transmitted over many generations. Sometimes, archaeological findings can shed light on ancient conflict. In South America, for example, tombs have been found with inscriptions, weapons, and battle dress that shed some light on ancient warfare.

NORTH AMERICA

Among the many nations of North America, conflict was inevitable and probably frequent. Numerous examples could be cited, but one that dates back to at least 1000 B.C.E. is the conflict between the ancient ancestors of the Lenape and the Allegewi (the source of the name given to the Allegheny Mountains and the Allegheny River in the eastern United States)—though again, historians have to rely on oral tradition and archaeological finds. The Lenape, also known as the Lenni Lenape, migrated eastward until they came to the Mississippi River, which they called Namesi Sipu (“River of Fish”), the source of the word *Mississippi*. Here they met up with and formed a peaceful alliance with the Mengwe, who had migrated from the north in the region around the source of the river.

On the other side of the River of Fish were the Allegewi. The Lenape sent scouts across the river to reconnoiter, and the scouts came back with tales of giants who lived in walled cities and appeared to be warlike. The Lenape had no wish to do battle with the Allegewi, so they sent emissaries requesting permission to travel through Allegewi territory to points farther east. The Allegewi granted permission, so the Lenape began to cross the river in great numbers. The Allegewi, not knowing that so many people would be crossing their land, felt threatened, and they attacked, killing a large number of Lenape. The Lenape, in turn, fought back and, according to oral legend, routed the Allegewi and drove them southward. The Lenape then occupied the region around the Ohio River valley, while the Mengwe returned to the north. In time the

Lenape continued their eastward trek into the forested regions of the eastern United States, giving rise to at least 40 nations, including the Delaware, which found homes in New York and along the eastern seaboard. The Mengwe in time evolved into the Iroquois. Ironically, the two nations that had formed an alliance during war and lived in harmony for many centuries after defeating the Allegewi themselves became bitter enemies.

Native North Americans did not mount “armies” as the term is conventionally understood. Rather, the war party generally constituted the fighting forces of Native Americans. Generally, the leader of a war party was a chief or another member of the nation who had shown courage in battle on a former occasion. Usually, such a person was said to have “medicine,” meaning a kind of spiritual power that would make him and his force victorious. Individual warriors also had medicine, and this medicine was typically symbolized by an object, such as an amulet, that the warrior carried into battle. Interestingly, it is believed that among some nations, women as warriors were as fierce as men. Warfare among ancient Native Americans was not always intended to vanquish the enemy and seize his territory and resources. Rather, warfare was often regarded as a kind of ritual activity with spiritual implications. The number of casualties in these types of conflicts was often quite low, and in some cases, the goal of a warrior was merely to touch an enemy soldier and perhaps seize his weapon.

The most common battle tactic of Native Americans was stealth. Because large bodies of soldiers did not take part in battles, smaller bands of warriors moved swiftly and silently over the landscape, finding ways to sneak up on or ambush the enemy. Retreat was not considered a form of dishonor; rather, retreat was often a strategic move designed to lure the enemy to a place where he could be confronted and defeated. Related to strategic retreat was the principle of force concentration. Rather than allowing the line of battle to be spread out, it was common to lure enemy forces into a ravine, a small valley, a narrow mountain pass, or some other similar place where the attacking force could focus its attack. In many respects ancient Native American warfare was similar to guerrilla warfare. The goal was usually not to overwhelm the enemy with a large, superior force but to harass the enemy and pick off enemy soldiers one at a time or in small groups.

Weapons differed depending on the types of tools and materials that were available to a given tribe. Thus, for example, the groups of the Arctic North used spears—the same spears they used for fishing and hunting for sea mammals—often tipped with points made of bone. Other groups used spears that were otherwise used for big-game hunting, though they were likely tipped with stone. Other weapons included the bow and arrow, the club, the sling, and the tomahawk—any hatchetlike implement with a stone head, used primarily by eastern North American nations, whose soldiers

threw it at enemy soldiers. Sticks and knives were also common weapons.

Also important was hand-to-hand combat, and Native American warriors were skilled at forms of martial arts that enabled them to overcome enemy soldiers in close quarters. Some Native American nations adopted forms of armor and helmets. A form of psychological warfare that was implemented involved throwing weapons that were elaborately decorated with feathers and other objects; masks with fierce grimaces were often worn. Native American war paint on the face, arms, and upper body was also common. It should be noted that ancient Native Americans did not fight on horseback. Horses did exist in ancient North America prior to at least 6000 B.C.E., when they became extinct on the continent, but they were not domesticated, meaning that ancient peoples probably used them only as a food source. The horse became a weapon of war only after the arrival of the Europeans and their domesticated horses in the 16th century C.E.

MESOAMERICA

Archaeologists for many decades believed that the societies of ancient Mesoamerica were relatively peaceful. More recent findings, however, suggest otherwise—that warfare was a way of life for some Mesoamerican cultures, at least during portions of their history. Among the Maya, the most dominant culture of ancient Mesoamerica, warfare was conducted to capture victims for ritual sacrifices and to control trade routes and resources. Additionally, warfare was a source of slaves for building temples and other monuments.

The Maya defended their cities with earthworks and walls—often systems of double walls, where enemy invaders were trapped and slaughtered after breaching the outer wall. In common with other warriors in North and South America, they fought primarily with weapons they could hurl. The atlatl was a device that gave greater impetus and range to spears; it consisted of a shaft in which the spear rested, enabling the warrior to hurl the spear by propelling the atlatl, giving the spear much more energy. The *macahuitl* was a wooden weapon that was used like a club or a sword; sharp blades made of obsidian were inserted into the wood, making the weapon lethal. Blowguns were also used, and while bows and arrows were sometimes employed, they were not common weapons. Ordinary warriors wore no helmets, but they carried shields made of wood, animal skins, or woven mats. Leaders, on the other hand, dressed themselves for battle in padded armor and elaborate headdresses, all decorated with religious symbols designed to inspire fear in the enemy.

At the head of Maya military forces was the ruler of each city. Each city had a small group of soldiers who captured sacrificial victims; this group was supplemented by a militia during times of war. Commoners were often recruited to fight, but since they had no military-style weapons, they used hunting tools and rocks. On some occasions, women

took part in battles. A chief strategy was to use the forests as cover, luring in enemies and then ambushing them. Sometimes canoes were used to approach enemy cities located on rivers and lakes.

Among the Mesoamericans, warfare was very much a religious ritual activity. Warfare was sanctioned by the gods, and leaders were men of religious authority. Warriors called on help from the gods by singing, blowing horns and whistles, and beating drums as battles began. Religious items were carried into battle. Death in battle was regarded as a far more desired fate than capture by the enemy, for it was common for captured soldiers, especially their leaders, to be degraded with cruel treatment and for their religious symbols to be desecrated.

Mesoamerican warfare was much more sophisticated than warfare among more northerly Native Americans. Very often Mesoamericans fielded large armies, perhaps as many as 20,000 troops and often more. The Mesoamericans conducted warfare in a way that seems more modern. Armies sacked cities, but very often, too, they conducted field operations in open areas; in other words, while northern Native Americans conducted more guerrilla-type warfare, Mesoamericans conducted war based on superiority of forces. Further, Mesoamericans trained for war. Many young boys went to schools that emphasized not only academic subjects but the arts of warfare as well, particularly the use of weapons, such as the spear, the shield, and the others discussed earlier. When they turned 17, they were assigned to military regiments. Armies were highly organized, with trained generals, units, couriers, porters, flag bearers, bodies of foot soldiers, bodies of archers, and the like. Like modern armies, Mesoamerican armies had ranks of soldiers; a person moved up through the ranks by showing courage and skill, and a soldier's rank was indicated by an elaborate flag on his back that identified his clan, family, or city.

SOUTH AMERICA

Historians and archaeologists long believed that warfare in ancient South America was not common. They pointed to the fact that South American societies tended to be small and decentralized. Thus, dominant societies did not mount armies of conquest. However, much of the archaeological record shows defensive remains, such as walls, moats, ditches, and parapets, though some archaeologists question whether these "defenses" could possibly have been effective and suggest that they served more ritualistic purposes. For example, they note that "forts" had no source of water, suggesting that they could not have been used as refuges for armies for more than brief periods of time. Further, the forts had numerous points of entry and even gaps, making them inadequate for defense.

However, more recent archaeological thinking suggests that warfare may have been more common than was previously thought. These scholars emphasize, though, that South American warfare tended to be prosecuted not by large armies

in open fields of battle. Rather, it was conducted more like the wars of Native North Americans, with emphasis on guerrilla tactics. Further, warfare tended to be ritualistic and even relatively bloodless—more a form of social negotiation rather than an effort to destroy an enemy. The word used to convey this idea is *tinku*, which means something like "ritual battle." Scholars draw these conclusions by looking at the archaeological remains, which include many pictures of ritualized war and in particular ritualized conflict between people who are not adult males. This record shows that the most common weapons in ritualized warfare were clubs, slingshots, and even whips.

The practice of capturing enemy soldiers for ritual sacrifice was common in South America. Among the Moche, for example, the purpose of warfare was not to conquer enemies so much as it was to obtain captives for ritual sacrifices conducted by warrior-priests. Surviving decorations on pottery, for example, show these sacrifices being conducted, with enemy soldiers having their throats slit and warrior-priests drinking goblets of the soldiers' blood. In conducting war South Americans used weapons that were in most respects similar to those used in North America and Mesoamerica: knives, lances, and particularly clubs. Bows and arrows do not seem to have been as widely used.

South America also provides a clear example of the relationship between warfare, resources, and climatic conditions among the Andean people of Peru. Recent archaeological findings show that the Andeans developed a complex, thriving civilization beginning in about 3000 B.C.E. They built cities, including the city of Caral, pyramids, monuments, and plazas that have only begun to be explored fully. For about 1,200 years the Andeans lived peaceably with their neighbors. Very early on ocean currents provided rich marine life along the coast as well as a climate for growing fruits and vegetables. But at some point the climate turned much drier, so the Andeans built canals to irrigate what was becoming desert. Their problem was that over time the soil became progressively less productive, leading to a decline in their civilization. By about 1800 B.C.E. the region had been conquered by neighboring states.

Africa

~ Herodotus: "The Carthaginian Attack on Sicily,"
excerpt (The Histories, fifth century B.C.E.) ~

VII.165: They, however, who dwell in Sicily, say that Gelo, though he knew that he must serve under the Lacedaemonians, would nevertheless have come to the aid of the Hellenes, had not it been for Terillos, the son of Crinippos, king of Himera; who, driven from his city by Thero, the son of Ainesidemos, king of Agrigentum, brought into Sicily at this very time an army of three hundred thousand men—Phoenicians, Libyans, Iberians, Ligurians, Helisykians, Sardinians, and Corsicans, under the command of Hamilcar the son of Hanno, king of the Carthaginians. Terillos prevailed upon Hamilcar, partly as his sworn friend, but more through the zealous aid of Anaxilaos the son of Cretines, king of Rhegium; who, by giving his own sons to Hamilcar as hostages, induced him to make the expedition. Anaxilaos herein served his own father-in-law; for he was married to a daughter of Terillos, by name Kydippe. So, as Gelo could not give the Hellenes any aid, he sent (they say) the sum of money to Delphi.

VII.166: They say too, that the victory of Gelo and Thero in Sicily over Hamilcar the Carthaginian fell out upon the very day that the Hellenes defeated the Persians at Salamis. Hamilcar, who was a Carthaginian on his father's side only, but on his mother's a Syracusan, and who had

been raised by his merit to the throne of Carthage, after the battle and the defeat, as I am informed, disappeared from sight: Gelo made the strictest search for him, but he could not be found anywhere, either dead or alive.

VII.167: The Carthaginians, who take probability for their guide, give the following account of this matter: Hamilcar, they say, during all the time that the battle raged between the Hellenes and the barbarians, which was from early dawn till evening, remained in the camp, sacrificing and seeking favorable omens, while he burned on a huge pyre the entire bodies of the victims which he offered. Here, as he poured libations upon the sacrifices, he saw the rout of his army; whereupon he cast himself headlong into the flames, and so was consumed and disappeared. But whether Hamilcar's disappearance happened, as the Phoenicians tell us, in this way, or, as the Syracusans maintain, in some other, certain it is that the Carthaginians offer him sacrifice, and in all their colonies have monuments erected to his honor, as well as one, which is the grandest of all, at Carthage. Thus much concerning the affairs of Sicily.

Egypt

~ Pen-ta-ur: "The Victory of Ramses II over the Khita,"
inscription on the wall of five temples, one at Karnak (ca. 1326 B.C.E.) ~

THEN the king of Khita-land,
With his warriors made a stand,
But he durst not risk his hand
In battle with our Pharaoh;
So his chariots drew away,
Unnumbered as the sand,
And they stood, three men of war
On each car;
And gathered all in force
Was the flower of his army,
for the fight in full array,
But advance, he did not dare,
Foot or horse.

So in ambush there they lay,
Northwest of Kadesh town;
And while these were in their lair,
Others went forth south of Kadesh,
on our midst, their charge was thrown
With such weight, our men went down,
For they took us unaware,
And the legion of Pra-Hormakhu gave way.

But at the western side
Of Arunatha's tide,
Near the city's northern wall,
our Pharaoh had his place.
And they came unto the king,

And they told him our disgrace;
 Then Rameses uprose,
 like his father, Montu in might,
 All his weapons took in hand,
 And his armor did he don,
 Just like Baal, fit for fight;
 And the noble pair of horses that carried Pharaoh on,
 Lo! "Victory of Thebes" was their name,
 And from out the royal stables of great Miamun they
 came.

Then the king he lashed each horse,
 And they quickened up their course,
 And he dashed into the middle of the hostile, Hittite
 host,
 All alone, none other with him, for he counted not the
 cost.

Then he looked behind, and found
 That the foe were all around,
 Two thousand and five hundred of their chariots of war;
 And the flower of the Hittites, and their helpers, in a
 ring—

Men of Masu, Keshkesh, Pidasu, Malunna, Arathu,
 Qazauadana, Kadesh, Akerith, Leka and Khilibu—
 Cut off the way behind,
 Retreat he could not find;
 There were three men on each car,
 And they gathered all together, and closed upon the king.
 "Yea, and not one of my princes, of my chief men and my
 great,
 Was with me, not a captain, not a knight;
 For my warriors and chariots had left me to my fate,
 Not one was there to take his part in fight."

Then spake Pharaoh, and he cried:
 "Father Ammon, where are you?
 Shall a sire forget his son?
 Is there anything without your knowledge I have done?
 From the judgments of your mouth when have I gone?
 Have I e'er transgressed your word?
 Disobeyed, or broke a vow?
 Is it right, who rules in Egypt, Egypt's lord,
 Should e'er before the foreign peoples bow,
 Or own their rod? . . .
 Let the wretch be put to shame
 Who refuses your commands,
 But honor to his name
 Who to Ammon lifts his hands.
 To the full of my endeavor,

With a willing heart forever,
 I have acted unto you,
 And to you, great God, I call;
 For behold! now, Ammon, I,
 In the midst of many peoples, all unknown,
 Unnumbered as the sand,
 Here I stand,
 All alone;
 There is no one at my side,
 My warriors and chariots afeared,
 Have deserted me, none heard
 My voice, when to the cravens I, their king, for succor,
 cried.

But I find that Ammon's grace
 Is better far to me
 Than a million fighting men and ten thousand chariots
 be. . . .

To you my cry I send,
 Unto earth's extremest end,
 Saying, 'Help me, father Ammon, against the Hittite
 horde.'"

Then my voice it found an echo in Hermonthis' temple-
 hall,
 Ammon heard it, and he came unto my call. . . .

Then all this came to pass, I was changed in my heart
 Like Monthu, god of war, was I made,
 With my left hand hurled the dart,
 With my right I swung the blade,
 Fierce as Baal in his time, before their sight.
 Two thousand and five hundred pairs of horses were
 around,
 And I flew into the middle of their ring,
 By my horse-hoofs they were dashed all in pieces to the
 ground, . . .

Then the wretched king of Khita, he stood still,
 With his warriors and his chariots all about him in a ring,
 Just to gaze upon the valor of our king
 In the fray.
 And the king was all alone,
 Of his men and chariots none
 To help him; but the Hittite of his gazing soon had fill,
 For he turned his face in flight, and sped away. . . .
 Then his princes forth he sent,
 To battle with our lord,
 Well equipped with bow and sword
 And all goodly armament, . . .

(continued)

(continues)

Then, like Monthu in his might,
 I rushed on them apace,
 And I let them taste my hand
 In a twinkling moment's space.
 Then cried one unto his mate,
 "This is no man, this is he,
 This is Sutek, god of hate,
 With Baal in his blood;
 Let us hasten, let us flee,
 Let us save our souls from death,
 Let us take to heel and try our lungs and breath."
 And before the king's attack,
 Lands fell, and limbs were slack,
 They could neither aim the bow, nor thrust the spear,
 But just looked at him who came
 Charging on them, like a flame,
 And the King was as a griffin in the rear.
 Behold thus speaks the Pharaoh, let all know,
 I struck them down, and there escaped me none
 Then I lifted up my voice, and I spake,
 Ho! my warriors, charioteers,
 Away with craven fears,
 Halt, stand, and courage take,
 Behold I am alone,

Yet Ammon is my helper, and his hand is with me now."
 . . .

When my Menna, charioteer, beheld in his dismay,
 How the horses swarmed around us, lo! his courage fled
 away,

And terror and affright
 Took possession of him quite;
 And straightway he cried out to me, and said,

"Gracious lord and bravest king, savior-guard
 Of Egypt in the battle, be our ward;
 Behold we stand alone, in the hostile Hittite ring,
 Save for us the breath of life,
 Give deliverance from the strife,
 Oh! protect us, Ramses Miamun!
 Oh! save us, mighty King!" . . .

Then the king, he hurried forward, on the Hittite host
 he flew,

"For the sixth time that I charged them," says the
 king—and listen well,

"Like Baal in his strength, on their rearward, lo! I fell,
 And I killed them, none escaped me, and I slew, and
 slew, and slew."

The Middle East

Excerpts from Accounts of the Campaign of Sennacherib

FROM THE SENNACHERIB PRISM (CA. 701 B.C.E.)

In my third campaign I marched against Hatti. Luli, king of Sidon, whom the terror-inspiring glamour of my lordship had overwhelmed, fled far overseas and perished. . . . As to Hezekiah, the Jew, he did not submit to my yoke, I laid siege to his strong cities, walled forts, and countless small villages, and conquered them by means of well-stamped earth-ramps and battering-rams brought near the walls with an attack by foot soldiers, using mines, breeches as well as trenches. I drove out 200,150 people, young and old, male and female, horses, mules, donkeys, camels, big and small cattle beyond counting, and considered them slaves. Himself I made a prisoner in Jerusalem, his royal residence, like a bird in a

cage. I surrounded him with earthwork in order to molest those who were his city's gate. Thus I reduced his country, but I still increased the tribute and the presents to me as overlord which I imposed upon him beyond the former tribute, to be delivered annually. Hezekiah himself, did send me, later, to Nineveh, my lordly city, together with 30 talents of gold, 800 talents of silver, precious stones, antimony, large cuts of red stone, couches inlaid with ivory, nimedu-chairs inlaid with ivory, elephant-hides, ebony-wood, boxwood and all kinds of valuable treasures, his own daughters and concubines.

**FROM THE HEBREW BIBLE,
2 KINGS 18:13–15, 19:35–37**

In the fourteenth year of King Hezekiah, Sennacherib, king of Assyria, went on an expedition against all the fortified cities of Judah and captured them. Hezekiah, king of Judah, sent this message to the king of Assyria at Lachish: "I have done wrong. Leave me, and I will pay whatever tribute you impose on me." The king of Assyria exacted three hundred talents of silver and thirty talents of gold from Hezekiah, king of Judah. Hezekiah paid him all the funds there were in the

temple of the Lord and in the palace treasuries. . . . That night the angel of the Lord went forth and struck down 185,000 men in the Assyrian camp. Early the next morning, there they were, all the corpses of the dead. So Sennacherib, the king of Assyria, broke camp and went back home to Nineveh. When he was worshiping in the temple of his god Nisroch, his sons Adram-melech and Sharezer slew him with the sword and fled into the land of Ararat.

Rome

~ Polybius: "*The Roman Maniple vs. The Macedonian Phalanx*,"
excerpt (*The Histories*, ca. second century B.C.E.) ~

In my sixth book I made a promise, still unfulfilled, of taking a fitting opportunity of drawing a comparison between the arms of the Romans and Macedonians, and their respective system of tactics, and pointing out how they differ for better or worse from each other. I will now endeavor by a reference to actual facts to fulfil that promise. For since in former times the Macedonian tactics proved themselves by experience capable of conquering those of Asia and Greece; while the Roman tactics sufficed to conquer the nations of Africa and all those of Western Europe; and since in our own day there have been numerous opportunities of comparing the men as well as their tactics, it will be, I think, a useful and worthy task to investigate their differences, and discover why it is that the Romans conquer and carry off the palm from their enemies in the operations of war. . . .

Many considerations may easily convince us that, if only the phalanx has its proper formation and strength, nothing can resist it face to face or withstand its charge. . . .

It is clear that in front of each man of the front rank there will be five sarissae projecting to distances varying by a descending scale of two cubits.

With this point in our minds, it will not be difficult to imagine what the appearance and strength of the whole phalanx is likely to be, when, with lowered sarissae, it advances to the charge sixteen deep. Of these sixteen

ranks, all above the fifth are unable to reach with their sarissae far enough to take actual part in the fighting. They, therefore, do not lower them, but hold them with the points inclined upwards over the shoulders of the ranks in front of them, to shield the heads of the whole phalanx; for the sarissae are so closely serried, that they repel missiles which have carried over the front ranks and might fall upon the heads of those in the rear. These rear ranks, however, during an advance, press forward those in front by the weight of their bodies; and thus make the charge very forcible, and at the same time render it impossible for the front ranks to face about.

Such is the arrangement, general and detailed of the phalanx. It remains now to compare with it the peculiarities and distinctive features of the Roman arms and tactics. Now, a Roman soldier in full armor also requires a space of three square feet. But as their method of fighting admits of individual motion for each man—because he defends his body with a shield, which he moves about to any point from which a blow is coming, and because he uses his sword both for cutting and stabbing—it is evident that each man must have a clear space, and an interval of at least three feet both on flank and rear if he is to do his duty with any effect. The result of this will be that each Roman soldier will face two of the front rank of a phalanx, so that he has to encounter and fight against ten spears, which one man cannot find time even to cut away, when once the two lines are engaged, nor force his way through easily—

(continued)

(continues)

seeing that the Roman front ranks are not supported by the rear ranks, either by way of adding weight to their charge, or vigor to the use of their swords. Therefore, it may readily be understood that, as I said before, it is impossible to confront a charge of the phalanx, so long as it retains its proper formation and strength.

Why is it then that the Romans conquer? And what is it that brings disaster on those who employ the phalanx? Why, just because war is full of uncertainties both as to time and place; whereas there is but one time and one kind of ground in which a phalanx can fully work. If, then, there were anything to compel the enemy to accommodate himself to the time and place of the phalanx, when about to fight a general engagement, it would be but natural to expect that those who employed the phalanx would always carry off the victory. But if the enemy finds it possible, and even easy, to avoid its attack, what becomes of its formidable character? Again, no one denies that for its employment it is indispensable to have a country flat, bare, and without such impediments as ditches, cavities, depressions, steep banks, or beds of rivers: for all such obstacles are sufficient to hinder and dislocate this particular formation. . . . If the enemy decline to come down into it, but traverse the country sacking the towns and territories of the allies, what use will the phalanx be? For if it remains on the ground suited to itself, it will not only fail to benefit its friends, but will be incapable even of preserving itself. . . .

For no speculation is any longer required to test the accuracy of what I am now saying: that can be done by referring to accomplished facts. The Romans do not, then, attempt to extend their front to equal that of a phalanx, and then charge directly upon it with their whole force: but some of their divisions are kept in

reserve, while others join battle with the enemy at close quarters. Now, whether the phalanx in its charge drives its opponents from their ground, or is itself driven back, in either case its peculiar order is dislocated; for whether in following the retiring, or flying from the advancing enemy, they quit the rest of their forces: and when this takes place, the enemy's reserves can occupy the space thus left, and the ground which the phalanx had just before been holding, and so no longer charge them face to face, but fall upon them on their flank and rear. If, then, it is easy to take precautions against the opportunities and peculiar advantages of the phalanx, but impossible to do so in the case of its disadvantages, must it not follow that in practice the difference between these two systems is enormous? Of course, those generals who employ the phalanx must march over ground of every description, must pitch camps, occupy points of advantage, besiege, and be besieged, and meet with unexpected appearances of the enemy: for all these are part and parcel of war, and have an important and sometimes decisive influence on the ultimate victory. And in all these cases the Macedonian phalanx is difficult, and sometimes impossible, to handle, because the men cannot act either in squads or separately.

The Roman order on the other hand is flexible: for every Roman, once armed and on the field, is equally well-equipped for every place, time, or appearance of the enemy. He is, moreover, quite ready and needs to make no change, whether he is required to fight in the main body, or in a detachment, or in a single maniple, or even by himself. Therefore, as the individual members of the Roman force are so much more serviceable, their plans are also much more often attended by success than those of others.

► weaponry and armor

INTRODUCTION

Warfare has been a constant element of life since ancient times, yet relatively few ancient weapons and armor have survived to be studied. Iron decays easily, as does the wood and other organic materials that early people used for weapons. Bronze has a better rate of survival, but this material was not used in southern Africa, the Americas, and Oceania. The study of ancient weaponry is further complicated by confusion over how weapons were used. While surviving art and literature from Europe, the Near East, and Asia contains descriptions of weaponry and armor, the same sources are not available for other regions of the world.

In Europe weapons were used almost exclusively to kill enemies and prey. A few daggers and swords, highly decorated and in the possession of high-status men, had ceremonial purposes. Daggers, swords, and spears were typically used for combat, with only daggers intended strictly for attacks upon humans. Slings were the first missile weapon, followed by the enormously popular bows and arrows. The Greeks invented chemical warfare in the form of Greek fire and sulfur gas. Metal, wood, skins, and leather were employed to construct head and body coverings as well as shields. The users of weaponry and armor in Europe were almost exclusively male.

In the Near East warriors used the same sorts of weaponry and armor that were found in Europe. The Assyrians are the earliest warriors of history of whom we have detailed knowledge. They were armed with spears, battle-axes, maces, swords, and shields as well as bows and arrows. Assyrians show liquid fire on bas-relief artwork. Along with other people of the region, they employed simple incendiary materials such as blazing arrows, pots of boiling oil, and naphtha. Babylonian spearmen protected themselves with square shields held edge to edge, as did the Greek phalanxes and Roman legions 3,000 years later. The Assyrians were the first to develop scale armor that consisted of many small metal plates sewn on a leather jacket so that the rows overlapped.

In the Americas some of the aboriginal people used copper and bronze, but they never developed wrought iron or steel for weapons. Stone arrowheads and spearheads continued to be used century after century, as they were in Oceania. In Asia the Hindus became renowned as the best temperers of steel in the ancient world. Few clues to the weaponry of ancient Africa remain. The Africans passed from the Stone Age directly into the Iron Age, missing the Bronze Age entirely. In the context of ancient Africa a weapon has to be viewed as part of a highly complex system of interdependent actions and beliefs. Some weapons were empowered by the application of magical substances. No matter how thick the hide of a shield or well tempered the blade of a sword, both were considered incomplete without the symbolic designs applied to them. Even accessories such as sword sheaths seem also to have had great importance.

AFRICA

BY CARYN E. NEUMANN

Western understandings of weaponry have limited application to Africa. In ancient Africa the separation between military and civilian life was not as distinct as in the West. While European weapons were made to kill, ancient African weaponry came in a wide variety of forms developed for use in political, religious, or other ritual or ceremonial contexts; not all were designed to kill.

Weaponry in Africa began with rock. The oldest surviving weapons in the world are pebbles chipped into blades that were found in Africa. These weapons also could double as tools or perhaps were an adaptation from tools; their use as tools no doubt preceded their use as weapons. These rough weapons advanced into knives made of sharpened rock, spears with stone tips, and hand axes shaped like almonds. One type of hand ax, the cleaver, has been found only in Africa. It had a hefty blade used for hacking, slashing, and cutting.

A wide variety of raw materials, including quartzite, hornfels, mudstone, and chert, was used in southern Africa for stone point production. Herodotus reported that Africans used spears with heads constructed from the sharpened horns of antelope. The points, with distinctive tangs, were bound to spears with plant twine, bark, leather thongs, and sinew. The binding materials would have been moistened before application. Moistened bindings expand and become more pliable before contracting to their original size upon drying. This shrinkage, and the fact that individual strands on drying tend to adhere to one another, leaves the point firmly secured on the haft.

The first long-range missile weapon was probably a sling, although no ancient African slings have survived. Slings were originally used by ancient shepherds to scare predatory animals that were attacking their herds. They gradually became weapons of warfare, used by light-armed troops against similarly defenseless warriors. The sling consisted of two leather or sinew straps. Each strap was attached at one end to the sides of a small piece of leather or cloth. The other end of one

Stone ball, Lower Palaeolithic, about 1.2 million years old, found in Olduvai Gorge, Tanzania; such stone balls might have been tied to a leather thong and used in hunting to bring down game. (© The Trustees of the British Museum)

strap, held by the slinger, was looped securely around a finger or wrist, while the other strap, usually knotted to provide a grip, was held freely between the thumb and forefinger of the throwing hand. The missile, a stone, was placed on a piece of leather, and the straps were pulled taut, creating a pocket for the stone. A rotary motion of the wrist, usually three or four rotations, gave the stone momentum when the unlooped, held strap was released. A skilled thrower could be very accurate, and the high-speed missile could kill.

Copper technology indicates that ancient Africans mastered a considerable degree of the pyrotechnology needed for copper smelting. Evidence of early copper metallurgy has been radiocarbon dated from 4140 B.C.E. to 2700 B.C.E. in western Africa. Copper products included thin arrowheads. There is evidence of iron production in East Africa from about 1400 B.C.E. The date suggests that iron production might not have been introduced from elsewhere but instead developed in the region. Iron ore is distributed widely across Africa. Stone artifacts were always present at early Iron Age sites in the form of arrow points and axes, with metal weapons used as status objects. Africans employed iron to make tools, weapons, and points for weapons. Many central African people believed that, except on a few designated occasions, women should not come into contact with iron. To do so could render a woman barren and destroy the power of the iron products with which she came into contact. However, other parts of Africa accepted women warriors, and the Teda of the Tibesti region developed weaponry specifically for women.

The Iron Age brought the use of throwing knives as missiles. Throwing knives, additionally used as long-distance currency, were more popular than javelins. The sharp spikes of these weapons could inflict severe wounds on practically

nude enemies. The classic form of the northern variety of throwing knife consists of a narrow piece of iron, up to 2½ feet in length, with a projecting spur a little over halfway up. Below this spur are a straight shaft and a grip, which, if not made of bare iron, is usually made of hide or reptile skin. Above the spur is the blade, often broader than the shaft and curving forward in the same direction as the spur. Weapons of this type were distributed across a wide area of Sudanic Africa from northern Nigeria to the Blue Nile province of Sudan and deep into the Tibesti region of the Sahara.

The typical southern variety of throwing knife is generally smaller than the northern variety. It usually has a number of blades radiating from the central shaft and a grip of plaited vegetal material or, occasionally, of wire or hide. It is found in a small area of northern Gabon and in a broad belt from eastern Cameroon almost to the White Nile. The Zande *kpinga*, a southern type of throwing knife, is one of the few varieties whose aerodynamic qualities and consistent use as a missile have been well documented. The heavier northern throwing knife was used more often than the lighter southern variety for ceremonial purposes.

Not every weapon was intended for war. Weapons of various types were widely used in dance and masquerade throughout Africa. The *musele*, a Kota throwing knife conceived as a bird in profile with a long bill, was not designed to be thrown. The Kota, of the eastern Ogooué River region, saw the *musele* as a prestigious weapon of chiefs to be used in dances. Throwing knives of the Wadai region were also ornithologically inspired and designed for ceremonial purposes. Among the Kota and the Fang spears, knives, and swords were considered to be emblems of the owner's status and were left on tombs of chiefs after death.

To protect against weapons, Africans used light armor that befitted their hot climate. The protective armor of the Benin warrior was a large wooden shield with a curved top and straight bottom. It was designed to be set on the ground to cover a kneeling man. The shields in the Sudan were made of hippopotamus or elephant hide. The shields of the Dinka were oval in outline and reinforced by a staff threaded through loops cut into the hide. The staff served as a handgrip. The Shuli had shields of a more nearly rectangular form, while the Shilluk and Nuer both had shields that could serve as clubs. The club shields were reinforced with a log with a cutout for the grip. The skin cover of ox hide was applied tightly in order to keep the wood from splitting when delivering blows with this shield club. Chiefs and other distinguished warriors throughout Africa wore helmets of padded basketwork or crocodile skin. For body armor they had quilted ponchos covered with leopard skins.

EGYPT

BY AMR KAMEL

Ancient Egyptian weapons apparently were manufactured in the workshops attached to royal palaces, great temples, and

military headquarters. There are a few scenes from the Old and Middle Kingdom (ca. 2575–ca. 1640 B.C.E.) that depict bows and spear shafts being smoothed and others that show arrows. From the New Kingdom (ca. 1550–ca. 1070 B.C.E.) there is much pictorial evidence showing various techniques used in weapons manufacture. Scenes include a craftsman straightening the shaft of a spear over a fire after wetting it from a cup of water beside him, a bow being tested for resilience, arrows being made, metal helmets being weighted, bow cases being sewn up with an awl (a pointed tool for punching holes), and an arrow being checked for straightness by one workman while a second uses an adze (a bladed tool) to plane out another arrow resting on his knees.

A letter sent by Dhutmose, a scribe who was on a military mission in Nubia, to his son, Butehamun, the scribe of the Necropolis at Deir el-Medina, requests “fresh supplies of copper spear-heads” made by the local coppersmiths as well as spare parts for war chariots, new material for clothing, and old material “for bandages,” a rare sign of concern for the wounded. Several New Kingdom tombs include representations of carpenters, joiners, and leather workers, all working on a chariot together. In addition to wood, they required large amounts of leather for fastening parts together, covering the body, tiring the wheels, and making reins, blinkers, and bits.

During the New Kingdom the Egyptians imported highly developed weapons from the Near East and adopted Near Eastern military technology. There is perhaps some evidence that non-Egyptian craftsmen participated in weapons manufacture. Bows and arrows, the most important long-range weapons, can be dated to the Late Paleolithic Period (ca. 12,000–10,000 B.C.E.). During the Second Intermediate Period (1640–1532 B.C.E.) the composite bow was introduced from the Near East. It was made from laminated wood, horn, and sinew and had a much improved range and power. It had an effective range of 500 to 600 feet, and an exceptional shot could attain a distance of 1,500 feet. Because of the laminate construction of composite bows, they were sensitive to heat and moisture and thus were usually stored in cases. Two types of cases have been discovered from New Kingdom Egypt: One was carried, and the other was attached to the body of a war chariot. They could be made of leather or wood and were sometimes ornamented.

Handheld stabbing weapons can be traced to Paleolithic times. The earliest artistic representation of a spear is on the Hunters Palette. Spears were regularly used in military contexts in later times as well. For example, the Egyptian soldiers on Hatshepsut’s (r. 1473–1458 B.C.E.) mission to Punt are shown carrying spears and shields on the Deir el-Bahri reliefs, as are troops following Tutankhamun (r. 1333–1323 B.C.E.) as he drives his chariot on the “painted box.” Some of the Near Eastern men in the Beni Hasan tomb painting carry spears, and the Shasu Bedouin in the Seti I (r. 1306–1290 B.C.E.) reliefs at Karnak brandish spears and axes against Egyptian forces. Spears were ideal defensive weapons in siege warfare.

A spear with much longer shaft, known as a lance, is illustrated in siege scenes from the Middle Kingdom Beni Hasan tombs. In these scenes a portable defensive structure covers a group of soldiers who attack a fortified city with a large lance, in the manner of a battering ram. Maces with mace heads of varying form were the most powerful weapons of close combat in the Predynastic Period (before roughly 3000 B.C.E.). In the Late Period (712–332 B.C.E.) and into Greco-Roman times (332 B.C.E.–395 C.E.) kings are shown brandishing maces in the head-smiting motif on temple walls. Disc- and oval-shaped mace heads are found in the Naqada I and II periods of the Predynastic Period. These shapes continued to be used through pharaonic history and beyond. The mace (and club) probably had a more ceremonial function after the Old Kingdom, despite Thutmose III’s (r. 1479–1425 B.C.E.) boast on the Gebel Barkal stela regarding his victories in the Near East: “It was my mace which overthrew the Asiatics, my club which smote the Nine Bows.”

The earliest form of ax was the handheld implement from Paleolithic times. When the stone blade was first affixed to a handle is not known, but at that point of development the ax became a deadly weapon. During the Old Kingdom copper blades were introduced. The ax blades were long and rounded and continued to be used during the Middle Kingdom. The duck-bill blade is the ax shown in the tomb of Khnumhotep at Beni Hasan. In two Old Kingdom battle scenes the ax is used by Egyptian soldiers to repel their enemies and to hack up the city wall. In the New Kingdom the blade is much more narrowly shaped.

Swords and daggers were of great military importance throughout Egypt’s history. These weapons are similar in construction but different in length and usage. A sword is generally defined as longer than 16 inches, and a dagger is shorter. The Third Dynasty relief of King Sekhemkhet (r. ca. 2611–ca. 2603 B.C.E.) at Wadi Maghara (Sinai) shows a dagger tucked in the monarch’s belt. These early daggers were made of copper and had no midrib (thickening down the middle for added strength). The dagger’s usefulness as a weapon would have been in hand-to-hand combat. As copper gave way to bronze in the third millennium B.C.E., daggers in Egypt evolved into swords. Preserved examples from the Middle Kingdom resemble the daggers of earlier periods. However, swords were not commonly used in Egypt until the New Kingdom, when longer, double-edged swords were introduced from Anatolia.

Shields were the oldest means of defense and were made of wood covered with leather. They were used first by infantry. In the New Kingdom they were held by drivers of war chariots, to protect the archers standing beside them. The tomb of Tutankhamun contained wooden shields, some of which had leather or animal skins over them. Combining wood and leather made the shield a more effective defensive tool, and a metal protective surface was especially useful against arrows fired from composite bows. Helmets appeared in the Eighteenth Dynasty (ca. 1550–ca. 1307 B.C.E.), when some troops acquired helmets of bronze or leather in imitation of

the Asiatic model. Other troops wore shirts made of leather strips sewn together in rows. Armor made of iron lamellae (thin plates) appeared in the reign of Sheshonk I (r. ca. 945–ca. 924 B.C.E.).

The two-wheeled, horse-drawn chariot was introduced to Egypt from Asia in the Second Intermediate Period. From that time onward the chariot significantly contributed to the art of Egyptian warfare, useful for its mobility and the element of surprise. It was constructed of wood with some leather and metal elements, making it a light vehicle on the battlefield. It was manned by two soldiers: the charioteer, who held a shield, and the chariot-warrior, who was armed with a bow and a spear. The chariot was not armored in any way and therefore was not suitable for a direct attack. Once the enemy lines were broken, the chariot was ideally suited for pursuing and harassing the scattered infantry.

THE MIDDLE EAST

BY JAMES A. CORRICK

Through the sixth millennium B.C.E. weapons in the ancient Near East were made from stone and wood. Spears with long wooden shafts and arrows made from reeds or wood were tipped with chipped-flint heads. Some crude spears and arrows lacked heads, with one end being nothing more than a fire-hardened point. Axes with stone blades were also used. During the fifth millennium B.C.E. the flint and stone heads of these weapons were often replaced by copper, and by 3500 B.C.E. bronze was in use for weapons. Around 1200 B.C.E. the Hittites were among the first to use iron for armaments. However, the quality of this iron was not good, and bronze weapons were still stronger and better made. Good-quality iron weapons did not become common until after 1000 B.C.E., with steel—iron hardened by the addition of carbon—appearing in arms manufacturing after 500 B.C.E.

Many of the weapons that became common throughout the ancient Near East were first used by the armies of Sumer. By 2500 B.C.E. infantry troops were armed with 5- to 6-foot-long thrusting spears and lightweight throwing spears, or javelins. Others carried bows with an effective range of between 150 and 300 feet. Many also carried daggers, ranging in length from 6 to 12 inches. Some weapons carried by Sumerian soldiers were everyday tools. Hunters brought slings for throwing stones that could down either game or enemy warriors in battle. Fishermen brought their nets, using them to entangle their opponents, whom they then either speared or stabbed. Nets did not long remain a part of the Near Eastern battle equipment, but slings would be used by most Near Eastern armies through the early centuries C.E., although the ammunition would sometimes be clay or lead pellets rather than small stones.

Another important Sumerian weapon was the socket ax. The bronze head of this battle-ax was narrow for better cutting and had a socket that slipped down over the end of the ax's wooden handle. A rivet driven through the socket into the handle held the head in place and allowed the wielder

to deliver a strong blow without dislodging the head, as often happened to axes with heads tied to the haft. Able to cut through most forms of armor, the socket ax, its head made of iron during the last centuries B.C.E., would remain one of the most deadly ancient Near Eastern weapons.

The composite bow was the next important advance in personal weaponry, appearing sometime after 2300 B.C.E. during the Akkadian reign. Until this time bows had been carved from a single piece of wood. The composite, however, was built by gluing together different types of wood, along with bone and sinew. The resulting bow was stronger and capable of shooting an arrow twice as far as the older bows. The composite eventually became the bow of choice throughout the ancient Near East and was still being used by the Persians of the Sassanian Dynasty (224–651 C.E.).

Both Sumerians and Akkadians carried the sickle-sword, which had a curved blade much like the sickle used in harvesting crops. The straight-bladed sword eventually developed from the dagger, and Assyrians began carrying straight-bladed swords during the first millennium B.C.E., as later did Persian and other Near Eastern armies. The sickle-sword, however, continued to be used in the ancient Near East into the early centuries C.E. Its curved blade was designed for slashing at an enemy and was sharpened only on its outer edge. The straight-bladed sword might have either one edge sharpened for slashing or both edges for thrusting and stabbing as well as slashing. Long swords, measuring more than a yard, were found in the arsenals of many Near Eastern armies, but short swords, normally ranging in length from 2 to 2.5 feet, were more common. The Persian infantry of the Achaemenid Dynasty (550–330 B.C.E.) carried a very short, straight-bladed sword called an *akinakes*, which was made of iron and measured between 14 and 18 inches in length, making it not much longer than a dagger; indeed, the difference between a long dagger and a short sword was vague. Sword blades were often leaf-shaped, swelling in the middle and then tapering at the end. Bronze and iron blades were formed from a single piece of metal, while steel blades had a core of iron over which was layered a coat of steel.

The primary defenses against all weapons were armor, helmets, and shields. Sumerian armor was a linen or leather cloak to which copper or bronze disks were sewn. The most common form of armor in the ancient Near East was that worn by the Assyrians and later the Achaemenid Persians. Known as scale armor because it resembled the scales of a fish, this protective gear was made by sewing overlapping small oblongs of bronze or iron to a shirt of linen or felt. Originally, among the Assyrians, an armor shirt reached to the knees or lower, but later it was shortened so that it reached only to the waist. This short armor was also preferred by the Persians, probably because it allowed for more maneuverability. The sleeves, even on the longest armor shirts, ended well above the elbow. Sometimes Near Eastern armor was nothing more than quilted linen, as was the case with some Achaemenid Persian troops.

The first helmets were worn by the Sumerians and were either cloth or leather caps. The Sumerians eventually began using headgear made from copper that looked like metal caps. Bronze helmets appeared later. The Assyrians were among the first to wear iron helmets, although both copper and bronze helmets would remain in use in the ancient Near East throughout the last millennium B.C.E. The Assyrian helmets were noteworthy for their conical shape. They were designed so that a blow by a sword or ax, unless aimed directly, would slide down the side of the helmet. A curtain of scale mail also hung from these helmets. Modifications of this design would be adopted later by the Parthians (250 B.C.E.–226 C.E.) and the Sassanian Persians, among others.

Achaemenid Persian troops generally wore tight-fitting helmets, when they wore any headgear at all. Indeed, it was not unusual for ancient Near Eastern warriors to fight without helmets or armor. This was particularly true of archers, who might be hampered by the weight of protective gear. Instead of armor worn on the body, these troops were protected by shields, often carried for them by others known as shield-bearers. But armored and helmeted troops also generally carried shields. The earliest shield, and one that would be used as late as Sassanian times, was the wickerwork shield. It was made of woven reeds or twigs, supported by a wooden frame and sometimes lined with leather for extra protection and given additional strength by bands of metal. Even the Assyrians, with their iron scale armor and helmets, used these wickerwork shields because they were lightweight. Metal shields, made first of bronze and then of iron, also existed during this period. Shields were rectangular, circular, or oval and could be small (no more than 2 feet across) or large enough to tower above a warrior's head. The smallest shields were normally made of metal, but large metal shields were too heavy to carry into battle.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

The basic weapons in ancient Asia were spears, swords of various designs, and bows and arrows. In prehistoric times weapons were made of wood, bone, horn, stone, and hide; bones and stones can be fashioned into very sharp points. As people learned how to work metals, they started making

weapons out of them. Bronze weapons appeared during the early second millennium B.C.E. Iron weapons gradually replaced them in the next millennium, although people continued to make bronze weapons until the early years of the Common Era. Chinese weapons makers became experts at metallurgy; weapons produced during the Qin Dynasty (221–207 B.C.E.), for example, are made of carefully composed alloys of copper, nickel, chrome, iron, and several other metals. Some arrowheads contain lead, presumably for its poisonous effect. Chinese weapons makers of this period coated their blades with a thin layer of chromic salt oxide to prevent rust; this coating has preserved many weapons in good condition for more than 2,000 years.

Most ancient weapons were meant for hand-to-hand combat. Projectile weapons were harder to use and supply because they needed a stream of ammunition in battle. The sling was the most basic projectile weapon; throughout ancient Asia people used slings made of leather or some other flexible material to fling rocks or other projectiles. Bows and arrows were more effective and could propel weapons farther than slings, but the simplicity of the sling kept it in use throughout the ancient period, especially in the more remote islands of the Pacific.

The spear, or *qiang*, is one of the oldest Chinese weapons. Spears were simple to make; affixing a small, sharp tip to a long shaft did not require technological expertise. Chinese warriors began using spears in prehistoric times. Spears with bronze tips became popular starting in the 17th century B.C.E. Weapons makers started using steel instead of bronze for spear tips during the Eastern Zhou Dynasty (770–256 B.C.E.). The *qiang* spear was the most important long weapon of the Western Han Dynasty (202 B.C.E.–9 C.E.).

One of the classic Chinese weapons was the saber, or *dao*. These early *dao* were more like knives, with a straight or slightly curved blade. The oldest *dao* were made of bronze. Smiths began to make them of iron and steel between the sixth and third centuries B.C.E. As the *dao* evolved, its blade became curved, and it was often attached to a long handle, though many types of *dao* existed. The *dao* was especially popular during the late Qin Dynasty and early Han Dynasty. During the Han Dynasty cavalry became more important, and warriors took to carrying long *dao* that had single-sided blades attached to long shafts, which they could wield on horseback. Infantrymen of this time often carried short *dao* or broadswords.

Short sword of steel, bronze, and gold from east-central Asia, ca. fourth to first century B.C.E. (Copyright the Metropolitan Museum of Art)

The *jian* was a straight sword. The earliest *jian* date to the sixth century B.C.E. This weapon was most popular during the Zhou Dynasty and the Western Han Dynasty, when famous sword makers developed their craft to an art form. After the first century C.E. the warrior's *jian* grew less popular than the *dao*, which became the preferred combat weapon, especially of the cavalry. Men still wore *jian* as part of their ensembles and as a status symbol, and some warriors continued to use *jian* in combat. Martial artists of this time adopted the *jian* as a weapon to use in symbolic martial arts.

The *ji*, or halberd, was a sort of combination spear and sword; it consisted of a long shaft with a bronze point at its tip and a curved blade parallel to the shaft close to the spear tip. Sometimes a *ji* had two blades affixed opposite each other. The *ji* could be used for slashing and stabbing, and it could be wielded by men on foot or in chariots. It was popular during the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) and Zhou Dynasty. During the Han Dynasty the *qiang* spear gradually replaced the *ji* as the long weapon of choice, relegating the *ji* to martial artists.

Crossbows with bronze mechanisms are common in the archaeological record in China beginning in about 600 B.C.E. Chinese historians started mentioning crossbows in the fifth century B.C.E. Soldiers used crossbows at the battle of Maling in 341 B.C.E. During the Han Dynasty the crossbow was commonly used in infantry battles and also was occasionally deployed during fighting on horseback. Early crossbows were made of cast bronze parts attached to a wooden frame.

In India the people who lived in the Indus Valley between 2500 and 1500 B.C.E. made numerous weapons that they used for war, war games, and hunting. The Vedic sacred texts of this period describe warfare and the weapons that soldiers were expected to master. These weapons included the bow and arrow, the discus (the god Krishna was said to be an expert with the discus), the javelin, the ax, the mace, and the dagger. Archery, in particular, was highly esteemed as a soldierly skill. Indian weapons makers were among the first to build bows out of steel. Indian peoples also used swords in battle. The chariot played an important role in Indian warfare. Indian chariots were large, heavy, four-wheeled devices made of iron and wood and pulled by several horses. They could carry several soldiers, including a driver, an archer, and up to five foot soldiers. The chariots themselves were heavy enough to crush enemy soldiers, and the soldiers who rode on them used the chariots' height and speed to overpower their enemies. Indian armies also used elephants in battle starting in about 1500 B.C.E. The elephants could carry several soldiers on their backs and were themselves armed with long blades attached to their tusks.

In Japan during the Jōmon Period (ca. 13,000–ca. 300 B.C.E.) people made simple weapons from chipped and polished stone, but it was not until the Yayoi Period (ca. 300 B.C.E.–300 C.E.) that people engaged in large-scale organized warfare. During this time Japanese people began using swords and spears made of bronze and iron. Japanese weapons of this

period are similar to contemporary Chinese weapons, and historians believe that Japanese weapons makers might have borrowed bronze- and iron-smelting techniques from China. The basic weapons of spears, slings, clubs, bows and arrows, and blades were used throughout the Pacific region. Australian aborigines used boomerangs, curved wooden blades that could be thrown, both for hunting and in warfare. Pacific islanders made weapons out of locally available materials. In Hawaii, for example, soldiers used slings to fling volcanic rocks. They made daggers out of swordfish spears, hammers out of stone, and spears with points made of shark teeth.

EUROPE

BY CARYN E. NEUMANN

War shaped the ancient world, with weaponry and armor determining the success of the combatants. The sheer number and wide range of military artifacts that have been unearthed speak of large-scale production and large-scale deposition of arms and armor in Europe. During the Paleolithic, Mesolithic, and Neolithic periods weapons generally included whatever blunt object was close at hand as well as any sharp object that could be thrown. Skeletons in the Neolithic mass grave at Talheim in Germany bear the traces of blows from stone axes on their skulls, and many other skulls in Neolithic burials also have evidence of blows from hard objects. Sometimes the victim survived to fight another day, but often these blows were fatal. The bow and arrow was invented during the Mesolithic, but it was some time before bows were strong and accurate enough to deliver a lethal shot to a vital organ. More often, a lucky shot would wound the victim, who then would have to be finished off by spear or ax if he had not escaped. The so-called Iceman found frozen in the Alps in 1991 had an arrowhead lodged in his shoulder, either a fatal wound or a debilitating injury that contributed to his eventual demise. He was also carrying a bow (but it was unfinished, so of no use to him) and a quiver of arrows as well as a flint dagger.

During the Copper Age, between about 3500 and 2000 B.C.E., depictions on rock carvings and finds of arrowheads indicate that the bow and arrow had increased in accuracy and killing power to become apparently the most popular weapon throughout western and central Europe. Yew and elm were the favored woods for making bows, while arrow shafts were generally made from the straight twigs of hazel. Bowstrings could have been made from animal sinew, but the Iceman's bow had a flax string. Arrowheads were often made of flint, bone, or bronze and were attached to their shafts with resin and pitch. Thus, many different raw materials had to be procured and integrated to make an effective bow and arrow. Some of the metal arrowheads were barbed to inflict more substantial wounds. Curiously, arrowheads become less common after about 2000 B.C.E., suggesting that the bow and arrow declined in popularity.

Daggers were one of the most popular weapons of the Bronze Age (2800–700 B.C.E.) and were still in common use

in the Early Iron Age (beginning in 1000 B.C.E.). While some elaborately decorated daggers were apparently intended only for ceremonial use, most daggers were employed for fighting at close quarters. Unlike the bow and arrow, daggers probably were meant only for human fighting rather than hunting. It is possible, however, that they were used to deliver a coup de grace to wounded animals and people and, in the absence of other implements identifiable as knives, daggers also might have been used to butcher prey. Daggers typically had rounded pommels.

Two types of weapons emerged early in the Bronze Age that would have a substantial impact on warfare for many centuries. The sword and the spear were critical elements in combat. The spear developed out of a daggerlike blade with a long tang (attaching the blade to the handle) that might have been mounted on a long shaft rather than held close to the body. By 1800 B.C.E. the socketed version, fitting over the shaft, was in use in central Europe. With only small differences, this is the form that existed throughout the ancient era. Depictions of spears do not clearly indicate whether they were typically held or thrown. In Europe small and large spearheads were used, as were those of intermediate sizes. It is most likely that small spearheads were intended for light javelins that could be thrown over long distances. Large spearheads were probably used for heavy spears that were held firm by a warrior or group of warriors under close-quarters thrust at an opponent. Collective finds of spears in Scandinavia indicate that spear owners acted and fought in collaboration, with some throwing their spears and then taking cover behind others, who advanced holding their spears. At the moment of encounter the throwers could then have emerged to use cutting or thrusting weapons (daggers, rapiers, swords) in hand-to-hand combat.

While spears were obviously important, they were not usually decorated or given the appearance of prestige weapons, unlike swords. Early versions of the sword were in ex-

istence by 1800 B.C.E. The cut-and-thrust sword developed several centuries later. In combat, swords were usually accompanied by daggers or knives and sometimes by spears. Not everyone relied on a sword—a few relied on spears or daggers. Still, swords were the commonest weapon.

To fend off arrowheads and the blows of blades, ancient Europeans devised various types of armor. Most of the earliest examples of body armor in Europe date to the 13th century B.C.E. Leather and wood were the most popular materials for protection. Wooden shields were produced in Ireland around 1800 B.C.E. Leather, always in use, had more flexibility than bronze, and it was considerably cheaper and easier to produce. Few warriors were protected entirely by bronze, but hammered sheet bronze is so thin that it would have been relatively useless as protection against a spear or sword.

Pelts were also used as a sort of armor that offered not only the physical protection of the animal's fur and hide but also the psychological reinforcement brought about by taking on the animal's fighting skills. Warriors wore the pelts of wolves, bears, and other fierce animals when going into battle. The head of the animal sat on the warrior's head like a helmet. The animal's front legs ran down the warrior's arms, protecting them from sword blows, while its hind legs were attached to the warrior's legs. In this way the warrior inhabited the animal and took on its spirit, often in an intensely ecstatic state that made him relatively impervious to wounds and to fear and, consequently, very hard to stop.

There was another kind of ecstatic warrior that fought wearing no armor—indeed, no clothes at all. A representation of such a naked warrior has been found carved into a stone slab left by the Kemi-Oba culture at Kernosovka in Ukraine. It is the oldest-known image of a European warrior and dates from 4000 to 3000 B.C.E. The warrior is dressed in nothing but a belt, but he is heavily armed with a club, a knife or spear, and three axes. His hair is long, his arms are held tightly to his chest with his shoulders pulled up, and his penis is erect, all indicating a heightened state of passion and alertness. The same representations of tightly held arms, tense shoulders, and erect penis are also found on a Celtic statue of a “berserk” warrior. The Celts adorned their nakedness with golden neckbands, which served the double purpose of accenting their white skins and taunting their enemies to come and take the bands off their necks if they dared. They wore their naked paleness with similar bravado, as a kind of psychological armor that showed off the red blood of their wounds. Without the burden of armor, they were also faster than ordinary soldiers. At the battle of Cannae in 216 B.C.E. the Romans ran in terror from the troops of bare-chested Gauls that Hannibal had assembled. In these cases, the most effective armor was no armor. Berserks scared their opponents into fleeing the field of battle. When men did fight, wooden shields and leather coverings offered little protection against arrowheads and swords. In ancient Europe weaponry advanced more quickly than personal defenses against it.

GREECE

BY CHRISTOPHER BLACKWELL

The wall and vase paintings from the Minoan and Mycenaean Bronze Age, during the second millennium B.C.E., are the earliest evidence of the existence of weaponry and armor in the ancient Greek world. These paintings show warriors carrying shields in the shape of a figure eight, an oval with semicircles cut out on either side of the middle; these warriors wear helmets and carry long, narrow swords.

The Homeric epics, composed in their present form around the seventh century B.C.E., present a backward-looking view of warfare from an earlier age. They describe warriors armed with bronze helmets—although Odysseus, in book 10 of the *Iliad*, goes on a nighttime raid wearing a leather helmet studded with boars' tusks, bronze breastplates, and greaves (metal armor covering the shins) and carrying one or two spears and a sword. These Homeric warriors would throw their shields, either from chariots or while standing, and then engage the enemy, one on one, with their swords.

The Archaic Period (ca. 600–ca. 480 B.C.E.) saw the so-called hoplite revolution. The term comes from the Greek word *hoplon*, or “weapon; a *hoplitēs* was a soldier outfitted with heavy bronze armor and trained in the tactics of the phalanx. The phalanx was a line of infantry in close formation, each man's shield covering half of his own body and half of his neighbor's, trained to present a theoretically impregnable mass of spear points and shields. Victory depended on numbers and on the discipline of the individual soldiers.

The hoplite's armor consisted of a breastplate, or *thorax*, made of bronze; a bronze helmet, *kranos* or *korus*, closely fitted and covering the whole head and with a T-shaped slit exposing the eyes and mouth (and often a noseguard descending

from the brow); bronze greaves, *knēmides*, for covering the shins; and the bronze and leather shield, *aspis* or generically *hoplon*. The hoplite's weapons were the sword (or *xiphos*), a short-bladed stabbing weapon for close combat, and the spear (*doru*), a longer thrusting weapon. Hoplites typically did not fight with the thrown spear, *akontion*, although mounted cavalry and some more lightly armed units did.

Because each soldier was responsible for providing his own armor, at his own expense, there must have been a certain amount of diversity in the style and quality of arms. The historian Thucydides, in recounting how the Athenians prepared for their invasion of Sicily in 415 B.C.E., describes a certain competition among soldiers to show off by acquiring the best armor, saying that “the land forces had been picked from the best muster-rolls, and vied with each other in paying great attention to their arms and personal accoutrements.”

The cost of this armor limited participation in land combat to those who could afford to arm themselves; these were generally men who owned land and who therefore had the most at stake in any conflict between neighboring states. But in contrast to the Bronze Age “heroic” warfare described by Homer, which was a series of acts of single combat between champions, hoplite warfare was communal, requiring cooperation and mutual trust. Historians see connections between the rise of this form of fighting and the increasing broadening of political participation in the Archaic Period, as power moved out of the hands of individual kings and into the hands of aristocracies or oligarchies, with governance being shared by those who were in a position to fight on behalf of the state.

The weight of metal that provided protection presented its own problems, and vase paintings of soldiers from the sixth, fifth, and fourth centuries show them, more often than not, with their heavy helmets perched back on the top of their heads, leaning on their shields, or standing by their unworn armor. Historical accounts, particularly those of Xenophon, a historian and mercenary commander of the fourth century B.C.E., contain many anecdotes of soldiers waiting to put on their armor until literally the last minute before engaging the enemy.

Cavalry did not have a large role in land warfare among Greek states until the period of Macedonian supremacy in the fourth century B.C.E. Likewise archery played a limited role, except when Greeks fought as mercenary units in the larger armies of Asia Minor. Archers, *toxitai*, do appear in accounts of siege warfare, as well as in the Homeric epics, where the Trojan Alexandros (Paris) is shown using a bow, as is the Greek Odysseus.

During the fourth century B.C.E. some Greek armies experimented with units of more lightly armed foot soldiers, called *peltasts*, some armed mainly with throwing javelins or slings. But the most significant improvements to arms came through innovations among the armies of Philip of Macedon, who arrayed his phalanxes several rows deep and armed each row with the Macedonian spear, the *sarisa*, using different

ARMING SCENES

A common feature of ancient Greek heroic poetry was the “arming scene,” a description of the hero putting on his armor and gathering his weapons before entering battle. The Homeric *Iliad* has many such scenes. Book 3 of the poem describes the Trojan Paris arming for single combat with the Greek Menelaus. According to this description, Paris first “covered his legs with greave of good make and fitted with ankle-clasps of silver; after this he donned the breastplate of his brother Lykaon, and fitted it to his own body.” Then “he hung his silver-studded sword of bronze about his shoulders, and then his mighty shield. On his comely head he set his helmet, well-wrought, with a crest of horse-hair that nodded menacingly above it, and he grasped a redoubtable spear that suited his hands.”

The poet’s vivid descriptions of the opulence of the metal and often of the history of the various pieces indicate a hero of elevated status—these heroes are rich and from illustrious families. The descriptions serve to build tension in the narrative as well: The weapons hold potential for death and destruction, but only battle itself would reveal the outcome. In the *Iliad* the arms of a hero hold talismanic powers, and fierce battles rage over the bodies of fallen warriors, with each side trying to strip the dead hero of his weapons.

The narrative technique of including an arming scene before battle, used to such good effect by Homer, is not unique to Greek poetry but appears throughout literature and art, from antiquity to the present. They range from the somewhat comic scene of King Saul arming David before his battle with Goliath (1 Samuel 17: 38–40 in the Bible) through medieval epics such as *Sir Gawain and the Green Knight* to modern depictions of historical battles in literature and film.

lengths for the different ranks. The longest of these spears measured 17 feet and had a leaf-shaped iron tip, a change from the straight-sided tips of earlier hoplite spears. To offset the weight of these long spears, and reflecting the added unlikelihood of enemies penetrating the bristling hedge of iron points that the phalanx presented, the shield was reduced from a large, full-body-size rectangle to a smaller, more maneuverable disk. The supremacy of Macedonian tactics, which combined this newly re-formed phalanx with *peltasts* and cavalry, appeared most dramatically at the battle of Chaeronea in 338 B.C.E., when Philip’s army defeated the forces of Athens and Thebes, and even more dramatically during Al-

exander the Great’s campaigns against the Persian Empire in the last years of the 330s B.C.E.

By the Hellenistic Period, the period after the death of Alexander in 323 B.C.E., Greek armor had become light and tactics more fluid. Soldiers abandoned greaves and increasingly adopted a helmet with a more open face, the so-called *pylos* helmet instead of the older, more closed Corinthian style. The new helmets increased the soldier’s field of vision, made breathing easier, and weighed less, and these advantages seem to have outweighed the reduced protection afforded by the open face. The old Corinthian style continued to appear on vase paintings, however, and seems to have been an iconic symbol of the warrior tradition extending back through the Classical Period to Homeric times.

ROME

BY MICHAEL M. SAGE

Little can be said about Roman arms, armor, and other military equipment before the middle of the sixth century B.C.E. Literary sources offer scant evidence, and the site of Rome has provided few archaeological finds of a military nature. There are a few fragmentary pieces of metal protective equipment and a number of spearheads, which point to the importance of the javelin.

The middle of the seventh century B.C.E. saw a profound change in military equipment in central Italy, especially to the north of Rome in Etruria. Again, there is little evidence at Rome, but given the close cultural ties of Rome and Etruria, there is every reason to suppose that the same developments took place at Rome. Greek heavy infantry equipment of the hoplite type appears in Etruria, probably under the influence of the Greek colonies of southern Italy. This hoplite equipment consisted of a metal helmet, a metal cuirass (body armor) made up of back and front plates, and the hoplite shield. The hoplite shield was usually a convex circular device, 3 feet in diameter, made of a wooden core with metal facing, usually of bronze. The arm was inserted through a curved metal band, and the hand gripped a strap on the rim of the shield. This holding mechanism distributed the weight of the heavy shield along the length of the arm, allowing the shield to be held for long periods. The usual offensive weapon of the hoplite was a heavy thrusting spear with a short slashing sword as a secondary weapon.

By 550 B.C.E. the literary sources show that the hoplite style of fighting had been adopted at Rome. Despite the artificial character of the descriptions that survive, it is clear that at Rome, as elsewhere in central Italy, there was a greater variety of equipment than in Greece. Especially important is the reference to a type of shield later known as the scutum. The construction of this shield is described in detail by the Greek historian Polybius (ca. 200–ca. 118 B.C.E.). It was 4 feet long and 2.5 feet wide, made of two wooden boards glued to each other. Its convex outer surface was covered in linen topped by leather. It was rimmed with iron and had a central iron spine

to strengthen the shield and to aid in warding off blows. This type of shield first appeared in Italy in the mid-eighth century B.C.E. and eventually became the standard Roman heavy infantry shield with some modifications until the end of the ancient world.

The early Roman army fought in the manner of the Greek phalanx as a dense rectangular formation that relied on its weight and the points of its heavy thrusting spears to achieve victory on the battlefield. During the fourth or perhaps as late as the early third century B.C.E. the Roman army underwent a tactical revolution. In place of the phalanx it adopted a three-line formation, which depended not on the heavy thrusting spear but on a combination of javelin and sword for its offensive power. The front two lines carried two javelins, called *pila*, one heavy and one light. The heavy *pilum* weighed about 10 pounds, and the lighter one was about half that weight; both were about 6 feet long. The barbed spearhead and its metal tang were made as a single piece, and the head was attached to its wooden shaft by driving the tang into it. The sword that eventually became standard was a short sword with a blade, approximately 2 feet long, with two cutting edges and a long, sharp point. It was well adapted for both slashing and stabbing strokes. The third line retained the heavy thrusting spear.

The legionnaire was protected by a bowl-shaped metal helmet of bronze with a short neck guard at the rear and attached cheek pieces. His chest was protected by a small square metal pale held on by straps and worn over a leather tunic. Wealthier legionnaires provided themselves with a mail shirt. A greave (shin armor) was worn on the left leg, which was thrust forward in combat.

Each legion also contained light-armed troops. They were equipped with a light wicker shield 3 feet in diameter and a leather helmet; they carried the legionary sword and a number of light javelins. Little is known about Roman cavalry equipment during the republic. The cavalry probably carried a round shield, wore some form of chest protection, and carried a lance and a sword. Although there was some variation in equipment down to the end of the first century B.C.E., the only major change was the standardization of offensive weaponry for all legionnaires.

For the first two centuries of the empire until 200 C.E., changes in legionary equipment were evolutionary. From the middle of the first century C.E. the sword point was shortened to make it more effective in stabbing, and helmets evolved to provide increased protection for the nape of the neck and the forehead. Toward the end of the second century C.E. a longer sword with a blade of between 32 and 40 inches appeared and eventually replaced the traditional legionary sword. The most striking change was visible in chest protection. Several types appeared. The mail shirt was now standard for legionnaires, with scale armor also found. A new type of body armor was developed, consisting of metal strips attached to leather straps for both the chest and the back; this new armor was more flexible and provided greater

Sixteenth-century shield depicting Roman battle scene; the scene shows accurate armor and clothing of the time, as drawn from antique coins and sculpture. (Copyright the Metropolitan Museum of Art)

protection against blows. The scutum, though constructed in the same way, now became rectangular instead of oval to increase the protection it offered.

There appears to have been a tremendous variety in the body armor of the Roman cavalry of this period. Mail shirts frequently appear in pictorial representations, but other types of cuirasses are also found. Helmets display a similar diversity. Offensive weapons also varied greatly, as many units were highly specialized, such as archers from the eastern provinces. One striking development beginning in the mid-second century C.E. was the appearance of a new type of cavalry patterned on eastern models. These were the *Clibanarii*, who wore a tight-fitting conical iron cap and a coat of either mail or scale armor, which covered the upper body and the thighs; the lower body was protected by metal bands. This cavalryman's main offensive weapon was a heavy lance.

Artillery was used in siege and naval warfare and on the battlefield. Roman artillery evolved from Greek models. Its propulsive force was supplied by torsion, that is, the building up of energy in some elastic material, such as braided ropes of hair or animal sinew, by twisting them and then suddenly releasing them. These devices were generally constructed of wood, though in the Imperial Period there was a greater use of metal for increased strength and durability. These machines varied in size and were used to propel either arrow-shaped projectiles or large stone balls. The larger catapults were could hurl stones of up to 60 pounds with devastating results.

THE AMERICAS

BY J. J. GEORGE

The principal weapons used by ancient indigenous North Americans were the spear-thrower, or atlatl; the sling; the spear; and the club, all of which were used in both warfare and hunting. Instruments used only for hunting included the harpoon, the bola, the blowgun, the rodent skewer, and the reptile hook. Shields and rudimentary body armor were used defensively in warfare. Weapons were normally made of stone, bone, horn, and wood. Often they were composite, the point, head, or blade being made of stone or bone and the handle or shaft of wood. Metal was rarely used for weapons because metallurgy was limited to softer metals, such as gold and silver, and largely only for decorative rather than utilitarian purposes. In Mexico, where metallurgy was most highly developed, there was an abundance of obsidian and other igneous stone, which was superior to copper and copper alloys for weapon points and blades. Iron and steel tools and weapons arrived with the Europeans in the 15th and 16th centuries C.E.

The earliest projectile points discovered in North America date from about 11,000 B.C.E.; they are attributed to the Clovis culture and were probably spear points because they are too large for arrows. The blade's unique design, a narrow, tapering profile with sharpened side edges and a technically challenging "flute" at the base for hafting, was intended to maximize the lance's ability to pierce hide or skin. The lance would have been used in close proximity to the intended target. In several instances, recovered Clovis points were found hundreds of miles from where they had been quarried, sometimes in burial caches, leading to continued speculation about who made them, how the technology was transferred, and what it meant when they were ceremonially buried. It is not until about 500 C.E. that chipped stone points, comparable in size and workmanship to modern arrowheads, first became known.

The atlatl, a device that supplies leverage by adding length to the user's arm and increases the range, force, and accuracy of the spear, seems to have been distributed throughout the world by migration or diffusion. It was used by the polar Eskimo in the Arctic, the Tlingit of the Northwest Coast, groups in Baja California and northwestern New Mexico, and Native Americans at the mouth of the Mississippi; it was also used throughout Mesoamerica and by many people of the circum-Caribbean area. The spear-thrower has existed in Europe for at least 20,000 years, but the oldest-known examples from the Americas date to about 5000 B.C.E. The spear probably preceded the bow by many thousands of years; indisputable evidence of the bow is not known until about 500 C.E.

The decline of Hopewell sites in the Illinois Valley around 400 C.E. coincides with the disappearance of finely made atlatl weights from the archaeological record, which seems to reflect the replacement of the atlatl by the new weapon system of the bow and arrow; small points, probably from arrows,

occur at Illinois sites at this time. The greater range and accuracy of the bow and arrow may have affected hunting practices and probably altered the way warriors engaged. Also, an increased incidence of warfare in the Ohio Valley has been inferred from the seemingly defensive location and layout of some hilltop enclosures, a change in site planning possibly necessitated in part by changes in weapons technology.

Handheld spears varied greatly in length, diameter, and type of point. They were employed more in hunting than in warfare and appear to have been in use by at least 8000 B.C.E. in the Pleistocene to kill bison in North America. In areas where atlatls and the bow and arrow were present, it appears that the spear was not used javelin style and tended to be reserved for heavy duty at close range. Recent excavations at New Haven Harbor in Connecticut have uncovered more than 5,000 stone artifacts dated to before 1000 B.C.E., including unfinished points and dart points made of fashioned quartzite that could have been used to form the lethal end of an atlatl dart. Used primarily in hunting, the projectiles would have proved lethal against enemies.

In Mesoamerica early examples of defensive armor include quilted or rolled cotton. At Teotihuacán (ca. 1–650 C.E.) spun cotton body armor, called *escupil*, and helmets were introduced to protect the head, body, and limbs. Some scholars have tied the sudden increase in the need for and use of cotton to acceleration in the downfall of Teotihuacán. One argument suggests that because the military was essentially a state enterprise, the state's decline was facilitated by its inability to provide armor to everyone due to its cost. The art historical record also provides insight into the nature of Teotihuacán weaponry. Warriors are depicted wielding atlatls and rectangular shields or thrusting spears and bucklers. The depictions suggest standardized weaponry, which typically indicates state control, formations, and complimentary arms use. One likely scenario inferred from the depictions of warriors and weaponry suggests that the atlatlists would first engage the enemy with projectile fire, and then the spearmen would close and engage the enemy in hand-to-hand combat.

For a long time scholars believed the Mayan civilization to be peaceful and idyllic. A brief inventory of their weaponry dispels that notion: Spears, atlatls, darts, and arrow points used as weapons were common in Mayan civilization of the Classic Period (ca. 150–ca. 650 C.E.). The art historical record shows that the Maya were clearly equipped to fight. Stela 31 from Tikal records Stormy Sky, the name of a ruler in the mid-fifth century C.E., flanked by two guardians dressed in Teotihuacán-style military garb, carrying shields, spear-throwers, and feathered darts. Spear and dart points found at the rapidly abandoned fortified city of Aguateca, Guatemala, suggests that both the royal family and elite scribes and artists used them for intergroup warfare as well as for artistic and craft production under enemy threat. An important implication is that the ruler and elite scribes and artists were also warriors. In another example, an unusually high concentration of identifiable weaponry at the hilltop center of

Cerro de las Mesas indicates that warfare was critical in the development and downfall of classic Mayan civilization.

Weaponry prevalent throughout South America, including the Chaco region, which comprises territories in north-eastern Argentina, eastern Bolivia, and western Paraguay, shows that warfare was a main concern, and weapons like bows and arrows, spears, and clubs, mostly made of wood, were quite common. Bolas, stones connected by cords, thrown to entangle and fell prey or an enemy, were a typical weapon. In northern Peru's Moche culture painted pottery dated to the sixth century C.E. provides a stylized glimpse of the Moche warrior and his weaponry and armor. Two animated warriors, their faces covered with fox face masks, wearing decorated helmets and belted tunics, carry round shields and war clubs. Celebrating warriors on painted pottery shows clear veneration of the warrior culture.

► weights and measures

INTRODUCTION

For a prehistoric hunter-gatherer a system of weights and measurements would likely not have been very useful. It was enough to know that an object was so heavy that it required two people to move it or that it would take a day to move to an encampment on the other side of a distant hill. The development of systems of weights and measures coincided with the development of civilization itself. As people settled into permanent communities that evolved into towns and cities and as they developed trade relationships with other communities, they needed agreed-on systems for measuring and weighing food and other goods. While these systems differed from culture to culture, they all had common elements and served common needs.

The earliest units of measurement were often based on the human anatomy. Thus, hand spans, forearms, fingers, feet, and other parts of the body were used to specify length. By extension, distance could be measured by, for example, how far a person could walk in a day, while area could be measured by the amount of land a worker could plow in a day. Similarly, ancient cultures used natural objects as the basis for specifying weights and measures. A reed, for example, could have been used to measure length. The people of ancient India used such natural objects as louse eggs and dust particles to measure very small units of length. Other cultures used such objects as mustard seeds as units of measure.

The problem with these units of measurement, of course, is that they varied from person to person and place to place. Accordingly, ancient civilizations made efforts to standardize their weights and measures. Often, this was a task assigned to the king or other ruler. The king had a vital interest in accurate weights and measures. Taxes, for example, were collected on volumes of grain or, in the case of ancient India, bolts of cloth. Similarly, agriculture required some agreement on land boundaries. Ancient builders had to have a common basis for measuring building materials. If a building was to be made of bricks, then calculating the number of bricks needed to construct a building of a given size required agreement on the dimensions of a brick.

Usually, systems of weights and measures developed in connection with systems of counting and numbers. Indeed,

counting emerged because people had to weigh and measure. Systems of mathematics provided people with common units of measurement, which could then be divided by common factors to produce smaller units or multiplied by common factors to produce larger units. In this way, for example, the modern yard consists of 3 feet, a foot consists of 12 inches, and so on.

Trade and exchange, too, required systems of weights and measurements. If one country was trading wine for lumber, the merchants making the trade needed some way of measuring and agreeing on the volume of wine and lumber to determine prices. The result was that systems of weights and measures were often imported and exported along with the goods they measured. When the value of commodities came to be measured by money as a medium of exchange, it was vitally important for merchants to be able to weigh accurately coins and the gold and silver with which they were made.

AFRICA

BY MICHAEL J. O'NEAL

Historians, archaeologists, and scientists use the term *metrology* to refer to the study of weights and measures, particularly as it applies to the premodern world, when weights and measures were not universally standardized. Metrology, though, does more than simply seek to discover which specific units of measurement and weight the ancients used. It also seeks to understand the underlying system that gave rise to weights and measurements.

Thus, the types of questions metrologists ask include: Were units of weight and measure arbitrary values, or were they based on some phenomenon from the natural world? How was one unit divisible into, or a multiple of, some other unit? How did ancient traders and others convert units of weight and measure into those of another people in the process of striking trading bargains? To what extent were units of measure and weight standardized in a kingdom or region? Did royalty have one unit of measurement or weight and common people another? What can ancient artifacts, such as buildings and their dimensions, reveal about systems of measurement? What was the relationship between systems of weights and measurements and mathematical, astronomical, calendrical, timekeeping, and other systems?

The grandest question of all, however, is this: Did ancient systems of measuring weight, volume, distance, and the like derive from some common system that was spread throughout much of the ancient world, including parts of Africa? Many metrologists have devoted careers to finding common units of measurement that underlay the construction of artifacts as widely dispersed as the pyramids of Egypt and Stonehenge in England. Some claim to have found commonalities, in various cases based on common astronomical observations from which the circumference of the earth at the equator may have been deduced. Many of these conclusions, though, are highly speculative.

Few of these questions can be answered with any certainty about ancient Africa (other than Egypt). The absence of written records inhibits the work of metrologists who focus on the continent. Further casting a veil over the subject is the fact that ancient African kingdoms, cities, and settlements rose and fell with great frequency. People migrated throughout the continent, often in response to climatic change, taking with them their culture and knowledge systems and mingling them with the culture and knowledge they found in their new homes. Warfare wiped out some African cultures—the kingdom of Kush, for example, fell to the kingdom of Axum, and the Carthaginian kingdom was totally destroyed by the Romans—contributing to the lack of records and artifacts.

At the same time, more powerful empires, including that of Egypt and later the Roman Empire, would have imposed their systems on tributary people in Africa; in particular, Egyptian units of measurement probably became the norm throughout much of northern Africa. Later, Roman units probably became accepted. These units were derived from Greek measurements, which the Greeks in turn had adopted from numerous cultures in the Near East, who in turn had adopted them from such places as Mesopotamia. Furthermore, because much of Africa, particularly the northern stretches of the continent (as opposed to the nomadic southern portions), engaged in trade and other activities with a large set of other civilizations who routinely passed through the region known as the Sahel, a strip of settlements that spanned the continent below the Sahara Desert, the notion of any kind of standardized, “African” system of weights and measures remains elusive.

Despite these problems, historians and archaeologists can make some inferences. It is highly likely that ancient Africans, in common with numerous other ancient peoples, measured distances using, at least as a starting point, the human body. Thus, for example, hand spans, knuckles, arm length, feet, and forearms were probably used as units of distance. Indeed, the cubit is a unit of measurement used throughout the entire region of Africa, Rome, the Near East, and eventually Europe. The cubit was a unit of length that originally measured the distance from a man's elbow to the tip of his longest finger, although eventually the cubit settled into a measurement of about 18 inches. Such a unit of measurement, of course, would necessarily be imprecise, since the unit would be longer for a taller man than for a shorter one. In the case of royalty, the “royal cubit”—a slightly larger unit of measure—would have been longer than that used by others, in an effort to suggest that royals were larger than common mortals. Similarly, it is little accident that in the modern world, the foot continues to be a common unit of measurement. The foot was used throughout the ancient world to measure a unit of distance that was, in fact, just about a foot, or 12 modern inches. The knuckle of the thumb could be used to measure relatively small distances, and thus corresponded to a modern inch.

Longer distances were probably measured by human activities. Thus, for example, distances corresponding to modern miles were probably measured in a way that gauged the amount of ground a person could walk in a certain period of time. Similarly, a unit of area probably was measured by the amount of ground, for instance, that a farmer could plow in a given period of time.

Ancient Africans undoubtedly used natural objects in the calculation of weights. Indeed, the modern word *grain*, still used in weighing precious metals, reflects this ancient heritage. Thus, any African culture probably would have developed a system that used small stones or quantities of seed, such as wheat seed, as a unit of weight. Other objects included items such as bird claws, feathers, and, for large weights, elephants. The ancient Egyptians used a system of weights called beqa weights to measure quantities of gold. Examples have been found of beqa stones, which standardized weights, and some of these bear royal insignia. Given Egypt's dominance over much of northern Africa, this system for weighing precious metals and perhaps other commodities probably was imposed on trading kingdoms to Egypt's south and west. Such a system would have governed coinage, which ancient Africans would necessarily have had to accept.

Another natural object that played a role in ancient weights and measurements was water. Thus, for example, a cubic foot of water represented a unit of weight called the talent, divisible into various units. The Romans divided the talent into 60 minas, and various Mediterranean cultures that accepted the talent and the mina subdivided the mina into varying numbers of shekels. These units were used by Syrians, Phoenicians (the ancestors of the African Carthaginians), and others, who carried them into Africa for purposes of trade and exchange.

EGYPT

BY AMR KAMEL

With the emergence of the centralized government in the Nile Valley as early as the Third Dynasty (ca. 2649–ca. 2575 B.C.E.), Egyptians formed accurate systems of weights and measures. They developed methods for weighing grain, counting cattle, drawing up building projects, and sizing huge slabs of stone as well as issuing rations and materials to workmen and, above all, measuring the level of the annual Nile flood, on which the levying of taxes depended. This system was valid throughout the whole country and remained active until the Greco-Roman Period (332 B.C.E.–395 C.E.), without real significant changes. In general, the system that the Egyptians set up included three main subsystems that measured capacity, length, and weight.

In their literary texts ancient Egyptians frequently expressed quantities of products counted either by the piece or by a usual grouping of pieces, such as bunches of flowers, jars of wine, baskets of grapes, pots of honey, bundles of vegetables or flax, handfuls of reeds, and even pairs of geese. Nonethe-

less, ancient Egyptians used many other measures that are still obscure, such as the *gsr*, which was used only for milk, the *g3t*, which was used for cream, and the *thab*, which was used for salt.

Several pieces of textual evidence suggest that the measures used for official purposes, such as tax payments, were checked on a regular basis. In conducting personal business Egyptians apparently preferred to use their own measures. For example, Hekanakhte, a farmer of the Eleventh Dynasty (ca. 2040–ca. 1991), sent a messenger to his family in the delta to bring to him his own corn measure to use in measuring his grain in Thebes (modern-day Luxor) rather than using other local measures, which might not be wholly accurate.

The Egyptian capacity system was apparently grounded on the *hnw* for measuring fluids, now reckoned conventionally at around 1 pint. The Egyptians used multiples of 10 *hnw* to describe greater units: 40 *hnw*, 50 *hnw*, 100 *hnw*, 160 *hnw*, and 200 *hnw*. The basic unit for cereals and other dry goods was the hekat, or bushel, of 4.3 quarts. In the Old and Middle Kingdoms (ca. 2575–ca. 1640 B.C.E.) 10 *ghar* made the larger unit *khar*, or sack, of 11 gallons. With the beginning of the New Kingdom (ca. 1550–ca. 1070 B.C.E.), the value of the *khar* was increased to equal 16 hekat, or 17.5 gallons. This increase reflected not an economic crisis but rather the change of a decimal system to a new binary system, which made accounting easier. These 16 hekat were later subdivided into units of 4 hekat, 4.36 gallons each.

Smaller quantities were expressed as fractions of *oipe*, more precisely as one of the fractions of the geometric progression $\frac{1}{2}$, $\frac{1}{4}$ (the former hekat), $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, and $\frac{1}{64}$. The last quantity equaled 0.2 quarts and was divisible into 5 *ro*, or parts, of 0.05 quarts each, reflecting the ancient division of the hekat into 80 and of the 4-hekat into 320 *ro*. In the Greco-Roman Period the *artabe*, a Persian unit, played a major role, varying in size from 29 to 40 of the Greek *choenix*, a capacity unit of about 0.9 quarts.

For general length measurement the standard unit was the royal cubit. The cubit represented the length of the forearm, from the elbow to the tip of the fingers, estimated conventionally at 18 inches. The measure was composed of 7 palms, (the hand's width without the thumb), each consisting of 4 fingers, $\frac{3}{4}$ inch each. Apart from the cubit of 7 palms, there were the small cubit of 6 palms (about 17.64 inches), the *remen* of 5 palms (14.7 inches), the *djsr* of 4 palms (11.76 inches), the great span of 3.5 palms (10.29 inches), the small span of 3 palms (8.82 inches), the *dopple* or double palm (5.88 inches), and the *fist* of 1.5 palms or 6 fingers (4.4 inches). Furthermore, Egyptians of the New Kingdom sometimes used a larger unit, called a *nebi* ("pole"); its length has been estimated at 1.25 cubits.

Land surveying required a longer unit than the cubit; thus, the ancient Egyptians seem to have used the *khet*, or "rod," of 100 cubits (160 feet) as the base, since a land-measuring rope was 100 cubits long, stretched between two rods driven in the ground. A larger unit, *itrw*, or "river," measured

20,000 cubits (6.5 miles) and was used to measure land distances, originally representing the length of a day's towing of a boat along the Nile. Textual evidence from the Twelfth Dynasty (ca. 1991–ca. 1783 B.C.E.) refers to an official estimation of the Egyptian land, from Elephantine in the south to Tell el-Balamun in the delta, at 106 itrw (670 miles), divided into 86 itrw for Upper Egypt and 20 itrw for Lower Egypt.

The basic measure of area was the stat, which represented a square of land of 100 by 100 cubits, or 1 khet by 1 khet (3,271.38 square yards). Multiples and submultiples were not defined by squaring multiples or submultiples but rather by multiplying or dividing the width while retaining the length as 100 cubits.

Volume measures were based on the denit, which was a cubic cubit (0.187 cubic yards). In the Ptolemaic Period (304–30 B.C.E.) volume and capacity measures seem to have been linked, but the absolute norms on which this relationship was based are still uncertain. This measure was used exclusively for calculating the progress made by workers in the excavation of a tomb.

The saqed expressed the slope of a masonry massive, such as a pyramid, by giving the length in palms of the horizontal base of a right triangle of 1 cubit high, whose hypotenuse was a section of the expected or measured slope. In Old Kingdom construction, for instance, there is clear evidence for the use of a saqed of 5.5 palms or 5.25 palms, corresponding to slopes of $51^{\circ}51'$ and $53^{\circ}7'$, respectively, as notably illustrated in the Giza pyramids.

Ancient Egyptians' basic unit of weight was called a deben. From the Old Kingdom the deben seems to have been around 0.48 ounces; it increased during the Middle Kingdom to 3.2 ounces. In the New Kingdom it was divided into 10 qite of 0.32 ounces each, with lesser weights expressed as fractions of qite.

As early as 1300 B.C.E. the Egyptians had developed accurate balance-beam scales that could weigh small quantities or materials with an accuracy of plus or minus 1 percent. The scales were simple in concept and consisted of a horizontal beam centered on a vertical post. Suspended from the ends of the beam were the platforms. One platform held the object or material to be weighed. The other held an object of known weight.

THE MIDDLE EAST

BY AMY HACKNEY BLACKWELL

People living in the ancient Near East standardized weights and measures so that they could accurately measure quantities—by weight and volume—of commodities important in their lives. These included seed, precious metals like silver and gold, base metals like copper and lead, and liquids like oils, beer, and wine. In conducting transactions with other peoples, traders used their own systems of weights and measures and calculated conversions to other systems developed by their trading partners, such as Egypt and the Indus Valley,

referring to such alien systems in their economic texts with a phrase like “according to the standard of Land X.”

Archaeologists and Assyriologists have been able to reconstruct the weights and measures of Mesopotamian civilizations because of the survival of both the weights themselves (and occasionally balance mechanisms as well) and written sources that give detailed calculations of commodities, everything from gold to grain. In some cases, annotations were inscribed on the rims or shoulders of storage jars, indicating a vessel's capacity in volumetric terms.

The shiklu, or shekel, was the basic unit of weight. One shekel weighed about 0.3 ounces. Small items were measured in she, which was $\frac{1}{600}$ ounce and originally represented the weight of a single grain of barley. Larger items were measured in manu, usually called minas in English, which was a unit of 60 shekels, or in biltu, which was a unit of 60 minas. Although these terms were used widely throughout the ancient Near East, the absolute value of these weights varied so that the mina of Ur around 2000 B.C.E. is not necessarily the same as the mina of Ugarit 500 years later. Most weights were made of stone, many in the shape of a duck with its head and neck lying on its back, as though the bird were asleep. Fine, barrel-shaped weights of hematite were also common.

The Old Testament mentions seven different kinds of weights, which were equivalent to coins. In biblical times people used units of weight to barter goods for silver, long before silver was minted into actual coins. One Mesopotamian biltu was equivalent to 1 talent, the largest measure of weight in biblical and ancient times. One talent of gold was somewhere between 50 and 100 pounds of gold; it represented either a man's weight in gold or the amount of gold one man could carry, depending on who was defining it. The biblical

Bronze duck weight, found in the treasury at Persepolis, Persia (modern-day Iran) (Courtesy of the Oriental Institute of the University of Chicago)

talent was equal to 3,000 shekels instead of the 2,600 shekels of the Mesopotamian talent.

Ancient Mesopotamians measured volume in sila or qa; 1 sila was equivalent to about 1.5 pints. A sila was made up of 60 gin, each equal to about $\frac{2}{3}$ ounce. Sixty sila made 1 mas-siktu or pi, which was about 11 gallons or 1.3 bushels. One hundred sila made 1 imeru, which was about 18.3 gallons or 2.25 bushels and was the amount one donkey was expected to be able to carry. A qurru or gur was 180 sila, about 33 gallons or 4 bushels.

The basic Mesopotamian measurement of length was the ammatu, or cubit, which was about 15 inches long. It originally was the length of a man's arm from elbow to fingertip, a convenient measuring device for merchants anywhere. An ubanu was about $\frac{2}{3}$ inch, the length of a finger joint; 24 or 30 ubanu made up 1 ammatu, depending on the time and place. A kanu was 6 ammatu (around 8 feet), and a gar was 12 ammatu. One ashlu consisted of 10 gar. A beru was 1800 gar, about 5.25 miles.

Fields and land were measured in iku, which consisted of about $\frac{1}{2}$ acre. One musaru was equal to 1 square gar, about 27.5 square yards; this was the standard measurement of a garden plot. One buru was equal to 18 iku, or 15 acres. One shar was equal to 1,080 iku, or 25.3 square miles.

During the Hellenistic Period (323–31 B.C.E.) Greek units of weights and measures spread throughout Mesopotamia and the Near East. During the Roman Republic and Empire (509 B.C.E.–476 C.E.) many people in the Near East and Mesopotamia used the Roman system of weights and measures. Throughout the ancient world there was much flexibility of weights and measures. For example, archaeologists have found objects in Greece and Rome that appear to have been made according to Persian weights and measures. Although these objects could have come from Persia, historians believe it is more likely that people in Greece and Rome occasionally used foreign measurement schemes to make certain objects. Even within the well-regulated Greek and Roman systems, there was a great deal of local variation, as individual towns customized weights and measurements to fit their needs.

ASIA AND THE PACIFIC

BY AMY HACKNEY BLACKWELL

The earliest documented systems of precise measurements were created in the fourth and third millennia B.C.E. in the Indus Valley, Mesopotamia, and Egypt. Chinese people are known to have developed precise weights and measures by the late second millennium B.C.E., though they may have done so several centuries earlier. Chinese systems of measurement spread throughout the rest of eastern Asia toward the end of the ancient period.

The peoples who lived in the Indus Valley between 3300 and 1500 B.C.E. developed precise systems of measurement. They divided weights and measures into units of 10. The basic unit of weight was about 10 ounces. Weights were multiples

of this unit; the standard weights were 1, 2, 5, 10, 20, 50, 100, 200, and 500 units. Smaller weights were measured as fractions of the basic unit; the main fractional weights were 0.5, 0.2, 0.1, and 0.05 units. The Harappan people who lived in the Indus Valley at this time built cities and houses according to precise plans, which required them to measure bricks, boards, streets, and other units carefully. Bricks were made according to a ratio of 4 to 2 to 1; that is, a brick was twice as wide and four times as long as it was tall.

By the late first millennium B.C.E. in India, overseeing weights and measures was considered the government's responsibility. The *Manusmriti*, a book of Hindu laws written around the first or second century B.C.E., observes that one of a ruler's duties was to ensure that weights and measures remained constant. During the Maurya Dynasty (321–185 B.C.E.) the government established a system of measurements that was used throughout the realm. Despite standardization, all measurements were somewhat flexible; it is impossible to know exactly how long any of these measurements really were because they varied somewhat from place to place. Many of them were determined by body proportions and so would naturally vary from person to person.

The smallest unit of length under the Indian system was a parmanu, which was microscopically small and could not be subdivided; the parmanu was a strictly theoretical unit because no one had the technology to work with such small items. From there, units were generally defined by groups of four or eight. Eight parmanu equaled 1 rajahkan, the length of a dust particle. Eight rajahkan equaled 1 liksha, the length of a louse egg. Eight liksha equaled 1 yookamadhyā. Eight yookamadhyā equaled 1 yavamadhya.

Eight yavamadhya equaled 1 angul, the width of a finger, or about $\frac{3}{4}$ inch. Eight angul equaled 1 dhanurmushti, the length of a fist with the thumb sticking out, or about 6 inches. Four angul were the width of a bow grip, called dharnugrah. Twelve angul made 1 vitastā, about 9 inches, or the distance between a stretched-out little finger and thumb. Four vitastā equaled 1 aratni or hast, about 18 inches, or the distance from an elbow to an outstretched middle finger, a unit known as the cubit in European systems. Four aratni made 1 dand or dhanush, about 6 feet, or the length of a bow. Ten dand made 1 rajju, which was about 60 feet. Two rajju equaled one paridesh, about 120 feet. Two thousand dand equaled 1 krosch, which was about 2 or 2.25 miles. Four krosch made 1 yojan, which was about 9 miles.

The system of weight measurement in India was closely tied with ayurveda, the main type of medicine. Ayurvedic medicine used many herbs and oils as treatments, and ayurvedic practitioners developed a precise system of weights and measures to ensure accuracy in their preparations. Doctors typically needed to weigh very small amounts of substances, and they used natural seeds as standards. Mustard seeds, sesame seeds, and madatiya seeds were all common weights. Texts on ayurveda list tables describing numerous weights and measures to be used in making drug preparations.

China may have developed systems of weights and measures around the same time as the Indus Valley civilizations. According to Chinese tradition, the Yellow Emperor (ca. 2697–ca. 2598 B.C.E.) was the first ruler to issue guidelines for weights and measures, but little is known about this system. The first well-known official units of Chinese weights and measures were invented and standardized between the 13th and 10th centuries B.C.E.; these units became the basis for measurement in China for the next three millennia. The actual lengths and weights that went with the standardized measurements varied over the centuries. Governments would occasionally step in and define units; for example, during the Qin Dynasty (221–207 B.C.E.) the Chinese government standardized weights and measures.

The basic Chinese unit of length was the chi, which is about 9 or 10 inches long and served as an equivalent to the English foot. It was determined by the distance between the thumb and middle finger of an outstretched hand. One cun was equivalent to about an inch. Ten chi made up one zhang. One li was equivalent to about $\frac{1}{3}$ mile. Long distances were generally expressed in li. One important measure was the length of one bolt of cloth, or one pi, which was about 40 feet long; most households had to pay some of their taxes in cloth, which was measured in pi. The most common unit of land area was the mu, equivalent to about 733 square yards. One qing was 100 mu.

The standard units of weight in China were the qian and the liang. The liang was a small amount, $\frac{1}{2}$ ounce in the ancient period. The qian weighed between 7.7 and 9.2 ounces. These weights were based on the actual weight of coins used as cash; the minting of coins was not done according to a uniform weight standard, so weights fluctuated. The Chinese people did not use coins as currency very much, preferring to keep their gold as valuable property. Weights were more important in trade, for buying and selling specified amounts of goods. Chinese medicine, like ayurvedic medicine in India, required precise measurements of herbs and other medicinal items.

During the centuries between about 500 B.C.E. and the fifth century C.E., the Chinese system of measurement gradually spread through Southeast Asia, Korea, and Japan. The people of these nations adapted the Chinese measurements into their own languages. For example, in Japan the main unit of length was 1 shaku, equivalent to the Chinese chi. It was broken into 10 sun and 100 bu. Six shaku made up 1 ken, slightly less than 6 feet. Three hundred sixty shaku equaled 1 cho; 36 cho made up 1 ri, which was about 2.6 miles. The most common measurement of land area was the tan, which was about $\frac{1}{4}$ acre.

EUROPE

BY MICHAEL J. O'NEAL

Systems of weights and measures throughout the ancient world were highly complex, and historians have been able to decipher them only in part. In many cases they have to rely on

archaeological evidence; for example, they can make inferences about systems of weights and measures from regularities they find in the measurements of surviving buildings or the volumes of containers. An essential requirement for any system of weights and measures is the ability for a community or a society to come to common agreement about their values. At the boundaries between systems of weights and measures, some understanding must be established about how these values will be converted from one system to another.

Understanding systems of weights and measures before the advent of writing is nearly impossible. The Scottish engineer Alexander Thom (1894–1985) claimed the existence of a “megalithic yard” of about 2.72 feet that served as a unit of measurement in laying out monuments such as Stonehenge, although this is impossible to document conclusively and also does not seem to be supported by evidence outside Britain. With the emergence of metallurgy, prehistoric European people appear to have developed some common understanding about units of weight. For example, copper and tin ingots of standard sizes are often found in Bronze Age shipwrecks in the Mediterranean Sea. In northern Europe bronze and gold artifacts such as axes and neck rings may have served as standard units of exchange, a sort of primitive currency. Although it is likely that there were rules for measuring and weighing commodities, we simply cannot do more than speculate about their nature.

Some ancient civilizations, including the Greeks, Romans, Egyptians, and Mesopotamians, were able to develop fairly regular, stable systems of measurement largely because they ruled over extensive empires. Because so many people from diverse areas were under their control, particularly in the extensive Roman Empire, they adhered to standards of weights and measures imposed on them from a central authority, usually by royal decree. Because of the importance of trade to these empires, both between countries within the empire and between the empire and other regions, merchants and public officials needed accurate ways of measuring volumes of goods and determining their price. They also needed accurate ways to measure the weight of gold and silver coins minted by other nations and used to pay for goods.

While the Romans were expanding their empire in western Europe, northern and eastern Europe were peopled by largely autonomous extended tribes: the Scandinavians, an assortment of Germanic tribes, the Celts, various Slavic peoples, and others. Without a central authority, each of these communities developed its own standards for weights and measures, and these standards often changed gradually over time. In time the Romans, who adopted many features of the Greek system, imposed their system of weights and measure on portions of Europe, particularly Italy, Gaul (France), and the British Isles. Many of these standards survived and were imported eventually to the New World, where such measurements as the inch and foot continue to be used. In other respects the standards shifted and have presented a challenge to historians.

Bronze steelyard with lead weights from Roman Britain, first to second century C.E.; such weights were used by shopkeepers and traders. (© The Trustees of the British Museum)

Some historians argue that the standards of weights and measures used in ancient Europe, as well as around the Mediterranean Sea and among the Slavic peoples of eastern Europe and Russia, all descended from a common root system, probably that of the ancient Babylonians. Thus, as people spread northward and westward throughout Europe, they based their system of weights and measures on an earlier one. Historians base their argument on sophisticated mathematical analysis that shows that these systems often had common arithmetical factors. Mathematicians refer to the science of weights and measures as metrology, and an important component of metrology is the notion that a particular unit of measurement is divisible into smaller units or can be multiplied into larger units. Ancient Europeans may have developed different standards of measurement, but those standards were convertible into the standards used by other cultures in much the same way that, for example, American dollars can be converted into Japanese yen according to an agreed-on exchange rate. Without common arithmetical factors, it would have been nearly impossible for far-flung communities to engage in trade or determine the value of gold and silver coins.

Many of the measurement units known to us from historical accounts in medieval Europe probably had their roots deep in antiquity. In Europe, as elsewhere in the ancient world, early units of measurement typically had some relationship with the physical world. The ancient Europeans started with the human body, using such standards as hand spans, the width of a finger, the length from the elbow to the tips of the fingers, and the length of a foot to measure linear distance. In this regard, their units of length were little different from those of the ancient Egyptians and Babylonians. Thus, for example, the ancient Irish had a unit of measure called the troigid, which was the length of a man's foot, so a troigid was a "foot." A troigid was made up of 12 ordlochs, or inches, with 1 ordloch being the width of a man's thumb. Sometimes objects were used. The Germans measured length by the ell, which was the length of a bolt of cloth.

Also commonly used to measure distance was the stride. The Romans, for example, used the pace of a marching soldier, based on two consecutive positions where the right foot landed, to measure a Roman mile, which consisted of a thousand paces. This measurement was imposed throughout the empire, and it remains fairly close to the British mile that survives in modern life. Evidence also suggests that ancient peoples had a fairly accurate understanding of such large measurements as the circumference of the earth and the distance between the poles. These measures were then broken down to provide smaller units of measurement that were used, for example, in determining the length and width of monumental buildings. Again, the ancient Europeans inherited some of these systems by a process that historians do not fully understand.

To measure weight, the ancient Europeans used the materials that surrounded them. In the British Isles, for example, the stone, or 14 pounds, is still commonly used to measure a person's weight, though in the past the stone was probably more like 16 pounds. Further, agricultural commodities, often the basis of trade, were used to determine weights. Throughout the ancient world people were able to develop growing, stable civilizations because of a major staple crop. In Asia the crop was rice. In the Americas it was maize, or corn. In Europe and around the Mediterranean wheat was the staple crop, so grains of wheat were often used to form a common standard of weight. Thus, for example, the weight of a certain number of grains of wheat equaled a certain measure of silver; in turn, these measures were used to determine such measures as the ounce, from the Latin word *uncia*. This system is preserved in modern medicine, where pharmaceuticals are still often measured in grains, as well as in modern measurements of precious metals. The carob seed was often used to measure silver and gold, giving rise to the modern word *carat*.

Grains of wheat were also used to measure length. Again, in ancient Ireland measurements based on wheat ran as follows: The length of three grains of wheat equaled 1 ordloch,

or an inch; 4 inches were regarded as 1 bas, or hand palm; 3 palms were a troigid, or foot; 12 troigids were a fertach, or rod; 12 fertachs were a forrach; and an area 12 forrachs in length and 6 in width was a tír-cumaile. The last of these measures was significant because it represented an area sufficient to graze a cumal, or three cows. Property was often measured according to the amount of work that could be performed on it. The acre, for example, developed as an amount of land that a worker could plow in a day.

GREECE

BY SPYROS SIROPOULOS

The ability to measure and compare physical objects and to express their attributes in symbols easily understood by everyone constitutes a standard of communication and provides a way to relate abstract thought to reality. To define a measurement, it is necessary to establish a *metron*, a unit with which to count objects and various subunits or multiples. Various metrical systems have developed to measure elemental dimensions such as length, area, capacity, and weight.

From an early stage of their communal life, people realized the need for specific measurements. Representations of simple forms of balances or scales have been discovered at Knossos in Crete. The Egyptians had used scales since 2500 B.C.E., and it is possible that the use of such mechanisms passed from Crete to Greece. In any case, the first units of measurement were inspired by the human anatomy. The finger, palm, and foot were the first natural measures. Needless to say, the degree of standardization varied from place to place. Furthermore, there were situations in which these measures were inadequate; for example, in the case of measuring longer distances, the cast of a stone or spear or the distance covered by a walker in one day were used as basic units. The Greek poet Homer (eighth or ninth century B.C.E.) uses phrases like these to describe long distances.

People also needed to measure the fields they plowed, the liquids they stored or exchanged in trade, and the amount of grain they produced. Various metrical systems developed, all of them based on local conditions, habits, and needs, yet all of them interdependent and volatile because of international trade and the contact of people with their neighbors. In classical Athens the prototype measures of capacity used for market inspection were kept in the dome of the Athenian Agora (market).

The principal unit for measuring length was inspired by the foot, or pous, but its length was not standard and varied greatly from place to place. The foot of Olympia was 1.050 modern feet, the foot of Pergamon was 1.083 modern feet, and the foot of Aegina (which was used more frequently) was 1.093 modern feet. The subdivision of the pous is called daktylos, or a finger breadth, which is equivalent to $\frac{1}{16}$ of the pous, or 0.063 modern feet (0.76 inch). Further subdivisions are taken by the fingers. Thus, 4 daktyloi = 1 palaesté (palm);

8 daktyloi = 1 dichas or hemipódion (half foot); 11 daktyloi = 1 orthódoron; 12 daktyloi = 1 spithamé (span of all fingers); 16 daktyloi = 1 pous (foot). Measures for higher dimensions are taken from the arm: 18 daktyloi = 1 pygmé (the length between the elbow and the beginning of the fingers); 20 daktyloi = 1 pygón (the length between the elbow and the knuckles of the fist, used by the Greek writers Homer and Herodotus); 24 daktyloi = 1 péches (the length between the elbow and the fingertips).

From farming life the Greeks developed the measure of a stádion, the distance covered by the plow in a single draft. Originally the stádion contained 600 feet, irrespective of the foot's size. The Attic stádion was therefore 606.889 modern feet; the Olympic stádion was 630.807 modern feet; and the odoiporikón (pacer's stadium) was 516.732 modern feet. The stádion produces further units, such as these: 2 stádia = 1 diaulos; 4 stádia = 1 hippikón; 12 stádia = 1 dólichos; 30 odoiporiká stádia = 1 persian paraságes; 40 odoiporiká stádia = 1 Egyptian schoinos.

The minimum measure for area was the amount that a pair of oxen could plow in the course of one day. This was called pléthron, a square of 101 by 101 modern feet. Divisions of the pléthron were the árura ($\frac{1}{4}$ of the pléthron) and the

Red porphyry 1-talent weight, from Knossos (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

hékτος ($\frac{1}{6}$ of the pléthron). A different measure introduced to Athens from Sicily and Cyrenaica was called médimnos, and it represented the amount of land that could be sown by a certain quantity (a médimnos) of wheat.

Since corn and wine were two of the main agricultural products, two different measuring units were established for measuring dry or wet products. The measuring unit for dry products was called kýathos. According to different local systems, it varied from 0.048 to 0.075 gallons (or 0.191 to 0.300 quarts), although it most usually was 0.055 gallons (0.218 quarts). The following units are derived from the kýathos: 6 kyathoi = 1 kotýle; 3 kotýlai = 1 kséstes; 2 ksestai = 1 choinix; 4 choinikai = 1 hemiektos; 8 choinikai = 1 hekteus; 6 hekteis = 1 medimnos (88.19 pounds).

The Athenian statesman Solon (ca. 630–ca. 560 B.C.E.) used the medimnos to calculate the citizens' wealth and to classify citizens according to their economic position. The social classes of the Athenian citizens were ordered thus: The *pentakosiomedimnoi* were those with 500 medimnoi of annual produce; the *triakosiomedimnoi* or *hippeis* were those with 300 medimnoi of annual produce; the *diakosiomedimnoi* or *zeugitai* were those with 200 medimnoi of annual produce; and the *thetai* were the poorest citizens, without land of their own.

During the Archaic and the Classical periods (ca. 600–ca. 323 B.C.E.) Greeks used the kotýle for measuring both wet and dry products. The measuring units for liquids are formed thus: 1.5 kyathoi = 1 oxýbaphon; 2 oxýbapha = 1 hemikótylon; 2 hemikótyla = 1 kotýle; 2 kotýlai = 1 ksestes; 16 ksestai = 1 chous; 12 choai = 1 metretés (10.41 gallons).

Various measures were used for weight in Greece. Clay tablets from Knossos, Mycenae, and Pylos present a weighing system in which the largest unit was about 66 pounds. The typical weight of historic Greece was a lead plaque, sometimes with the name of the issuing city or badge. Solon introduced to the Attica region the weighing measure of the Greek island of Euboea, called obolós. Initially the obolós was in the shape of a spit, or the sharp end of a lance (*obelos* in Greek), and it was $\frac{1}{6}$ of a drachma (0.159 to 0.212 ounces of silver coin in Attica). A drachma indicates the amount that can be held in the palm of the hand, equivalent to six such spits, or oboloi. The weight of the obolós either in silver or gold depended on the local value of the coin. Thus, in Athens and Euboea the obolós was 0.026 ounces, while in Aegina (the second most established measure) it weighed 0.037 ounces. Various values of the obolós are formed thus: 1 dióbolos = 2 oboloi = $\frac{1}{3}$ drachma; 1 dekábolon = 10 oboloi; 1 hemiobólion = $\frac{1}{2}$ obolos; 1 tritemórion = $\frac{2}{3}$ obolos; 1 tetartemórion = $\frac{1}{4}$ obolos; 1 chalkens = $\frac{1}{8}$ obolos (copper).

There was also the mina, equivalent to 100 drachmae, and the talent, equivalent to 100 minae. A talent represented a man's load, and it would be relevant to the local standard used. An Attic-Euboic talent would weigh approximately 57 pounds, while the Aeginitic talent would weigh approximately 83.33 pounds.

ROME

BY KATIE PARLA

The use of a sophisticated system of weights and measures was born in the Middle East. As far back as the third millennium B.C.E., the Mesopotamians used common units for calculating weight, area, volume, and distance. The development of such a system was due to a growing territory and economy as a result of increased conquest and commerce. A standardized system of weights and measures was needed to ensure smooth trade across vast distances. Persians, Egyptians, and Phoenicians also implemented standardized weights and measures that would later be adapted by Greeks and Romans.

As a city-state or empire grows, it is necessary that all people in that territory have a common vocabulary in order to facilitate commerce. This vocabulary applies not only to the quantity of commercial goods but also to the monetary system, provided it is based on the gold or silver standard. For this reason the Romans, like so many civilizations before them, instituted a system of weights and measures that was used throughout their territory. While Rome's many standards of measurement were influenced primarily by Egypt and Greece, the Romans also developed their own native units.

The Romans were the first to employ the mile to measure long distances. The word *mile* comes from the Latin *mille passum*, or 1,000 paces. Each mile was equivalent to 1,000 double paces (2,000 individual steps) for a total of 5,000 Roman feet. The Roman mile was standardized in the first century B.C.E. by the emperor Augustus (r. 27 B.C.E.–14 C.E.) as part of his legendary administrative reform. He erected a pillar in the Roman Forum known as the *Milliarium Aureum*. This "Golden Milestone" listed the distances in miles from that point in Rome to important cities in the empire.

The Romans borrowed the concept of short-length measurements from the Egyptians. In Egypt finger digits, palms, feet, and arms were all used to measure short distances. These body parts were convenient rulers that could be used in daily life and casual commerce. However, for building and trade, the units were rigidly standardized, so these units would be uniform all across the Egyptian sphere of influence. The Romans used digits, palms, feet, and cubits (the distance from the elbow to the tip of the middle finger) for measuring lengths, although their values were slightly different from the Egyptian standards and also varied across Roman territory, particularly during the republic (509–27 B.C.E.). There was also a slight difference between the length of feet and their units during the republic and the length of feet and their units during the empire.

A Roman foot, or *pes* was divided into 12 equal units called *unciae*. During the republic the Roman foot measured 11.65 inches, and during the empire it measured 11.5 inches. A cubit was equal to 1.5 Roman feet, and a *passus*, or a double step, measured 5 feet. A *stadium* was another unit of measurement for greater lengths derived from the distance

Roman cup or bowl depicting a man carving the number 7 on a nilometer, a device used to measure the water level of the Nile's annual flood (© The Trustees of the British Museum)

around a Greek racing stadium. It was equal to 625 Roman feet, $\frac{1}{8}$ of a Roman mile.

Romans measured weight in a unit called a libra, which was divided into 12 base units of equal weight, also called unciae. A libra weighed 11.5 ounces, just short of a modern pound. Accordingly, each uncia weighed just a bit less than an ounce. Another term for libra was as. Asses or librae were not just units of measurement for weighing commercial goods; they were also used to establish the value of Roman currency, emphasizing just how critical a standard of weights and measures was to the Roman economic system.

Liquid volume was measured in a unit called an amphora. Borrowed from Greece, this unit was equivalent to 6.8 gallons of liquid. In the ancient Mediterranean terra-cotta vessels called amphorae were used to transport liquids like oil and wine. The volume of the amphora is equivalent to 1 cubic foot of liquid and is thought to be derived from the amount of liquid a human being can comfortably carry. The Romans also employed smaller volume units. For example, 1 amphora was equal to 8 congii, each of which had a volume of 0.85 gallons. One congius contained 12 heminae, each of which had a volume of 0.57 pints. A sextarius consisted of 2 heminae. For measuring either dry or liquid volume, the Romans used the modius (pl. modii). This volume was equivalent to 2.4 gallons of liquid. The modius was further subdivided into 16 units for liquid measure called sextarii; each had a volume of 1.1 pints.

Romans used four main units to measure land area. They were used in land division and distribution for colonial, agricultural, and military endeavors. The basis for these calcula-

tions was the actus, a unit of length equal to 120 feet. A square actus, actus quadratus, was equivalent to 14,400 square Roman feet, or about $\frac{1}{3}$ acre. Next was the jugerum, possibly derived from the average area two oxen could plow in a single day. One jugerum equaled 2 actus quadrati. Two jugera made a heredium, which measured approximately 1.25 acres. The largest denomination of land area was the centuria, which was equivalent to 100 heredia, approximately 125 acres during the republic but up to 200 heredia in the empire. The origin of the centuria was the approximate area occupied by an encamped century of the Roman military.

The Roman system of weights and measures was partially standardized during the late republic. Although there were slight regional variations in units, the basic units of distance, length, weight, volume, and area were uniform throughout republican and imperial territory. Elected officials called aediles were responsible for regulating the system of weights of measures in towns and cities throughout Roman territory. In Rome the standards for weights and measures were kept at the Roman Forum in the Temple of Castor and Pollux. Employing a uniform system of weights and measures, Rome was able to divide its land, mint money, and exchange commercial goods over a vast territory while using a common vocabulary from Britain to the Persian Gulf.

THE AMERICAS

BY KIRK H. BEETZ

Exactly what the weights and measures were for ancient Americans is among the mysteries of ancient American life. For most ancient cultures archaeologists rely heavily on written records for identifying weights and measures, and most ancient Americans left no such records. Some ancient American cultures did have written languages, but it seems that they did not deem their weights and measures worthy of recording. For instance, merchant transactions among the ancient Maya were written on the ground, in dirt, with stones, seeds, or other small objects serving to mark numbers, presumably including those that stood for weight, volume, and length; the transactions were then memorized and the dirt and markers reused for other transactions. A lack of physical evidence adds to the mystery. For instance, in other parts of the world metal scales for weighing objects have been found and their uses identified, but Americans made little use of metal in the ancient era. They may have used wooden measuring devices or devices that combined wood, bone, and stone. If both the wood and the bone decayed, archaeologists would have only the stones, and the stones may look like nothing special.

Researchers expect weights and measures to appear in cultures that trade extensively among themselves and with outsiders and that have a central government which can impose standards for weights and measures on people. This assumption would seem to leave the cultures of the Innuit and the people of the plains of North America out of the picture.

They may have formed weights and measures of their own, but it seems unlikely that they did.

Cultures that might have had weights and measures existed in northeastern North America, along the Mississippi River, in Mesoamerica, and in northern South America. In each case, between 1000 B.C.E. and the end of the ancient era, cultures created urban areas, the most sophisticated of which were in Mesoamerica. Towns of as many as 30,000 people may have been built in North America in the northeast and along the Mississippi River, and they seem to have had extensive trade networks, implying a need for weights and measures, as well as the opportunity for the formation of central governments that could establish weights and measures; however, evidence for these is absent at present.

One way for archaeologists to gain hints about ancient customs is to study modern descendants of the ancient cultures in the hope of finding practices that can be dated back to ancient times. In northeastern North America the cultures of the ancient towns were long gone by the time people who could read and write arrived. Along the Mississippi disease wiped out the town dwellers, who may or may not have been descended from the ancient town builders, before they could be studied. In northern South America the ancient builders of impressive monuments and towns were gone before the coming of Spanish record keepers. Nevertheless, in Mesoamerica the Mayan culture still exists. However, by the time anyone wrote about Mayan weights and measures, the Maya had adopted Spanish weights and measures. Only something to measure distance overland has survived, called a “pace.”

The Aztecs known to the Spanish seem to have adopted many practices from the Maya, probably including some weights and measures. Some of their records for payments of taxes and tribute have survived, indicating a few of their measures. Gold was made into disks about 2 inches in diameter and 1 finger thick. Cotton was traded in bales, although the size of a bale is as yet unknown. Maize and other grains may have been measured by baskets, although again the exact size is not known. In each of these instances, it is possible to visualize ancient Maya making similar measurements.

There are good reasons to believe that the ancient Maya had systems of weights and measures. Their cities levied taxes on their subjects, and they exacted tribute from conquered lands. In each case, being able to weigh and measure goods would be necessary for making sure the correct amounts of taxes and tribute were paid. Further, the ancient Maya had complex legal systems that included the ability of people to file lawsuits against merchants they believed had cheated them. Weights and measures would be useful for determining whether someone was overcharged or shortchanged. In addition, kings were expected to ensure that resources were properly distributed among their people; managing the distribution of food, cloth, and other goods would be made simpler if a system of weights and measures were employed. Complicating matters is the possibility that every city or per-

haps every king may have had a unique set of weights and measures.

With all those possibilities in mind, archaeologists use generalized words to represent weights and measures they hope to identify someday. For example, the word *load* may be used to represent the weight or size of goods. This term does not represent a random weight or size; instead, it represents what archaeologists believe was always a fixed amount. The term *loads* would apply to large weights or sizes, such as harvests being brought to the city from farms. Smaller sizes would be packets, articles, and bundles, which would be traded in marketplaces to families. The word *length* applies to cloth. For the Aztecs, 20 lengths would be equal to 1 load, although such may not have been the case for the ancient Maya. Such terms allow archaeologists to discuss the use of weights and measures without knowing their exact amounts.

Cotton was traded extensively among the Maya and neighboring cultures. Cotton was almost certainly baled for ease of transport, and it may be assumed that the bale was a standardized unit of measure. Of all Mayan goods, the likeliest to have been weighed or measured was cacao. The cacao bean was treasured because it could be made into a variety of drinks that were valued for their taste, either bitter or sweetened with sugar or honey, as well as incorporated as flavoring into foods. The beans were probably traded by how many there were, but they may have been traded by weight. Ground cacao would have been either weighed or measured by volume. So highly valued was cacao that it was almost certainly measured down to tiny grains. It is with cacao that archaeologists have their best hope of discovering a Mayan weight or measure because the consumption of cacao was something the Maya deemed worthy of recording, even on their monuments.

► writing

INTRODUCTION

The earliest writing systems, often referred to as proto-writing, emerged during the Neolithic Period, probably in about the seventh millennium B.C.E. Archaeologists have found this type of writing, which consisted of symbols that stood for objects or ideas, inscribed on tablets or such objects as tortoise shells. Not much information, however, could be recorded by this type of writing. Writing proper is believed to have originated in ancient Sumer in the Near East during the Bronze Age, in about the fourth millennium B.C.E. At roughly the same time, a form of writing called Proto-Elamite developed in Persia (modern-day Iran), and by 3200 B.C.E. the ancient Egyptians had a form of writing. By 1900 B.C.E. writing had developed in India. The Chinese, meanwhile, produced proto-writing as far back as 6000 B.C.E. and had formed a script by 1600 B.C.E. Other early writing systems that historians have discovered (and in some cases have been unable to decipher) include Anatolian hieroglyphs and writing from the island of Crete, both from around the second millennium B.C.E., and various Semetic languages that emerged in the Near East in roughly 1800 B.C.E. With only very few exceptions, such as the writing system of the ancient Maya in the Americas, all writing scripts throughout the world descended from the writing systems of the Near East or China.

Writing in the ancient world took various forms. The earliest is called *logographic*, from the Greek word *logos*, meaning "word." Logographic writing consisted either of pictographs (symbols that were essentially pictures of the thing represented) or ideographs (symbolic representations of concepts). Later, more flexible writing systems consisted of syllabaries, or lists of symbols that stood for syllables.

These types of writing systems, however, were cumbersome and difficult to learn, for they required the use of hundreds, if not thousands of symbols. A major step forward was the development of alphabetic writing during the Iron Age. Now a small number of symbols could be used to represent the sounds contained in a word. The earliest-known alpha-

betic systems of writing were those of the Semitic languages, and the written languages of ancient Greece and Rome were alphabetic. Some ancient writing systems were a mixture or two or even all three of these types of writing.

Two other terms are often used in connection with ancient writing systems: *cuneiform* and *hieroglyphs*. The writing of the Sumerians was cuneiform, a word that derives from a Sumer meaning "wedge." Cuneiform writing consists of wedge-shaped symbols that took this shape because they were pressed with a stylus into wet clay. The word *hieroglyphs* is commonly used to refer to the writing of ancient Egypt as well as the Anatolian script mentioned earlier. While the word is widely used, specialists in Egyptian archaeology and history discourage it, primarily because the word is of Greek origin and does not have a precise meaning. Generally, though, hieroglyphs refers to the complex artistic writing of the ancient Egyptians, typically practiced by trained scribes and the priestly class. This system consisted of three classes of symbols: phonetic symbols that functioned like an alphabet, logographs, and a third set of symbols called determinatives that narrowed the meaning of a logograph.

AFRICA

BY DIANNE WHITE OYLER

Writing in the African society and culture of the ancient world dates back to 3000 B.C.E. in the Nile River valley after the political unification of Upper and Lower Egypt by King Menes. *Hieroglyphics*, a Greek word meaning "sacred text," is the first indigenous African writing system.

Along the upper Nile River, south of Egypt, Nubia had been influenced by Egypt in the use of the Egyptian language and writing system through trade and conquest. Although hieroglyphics were known by people living along the upper Nile, the region was not receptive to adopting a writing system. The more rural part of the river lacked the urban, centralized government that required detailed record keeping. Both Nubia and the kingdom of Kush adopted the hieroglyphic writing system from Egypt. However, although the kingdom of Kush and the kingdom of Kush at Meroë possessed literate societies, not everyone was able to read and to write. Members of the royal and upper classes, priests, and scribes enjoyed an education through which they controlled society by possessing written knowledge. Everyone else lived in a preliterate world that coexisted in a symbiotic relationship with the literate one.

The Egyptian hieroglyphic writing system was adapted between the eighth and fourth centuries B.C.E., during the Napatan Period, when a form of hieroglyphic writing was used in texts. The Kushite rulers of Egypt's Twenty-fifth Dynasty—Kashta, Piye, and Shabaka—used hieroglyphics to write about their conquests on steles placed throughout the combined kingdoms. In 170 B.C.E. Queen Shanakdakhete became the first female ruler of the Meroitic Period. During her 10-year reign she used Meroitic hieroglyphs to inscribe

texts on stone and brick walls. These texts represent the oldest-known Meroitic hieroglyphs, which were adapted from Egyptian hieroglyphics and changed to meet Nubian needs. Although the two forms of hieroglyphs appear similar, they do not represent the same meanings. Based on their connection to Egyptian hieroglyphics, the written Meroitic marks can be deciphered; however, the Meroitic language has not been translated, so it is impossible to understand what has been written.

The kingdom of Axum created its own indigenous alphabet and imported other alphabets through trade and migration. Axum's indigenous Ge'ez language and alphabet were based on the language and script of migrants from southern Arabia; the Sabaean alphabet dates from about sixth century B.C.E. The Hebraic alphabet also may have been migratory. According to one origin myth, Menelik I, son of the Queen of Sheba and Solomon of Israel, brought the alphabet from Israel in the 10th century B.C.E. Another myth proposes that the Hebraic alphabet was brought in the ninth century B.C.E. by the Hebrew tribe of Dan living in the Ethiopian highlands. In the 12th century Jewish clerics dated to antiquity the Torah used by the descendants of the tribe of Dan. The Egyptian Coptic missionaries brought their alphabet to Axum during the fourth century C.E., and the Greek language and alphabet and Latin language and Roman alphabet came through the Port of Adulis through the Red Sea trade.

Present-day Ethiopia's Ethiopic script reportedly originated in Axum in the second century C.E. and is based on the ancient writing system of Ge'ez. This writing system was used in religious and secular inscriptions on stone and metal objects. During the fourth century C.E. King Ezana adopted Christianity as the religion of the state, and biblical texts were translated from the Coptic language and script to the Ge'ez language and Ethiopic script.

In the North African region of Maghreb inscriptions in an indigenous Berber writing called Tafineq date from as early as 500 B.C.E. This writing system was used to communicate messages, for funerary inscriptions, and to mark property lines. Tafineq may have been influenced by the Punic writing system based on the Phoenician alphabet used in the colony of Carthage. In addition, the Greek language and alphabet and Latin language and Roman alphabet were imported first through trade and later through Roman conquest in the Punic Wars (264–146 B.C.E.). From 155 to 160 C.E. the Latin language and Roman alphabet were used by the Roman Catholic Church to spread Christianity in North Africa.

Ancient African writing is the second oldest in the world. Written hieroglyphics changed as the need arose to streamline complex writing system. Egypt's gift to the world was its writing system, which was adapted by other civilizations to meet their unique needs, and papyrus, on which texts covering various subjects and in various languages and scripts are preserved for posterity. Other writing systems were imported through cultural diffusion as various groups traded with, migrated to, or conquered civilizations on the continent.

EGYPT

BY LEO DEPUYDT

Egyptians wrote their language in the pictorial hieroglyphic script. *Hieroglyphic* is a Greek word meaning "pertaining to holy carving." The unit of the writing system is the hieroglyph. Hieroglyphs are stylized but realistic pictures of beings and objects. The earliest hieroglyphic writing dates to about 3000 B.C.E. Early attempts are imperfect and difficult to decipher. Full-fledged hieroglyphic writing emerged around 2500 B.C.E. The hieroglyphic tradition steeply declined in the second century C.E., and the latest surviving texts date to the fourth and fifth centuries C.E. The last scribe presumably died sometime in the sixth or seventh century C.E. In 1822 the French Egyptologist Jean François Champollion deciphered hieroglyphic writing.

Because writing represents language, any description of a writing system must be preceded by a description of the language system. Language is composed entirely of signs. Signs have two sides, the signified and the signifier. An example of the signified is a person's image of a dog. The signifier attached to this signified is the sound pattern consisting of the three sounds written *d + o + g*. In other words, the signifier is the code in the brain that prompts the speech organs to produce the sounds. Signified and signifier are independent. The proof is a comparison of languages. French speakers also know the signified of a dog but use different sounds as the signifier, namely *chien*. In English and French the image of a dog is about the same, but the sound pattern changes. Language is neither signifieds nor signifiers but rather the links between the two. English speakers tacitly agree to link the image of a dog always to the sound pattern written *dog*. The biochemical configurations of signifiers, signifieds, and the links between them in the brain are unknown, but their existence seems certain.

Hieroglyphs can refer to either signifieds or signifiers. The hieroglyphic script is one of the few scripts that does both. A hieroglyph denoting a signified is an ideogram—that is, an "idea character." A stroke included in a hieroglyph indicates that the hieroglyphs meet two conditions: They are ideograms, and they denote a whole word by themselves. A hieroglyph denoting a signifier (one or more sounds linked to a signified) is a phonogram—that is, a "sound character." Phonograms represent one, two, or three consonants. They are therefore uniliteral, biliteral, or trilateral. Vowels are not written. Phonograms also function as phonetic complements.

Pictures come to denote sounds through the rebus principle. *Rebus* is Latin for "representing sounds by depicting objects." In English the sound made by the letter *I* might be represented by a picture of an eye. It is in this way that phonograms are derived from pictures. In rebus derivation a hieroglyph that denotes a signified as an ideogram—and that secondarily denotes the signifier attached to that signified—is cut loose from the signified and left to express only the signifier as a phonogram. Like any language, Egyptian consists of a limited set of distinctive sounds, about 25. Each sound can

Abu Simbel—hymn in praise of King Ramses II (Courtesy of the Oriental Institute of the University of Chicago)

be represented by its own phonogram. The group of phonograms in the language is called the alphabet. But hieroglyphic writing is not purely alphabetic. It uses other signs besides the alphabet. Still, about half of the signs in any hieroglyphic text are those of the alphabet.

Ideograms always denote both sound and meaning. Phonograms always denote sound but only sometimes denote meaning. The result is asymmetry. An ideogram denotes the signifier of a word. The signifier is linked to the signified in the sign. That is why an ideogram indirectly denotes a sound. In referring to both sides of a word—that is, a whole word—an ideogram is always a logogram, or a “word character.” Only a full sound pattern as signifier is linked to a signified. Therefore, only a phonogram denoting a full sound pattern is also a logogram.

A third type of hieroglyph is the determinative. It appears at the ends of words and determines the meaning class to which a word belongs. Hieroglyphs often function in more than one capacity. Ideogram, phonogram, and determinative are therefore functions rather than types of hieroglyphs. A word can be written in many combinations of one or more of the three types—ideogram, phonogram, and determinative—and contains from one to five or six hieroglyphs, sometimes more.

Hieroglyphs normally exhibit their full pictorial quality only when chiseled or painted. This is hieroglyphic writing proper. When writing with a pen on papyrus, scribes used cursive variants. Pen-written hieroglyphs are called hieratic, which is derived from the Greek word for “priestly.” The distinction between hieroglyphic and hieratic appears first in the religious writings of Clement of Alexandria (ca. 250–210 C.E.). Hieratic was by that time used mainly in religious texts inscribed by priest-scribes on papyri. Earlier, hieratic had been used for all pen-written texts composed in the first three stages of the language: Old, Middle, and Late Egyptian.

From about 650 B.C.E. onward an extremely cursive variant of hieroglyphic writing called demotic was used for more than a millennium. It denotes the fourth stage of the language, also called demotic. Demotic means “of the people.” The name first appears in the writing of Herodotus (fl. fifth century B.C.E.). Hieroglyphic proper and hieratic had by then become limited mainly to monumental and religious texts. In demotic the hieroglyphs of a word often merge into a single composite sign taking on a life of its own. Therefore a demotic word was often written with its own signs. Demotic therefore makes great demands on a reader’s paleographic memory.

Hieroglyphic writing as a rule runs from right to left, with people and animals facing right. Texts were mostly written in lines. Columns of hieroglyphs were commonly used in monuments and were the norm in hieratic in the third millennium B.C.E. The sign list in A. H. Gardiner’s *Egyptian Grammar* contains fewer than 800 signs. The number of signs used frequently is less than that.

THE MIDDLE EAST

BY BRADLEY SKEEN

The cuneiform script is the oldest form of writing in the world. Its earliest form was semipictographic, devised around 3400 B.C.E. to record the language used by the ancient inhabitants of Uruk in southern Mesopotamia. This so-called protocuneiform may have been developed to write the Sumerian language (which is related to no other known language), but early cuneiform writing was not used for Sumerian until the middle of the third millennium B.C.E. After 2500 B.C.E. it was quickly adapted to record the east Semitic Akkadian language of people living in the same area. Eventually many other linguistically unrelated languages used cuneiform, including Elamite, Hittite, Ugaritic, Canaanite, Hurrian, Urartian, and Old Persian.

Writing was invented at Uruk in the context of a complex society that produced a large agricultural surplus and needed to record the incomings and outgoings of that produce and other commodities. The invention of writing at Uruk by administrators managing the large agricultural estates and workshops of Eanna, the household of the goddess Inanna, was thus a very specific, pragmatic development driven by the need to record estate activities. Because of its difficulty, the cuneiform writing was used only by professional scribes, educated bureaucrats, and other elites whose positions in society were bolstered by their access to writing, especially in the form of legal and religious documents.

The precursors of cuneiform writing began to develop as early as 8000 B.C.E. The first step was the use of tokens—small clay objects marked with simple symbols—to record business transactions, such as the transfer of livestock from a shepherd to a temple estate. Eventually traders documented transactions by sealing tokens inside a large hollow clay ball known as a bulla. Seeing the specifics of what was recorded, however, required breaking the bulla, thus making it useless. The so-

lution was to impress another symbol on the outside of the bulla for each token it contained. In time the documentation system was simplified by writing transactions on flat clay tablets of various sizes. Once this became common practice, the set of signs expanded, enabling people to write longer texts.

Cuneiform is a Greek word meaning “made of wedges” and is used by modern scholars to describe the Sumerian script and its offshoots. Although the writing system began as schematic drawings of things named, the images, called logograms, were quickly abstracted and reduced to a set of a few hundred signs, each composed of a unique group of wedge shapes impressed in the wet clay with the tip of a stylus made from a reed. Typically a sign had a syllabic value, and a series of signs strung together formed a word. Much cuneiform literature has survived because the clay tablets on which it was written were very durable. Even when ancient cities were burned by enemy armies, tablets survived because the fire of the burning libraries actually hardened and preserved the clay. Thus, large collections of tablets are preserved from Nineveh, Assur, Ur, Uruk, Mari, Ebla, Ugarit, and many other cities that were destroyed by fire.

Egyptians learned of cuneiform through trade contacts with Mesopotamia and, after 3000 B.C.E., created their own hieroglyphic script that shared many features with cuneiform. When Indo-European Hittites and Persians conquered Mesopotamia, they adopted cuneiform for writing their languages, which previously had been without any form of script. Because of the prestige of the Mesopotamian empires, even the Egyptian court had to maintain an office of scribes trained in the cuneiform languages to handle diplomatic correspondence. In the Iron Age (1000–550 B.C.E.) languages written in alphabetic scripts became predominant, but Akkadian and Sumerian survived as scholarly, religious, and literary languages until the first century C.E., in much the

same way Latin did in western Europe after the fall of the Roman Empire.

As early as 1900 B.C.E. many people who spoke northwest Semitic languages developed the first alphabetic writing. This ancestor of the alphabetic scripts used in the modern world is known as the Proto-Sinaitic script because it was first discovered in graffiti and other inscriptions left by copper miners in the Sinai Peninsula. It has since been found in inscriptions from all over Egypt. Rather than a simple transliteration of words into hieroglyphs, the Proto-Sinaitic script comprises roughly 30 hieroglyphs that began with the sound of the consonants in Semitic languages; systems of adding vowels in Semitic languages were not developed until the Middle Ages (ca. 1000 C.E.).

The city of Ugarit on the Mediterranean coast of modern Syria was destroyed by invaders about 1200 B.C.E. Several surviving clay writing tablets show that many languages were spoken and written in that cosmopolitan trading city, but texts in the native language, a northwest Semitic dialectic called Ugaritic, were written in an alphabetic script that was adapted from cuneiform and inscribed on clay tablets. The influence of the cuneiform script among northwest Semitic speakers was so great that every city would have had scribes and scribal schools trained in cuneiform. The new form of writing, therefore, must have been developed in an appeal to the prestige of cuneiform writing while maintaining the relative ease of an alphabetic script. Ugaritic also reveals the first use of alphabetic letter order.

By 1000 B.C.E. the Phoenician cities developed their own form of alphabetic writing based on both the Proto-Sinaitic script and the Ugaritic script. This was important because all later alphabetic writing was derived from the Phoenician script. It was from the Phoenicians that Greeks learned the alphabet for trading purposes (before 900 B.C.E.), after which they devised their own version of the alphabet to write the Greek language (no examples of Greek texts survive from much before 700 B.C.E.). In fact, the term *alphabet* comes from the names of the first two letters of the Greek alphabet, *alpha* and *beta*. Needing fewer signs to write their consonants than did the Phoenicians, the Greeks used the spare signs to represent vowels, thus completing the development of the elements associated with the alphabet. The Greek alphabet was passed on to the Etruscans and then the Romans, who modified it into the Latin alphabet that is still used for many Western languages.

The Phoenician alphabet was adapted by people all over the Near East and turned into a different alphabet by the speakers of each Semitic language. The most important language in the Iron Age was Aramaic. People in Mesopotamia and many other areas spoke Aramaic, and its alphabetic script was written on sheets of papyrus or vellum in ink with reed pens. Because it was more convenient than writing cuneiform on clay tablets, most written pieces, such as personal letters, were probably composed in this way. Because papyrus and vellum are highly perishable materials, however, very

few manuscripts of any northwest Semitic language remain from before the Common Era (although inscriptions in stone survived). Hebrew developed its own version of the alphabetic script and used it to write the Hebrew Bible (the Old Testament). The Hebrew language, script, and biblical texts became important factors in forming and maintaining Jewish identity.

ASIA AND THE PACIFIC

BY KIRK H. BEETZ

Writing in Asia and the Pacific seems to have developed and evolved to answer specific needs of societies. For example, the ancient Australians did not develop a writing system but painted rocks with images of their history and religious beliefs. Similarly, the Chinese of the Shang Dynasty (ca. 1500–ca. 1045 B.C.E.) used pictures to represent words. Although the pictorial lexicon of the ancient Australians could be interpreted only by people specially acquainted with them, it seems to have been enough to satisfy the religious needs of the ancient Australians. It was not enough for the Shang, however, because their religious beliefs included the ability to contact dead ancestors and ask them questions. These questions had to be written down on animal bones or the shells of turtles, which seers would transmit to the dead for their answers. A seer would drill a hole in the bone or shell and then touch a red-hot bronze pin to the hole, making the bone or shell crack. These cracks were the replies of the ancestors, which the seer would read and then record in writing.

Religion was not the only motivation for developing a written language. In the Harappan civilization (ca. 2600–ca. 1500 B.C.E.) of the Indus River valley, the creation of writing seems to have followed a path similar to that of the first written words of the Near East. Harappan writing is almost universally associated with commerce, with most of it being found on seals used to mark goods. As was probably the case for the Near East, writing appears to have begun as symbols representing goods and ownership of goods for trade. As time passed, those symbols may have evolved into symbols for words, which may have separated into symbols for syllables and then symbols for spoken sounds. Harappan seals were carved in tiny stones, usually soapstone, and they were impressed into clay. Although about 2,000 seals have been found, almost all in or near marketplaces, the words written on them have yet to be translated.

About 5,000 characters for the Shang written language have been found, with about 2,500 having so far been translated. Each Shang character represents a single word. Linguists call the characters logographs. They were not only written on bones and turtle shells but also on bamboo and wood. The writing implement was probably made of metal, with a sharp edge used to incise the logographs.

During the Zhou Dynasty (ca. 1045–ca. 256 B.C.E.) the Chinese written language became more complicated and versatile. Characters represented things or ideas, and when

new things or ideas were to be expressed, the Chinese writers combined two or more characters to form a new image. Characters that represent things or ideas are called ideograms. The Zhou favored writing on wood, bamboo, and silk. For writing on wood and bamboo they used sharp writing implements. Silk required new tools: brushes and ink. Silk was expensive, but it was possible to write something long on silk and be able to roll it up and store it. The oldest silk scroll found dates from about 500 B.C.E.

It was during the brief Qin Dynasty (221–207 B.C.E.) that Chinese writing took on its modern form. During the Zhou Dynasty many languages were spoken in the empire, and in various parts of the empire new ideograms were added to Chinese writing to express words from the local languages. Had this process been allowed to continue, written Chinese probably would have split into several distinct and mutually incompatible written languages. The Qin Dynasty pulled together all the diverse strands of writing that had developed during the Zhou Dynasty, eliminated about 25 percent of the ideograms, and created a standard script that the law required to be used for all official business. This script has undergone little modification since.

As a matter of political policy during the Han Dynasty (202 B.C.E.–220 C.E.), government officials had to be scholars. To assume a position in government, a person had to read and write Chinese fluently; it took about 10 years for a student to learn enough ideograms to be fluent. Every scholar carried a writing toolkit—a wooden box containing a brush, a knife, sticks of solid ink, and a mortar and pestle. Ink was usually carbon made from soot, with pine soot being the most common. Ink makers made sticks of ink that were often works of art designed to remind the writer to do his best because he was destroying a beautiful object to create a written work. At the start of the Han Dynasty most brushes were tipped with horsehair, but rabbit hair came to be favored during the middle of the era. When the writer wished to erase writing on wood or bamboo, he used a knife to peel away a layer from the wood. The wood or bamboo would be prepared for writing by being dried and then cut into slats, which were then stitched together by string or thongs so that the slats could be wrapped around each other into a tube for carrying. Calligraphy was considered an art as well as an important skill; the written work, even a simple one, was supposed to be beautiful.

Less is known about the development and evolution of writing in India than about the Chinese writing system. The Indians did not have a single written language that remained intact or changed slowly. They had many. Until the 1830s scholars thought that the history of India began at about 1200 C.E., because no readable government or historical records survived from before the Muslim invasion. In 1837 a British civil servant in India released a translation of writings found on pillars. The written script is called Asoka Brahmi, after the emperor who had the pillars erected. Since then archaeologists have searched for more such inscriptions.

Pillar edict of Emperor Asoka dating to 238 B.C.E., from Uttar Pradesh, India: an example of the earliest readable Indian script (© The Trustees of the British Museum)

Scribes were a standard part of ancient Indian governments. Every court of law was required to have one. Kings had them for recording government business. Professional scribes attended births to record the predictions for the infant made by the attending astrologer. That Asoka had his edicts placed all over his kingdom in prominent places suggests that Indians were mostly literate. Some writings on stone, copper, and gold have survived, while those committed to bamboo and leaves have disintegrated.

The Harappan script seems to have died sometime after the Aryan invasion of the 1000s B.C.E. In about 500 B.C.E. Brahmi script emerged, becoming a robust written language by the era of Asoka (r. ca. 268–ca. 233 B.C.E.). The letters are beautifully graceful. From the end of the Maurya Empire in 185 B.C.E. to the start of the Gupta Empire in 320 C.E., Brahmi split into two or three written scripts. By the end of the ancient era the scripts derived from Brahmi were being split into new scripts to suit the languages of southern India.

EUROPE

BY BRADLEY SKEEN

Writing was invented about 3000 B.C.E. in Mesopotamia and spread from there through contacts between cultures. Writing that uses the alphabet—a small number of signs representing the various distinct sounds of speech—was developed by Semitic-speaking peoples living in Egypt after 2000 B.C.E. This system spread through the Near East and then to Greece. From there it was adopted after 800 B.C.E. by the Etruscans and Romans. Writing came to northern Europe from the Roman Empire.

By the end of the Roman Empire (476 C.E.) most societies in northwestern Europe had some familiarity with the Latin alphabet and language. The Latin alphabet is the system of writing still used for English and other modern European languages. Literacy was not very widespread and was limited primarily to churchmen and government officials. Literacy in northern and eastern Europe came with the spread of Christianity into those areas.

Before writing, ancient European peoples expressed their ideas visually through a variety of media. Their modification of the landscape and the size and positions of monuments and tombs provided signals of group identity and territorial ownership. In Scandinavia and the Alps, beginning around 5000 B.C.E. but especially during the Bronze Age after 2000 B.C.E., people inscribed figures on boulders and rock outcrops to depict people, animals, and objects that had symbolic and ritual significance. Pottery designs were another important medium of communication about group identity. Other claims for writing in prehistoric Europe, such as the Tărtăria tablets from Romania, do not stand up to scholarly scrutiny.

Paper made from cotton fiber was a Chinese invention that did not become widely used in Europe before 1100 C.E. The main writing material used in classical antiquity, papyrus, was made from reeds grown in Egypt and was not widely available outside the Roman Empire. The most common writing material used in northern Europe, therefore, was parchment. This was made from animal skins. The skins were not tanned as for making leather but were stretched and scraped while held tightly in a frame. The parchment was typically cut into single sheets or bound into a book, or codex. More permanent documents, called inscriptions, were made by carving letters into stone or metal plaques. Inscriptions were sometimes made on wood, but because wood is highly perishable, they have not survived in large numbers.

Runes are the earliest system of writing the Germanic languages. They exist only as inscriptions. The runic characters appear for the first time on artifacts such as combs and jewelry dating to the middle of the second century C.E. The runic letters are clearly a variation of the Latin alphabet, but they bear a close similarity to older forms of the alphabet that were used in northern Italy as early as the fifth century B.C.E., suggesting that runes might have been invented and used

Painted pebbles from cave of Mas d'Azil, Ariège, France, dating to 8,000–10,000 B.C.E.; the decorations, which include dots and bands, are thought to represent a kind of writing. (© The Trustees of the British Museum)

for some time before the oldest surviving examples of runic script were written. Early runic inscriptions consist for the most part only of names, perhaps of the person who made the object bearing the inscription or the object's owner. In the Middle Ages some longer inscriptions were made to record, for example, the lives of important people. Once a particular Germanic tribe was converted to Christianity, the people generally ceased to use runes and began to use the standard Latin alphabet of the new Christian writings.

A major effort was made in the ancient period to equip a language from northern Europe with its own alphabet. It was carried out by Christian missionaries in connection with translating the Bible into the target language. This was the Gothic alphabet, created to accommodate the language spoken by the Germanic tribe of the Visigoths. They originated in southern Sweden and migrated as far as the Crimean Peninsula in the southern Ukraine before turning to the Roman Empire and eventually conquering and settling in Spain. This language is not ancestral to modern German and died out not long after 700 C.E. This was because Gothic speakers gradually adopted the Latin language that was spoken by their Spanish subjects. However, in the mid-fourth century C.E. Bishop Ulfilas (ca. 311–ca. 382 C.E.) translated the Greek text of the Bible into the Gothic language for the benefit of Visigoths then living in Moesia (modern-day Bulgaria). Most of the Bibles transcribed in Gothic were eventually destroyed because Ulfilas was later denounced as an Arian heretic (that is, as holding disapproved ideas about the Christian Trinity), but a few hundred pages have survived from various handwritten manuscripts of the Gothic Bible. These texts are extremely important for the study of the history of languages (philology), since they are by many centuries the oldest substantial texts written in any Germanic language.

Ulfilas invented a new alphabet for writing the Gothic language, which before had never been written. (A very small number of runic inscriptions, however, are possibly Gothic.) In general he used contemporary Greek letters. In some cases the pronunciation of a letter was changed to fit the needs of the Gothic languages. A small number of other letters were borrowed from Latin, such as the *F*, whose sound did not precisely exist in Greek. Some scholars suspect, however, that these letters may instead have been borrowed from the runic alphabet since the runes were themselves derived from Latin. The names of the Gothic letters, in any case, are derived from those of a runic alphabet. Furthermore, these Gothic letters are different from the style of handwriting in the Latin alphabet commonly called Gothic in the sense of belonging to the medieval period.

GREECE

BY MICHAEL J. O'NEAL

Among the nations of Europe the Greeks were the first to write using an alphabet rather than such writing systems as pictographs used in other ancient cultures. The Greek alpha-

bet formed the basis of the Roman alphabet, which in turn spread throughout Europe and much of the world. Thus the ancient Greek alphabet was the foundation on which western writing systems were built.

The genealogy of the Greek alphabet begins with the Proto-Sinaitic script, sometimes called Proto-Canaanite, which emerged from Egypt and spread throughout the western regions of the Middle East that Egypt controlled. Beginning in about 1100 B.C.E. an important trunk of this family tree of languages was developed by the Phoenicians, who wrote using a 22-letter alphabet with no vowels. The Greeks adopted the Phoenician alphabet and later adapted some of its letters to form vowels. Interestingly, many of these letters had pictographic meanings of their own, meanings that, with a little imagination, can still be seen in the Greek and Roman alphabets. Thus the letter *M* (Greek *mu*) originated in the Phoenician script as the letter *mem*, which means "water" and was formed to suggest the peaks and troughs of a wave. Similarly, the Phoenician letter *heth*, which means "fence," evolved into the *H*, which bears some resemblance to two fence posts with a cross rail. The ancient Phoenician letter *O* also meant "eye." These similarities are not accidental.

In about 800–750 B.C.E. numerous dialects of Greek began emerging, each using a variant of the ancient script, though the dialect called Ionic and its script became the standard in the fifth century B.C.E. Another important dialect was the Eurobean, which the Greeks carried to their colonies on the Italian Peninsula, where it was adopted by the Etruscans and eventually evolved into the Roman alphabet. A third important dialect of Greek that predated these, called Mycenaean, was spoken on the island of Crete and parts of the southern Greek mainland. The only record of this dialect is a written script called Linear B, which was written from about 1500 to 1200 B.C.E. This script consists of many symbols that represent variously letters and syllables. Historians regard it as a kind of "proto" Greek, and deciphering it was a lengthy and laborious process. (Linear A is the name given to the written script that predated Linear B on Crete.)

Writing, along with art and architecture, was one of the highest achievements of ancient Greek civilization. Originally, Greek was written right to left. Sometimes written texts "snaked" their way down the page, with the text going from right to left, continuing on the next line from left to right, and so on. The ancient Greeks used writing materials common among ancient civilizations, including the Romans. One was a metal stylus, similar to a pen, for inscribing letters on tablets covered with wax. The letters could be rubbed out with the flat end of the stylus, making the wax tablet reusable.

The ancient Greeks also wrote on papyrus, a type of early paper that came from the papyrus plant. To make papyrus, first long slits were made along the length of the plant, and then the material was unrolled. Material from the pith, or center, of the plant worked particularly well. The unrolled strips were placed side by side vertically, and then additional strips were affixed horizontally to hold the materials together.

Bilingual milestone marker (Alison Frantz Photographic Collection, American School of Classical Studies at Athens)

Generally, the writing was done on the horizontal strips. Sheets made in this way were joined into scrolls about 5 or 6 yards in length, though longer scrolls were not uncommon. Sometimes single sheets were used for business documents, letters, and writing instruction. Papyrus was typically purchased from Egypt and sold by vendors.

Papyrus, though, was stiff; it could not be folded, and writing on it with pen and ink could be difficult because the writer had to fight the grain of the material. Thus parchment was often used because it was easy to write on and its light color formed a readable contrast with dark ink. The disadvantage of parchment was that it was even more difficult to make than papyrus, so it was more expensive. Parchment was made from the hides of domesticated animals, preferably very young or even unborn animals. The hide was washed to remove hair, soaked in lime, and then stretched on a frame. The stretched hide was scraped, wetted, coated with chalk, rubbed with pumice, and then allowed to dry. Another disad-

vantage of parchment was that the ink was easily erased. Historians believe that many important Greek documents have been lost simply because the parchment on which they were written was recycled.

Ink was often made of soot, charcoal, or resin. Examinations of many ancient Greek manuscripts reveal that their inks contained a high concentration of iron. Of course, Greek writing techniques were not limited to using a stylus on wax tablets and pen and ink on papyrus or parchment. Carving inscriptions in stone on buildings and tombs was also common.

Additionally, in roughly 440 B.C.E. the Greeks invented a form of writing called steganography, which means “covered or hidden writing.” Steganography differs from modern cryptography in that the latter encodes messages that can still be seen but cannot be deciphered unless the reader has a key to the code. Steganography, in contrast, is the writing of messages that literally cannot be seen. The ancient Greeks used it for military communications, when the sender was concerned that the message could fall into the enemy’s hands. The simplest form of steganography was scratching a written message on a board and then covering it with wax. The board looked like nothing other than an unused wax tablet. Some military commanders were more inventive. The Greek historian Herodotus records the story of a military commander who shaved the head of one of his slaves and tattooed his message on the slave’s head. The message was hidden as the slave’s hair grew out and then retrieved when the recipient reshaved the slave’s head.

ROME

BY MICHAEL J. O’NEAL

The Roman alphabet has had an enormous influence on writing systems worldwide. In the modern world, languages from Afrikaans to Zulu, with scores of others in between, are written using the Roman alphabet. For ancient Romans the alphabet made the task of writing simpler compared with earlier pictographic writing systems used by other cultures. Because of this relative ease of writing, combined with fairly high literacy rates among upper-class Roman citizens, large numbers of written texts survive from Rome, though the ones that survive are only a fraction of the number produced. These texts survive not only as written documents but also in such forms as inscriptions on buildings, monuments, and even coins.

No examples of writing on the Italian Peninsula existed before the Greeks established colonies there in about the eighth century B.C.E. The native Etruscans then adopted and modified the Greek alphabet during the seventh century B.C.E. The Roman alphabet in turn developed out of the Etruscan alphabet. (Note that the word *alphabet* is composed of the first two letters of the Greek alphabet, *alpha* and *beta*.) In time the Roman alphabet spread through the earliest Roman settlements and from there throughout the Roman Empire.

Writing was important for official and military communication throughout the vast empire. One of the most important archaeological finds pertaining to ancient Rome's written communications with its colonies are the so-called Vindolanda tablets, found at the site of the Vindolanda fortress near Hadrian's Wall in ancient Britain and now housed at the London Museum. When Christianity, based in Rome, spread in the vacuum left by the collapse of the Roman Empire, it continued to use the Roman alphabet, making the alphabet a fixture of Western life.

The alphabet the ancient Romans used to write Latin consisted of 23 letters. The letters *J*, *U*, and *W* were added later, *J* as a variant of *I*; *U* as a variant of *V*; and *W*, or double *V*, added to distinguish the sounds of *W* and *V*. Also, the ancient Romans used the letters *K*, *Y*, and *Z* only in transcribing Greek words. The ancient Roman alphabet comprised only capital letters. Most look similar to modern-day letters, although because of the nature of ancient writing tools many, such as *B*, *D*, and *P*, had an angular rather than rounded look.

In ancient Rome children learned to write using boards covered with wax. They wrote in the wax using a stylus—a pointed metal tool similar to a pen—and could rub out what they had written with the flat end of the stylus. In this respect tools for teaching writing were similar to the modern blackboard or ink board. Otherwise, documents were written on wax tablets or very thin pieces of wood. The wax was poured into hollowed-out slabs of wood or sometimes into bronze frames. People who wrote letters often used wax tablets made of wood or ivory, which were then tied together and sent in a box called a seal box. More important documents, such as legal contracts, government proclamations, and such, were written with pen and ink on papyrus, a kind of paper extracted from the pith of the papyrus plant and then pressed into a flat material to write on. Because this stiff material could not be folded, documents were stored and transmitted in the form of rolled-up scrolls. Parchment—made from the skins of domesticated animals like sheep and goats—was also used as an early form of paper. Ink was made from various substances, including charcoal, soot, and gum. It is unclear what was used to bind these materials together, though vinegar may have been used. Other ink ingredients included copper, burnt resin, various minerals, and glues made from remains of animals such as oxen.

Ancient Roman books were nearly always preserved in the form of scrolls, formed by attaching single pieces of papyrus into long, continuous texts. A reader moved on to a new page by rolling it out and then rolling up the part that had already been read. The chief disadvantage of scrolls was that it was difficult for the reader to browse or go back to an earlier page; the entire scroll had to be unrolled and rolled up. In about the first century of the Common Era the Romans invented the book, using flat sheets that were sewn together. This type of book, called a codex, made storage much easier. Scrolls had to be stored in boxes or baskets, whereas flat books could be arranged on shelves.

Ancient Rome produced a large number of writers, many of whose works continue to be read for their insights into art, philosophy, history, politics, religion, and other areas of thought. These works were some of the highest cultural achievements of the Roman Empire. But much writing, too, survives in the form of tomb inscriptions, inscriptions on the walls or capitals of monumental buildings, and even in the form of *graffiti*, a word that comes from the Italian for “scratch,” as in scratching an inscription on a wall or other surface. The ancient Romans were lovers of graffiti, even on the walls of their homes. Many poets enjoyed writing epigrams, or short, pithy sayings, on walls.

The ancient Romans carried the writing of personal letters to great heights. Roman letters were highly stylized, with a system of abbreviations used in the salutation and closing, initials similar to the kind of abbreviations used in modern e-mail communications. Thus, for example, *S.P.D.* stood for *salutem pluriman dicit*, or “sends very fond greeting.” Because Rome had no postal system, wealthy letter writers hired messengers to deliver letters, often at great distances. One concern was that a letter intended as a personal communication might go astray and be revealed to a larger public. For this reason, Roman letter writers devoted considerable attention to the literary style of their letters in an attempt to avoid embarrassment if someone other than the addressee read them. Sometimes recipients of letters replied by writing notes in the margins of letters they received. Also, because of the danger that letters and other documents might be lost or missent, copies were generally made and kept. In the case of official documents a class of scribes and copyists did the work. It

Pottery inkwell from Roman Britain, inscribed with its owner's name, *Lucundus* (dating to first to third centuries C.E.) (© The Trustees of the British Museum)

could be said that ancient Romans lived in a culture of letter writing, often using daily letters and replies as a way of keeping in touch with friends, loved ones, and business colleagues throughout the empire.

THE AMERICAS

BY MIGUEL ARISA

The indigenous languages of the North and South American populations produced a diversity of writing systems, the most important of which were the hieroglyphic writings that evolved in the Mesoamerican zone. In the region of modern Canada and the United States, Native American writing systems did not develop fully until the advent of the Europeans, when syllabaries became the norm. These were symbols representing syllables, but they did not become widespread until the 19th century C.E.

Mesoamerican writing is believed to have developed with religious and political ends in sight. Writing was cunningly used for political advantage in identifying rulers and deities and driving the propaganda machine of the powerful. The calendar and a number system may have been the earliest examples. Bar-and-dot numerals made an early appearance and spread quickly. With time the ideographic signs became logographic, representing whole morphemes (collections of speech sounds) or words; finally, by the time of the Spanish conquest, logophonetic systems had developed, representing speech.

Some of these writing systems date to as early as 1500 B.C.E. At a very early stage in the Formative Period (as early as 1800 B.C.E.), elaborately carved icons in stone served the purpose of representing concepts, and they seem to have been sufficiently conventionalized to have been understood in a widespread area. This area includes a number of cultures, such as the Olmec, the Aztec, the Maya, the Zapotec, the Mixtec, and others whose writing systems evolved in tandem with reciprocal influences at different times over a millennium.

The major systems of the so-called Late Formative Period, from 400 B.C.E. to 150 C.E., were the Zapotec, the Epi-Olmec, and the Maya. The earliest forms of writing were highly pictorial, and their most important function was to record dates and the names of government officials and rulers. The illustration of myths, liturgical instructions, and mnemonic devices cannot be ruled out in the more developed stages.

The Olmec, a culture that flourished in the Gulf not far from the Yucatán peninsula, are generally considered to have developed the first system of writing. Hieroglyphs carved in basalt columns at La Venta have led scholars to conjecture that they represent the name of a person, since the image of a bearded man is also present. Notwithstanding, glyphs in a cylinder seal and on carved greenstone discovered in San Andrés, an Olmec site in the vicinity of La Venta, have been dated to about 650 B.C.E. and are now regarded as the earliest artifacts reflecting a system that combines pictures and glyphs and that may represent oral speech patterns. The glyphs show lines coming from the mouth of a bird, in fact rendering the act of

speaking. One of the symbols is *ajaw*, which means “king” or “lord,” and the other is *three ajaw*, a day in the calendar.

A stone discovered in Veracruz has revealed a new system heretofore unknown, predating the Olmec but with obvious references to that neighboring culture. The 62 signs inscribed on a stone slab, called the Cascajal stone, have been dated to around 900 B.C.E., the earliest yet for such a complex set of symbols. An insect, an ear of corn (representing perhaps both deity and ruler), inverted fish, and various other pictographs displayed in repeated patterns show a distinct language system whose arrangement seems analogous to sentences. These signs show patterns that can be deduced to be syntactical (that is, making up an orderly and connected arrangement or structure) and whose repetition can even be construed as representing poetical forms, as in a couplet.

The Zapotec seem to have followed the example of the Olmec and developed a system of writing around Monte Albán, their capital, from 600 to 200 B.C.E. Carved images of dancing men now thought to be captives ready for sacrifice appear next to what some scholars deem is their names; others interpret the images as calendrical signs. Other pictographs found in tablets in a Late Formative building at Monte Albán have been considered a record of conquest and the submission of nearby towns. Not conducive to phonetic writing like the Mayan system, Zapotec inscriptions are more logographic, like Chinese, in which a symbol represents a word.

Another early form of writing is called the Isthmian script, a precursor of the Mayan. A stela found at La Mojarra, near Veracruz, contains 465 glyphs in 21 columns with the image of a ruler. It is structurally similar to the Mayan because it is logophonetic and uses morphemes for meaning. Mayan writing is thought by some to predate even the Olmec system. New research from Guatemala on fragments inside a pyramid at the Mayan site of San Bartolo reveal that one hieroglyph sign may be an early version of *ajaw*. Carbon dating demonstrates that the paintings and the glyph were made around 300 B.C.E. The script next to an image of the maize god evidences the relationship between writing, kingship, and religion.

Even though Mesoamerican writing systems had undergone a long process of evolution by the time the Spaniards arrived in the New World, the conqueror's zeal in eradicating the cultures they considered heathen resulted in widespread burning and destruction of their records. Anthropologists, linguists, and art historians continue to decipher the inscriptions in temples and tombs and the few extant manuscripts from before and after the Conquest.

Glossary

- abacus** A device used for making calculations by sliding beads or counters along rods attached to a board.
- abax** A flat board with vertical columns, used for calculation; the Greek version of the abacus.
- ablution vessel** A vessel filled with alcoholic, herb-infused, or other liquids for physical purification before encounters with spirits.
- acephalous society** Human group in which there is no designated political leader.
- acrophonic notation** A Greek system of numbering using letters to represent the initial sounds of numbers.
- acropolis** Literally, “high city,” which was in many Greek cities the central, elevated, and fortified part of the town.
- acupuncture** A Chinese medical practice in which needles are inserted into various points in the body to free blocked energy, bringing the yin (the female principle) and the yang (the male principle) back into balance in the attempt to cure injury or illness.
- adobe** Bricks made of sun-dried mud and used for constructing buildings.
- adze** A bladed tool that is used to smooth wood.
- aedes** To ancient Romans, any site where a deity dwelled.
- aedile** In ancient Rome, a plebeian official in charge of various of Rome’s public works and functions, among them, streets, traffic, water supply, and markets and the organization of religious festivals and cult observances.
- aerarium** The Roman treasury.
- ager publicus** Public land confiscated from Rome’s enemies that could be leased by Roman citizens for farming, grazing herds, or performing other activities.
- agger** Rampart or embankment; the sloping of a Roman road from a high point in the center to a lower point at the roadsides to facilitate drainage.
- agni** Indian word for “fire,” one of the three basic elements described in the early Upanishads, or religious texts of Hinduism.
- agora** An open space in a Greek town or city, serving as a marketplace and a political forum; typically the main business district.
- agrarian** Characterized by farming.
- agropastoral subsistence** A livelihood based on a combination of farming and herding, often involving migration of herds among pasturelands.
- aguada** Small water reservoir lined with clay in the ancient Americas.
- ahauob** Mayan term for nobility.
- ahaw** Mayan word meaning “lord” or “king.”
- aivan** A type of veranda, or open-air entrance hall that leads into a reception hall.
- akhet** The inundation, or flooding of the Nile River, which ran roughly from July to December.
- ala (pl. *alae*)** Open rooms off the atrium of a Roman house, used for storage or work.
- alchemy** The quest to create sought-after substances, such as artificial gold or an elixir of eternal life, by experimentally combining chemicals or minerals or both.
- alfa** A wild grass (*Stipa tenacissima*) used for weaving.
- alliteration** The repetition of the initial sound of one or more words in a line of verse.
- alloy** A combination of two or more pure metals.
- altiplano** A high plateau or plain.
- ambergris** A waxy material originating from the innards of sperm whales.
- amelu** A class of patricians in Babylonia that also included skilled artisans.
- amphitheater** A large, oval-shaped, freestanding Roman structure designed for the staging of gladiatorial contests and other spectacles.
- amphora** A ceramic vase with two handles used in the ancient world to transport and store wine, oil, olives, and other goods.
- amulet** A charm, typically carved or engraved with a magical incantation to ward off evil.

- amurca** The dregs of pressed olives.
- ancestor worship** The spiritual veneration of one's deceased parents, grandparents, and so on, practiced widely in many ancient cultures.
- andrôn** Living quarters for men in ancient Greek homes.
- animal husbandry** Breeding, feeding, and management of animals, or livestock, for the production of food, fiber, work, and pleasure.
- animism** A religious belief that many (or even all) places, objects, and living things have their own spirits.
- ankh symbol** The Egyptian hieroglyphic sign for *life*, consisting of a loop-topped cross.
- annealing** A process in which metal is heated to reduce the hardness and brittleness that result from hammering, making the metal easier to shape.
- antediluvian** Dating to the period before the Flood, described in the Bible.
- anthropomorphic** Having human attributes or a human-like form.
- Antikýthēra device** An ancient instrument that used numerous interconnected gears to calculate the motions of the planets and stars.
- antiphonal** Containing musical verses to be sung in alternation.
- apiculture** The cultivation of honeybee hives in order to collect honey and beeswax.
- apoikia (pl. apoikiai)** The standard term for an official Greek colonial settlement, laid out according to specific procedures, which became an independent polis.
- apotropaic wands** Wands having the power to ward off evil or bad luck.
- appliqué** A decorative ornament made in a material such as needlework applied to another fabric surface.
- apron moldings** Joint stones that slightly hang over the bottom stonework of a wall.
- aqueduct** A man-made channel or pipeline designed to transport water across long distances; often raised above the ground, moving water by gravity.
- aquifer** An underground rock bed yielding groundwater.
- archaeoastronomy** The field of archaeology that focuses on sites with astronomical importance.
- archaeological culture** An assemblage of artifacts (and their stylistic attributes) that tend to be found together in a particular region at a certain time.
- archaic lyric** The earliest Greek poetry that expresses subjective thoughts and feelings, often in a songlike style or form.
- Archimedian screw** An irrigation device that uses a screw in a pipe to raise water from a river or pool to a field or container.
- archipelago** A group of islands.
- architrave** In architectural design, a beam that extends across a row of columns.
- archon** A chief magistrate of the Greek city-states.
- ard** A simple form of plow used to cut a furrow though the soil without turning it over.
- aristocracy** A political system under which a few prominent extended families share power and pass power from generation to generation.
- armillary sphere** An astronomical device that mirrors the positions and movements of the heavenly bodies.
- armlet** Band worn around the arm but not around the wrist, which would be a bracelet.
- Arretine ware** Ceramic wares from the region of Arezzo, Italy, made of fine red clay.
- artifact** An object created by human beings, especially one of interest to archaeologists.
- artisan** A skilled worker who performs a specific trade or craft.
- asafetida** The resin of a plant related to fennel, used to flavor Roman dishes.
- asbestos** A nonflammable substance, made from fiber extracted from certain rocks, that was used in the ancient world for lighting as well as fireproof clothing.
- ascetic** A person who forsakes comforts to live a life of severe self-discipline.
- asclepeion** A Greek sanctuary built to honor the god Asclepius and as a health retreat where the sick and injured were treated.
- ashlar** A style of building walls in which shaped stones are laid out in regular rows, one on top of another (as opposed to the more complex, but often stronger, techniques using irregular stones).
- aspect** Feature of a verb that describes the duration or completeness of an action.
- assimilate** To absorb into a culture.
- asterism** A small grouping of stars.
- astrolabe** An early astronomical instrument used in navigation.
- ataraxia** In ancient Greece, considered to be a life without disturbance, fear, and worry.
- atimia** Loss of citizen rights, used as a punishment in ancient Athens and other city-states.
- atlatl** A hand-held stick used as an arm extension for throwing a spear or dart.
- atrium** The open interior area of a Roman house that was the center of domestic life.
- augur** A member of ancient Rome's College of Pontiffs; a priest whose role was to interpret the will of the gods through signs and omens.
- aulos** A reed instrument with two pipes, capable of a great range of dynamic effects; used in many contexts in ancient Greece but particularly to accompany choral poetry.
- auroch** A type of prehistoric giant cattle that is now extinct.
- autochthony** Belief in origin from the earth or in having inhabited the same place since time immemorial.

- automata** Devices that use hidden mechanical forces (steam, water, pulleys) to move objects in such a way that they appear to be moving of their own accord.
- auxilia** Mercenaries hired by Rome to serve in its legions and protect its frontiers.
- avatar** A physical form, human or otherwise, taken on by a deity.
- axis mundi** Center of the world.
- axone** A wooden table or roller used to record ancient Greek writings
- ayurveda** A system of medicine used in India that emphasizes diet as a means of correcting imbalances within the body.
- azimuth** The angle measured from north, eastward along the horizon to the point where a vertical circle through a celestial object intersects the horizon.
- ba** For Egyptians, the soul.
- band** The simplest form of political and social group, consisting of members (from eight to 100, though typically less than 30).
- bandolier** A flat band worn over the shoulder and across the chest, often as official or ceremonial dress.
- barbaros (pl. barbaroi)** A word used by the ancient Greeks to describe a foreigner—specifically one who did not understand the Greek language; often used with reference to someone rude or rough.
- bard** A tribal poet-singer who gave recitation performances of ancient tales and epics.
- barrel vault** Solid, semicircular ceiling supported and framed by horizontal arches that rise from piers along the walls.
- barter economy** Trading goods for each other without the use of money.
- basalt** Gray-black volcanic rock.
- basileus (pl. basileis)** A king in ancient Greece, though one who typically enjoyed limited powers.
- basilica** A large Roman meeting hall for commerce.
- bas-relief** A technique of decorative sculpture in which the artist carves away unwanted material and allows the elements of a scene to emerge from a flat background.
- bast fibers** The outer stems of certain types of plants, including jute and flax, that can be extracted and used in textile production.
- beasts of burden** Animals that transport burdens such as goods or people.
- benben** In Egyptian cosmology, the first place the sun fell on earth when it emerged from the primordial waters and possibly the name of the mound itself.
- benu bird** A heronlike bird associated with the sun in Egyptian mythology.
- berm** A mound of earth.
- berserk** A warrior who fought, often naked, in an ecstatic state.
- beveled** Cut at a slant such that two surfaces do not form a right angle.
- bident** A two-pronged spear.
- bipod mast** A mast that is forked into two projections at the base.
- bireme** A ship with two banks of oars.
- birrus** A woolen hood.
- bitumen** A substance derived from oil deposits that was used in the waterproofing of porous material.
- black-figure pottery** Pottery painting in which black figures are placed on a red background.
- blank** A coin-shaped piece of metal without a stamp indicating its value and place of origin.
- bodhisattva** A person who can ascend to oneness with God but who chooses to put off salvation in order to help other human beings reach nirvana.
- bolas** Stones connected by cords, thrown to entangle and fell prey or an enemy.
- boule** A Greek city council elected by the citizens to serve as a lawmaking or advisory body.
- breechcloth** Sometimes called a “breechclout,” a strip of cloth that hangs between the legs from a waistband.
- bride-price** Money or property given to a bride’s family by the prospective groom.
- brine** Seawater that was commonly heated and evaporated, leaving behind salt for seasoning and preserving food.
- broad-cella** A central hall or room designed to be accessed through a maze of halls.
- brocade** Fabric with raised patterns.
- brochs** Circular stone fortifications in ancient Scotland.
- bronze** An alloy of copper and tin, with tin added to strengthen copper.
- brooch** A large, decorative pin or clasp.
- buckler** A small, round shield held by a handle at arm’s length.
- bucolic** Relating to the countryside.
- bullae (pl. bullae)** In the ancient Near East, a spherical clay container into which were placed tokens to record quantity of goods held in storage.
- burial goods** Objects that are placed in or around a grave to either protect or serve the dead person.
- burnishing** The rubbing of the walls of a vessel with a smooth stone or similar implement, creating a smooth finish and making the vessel less permeable to liquids.
- burnoose** A one-piece hooded cloak.
- butt joint** The ends of two pieces of wood placed at a 90-degree angle and held together with pegs or tied together with leather threaded through drilled holes.
- buttress** A projection from a wall that prevents a wall’s collapse, either under its own weight or under the weight of a roof.
- byre** A stable for cattle.
- caber** A pole or a young tree trunk used for tossing as a test of strength.
- cacao** Beans used to make chocolate, cocoa, and cocoa butter; in the Americas in ancient times, they were used as currency.

- cadastral** Relating to a register recording property ownership boundaries, typically used to apportion taxes.
- caementum** A mixture of sand, lime, and crushed volcanic stone known as pozzolana that provided the basic construction material for public and private buildings in ancient Rome.
- caesura** A break or pause in the middle of a line of verse.
- caiman** A small crocodile native to Central and South America.
- cairn** A mound of stones, often piled on top of a burial chamber.
- calcei** Formal laced shoes worn with the Roman toga outside the house.
- caldera** A crater formed by the collapse or explosion of the central part of a volcano.
- camelid** Any mammal from the camel and llama family Camelidae.
- cameo** A material, such as gem, shell, or glass, carved in relief, where the design and the background are of layers of contrasting colors.
- canon of human proportions** A technique used by Egyptian artists to guide them in maintaining the proportions of human figures, using a square grid and allocating a specified number of grid squares to the parts of the figure.
- canopic jar** In ancient Egypt, one of four jars holding the liver, stomach, lungs, and intestines of an embalmed person for entombment with that person.
- capital** The top of a column.
- caravan** A group of people, vehicles, or supervised animals that are traveling together for safety.
- carbon steel** An alloy of iron and carbon that is harder than pure iron.
- cardo** A north-to-south road that formed part of the central axis of a Roman city, crossing the *decumanus* (east-to-west road) at the city's center.
- carnyx** A European war or ceremonial trumpet with a stylized animal head at the bell end, usually made of beaten sheet bronze; played while being held vertically over the musician's head.
- cartouche** In ancient Egypt, an oval figure that enclosed the pharaoh's name.
- cash economy** An economy in which money rather than barter is used for buying and selling goods.
- cassava** A starchy root used in baking breads or cakes.
- caste** In ancient India, a social class based on birth that restricted the professions, civil rights, and marriage possibilities of people born into it.
- casting** A process in which molten metal is poured into a mold and allowed to cool, taking the shape of the interior of the mold.
- castros** Ancient fortified towns inhabited by the Celtiberians.
- cataract** A rocky outcrop that produces rapids when water runs over it; there are six major cataracts along the Nile south of modern Aswān.
- catasterism** The transformation of a mortal into a star, constellation, or other celestial object.
- cauterization** Burning tissue with a very hot metal instrument in order to stop infection.
- cavetto cornice** A concave molding shaped like a quarter circle.
- cella** The inner chamber, or sanctuary, of a temple.
- celt** A prehistoric ax of stone or metal.
- cenotaph** A symbolic place of burial not containing the remains of the owner; these false tombs were erected to perpetuate the mortuary cult of the deceased or simply to have an additional tomb in a sacred place.
- cenote** Freshwater-filled limestone sinkhole.
- ensor** The most senior magistrates in ancient Rome, with less power than consuls because they lacked imperium, the authority to lead an army and the power of life and death over citizens.
- centaur** A mythical creature that is part human and part horse.
- centuriation** The process ancient Roman surveyors used for marking out plots of land for Roman settlers.
- centurion** In the Roman army, the officer in charge of a century, a group of foot soldiers.
- century** In the Roman army, a group of foot soldiers, originally set at 100.
- chadar** A heavy strip of cloth worn by ancient Indians to protect the upper body.
- chaff** The husks of grain removed during threshing.
- chaitya** In Indian architecture, a building consisting of a set of halls that people could use when an outdoor stupa, or shrine, could not be used because of inclement weather.
- chamber pot** Small tublike pot specially made to be kept in the bedroom for use at night as a toilet.
- champlevé** An enameling technique where colored enamels fill channels cut directly into metal.
- chantress** A female singer engaged in religious rites.
- chappal** A type of sandal worn in ancient India.
- characters** The symbols representing concepts or words used to write ancient and modern Chinese (and some other languages) and borrowed to write Korean, Vietnamese, and Japanese.
- charnel** A building in which human remains are deposited.
- chasing** A way of working silver by hammering in a design from the outer surface.
- chassis** Framework attached to the axles of a cart.
- chattel** In law, personal portable property; in the context of slavery, a condition of ownership of slaves that included the owner's right to sell, donate, or devolve them to his heirs but also to liberate them at will.
- cheng** Chinese word for "city" or "wall."
- chi** Usually translated as "energy," the Chinese concept of the most basic physical element in the world.

- Chi-Rho** A symbol formed by the first two letters of Christ's Greek name (*Christos*), consisting of the letter *Rho* superimposed onto the letter *Chi*.
- chiton** A belted, knee-length tunic of seamless cloth worn by the ancient Greeks.
- chlamys** A short cloak worn by the ancient Greeks.
- chóra** The countryside surrounding a city.
- chorobates** A device resembling a long wooden bench, which allowed ancient builders to ensure that floors and other horizontal elements were correctly aligned and level.
- chorus** A group of performers who sang and danced in Greek dramas.
- chronometer** An accurate clock, particularly one used in seafaring and navigation.
- chultune** An underground chamber that ancient Americans used to collect water.
- chun** A Chinese skirt with pleats.
- cinerary urn** Containers used to hold the ashes of the dead.
- cinnabar** Red pigment derive from mercury.
- cist** A burial chamber formed from stone slabs set on edge.
- cistern** Rain collection device, usually cut out of rock and sealed with lime plaster.
- citadel** A city's fortress or stronghold.
- civic calendar** A calendar based on the sun and recognized for use in ordinary affairs.
- clan** A group of related lineages or kin groups tied together to a distant ancestor; often several lineage groups are contained within one clan.
- clepsydra** "Water thief," a term for water clocks of ancient Greece.
- cleruchy** A type of Greek colony in which settlers received shares of land (*kleroi*) but maintained citizenship in their native polis.
- clibanus** In ancient Rome, a portable oven for baking bread.
- clientage** A social system in ancient Europe whereby a member of the nobility provided a person or community protection in exchange for services.
- clogs** Blocks of wood used in hunting, intended to trip a running animal.
- cloisonné** An enameling process that uses thin wires to create settings for precious stones.
- cob** A mixture of wet clay and straw used as a building material.
- codex** A book in the modern sense of several groups (called quires) of pages stitched together between a stiff cover.
- cohort** The basic tactical unit that replaced the maniple around 100 B.C.E. and consisted of 400 to 600 heavy infantry.
- coil-build** To lay rolled lengths of clay, shaped into rings, on top of each other to form pottery.
- cold cutting** Carving a piece of glass with hammer and chisel in the same fashion as one would carve stone.
- collegium (pl. collegia)** A Roman society whose members paid into a common fund to cover the expenses of their funerals.
- colonnade** An outdoor walkway or gathering place, lined with columns and generally roofed, at least partially, to provide shade.
- colonus (pl. coloni)** A Roman peasant who was tied to the land despite being legally free.
- colophon** An inscription at the end of a text, citing the facts of its production.
- columbarium** An underground chamber housing the remains of the Roman dead within small niches, which held funerary urns marked by plaques and inscriptions.
- combined arms** The use of differently equipped soldiers in a single fighting force.
- commercium** The right of any Latin or inhabitant of Latium to own Roman land and to enter into a contract with a Roman.
- compluvium** A rectangular opening in the roof of the atrium that admitted light and rainwater into a Roman home.
- composite bow** A bow made by gluing together bone, sinew, and different bones for added strength, with a consequently longer range than a bow carved from a single piece of wood.
- concentric** Having a common axis or center point.
- conciliar calendar** A political calendar, in which the number of *prytaneis*, or months, varies with the number of phylai, or groups of citizens.
- concubine** A woman who is acknowledged as the sexual partner of a particular man; the man typically supports her and acknowledges her children as his own.
- confarreatio** The ancient form of marriage practiced by the Roman nobility.
- confinement pavilion** An ancient Egyptian structure made of plant materials and used to seclude a mother after the birth of a child and possibly for the birth itself.
- conscript** In Egypt, free people forced into government service for a week to a few months; their labor would substitute for paying taxes, or they would be paid.
- conscripted** Forced into public service.
- consul** The highest-ranking Roman official; this magistrate held imperium, the power to command Rome's armies anywhere and the power of life and death over citizens.
- contagious magic** Magic that looks to achieve its ends by using an object that has come into contact with the person or thing that a person is trying to influence.
- contour rivalry** Technique in which one set of lines creates two different images, as perceived by the viewer.
- controversia** In Roman rhetoric, an argument for or against a particular legal case.
- copal** A resin obtained from certain tropical trees.
- corbel vaulting** A method for building rough arches or domes; for a dome stones are laid in circles of successively

smaller diameter until the stones meet at the apex and can lean against one another for support.

cordage Twisted fibers that form thread, string, or yarn.

cordillera Parallel chains of mountains.

core forming Forming of glass by placing vegetal matter or animal dung mixed with clay and sand at the end of a wooden handle and either dipping it into molten glass or drizzling molten glass onto it, after which the core is rolled on flat stone or metal to even and smooth the surface.

core tools Tools that are shaped by striking off flakes from the central portion of a large pebble or cobble.

core-periphery model Economic and political relationship between well-developed centers and less-advanced ones that are in contact with them.

Corinthian One of the three orders, or styles, of Greek architecture, distinguished by long, slim columns and elaborate and detailed carvings on the capital.

cornice A molding at the corner between the ceiling and the top of a wall.

corroboree Australian Aboriginal festivity with singing and dancing, usually at night, to celebrate important occasions.

corvée Unpaid labor exacted in place of taxes by a governmental authority, usually for public works.

cosmogony The study of the origin of the cosmos or universe.

cosmology A system of beliefs used to describe the origin of the universe.

cosmopolitan At home with many different cultures of the world; having a worldwide scope or composed of influences or peoples from many parts of the world.

coulter A blade placed in front of the plowshare in order to cut a vertical slice through the soil.

course A horizontal layer of brick or stone; courses are laid on top of one another in building walls.

courtesan A prostitute who associates with socially elite people.

cowrie shells The shells of a sea mollusk from the family Cypraeidae, having shiny, colorful shells that are still used as money in parts of the South Pacific.

cranial deformation The practice of using boards, mats, or vices to shape the cranium or skull of an infant before the bone has fused together and hardened.

crannog Found in prehistoric Ireland and Scotland, a fortified island in inland waters or marshes built to protect a settlement.

crucible A heat-resistant container in which ores or metals are melted or heated.

cruciform Shaped like a cross.

cubicula Bedrooms opening from the atrium of a Roman house.

cubit A unit of length that is equal to the distance between a person's elbow and his outstretched middle finger.

cuirass Body armor that covers the neck and chest.

cult statue A statue of a god, believed to contain the god's essence and housed in a temple or sacred site to be used as the focus of worship and ritual actions.

cultic calendar The schedule of interaction between a community and its deity.

cultigen A cultivated or domestic organism which has diverged enough from its closest wild relatives to be classified as a species, subspecies, or major variety.

cuneiform A form of writing invented in Mesopotamia around 3400 B.C.E. that used a reed pen called a stylus to make triangular marks on clay tablets.

cupellation A process used to purify silver by heating it to remove lead and other impurities.

curia A building where the Roman Senate met.

cursive A form of writing Chinese characters in which brushstrokes for one character flow into the brushstrokes for the next character.

curule aedile In ancient Rome, patrician officials in charge of various of Rome's public works and functions, among them, streets, traffic, water supply, and markets and the organization of religious festivals and cult observances and also for public games.

cyfarwyddiaid Professional bards of ancient Wales.

cylinder seal A small object made of stone or other hard material in which a scene or symbol is carved away from the surrounding material; the seal is rolled across wet clay or papyrus to leave a permanent impression.

dactyl A poetic foot that has one long syllable followed by two short ones.

dais A raised platform that may be used for a table.

damask Thick, heavy cloth with a pattern woven into it; the weave is named after the city of Damascus, where silks were woven in this pattern after the first century C.E.

daub Mud or clay mixed with water as a kind of plaster.

daughter language Descendent languages from a protolanguage, or "original language."

dead reckoning A method for estimating a ship's position through its speed, the distance that it has covered, and the direction of its travel.

deben Egyptian unit of weight for measuring metals, mostly copper, the equivalent to about 3.5 ounces.

debt bondage A condition in which one who owes another money or goods is forced to work until the obligation is paid off.

decimal A system of representing numbers by assigning values to different places, such as 10s, 100s, 1,000s, and so on in the base-10 system.

declamatio In Roman rhetoric, practice speeches given to fellow students.

declension An inflection of a noun or an adjective—a change in its form to indicate a change in its grammatical function.

decumanus An east-to-west road that formed part of the central axis of a Roman city, crossing the *cardo* (a road running north to south) at the city's center.

- deferent** A hypothetical circle along which moves the epicycle, a theoretical orbit of the earth, sun, moon, and planets.
- Delphi** The most sacred and famous oracle of ancient Greece, dedicated to Apollo, god of prophecy.
- deluge** A flood; often used to refer to the Flood mentioned in the Bible in the story of Noah and his ark.
- demagogue** A leader who rises to power through playing on people's prejudices or one who champions the cause of the people.
- deme** Basic geographic unit of Athens, equivalent to a neighborhood or ward.
- democracy** A political system in which governing power rests broadly on the population generally.
- demography** The study of a population's characteristics, such as birth and death rates, density, growth, distribution, and breeding patterns.
- demos** The citizen body of Athens.
- demotic** A simplified form of Egyptian hieroglyphic writing.
- denarius (pl. denarii)** A Roman silver coin.
- denomination** A specific class of coin with a specific value.
- derrick** A tall platform over an underground well that is used to raise and lower drills and containers.
- desertification** Process that causes fertile land to become desert.
- deshret** "Red land" in the Egyptian language, referring to desert, in contrast to *kemet* (cultivable land), or "black land."
- desiccation** The process of drying something out thoroughly.
- determinative** A hieroglyph placed after the phonetic spelling of an ancient Egyptian word relating to the meaning of that word, like an ear placed after the verb meaning "to hear."
- deterministic** A theory or belief that any event or set of events is the inevitable consequence of what precedes and causes it and cannot be avoided.
- devaraja** The Hindu concept of the divinity of secular rulers.
- devolution of property** The transfer of land from one generation to the next.
- dharma** In Hindu and Buddhist philosophy, divine law as associated with the moral duty of individuals.
- dhoti** A wrapped Indian garment resembling loose, short trousers.
- dhow** A sailing vessel with triangular sails that was heavily used beginning in ancient times in the Indian Ocean, especially for trade between Africans and Arabs.
- di indigetes** Ancient Rome's native gods.
- di novensides** In ancient Rome, "newcomer gods" imported from foreign cultures.
- diadem** A headband, like a crown, worn as an adornment by the royalty.
- dialect** A subgroup of a language usually (but not always) comprehensible to speakers of the parent language.
- diaspora** Dispersal of a people from its homeland.
- diaulos** A running event in ancient Greece covering roughly a quarter mile.
- dictator** In ancient Rome, a special kind of magistrate appointed by the Senate to act in times of emergency and who had almost unlimited power but whose term was limited, usually to about six months.
- didactic poetry** Poetry that teaches a lesson.
- die** An engraved metal device for stamping a design into a softer metal such as a coin.
- dikai demosiai** In Athens, public lawsuits in which prosecution could be initiated either by magistrates or by private individuals not directly connected to the case.
- dioptra** In ancient Greece, a sighting rod used in mapping and surveying.
- diorite** A hard, grayish stone that was commonly used in ancient Mesopotamia for freestanding obelisks and commemorative slabs. Diorite could be polished to a glossy sheen.
- diphros** A simple stool or low chair in ancient Greece, without arms or a back.
- diploidion** A piece of material left long in front and folded at the shoulders worn by the ancient Greeks.
- distaff** Any tool used to hold fibers for spinning; in the Roman period it was a stick of wood, bone, metal, or even ivory.
- distributive economy** An economy in which a central authority collects food and other goods, stores the collections, and then redistributes them according to the people's social positions or needs.
- dithyramb** An impassioned choric hymn and dance of ancient Greece, performed in honor of Dionysus.
- divination** A ritual observation of nature for signs that the will of the gods is favorable or unfavorable to a specific action, as a way to determine whether a contemplated action should be taken.
- dolichos** In ancient Greece, a race of about 2.5 to 3 miles.
- dolmen** A type of stone monument in which a horizontal stone slab lies atop a set of upright stones.
- domestication** A process by which plants and animals are altered by human selection, resulting in loss of the ability to survive in the wild.
- domus** An ancient Roman home, especially in the cities.
- Doric** One of the three orders, or styles, of Greek architecture, distinguished by thick, sturdy columns and plain capitals.
- dowel** A pin fitted with holes to hold two pieces in place together.
- downcutting** Stream erosion that deepens a valley.
- down-the-line trade** A pattern of exchange whereby goods are passed from one person (or group) to another.
- dowry** Payment of property accompanying a bride to her new house, available for the husband's use but repaid to the wife's family should the marriage dissolve.

- drachm** Ancient Greek silver coin equal to the weight of a drachma, or approximately one-eighth ounce.
- drachma** A weight of metal in ancient Greece; a drachma of silver represented a reasonable day's wage in fifth-century Athens.
- draconian** Unusually harsh or severe
- draft animal** An animal used to pull plows, wagons, or other heavy loads.
- draft** The depth of a vessel's keel below the surface of the water.
- dressing stone** Carving stone into a desired shape and smoothness.
- Druid** An ancient Celtic priest or religious leader.
- drystone** Stones fitted together, as in a wall, without mortar.
- Duat** The netherworld in ancient Egyptian religion.
- dux bellorum** A military governor of the Roman Empire.
- dynasty** A succession of rulers from the same family.
- earspool** Circular ear ornaments that are hollow at their centers and worn by being placed within a hole in the earlobe.
- eaves** Roof edges that project beyond the walls of a building.
- eccentric** Rotation around a point that is not the center of the cosmos.
- ecliptic** The circle representing the apparent annual path of the sun.
- edge species** A species of plant or animal that lives at the edge of an environment, where it can take advantage of two different environments.
- effigy** An image or representation especially of a person.
- efflorescence** The process of developing and unfolding.
- egalitarian** Offering equal social and political rights, with no special privileges or status conferred by birth.
- einkorn** A kind of wheat (*Triticum monococcum*).
- ekklesia** The Assembly in Athens, responsible for all major state decisions and made up of all citizens who wished to attend.
- ekphora** The funeral procession from the deceased's house to the gravesite.
- El Niño** A recurrent warming of waters in the Pacific Ocean.
- electrum** an alloy made by combining gold and silver.
- elegiac couplet** A line of dactylic hexameter followed by one of dactylic pentameter and forming a complete thought.
- elegy** A short poem generally concerned with the passion of a lover and employing the elegiac couplet.
- elite** A group with higher status in a society that is differentiated by status, power, or wealth.
- embedded economy** An economic system in ancient Celtic Europe in which the aristocracy laid claim to a portion of a farmer's produce or a craftsman's goods in exchange for providing the worker with protection.
- embroidery** Threads added to cloth after it is woven, often in decorative patterns or colors.
- emmer** A kind of wheat (*Triticum dicoccum*).
- empire** Sometimes limited to government by a ruler known as an emperor but more generally rule over a wide area by a single political entity, such as a single nation ruling over many other nations.
- empiricists** Doctors in ancient Greece who relied upon observation and experience only, not on theory.
- emporion** The Greek word for a "market," also used to describe overseas settlements devoted to trade but lacking the status of formally established *apoikiai*.
- en** An official who oversaw the administration of a Mesopotamian city-state and who sometimes became a king.
- enceinte** The inner ring of fortifications enclosing a town.
- endemic** Belonging to a particular region or people.
- endogamous** Pertaining to the custom of marrying only within a tribe or clan.
- ensi** A governor who took over from an *en* the secular duties of running a Mesopotamian city-state; the office may have evolved into a kingship.
- entablature** The horizontal row of stone blocks under the roof of a building between the tops of the columns that support the building, often carved with friezes.
- ephebeia** A compulsory program of public education during the years of adolescence, designed to train young male citizens of the Greek democracy, especially in military arts.
- ephors** Board of overseers, five in number, who exercised control over the kings and Assembly in Sparta.
- epic** A long narrative poem that tells the story of the deeds of a single hero or a band of heroes and that can involve intervention by and conflict with the gods.
- epicyclic** Rotation around a point that is itself rotating around a different center.
- epigram** A short poem expressing a single thought or observation.
- epistemology** Theory about knowledge.
- epode** The third part of a three-part lyric ode.
- equinox** One of the two days in the year when the sun crosses the celestial equator. On these days, there are approximately equal amounts of sunlight and darkness.
- equites** The equestrian, or knightly class, of ancient Rome.
- eschatology** The usual modern scholarly designation for such religious themes as the fate of the human being after death, the end of the world, warfare between the powers of good and evil, the resurrection and judgment of the dead, the end of the world and related ideas.
- escupil** Spun cotton body armor used in ancient Mesoamerica.
- eskers** Long, narrow ridges of sand and coarse gravel deposited by glacial meltwaters.
- estuarine** Relating to an estuary, the section of a river that meets the sea and where freshwater mixes with saltwater.
- Etesian winds** The dry, relatively cool winds that regularly blow from north to south in the Mediterranean during the summer months.

- ethnocentrism** The concept that one's group, however defined, is superior to all other groups.
- ethnography** The study and systematic recording of human cultures.
- ethnologist** Someone who studies cultural and biological relationships among large groups of people.
- etymology** The structural and semantic history of words.
- eunomia** "Good laws," the Spartans' favorite phrase to describe their system of government.
- eunuch** A castrated man typically employed in a palace, often taking charge of a harem.
- eustasy** The phenomenon of rising and falling sea levels.
- excarnation** The practice of allowing a body to decay before burial.
- execration text** List of foreign kings and peoples written on Egyptian pottery and statuettes of prisoners of war.
- exomis** A short, sleeveless tunic with the right side open worn by the ancient Greeks.
- exorcist** A "magician" skilled in warding off disease and the other effects of evil demons.
- faience** Earthenware decorated with glazes.
- fauces** The hall leading into a Roman house.
- felt** Cloth made from wool treated with water, heat, and an alkaline.
- fenestration** Cutting out sections of a vessel wall in decorative patterns.
- feng shui** An ancient Chinese worldview that sought harmony and balance between the opposing forces of nature and between the physical environment and humans; its principles were applied to the siting, design, and construction of buildings.
- feria (pl. feriae)** The Latin word for "festival."
- fetch** The distance wind travels over water unimpeded.
- fetiale** In ancient Rome, a member of a priestly order whose job was to ensure that war was declared properly.
- feudal system** A social and economic system in which land is held on condition of loyalty to a higher authority, as in nobles holding land on the condition of their loyalty to their king.
- fibula** A clasp or brooch used to fasten clothing in the ancient world.
- fief** An estate ruled by a lesser lord within a greater feudal kingdom.
- filial piety** In Confucian philosophy, the unquestioning devotion to and respect for one's parents.
- filid** Ancient Irish bards.
- fillet** A ribbon used for binding the hair or as a headband.
- finial** An ornamental projection from the top of a wall or column or at the peak or corner of a roof.
- fired brick** Clay bricks that have been hardened in fires or ovens, making them much more water resistant than clay bricks dried in sunshine.
- firing** The practice of cooking clay vessels in a fire in order to make them harder.
- fishtail point** A ancient projectile point that takes the form of a fish.
- fjord** An inlet to the sea with high cliff walls, created by the retreat of a glacier.
- flagon** A type of drinking vessel with a handle and spout and typically a lid.
- flake tools** Tools that are made from the flattish pieces that are knocked off in the formation of core tools.
- flamen** In ancient Rome, a member of a class of priests who ensured that proper observances and sacrifices were made to the gods.
- flax** A plant material that is the basis for linen.
- fletching** The feathers on an arrow.
- fluting** Concave, semicircular grooves carved into an architectural column.
- fodder crops** Plants grown specifically for animal consumption.
- foot** A division of a line of verse that contains a specific number of long and short syllables.
- forging** Shaping metal by hammering, often when heated to white hot or red hot.
- forum** An open plaza at the center of a Roman town, used for commercial, legal, political, and religious activity.
- frame** A timber oriented perpendicular to a ship's keel, to which a ship's hull planking was fastened.
- fresco** Decorative wall painting on plaster with water-based paint applied when the plaster is wet, allowing the color to permeate the plaster and become permanent.
- frieze** A horizontal band of carved stone, typically depicting a progression of events and procession of figures.
- frontality** The convention of always having a statue of a human facing to the front.
- fundamental note** The lowest or most dominant note that an instrument is designed to play.
- funerary cult** Provisions a person makes before death to provide everything the deceased would need in the afterlife, such as food offerings.
- funerary priests** Religious officials who oversaw burial rituals and other offerings and sacrifices in honor of the deceased.
- futhark** Runic script of the ancient Germans.
- gables** Triangular sections fastened to the top of end walls in houses with double-pitched roofs.
- game drives** Hunting practices that involved preparing and setting nets for migratory fish and birds.
- gangue** The surrounding rock in a metal ore.
- garum** A condiment popular in the Roman world and produced mostly in Spain, made by allowing salted fish intestines to ferment in the sun for days or weeks.
- genos** A Greek family or clan that shared a common ancestor and family name.
- geocentric** Having the earth at the center of the universe, orbited by the sun, moon, planets, and stars.
- geoglyph** Large-scale earth drawing created using simple geometric principles and surveying techniques.

- gerontocracy** A form of social organization in which the oldest men and women in a society are expected to guide and lead the community because of their wisdom.
- gerousia** A council of elders in Sparta, made up of 28 prominent citizens over the age of 60.
- ghee** Clarified butter, created by boiling unsalted butter and drawing off excess water; used as lamp fuel in ancient India.
- glacial maximum** The time of maximum extent of ice sheets during an ice age.
- glacier** A river of ice flowing slowly downhill.
- gladiator** A slave who fought as a professional soldier in combats staged for entertainment.
- glaze** A glasslike coating that seals the surface of a ceramic object and decorates it.
- glyph** A symbol, such as a hieroglyph, carved into stone.
- gnomon** "Indicator," the vertical bar that casts the shadow of the sun on the face of a sundial.
- gorget** An ornamental collar or throat covering.
- gourd** Dried and hollowed out shell of a fruit from the squash or pumpkin family that is converted into a vessel.
- grafting** The practice of attaching the stalk of one plant to the root stock of another to provide strong roots to a plant that would naturally have weak roots.
- grammaticus** In ancient Rome, a public secondary-school teacher.
- grammatistēs** A teacher of reading, writing, arithmetic, and poetry in ancient Greece.
- granary** A storehouse for harvested crops.
- granulation** A method of decorating metal with patterns made up of small balls of the same metal, usually gold.
- gravitas** A dignified bearing, one of the Roman virtues.
- greave** Armor that protects the legs below the knees.
- griot** In ancient Africa, an oral historian who recounted cultural tradition through song.
- groin vault** A ceiling formed by the intersection of two barrel vaults, which are in turn supported by piers that are either freestanding or set into a wall.
- groma** A device that allowed Roman builders to ensure that vertical elements, such as columns and piers, were set at right angles to the horizontal.
- grotto** A cave enclosing a body of water.
- guano** Bat dung; used as fertilizer.
- gur** In the ancient Near East, a measure of the value of an item that was approximately equal to 43 gallons of barley.
- guru** A teacher in the Hindu tradition, seen as a god in human form and as the sole source of knowledge for his students.
- gurukula** A school in the Hindu tradition.
- gymnasium** An area devoted to intellectual and athletic pursuits.
- gymnastics** In ancient Greece, any athletic training.
- gynaikeion** Living quarters for women in ancient Greek homes.
- haft** The handle of a knife, an ax, or another weapon or tool.
- halberd** A battle-ax mounted on a long handle.
- handfasting** Engagement to marry.
- hangul** The system instituted in 1446 to write Korean phonetically; originally used along with Chinese characters but now generally used exclusively.
- haniwa** Small ceramic figures, usually depicting people, made by the ancient Japanese to surround tombs, protecting the tombs from evil spirits.
- harmika** A finial, or ornamental projection from the top of a wall or column, found in the architecture of India.
- harpy eagle** A large bird of prey native to Central and South America.
- haruspex (pl. haruspices)** Literally, "men who look at guts": Roman diviners who read the will of the gods by examining the entrails of sacrificed animals.
- heddle** A rod on a loom used to guide threads.
- heliacal rise** The first appearance of a star near the eastern horizon just preceding sunrise, following a period of nighttime invisibility due to proximity to the sun.
- heliocentric** Having the sun at the center of the solar system, orbited by Earth and other planets.
- Hellenization** The process of "becoming Greek."
- helot** In ancient Greece, a slave of the Spartans.
- hemp** A tall herb with tough fibers used to make durable cloth and ropes.
- hen** In ancient Egypt, the measure of a volume equal to half a quart or less, with a value that could vary according to the substance or liquid to be measured; generally regarded as equal in value to one deben.
- henotheism** The worship of a single most important deity without denying the existence of others.
- hep** Egyptian term for law, abstract moral order, normative custom, and every kind of rule, either natural or juridical, general or specific, public or private, literary or oral.
- herm** A statuette of the god Hermes, usually placed at house gates or as a marker on roads.
- hero** In ancient Greece, a great mythical or legendary human being who was usually considered the offspring of a god and a mortal and whose spirit was worshipped much like a god.
- hestia** A Greek cooking stove.
- hetairai** (or hetaerae) In ancient Greece, courtesans, often valued for wit and education as well as beauty; these women occupied a social space between that of a prostitute and a mistress.
- hexameter** A poetic meter that has six feet per line.
- hierarchical society** A society characterized by multiple levels of authority and status.
- hieratic** Sacred; associated with priests; also a cursive form of Egyptian hieroglyphs used for all domestic texts and records.
- hieroglyph** The Greek word for "sacred carving," describing the Egyptian writing system, which consisted of pictorial signs, used phonetically and pictorially.

- himation** A rectangular outer mantle draped in various ways and worn by the ancient Greeks.
- Hippocratic bench** A bench with moveable posts and straps, used for reducing dislocations and for traction.
- Hippocratic oath** A statement of basic principles followed by students and physicians at the ancient school of medicine on the island of Cos and which survives to this day as a foundation of modern medical ethics.
- historical linguistics** The study of the derivation, changes, and relationships of languages over time.
- ho boulomenos** A Greek term literally meaning, “the one who wishes,” a definition of who could initiate a public lawsuit.
- hogging trusses** On a ship, thick ropes that could be tightened to keep the bow and stern from sagging.
- homoioi** Literally “equals,” a term applied to the citizen body in ancient Sparta.
- honestiores and humiliores** Two broad classes into which Roman citizens were divided during the empire. The *honestiores* were aristocrats, soldiers, and public office-holders; they suffered lighter punishments than *humiliores*, who made up the rest of the population.
- hoplite** A heavily armed Greek foot soldier, protected by a metal helmet, breastplate, and large round shield.
- hoplitodromos** A race in ancient Greece that the athletes ran while wearing armor.
- hoplomachus** Gladiator armed with Greek heavy-infantry weapons.
- horos (pl. horoi)** Stones used to mark boundaries for various types of spaces: temple precincts, public spaces, and the edges of poleis, or city-states.
- hubris** In ancient Greece, an outrage or a deliberate affront to the dignity of another, particularly a citizen.
- humor** One of the elemental fluids of the body in Hippocratic, Galenic, and medieval medicine; the four canonical humors after Galen were blood, black bile, yellow bile, and phlegm.
- hunter-gatherers** People who survive by hunting wild animals and gathering wild plants, without agriculture.
- hybris** Any act that went beyond the established moral codes or surpassed human capacities, usually followed by *nemesis*, or divine punishment.
- hydraulics** The study of the mechanics of fluids, especially with respect to engineering.
- hydraulis** A water-powered pipe organ developed in ancient Greece; the world’s first keyboard instrument, it used bellows or a hydraulic pump to force air through pipes.
- hydria** A vessel to hold water mixed with concentrated wine.
- hydrostatics** The branch of mechanics dealing with the equilibrium of weights in water.
- hypaspists** Members of an elite infantry guard in the army of Alexander the Great.
- hypocaust** The space underneath the floor of a building from which heat rose to warm the floors above it.
- hypostyle hall** A hall with a flat ceiling supported by columns.
- iamb** A poetic foot that has one short syllable followed by a long.
- ibw** Tent in which bodies underwent ritual purification before embalming in ancient Egypt.
- ice core** a sample of the various layers in large ice sheets taken by drilling a long, hollow tube down into the ice sheet and used for research purposes, such as the study of past climate change or ecological conditions.
- iconography** Symbolic representation, especially the conventional meanings attached to an image or images.
- ideogram** A written character that represents an object, image, or idea.
- ideographic** In a writing system, having symbols that denote ideas rather than words.
- idiophone** An instrument producing a specific, unusual, often atonal sound.
- idolatry** The worship of images or statues of gods instead of the gods themselves.
- igneous rock** A type of rock that has been subjected to extremely hot temperatures, to the point of becoming molten, and then cooled to a hardened form.
- imagines** Images of the Roman dead carried by the living in the form of masks during a funeral procession.
- Imperial Cult** During the Roman Empire, the belief that the emperor was divine, usually declared after his death.
- imperium** The power of military and civilian command belonging to certain magistrates and promagistrates such as consuls and proconsuls.
- impiety** The crime of violating religious law in a way that was viewed as injurious to the nation.
- impluvium** The shallow pool in the floor of an atrium that collected rainwater directed through an opening in the roof of a Roman house.
- incertum** An early technique of Roman masonry in which blocks of tufa were inserted randomly into drying concrete blocks.
- incised or raised relief** Symbols, images, or writing cut or hammered into metal surfaces to distinguish them from the plane surface.
- infinitesimal** A number smaller in absolute value than any positive real number.
- inflected language** A language in which words take different forms to reflect grammatical information such as gender, tense, and singular and plural.
- inflection** Change in the form of a verb, noun, or adjective (for example, the adding of *s* in English to form a plural).
- ingot** A metal casting that is shaped for easy working or for recasting, typically oblong in shape.
- initiation** Any ritual, ceremony, or cultural practice that marks the transition from childhood to adulthood.
- inscription** Writing carved into a solid substance such as stone or bronze.

- insula** A Roman apartment building, usually multistoried.
- interaction sphere** In prehistoric cultures, groups that had social interaction and exchanged material goods.
- intercalation** The addition of an extra day in the month, or an extra month in the year, to ensure that the months remain synchronized with the seasons.
- interstadial** A short period of relatively warmer climate within an ice age.
- inundation** Predictable annual flooding events that renew the soil and sustain ecosystems; often used to refer to the flooding of the Nile.
- Ionic** One of the three orders, or styles, of Greek architecture, distinguished by slender columns and capitals ornamented with spiral scrollwork called volutes.
- isegoria** The principle in Athenian democracy under which all citizens had an equal right to speak in the Assembly and other public gatherings.
- isolate** An ancient language that has no similarities with other languages and thus may have developed independently.
- isonomia** “Equality under the law,” the basic idea of Athenian democracy.
- isostasy** The rebounding of the earth’s mantle after it has been depressed.
- ius privatum** Private law that was concerned with the legal dealings between individual Roman citizens or groups of citizens, as well as between citizens and noncitizens.
- ius publicum** Public law that regulated the relationship between the Roman state and its citizens.
- jamb** One of two uprights in a door frame that together supports a crosspiece, or lintel, and that transfers the weight of the wall above the door to the ground.
- jaundice** A yellowish discoloration of the skin symptomatic of diseases affecting the processing of bile.
- javelin** A lightweight spear designed to be thrown.
- joinery** Techniques or processes used to join pieces of wood, usually referring to ways of cutting the wood so that nails or screws are not required.
- ju** A Chinese shirt with a stiff, upright collar.
- Julian calendar** A solar calendar purportedly created by the Greek astronomer Sosigenes of Alexandria and instituted by Julius Caesar in 45 BCE.
- k’uhul ajaw** Mayan term for divine king.
- kalasiris or calasiris** A thin linen tunic.
- karma** In Indian spirituality, the positive or negative energy created by people during their lifetimes, determining the states they will take in future lives.
- kataginu** A Japanese vest with broad, stiff shoulders.
- keel** A large timber running longitudinally at the bottom of a ship from which the hull is built up and that provides stabilization.
- keep** A fortress within a fortress.
- kemet** “Black land” in the Egyptian language, referring to land that could be cultivated, in contrast to *deshret* (desert), or “red land.”
- khapusa** A heavy, knee-high boot that was worn in northern India.
- kinship** Ties (either biological or cultural) that determine human groups.
- kitchen middens** Accumulations of food and other debris of human occupation, such as discarded tools and ashes from hearths.
- kithara** An ancient stringed instrument used by the Greeks and Romans, similar to the modern guitar.
- kitharistēs** A music teacher in ancient Greece, who taught singing and playing the lyre, a stringed instrument like a harp.
- klinē** A bed or couch in ancient Greece, consisting of a wooden frame across which a webbing of leather or rope would be woven to support the occupant.
- klismos** A chair in ancient Greece, with curved legs, no armrests, and a curved, reclined back.
- knight** A member of the second-highest Roman social class, rated by the value of property according to the census. Knights were required to serve in the cavalry since they could afford to buy their own horse and equipment.
- knot** A measurement of speed at sea equal to 6,076 feet per hour.
- kohl** An eye cosmetic often composed of ground galena (a black mineral), sulfur, frankincense, and powdered antimony, which contains lead.
- koine** The “common” dialect based on Attic that developed starting in the third century B.C.E. and became the basis for Byzantine and Modern Greek.
- kore (pl. korai)** Representations of standing female nudes from the Archaic Period of Greek art.
- kouros (pl. kouroi)** A figure of a standing male nude from the archaic period of Greek art.
- krypteia** An annual secret campaign of assassination conducted by the Spartans in ancient Greece against their slaves, the helots.
- ku** Loose Chinese trousers.
- kudurrus** A boundary stone, which carried emblems and symbols of the gods.
- kurios** The legal lord of a Greek household, with power over and responsibility for all its members.
- lacquer** A coating used to make an object glossy; in China, lacquer at first came from the resin of the lacquer tree, *Rhus verniciflua*.
- lamassus** Large-scale architectural sculptures of human-headed winged bulls that abutted the entrance walls of Assyrian palaces.
- lamellae** Thin iron plates that were used in the construction of armor.
- lapis lazuli** Semiprecious blue stone used in creating jewelry and other objects.
- latifundium** Originally, in ancient Rome, a large estate relying largely on slave labor.
- latitudinal** Having to do with latitude, the geographic distance of any point on the earth north or south of the equator.

- laudatio** The Roman ceremony of displaying and eulogizing a dead person before cremation or burial.
- lay** Song of the Anglo-Saxon bard.
- lead line** A rope to which was tied a lead or stone weight and that was used to measure water depth; often the weight had a depression filled with tallow so that a sample of the sea bottom could be brought to the surface.
- lector priest** A ritual specialist who carried out ceremonies according to the secret books in ancient Egypt.
- lee shore** A shore toward which the wind blows, constituting a danger to a ship in a storm.
- legion** The largest independent formation in the Roman army, consisting of heavy infantry, light infantry, and cavalry and varying between 4,200 and 6,000 men.
- legionary sword** A short sword, used in ancient Rome, with a blade about 30 inches long with two parallel cutting edges and a long, sharp point.
- legionnaires** Members of a legion, or the basic unit of the Roman army.
- legume** A plant related to the pea family, notable for its protein content.
- léine** A long linen tunic worn in Ireland.
- leishmaniasis** A protozoan skin disorder carried by female sand flies.
- lekythos (pl. lekythoi)** A Greek vessel used to store olive oil for the anointing of the dead in preparation for burial or as a burial offering.
- leprosy** Chronic progressive bacterial infection affecting the skin and nerves, acquired by close personal contact over a long period, often among members of the same family.
- levee** An embankment or barrier meant to prevent flooding.
- lex frumentaria** In ancient Rome, a grain law, which provided grain to each citizen at a subsidized price.
- lex talionis** A legal concept of punishment based on equal and direct retribution, often popularly expressed as “an eye for an eye.”
- lexicology** A branch of linguistics concerned with the study of words and their application.
- libation** The act of pouring liquid as a sacrificial offering, typically to the gods but also to one’s ancestors.
- lignified** Hardened; used in reference to the hardening of the outer husk of corn.
- limes** A border defensive system of the ancient Romans.
- limestone** Stone formed from sediments laid down over eons; usually easier to carve than granite.
- limitanei** Light troops of the late Roman Empire who guarded the borders and frontiers to hold off invaders until heavier troops could arrive.
- lineage burials** Burials in grounds set aside for a single family lineage.
- lineage** Family ancestry traced through a line of parent-hood, either fathers or mothers but not both.
- linen** A flexible, durable, and usually soft cloth made from flax.
- lintel** A beam that rests on the uprights, or jambs, of a doorway and that transfers the weight of the wall above the door to the uprights and from them to the ground.
- lithic** Of, relating to, or being a stone tool.
- litter** A chair or similar vehicle suspended from poles carried by either humans or animals to transport one or more riders.
- litterator** In ancient Rome, a teacher of basic literacy and numbers.
- littoral** A region near a shore, especially of the sea.
- liturgy** An institution whereby private citizens in ancient Athens were obliged to pay for public works from their own resources.
- loan word** A word that one culture borrows from another, either as is or with modifications, suggesting contact between the two cultures.
- lodestone** A piece of magnetite, having magnetic properties.
- loess** Chalky clay or silt created by layers of wind-blown dust over a long period of time.
- logic** A system or principles of reasoning.
- logographic** In a writing system, having symbols that denote a whole word or a morpheme, a minimal language unit.
- logophonic** In a writing system, having symbols that denote the actual sounds of speech.
- loincloth** A strip of cloth wound about the waist and between the legs.
- long barrows** Elongated burial mounds.
- lost-wax casting** A method of creating metal objects by use of a wax cast set within a clay mold; the wax is heated and runs out of the mold to be replaced by molten metal.
- ludus (pl. ludi)** A show or performance; from the Latin for “play, game.”
- lugal** Literally, “great man”; in ancient Sumer, a leading citizen chosen to take charge in times of crisis.
- lunar calendar** A calendar that is based on the cycles of the moon, defining one month as the time it takes the moon to complete one revolution around the earth.
- lunation** The interval from new moon to new moon.
- lungi** An Indian skirt that resembles a loincloth.
- lunisolar calendar** A calendar that combines aspects of lunar and solar calendars, basing units of time on the earth’s movements relative to both the sun and the moon.
- lur** Cast bronze horns from northern Europe, made in distinctive pairs and thought to have been used for ceremonial purposes.
- lustratio** A purification ceremony performed for a Roman male infant at the age of eight days.
- lute** A stringed instrument with a long neck, rounded body, and flat front.
- lyra** A small type of Greek lyre, often with a sound box made out of a tortoiseshell.
- lyre** A stringed instrument like a U-shaped harp with strings fixed to a crossbar at the top of the U.

- lyric poetry** Short, very personal poetry that deals with the poet's feelings or state of mind.
- maat** In ancient Egyptian cosmology, cosmic harmony (personified as a goddess) as established by the creator god at the beginning of time, including truth, justice, moral ethics, and social and political order.
- mace** A ceremonial staff.
- madder** A plant used to make red dye.
- magic lantern** A device used to illuminate and project images and silhouettes onto a screen.
- maguery** A plant from the cactus family indigenous to Mexico, used for a variety of purposes, particularly for its fibers to create cloth.
- mail shirt** A body covering composed of interlaced rings or chain work and normally extending below the waist.
- major lunar standstill(s)** The moon's farthest rising and setting points north and south on the horizon over an 18.6-year cycle.
- malakaras** Garland makers in ancient India.
- malaria** Epidemic infection caused by a parasite transmitted through the bite of a mosquito and causing recurring chills and fever.
- mammoth** Any large, elephantlike mammal of the extinct genus *Mammuthus*.
- mangroves** Woody trees that live in coastal habitats.
- maniple** The basic unit of the Roman army, consisting of either 120 or 60 men.
- mantle** A large, rectangular cloth arranged around the neck and over the shoulders.
- mantra** A sacred word or phrase that a person chants over and over to achieve spiritual effects.
- manumit** To free a slave.
- manus** The power that a husband held over his wife in ancient Rome.
- manuscript** Writing on a sheet of papyrus or vellum.
- mastaba** Underground tomb carved down into rock and topped aboveground with a square masonry platform.
- material culture** The material remains (artifacts, dwellings, and other constructions) of past societies.
- matriarchal society** A society in which women hold dominant positions or in which inheritance follows the maternal rather than the paternal line.
- matrilineal** Descriptive of a culture in which lines of descent are traced through the mother and her ancestors rather than through the father.
- matron** A woman in the most legitimate and respected form of Roman marriage.
- mattocks** Digging tools or picks.
- maul** A heavy stone hammer used to break up rock.
- mead** An alcoholic beverage made by fermenting honey and water.
- meander** An ornamental pattern resembling a labyrinth.
- mechane** In ancient Greece, a crane-like device used to lift a performer above the ground.
- mechanics** The expertise of making and designing machines.
- medicine wheel** Large patterns of linear stone alignments, many of which have the appearance of a spoked wheel.
- medium of exchange** Any class of objects used by people as if it were money.
- megalith** Literally "great stone," referring to the use of large stones in the construction of Neolithic tombs and other features (for example, geometric figures, such as circles, as well as lines or avenues for which the massive stones served as markers), especially in central and western Europe.
- menhir** A single tall megalith, often posited as part of a sightline for astronomical observation.
- meridian** A great circle on the surface of a sphere that passes through both poles.
- meter** The rhythmic pattern of a poem.
- metics** Resident "aliens," or foreigners, with no rights of citizenship in a Greek city-state; this group was made up largely of immigrants and former slaves and was concentrated largely in Athens.
- Metonic cycle** A lunar calendar devised by the Greek astronomer Meton, using 19-year cycles totaling 235 months.
- metope** A pictorial panel, part of the frieze on the entablature of a building.
- metrological** A system of counting that separates the unit of measurement from the thing being counted.
- metropolis** A large and densely populated urban area.
- miasmas** Impurities floating in the air and resulting from any kind of pollution.
- microliths** Small retouched blades or blade segments usually made of flints and commonly used in composite tools or weapons such as knives, arrows and harpoons.
- microtonal scale** A musical scale that contains more notes within an octave than the traditional 12 notes of the Western scale.
- middens** Heaps of refuse, especially kitchen waste.
- midrib** A thickening down the middle of a dagger for added strength.
- midwife** A woman who helps other women give birth.
- millet** A small-seeded grass that is used for food.
- milpa** A form of agriculture in which a clearing is cropped for one or more seasons, then abandoned.
- mime** In ancient Rome, a popular form of theater that featured skits, songs, dances, magic acts, and acrobatics while emphasizing sexual jokes and parodies.
- mina** A weight of metal in ancient Greece, equivalent to 100 drachmas.
- miter joint** The ends of two pieces of wood cut at complementary angles and fitted together to create a 90-degree angle.
- mode** A set pattern of notes played over an octave using the white keys of a keyboard.

- model** A small-scale reproduction of an object that could magically be animated.
- moiety** One of two units into which a tribe or community is divided on the basis of unilineal descent.
- mold making** Producing glass objects by pouring molten glass into a hollow form, in order to make a certain shape or decoration.
- molding** A decorative recessed or relieved surface on an edge; a decorative strip used for ornamentation or finishing.
- monarchy** A political system under which a single king or queen holds supreme power, which is passed through the family line by hereditary descent.
- monotheism** The belief in the existence of only a single divinity.
- monsoon** A wind pattern that follows the same course every year, bringing predictable weather, such as rain, with it; also the intense rainfall or the season of rainfall associated with this wind.
- monstra** “Prodigies,” or a natural but strange occurrences, such as the birth of a calf with two heads, regarded by Romans as a warning from the gods.
- moraine** An accumulation of stones and debris carried and deposited by glaciers.
- morpheme** A collection of speech sounds considered to be the smallest language unit.
- mortar** A substance used as an adhesive to fasten courses of bricks or stones together or as a plaster to protect the surface of a wall.
- mortarium** A heavy Roman bowl with sharp stone fragments embedded in its interior surface, used to grind food.
- mortise and tenon** A method for joining two planks of wood by means of a series of projecting tongues cut into the edge of one piece and slots cut into in the other.
- mos maiorum** A sense of tradition, one of the Roman virtues.
- mosaic** A design made with small pieces of colored glass or tile.
- mud brick** Bricks made from mud and straw and then dried in the sun.
- mummification** The Egyptian process of preserving the body by the removal of internal organs, drying out the corpse, and protecting it with linen wrappings.
- mummy portrait** Painting on a wooden panel made to cover the face of an Egyptian mummy, usually done in encaustic (wax) technique.
- mundus** A hole in the ground near the center of a Roman city that was usually covered but when uncovered allowed earth spirits to communicate with the city.
- munus** Gladiator show; from the Latin for “duty.”
- murex** An aquatic snail that lived in the Mediterranean near Lebanon and was used as a source of purple dye.
- murus gallicus** “Gallic wall,” a type of rampart found at many defended sites in ancient Gaul, consisting of timber, filled with earth and stone, backed by stone walling, and often fronted by a ditch.
- music** In ancient Greece, any of the arts associated with the Muses: music, poetry, dancing, and drama.
- musk** A perfume originating from a sac inside the male musk deer.
- nadir** The point on the celestial sphere directly below the place on which the observer stands and opposite the zenith.
- natron** A mineral form of hydrated sodium salts found in dried lake beds.
- necromancy** Conjuring of the spirits of the dead in order to communicate with them.
- necrophilia** Sexual attraction or contact with a dead body.
- necropolis** A cemetery, especially one of large size and usually of an ancient city.
- nexum** Debt bondage.
- niche** A setback or indented enclosure; a small concavity.
- Nilometer** A series of steps that were used to mark the height of the Nile inundation as well as regular water levels
- nirvana** In Hinduism, the union of the human spirit with Brahma (the god of creation) and in Buddhism the state of blessedness in which the human spirit is released from the cycle of reincarnation.
- nomad** A member of a people who move seasonally from place to place to search for food and water or pasture for their livestock.
- nomadic pastoralism** A form of pastoralism in which all or most of the people move with their herds year-round to find pasture, living in temporary encampments and often traveling great distances.
- nomarch** The ruler of a nome, a political and geographical division of territory in ancient Egypt similar to a state in the United States.
- nome** A Greek term for an ancient Egyptian province, of which there were 42.
- nomoi** In Greek, “laws; the word could denote formally enacted laws as well as to established customs (“unwritten laws”).
- noncultic** Nonreligious.
- nopal** A type of cactus eaten cooked or raw by ancient Mesoamericans.
- numerology** The study of the occult, or mystical, influence of numbers on everyday life.
- numina** A term early Romans used to refer to their gods, usually translated as “presence” or “power.”
- numismatics** The study of coins and coinage.
- nun** The waters of primordial chaos in Egyptian cosmology.
- nundina** A market day in Rome.
- obelisk** A tall, tapered, four-sided monument with a pyramid at the top.
- oblite** A category of dependent person attached to the temples of the gods.

- obol** A weight of metal in ancient Greece, equivalent to one-sixth of a drachma.
- obsidian** A volcanic glass that was used in making tools.
- obverse** The “heads” side of a coin; this side of a coin often, but not always, contains a portrait bust.
- ocarina** A wind instrument, often oval in shape, with finger holes and a projecting mouthpiece.
- ocher** A powdery form of iron-rich earth or clay widely used as a pigment.
- octant** A navigational device used for measuring angles to a celestial body as a way to calculate position, with a calibration of 45 degrees.
- odeion** A Greek roofed hall used for musical performances
- oenology** The science of making wine.
- offering formula** A text inscribed on some funerary goods to magically provide sustenance for the deceased in the afterlife.
- offering table** A place where Egyptian priests or family members could place provisions for the deceased, often in the shape of a cone-shaped loaf of bread on a table.
- oikistes (pl. oikistai)** The founder of a Greek *apoikia*, responsible for establishing the city walls and distributing land among its settlers.
- oikonomia** A Greek word translating roughly to “household regulation,” from which the English word *economy* derives.
- oikos (pl. oikoi)** In Greece and the ancient Near East, a great household, typically a temple, palace, or large estate, that controlled the labor, production, and consumption of its many members, most of whom were not related; a basic economic unit.
- oligarchy** A form of government in which rule resides jointly in the hands of a few people, usually the wealthiest and most powerful.
- olla (or aula)** A deep, round-bottomed Roman vessel used for boiling stews or porridge.
- omen** Any event in nature that provides insight into the future.
- onomastica** Catalogues of things arranged under their kinds, not alphabetically.
- opening of the mouth ceremony** Funerary ritual that enabled the deceased to breathe, eat, and talk in the afterlife.
- oppidum (pl. oppida)** A type of fortified town that was developed before the Roman Iron Age in western Europe and was a center of residential, administrative, commercial, and industrial activities
- oracle bones** Bones of animals, typically shoulder blades (usually of oxen), and also turtle shells that were heated to produce cracks, which were analyzed by those seeking to divine the future.
- oracle** A person, such as a priest, through whom a god is believed to speak.
- oratory** The art of public speaking.
- orature** Oral literature in ancient Africa.
- orchestra** A flat, circular area in which much of the action of a Greek drama occurred, situated between the spectators’ seating area and the stage.
- order** The three ancient Greek styles of building design.
- ore** A naturally occurring mineral from which metals can be extracted.
- orrery** A mechanical model that reproduces the movements of heavenly bodies.
- orthogonal planning** City plan in which the perpendicular axes of streets create square city blocks.
- orthostat** An upright stone or slab used by architects in buildings.
- osteomyelitis** Bacterial infection of the bones and bone marrow.
- ostrakon (pl. ostraca)** A fragment of pottery, typically carrying an inscription or drawing.
- outcastes** A person in ancient India who had no caste or had been ejected from a caste for violation of customs and rules.
- outlier** A language geographically detached and possibly remote from the range of the languages closely related to it.
- outrigger** A float attached by spars, or poles, to a watercraft.
- overdying** Successively dying a thread with individual colors until the desired color is reached.
- overtone series** In music, a number of higher notes produced simultaneously above a lower continuous drone.
- oxidize** To combine with oxygen.
- pack animal** An animal used to carry loads on its back.
- paedagogus** In ancient Rome, an educated slave who served as a tutor in ancient Rome.
- paidotribēs** In ancient Greece, a gymnastics teacher, working on physical fitness and the vigorous games that formed the basis of public competition and prepared young men for war.
- palaestra** Facility for training in wrestling and boxing in ancient Greece.
- palanquin** A litter or carriage body on poles, carried on the shoulders of men or women.
- paleoclimatologist** A scientist who studies long-term changes in climate on the earth throughout the planets four-billion-year existence
- paleographic** Having to do with ancient writings.
- paleopathologists** Scientists who study disease in prehistoric populations through examination of skeletal and tissue remains, coprolites, and works of art.
- palette** A flat stone tray, often decorated with carved designs, upon which colored minerals (such as malachite or hematite) were ground to make cosmetics.
- palisade** A fence made of upright stakes or posts set very closely together; a stockade.
- pallium** A rectangular woolen mantle worn by lower-class Romans.
- panchayat** In India, a council at the village level, responsible for dealing with local crime and punishment.

- panegyric** Laudatory written or oral poem.
- pankratation** An event in ancient Greece that combined elements of boxing and wrestling.
- pantheistic** Relating to the worship of all gods.
- pantheon** The group of gods worshipped by a particular culture.
- papyrus** A tall aquatic plant used mainly by the Egyptians to make a writing material resembling paper.
- parapegma** A calendar that lists annual celestial events, such as the rising and setting of specific stars or constellations on given days of the year; a star calendar.
- parrhesia** In ancient Greece, frank or open speech, a cherished Athenian principle.
- passage tomb** A tomb where the burial chamber is reached through a low passage; secondary chambers may lead off from the main chamber.
- pastoral nomadism** An economic lifestyle that revolves around entire families or kin groups following domesticated animals during yearly cycles.
- pastoral poetry** Poetry that presents an idealized portrait of country life, often concerning the love between shepherds and shepherdesses.
- pastoralism** The breeding, tending, and exploitation of domestic herd animals as a principal means of livelihood for a community or society.
- paterfamilias** In ancient Rome, the male head of a household.
- pathogen** Any agent capable of causing disease.
- patria potestas** The legal authority (including the power of life and death) of a Roman head of household over his family (including slaves and other dependents).
- patriarch** A male head of a family.
- patriarchian** The upper social class of Rome, consisting of those who held social, political, and economic power.
- patrilineal** Descent traced through the male ancestors.
- patrilocal** A residence pattern in which married couples live with or near the husband's family.
- patronus** A Roman of wealth and status who extended his patronage and protection to one or more lower-status clients.
- pavimentum** Concrete foundation of a Roman road.
- Pax Romana** Term used to describe the relative peace and stability that the Romans imposed on their empire.
- payment in kind** The offering of crops, animals, and textiles, and other goods instead of money to pay taxes or a debt.
- peat** Partially carbonized plant matter, usually found in bogs.
- pectoral** A breastplate or breast covering.
- pederasty** An erotic relationship common in Greek culture between a youth (usually between the onset of puberty and the full growth of the beard) and an adult man.
- pediment** The triangular section just below a sloped roof, which may contain decorative or sculptural features.
- peltast** A Greek lightly armed infantry soldier.
- pemmican** A mixture of dried meat, dried berries, and rendered fat.
- pentameter** A poetic meter that has five feet per line.
- pentecontor** A 50-oared ship, rowed by arranging 25 oarsmen on each side of a vessel.
- peplos** A loose gown worn over a tunic by the ancient Greeks.
- peret** The “growing season,” one of three seasons in the Egyptian calendar, based on the stages of the Nile’s transformation.
- perioikoi** In ancient Greece, people from neighboring towns, especially those subject to the people of Sparta.
- periplus (or periplus; pl. periploi)** In ancient Greece, a narrative of discovery containing details of navigation, such as ports and coastal landmarks.
- peristyle** An open area or courtyard surrounded by columns.
- permafrost** Permanently frozen ground.
- petasos** A hat with a broad, floppy brim worn by the ancient Greeks.
- petroglyph** An image that is carved or pecked into a rock surface with a hard stone or some other tool.
- phalanx** A rectangular formation of heavy infantry, densely arrayed so that each man’s shield protected both himself and his neighbor to his left.
- pharmaceutical** Having healing properties.
- pharmacology** The study of drugs, especially their effects.
- phonetic** Having to do with the sounds of languages.
- phonogram** Written symbol used to express a sound.
- phratry** A kinship group found in many Greek cities.
- phyle (pl. phylae)** One of the main divisions of the citizen body in most ancient Greek cities; in ancient Athens the 10 phylae provided the organizational basis for many government functions.
- physis** Greek word for “nature”; can refer to the overall state of the physical body and its health and well-being.
- pictograph** Picture symbol representing by way of an illustration a person, idea, object, activity, event, or place.
- pietas** A sense of duty, one of the Roman virtues.
- pilaster** A rectangular column that projects from a wall to which it is attached.
- pile weave** Weaving that produces raised loops rather than a flat surface.
- piles** A beam of timber driven into the ground to be part of a foundation for a building.
- pilum (pl. pila)** The standard missile weapon of the ancient Roman legionnaire, similar to a javelin.
- pips** Small fruit seeds.
- pit house** An ancient form of dwelling consisting of a pit excavated in the earth and roofed over.
- pitch accent** In language, the form of accentuation in which the accented syllable does not receive additional emphasis (as in English) but instead is pronounced at a musical pitch different from the rest of the word.
- pitched roof** A two-sided, sloped roof.

- pithoi** Large terra-cotta jars used for storage in ancient Greece and Rome.
- placebo effect** The effect seen when patients improve as a result of their positive expectations about the treatment rather than as a result of the treatment itself.
- placer deposits** Glacial deposits that contain valuable minerals, especially gold.
- plain weave** A technique of passing weft threads alternately over and under the warp threads.
- plaiting** Braiding a number of strips of leaf to create one long strip for use in a basket or mat.
- plano-convex** A shape comprising five flat sides, each one forming a plane, and one side curved upward, or convex.
- plaza** Large open-air area for public gatherings, created by the enclosure of buildings or mounds.
- plebeian** In Roman society, a commoner.
- plinth** An architectural support or base, such as small stands for statues and larger platforms for entire buildings.
- plowshare** The metal blade of a plow.
- pneumatics** The study of the mechanical properties of gases.
- pneumoconiosis** A disease of the lungs caused by inhalation of other irritating particles in the environment.
- polestar** Known as Polaris, the star that hangs above the North Pole and is a useful navigational guide at night.
- poliomyelitis** Severe viral infection that affects the spinal cord and brainstem and can lead to muscle wasting and partial or complete paralysis.
- polis** (pl. poleis) A ancient Greek city-state.
- polity** A politically organized unit.
- pollen analysis** A type of analysis that studies pollen that has survived for many thousands of years in waterlogged or acid conditions in the soil to gain a picture of plants growing in the vicinity the sample was taken from.
- polychrome** Multicolored.
- polyculture** The practice of planting several different crops in the same place, such as growing wheat among the trees of an orchard or lentils between the rows of vines in a vineyard.
- polygamy** The practice of marrying more than one spouse.
- polyglot** A person who speaks several languages and, hence, a place where several languages are widely spoken.
- polygyny** The practice of having two or more wives.
- polyreme** A large, multi-oared warship.
- polytheism** A religious system based on the belief in and worship of multiple gods.
- pomerium** A ritual boundary that separated the sacred space of the Roman city from the nonsacred world beyond.
- pommel** A knob on the part of a bladed weapon that is held in the hand.
- pontifex maximus** The chief religious figure in ancient Rome.
- porcelain** A white, hard, almost transparent ceramic coated with colored glazes.
- pornai** Prostitutes in ancient Greece.
- port of trade** Place where emissaries from central places trade and exchange goods.
- portico** A porch with regularly spaced columns, or colonnades, often surrounding the sanctuary of a temple.
- portoria** Customs duties.
- post mast** A simple mast made of one long timber.
- post** Vertical timber joined to a ship's keel at the bow (stem) and the stern (sternpost) to receive the hull planking.
- post-and-beam construction** An important early architectural design in which vertical posts, made of wood or stone, support horizontal beams anchoring the walls and roof; also called "post and lintel."
- potsherd** A fragment of a clay vessel or other object.
- potter's wheel** A circular platform that spins, on which wet clay is shaped by a potter's hands.
- pozzolana** Hard volcanic stone that went into Roman *caementum*, or cement, helping to make the walls of Roman buildings impervious to fire and moisture.
- praetentura** The quarters of elite troops within a Roman camp or fortification.
- praetor** In the government of ancient Rome, officials who held imperium, or the authority to lead an army and the power of life and death over citizens, and who were in charge of litigation and courts of law.
- Praetorian Guard** The Roman emperor's private military troops.
- praetorium** The headquarters of a Roman camp or fortification, built to house the legionary commander and the unit's symbolic banners.
- precentor** A person who leads worshippers in singing or chanting prayers.
- precession** The movement of an axis of a rotating body, causing it to "wobble" slightly in its orbit.
- primogeniture** The legal right of inheritance belonging to the first-born child, most often the eldest son.
- proconsul** A Roman consul whose imperium was continued after his year in office as a promagistrate.
- proletari, (pl. proletarii)** People in ancient Rome who owned no property.
- pronominal** A term use to describe the nature of a pronoun.
- propylon** A porchlike structure that typically served as an entrance to the grounds of temples in ancient Greece.
- prothesis** A ceremony in which the corpse was laid out for mourning at home.
- protohistoric** Historical era immediately preceding the emergence of writing.
- protolanguage** An ancestral or root language, the basis for a family of languages.
- provenance** Place of origin.
- proyet** The period when the waters of the Nile receded, literally meaning "the emergence."
- prytaneion** A Greek city hall.

- prytanis** (pl. *prytaneis*) Member of the executive committee presiding over the Athenian *boulē*, or citizens' council.
- psephismata** Decrees, that is, decisions of the Assembly in Athens that pertained to a specific situation and did not establish a permanent law.
- pseudepigraphic** Having a false title.
- publicani** Wealthy partners in Roman companies that invested large sums in bidding for state contracts to collect taxes or operate facilities like state-owned mines.
- pueblos** Native American communal dwellings built in cliff faces.
- pulmentarium** In ancient Rome, stew or porridge made of grains or beans.
- pulque** An alcoholic beverage made by ancient Mesoamericans from the fermented juice of various agave plants, such as the maguey.
- purdah** An Indian woman's garment that covers the entire body.
- pututu** Traditional Andean musical instrument made by drilling a large seashell at its point to make a mouthpiece.
- pylons** Large gates with two abbreviated pyramids on each side.
- pyrotechnology** The process of transforming a raw material such as clay into its final form using fire.
- Pythagorean theorem** A technique for finding the length of a side of a right triangle if the other two sides are known, based on the fact that the area of the squares made from any two sides have a known relationship to that made by the remaining side ($a^2 + b^2 = c^2$, where c is the hypotenuse).
- qanat** An irrigation system of underground tunnels developed by ancient Persians.
- quadratum** A building technique in which blocks of dressed stone were fastened to a concrete wall to form a regular facing.
- quaestor** In the government of ancient Rome, an official who handled financial matters: collecting customs or duties at ports and rent for Rome's public lands, running the city's treasury, and helping a provincial governor administrate his province.
- quay** A wharf built parallel to the shoreline.
- quern** A smooth stone used as a surface for grinding grain.
- quetzal** A bird indigenous to Guatemala with feathers greatly favored for making ancient ceremonial garments.
- quinoa** A pseudograin, consisting of the seeds of a herb from the goosefoot family and used by ancient Mesoamericans in making bread.
- quinquireme** A large multi-oared vessel; the oars are thought to have been arranged in sets of three, with two men pulling each of the top two oars.
- quotidian** Relating to common, everyday life.
- radiocarbon dating (carbon-14 dating)** A method that relies on the carbon-14 isotope (a specific form of carbon), which has a predictable rate of decay over time, to date historical artifacts based on the amount of carbon-14 remaining within a particular sample
- raised relief** A form of stone carving where the background is cut away, leaving the figures to stand out from the surface of the stone.
- raja** Indian title of nobility.
- rampart** A raised fortification resembling a wall and surrounding a township or other area to be protected.
- rebate** A continuous rectangular recess along the top or bottom edge of the face of stonework.
- recession agriculture** A way of scheduling agricultural production by planting crops after the recession, or receding, of annual floodwaters in a river valley.
- reciprocity** Type of exchange that takes place between two individuals when neither is dominant.
- rede** A Germanic word meaning "leadership" or "governance," especially if favored by the gods.
- regent** Someone who rules in a monarch's stead, especially when the monarch is a child.
- regimen** Lifestyle, largely diet and exercise, prescribed by ancient Greek physicians to treat ill health.
- reincarnation** The rebirth of a soul into a new human being (or other creature).
- relics** Objects venerated by Christians, often fragments of a saint's body or objects related to a saint's martyrdom or life.
- relief** Artwork that projects outward from a flat background; a coin, with its raised forms, is a common example of relief work.
- rendered** Melted; used in connection with animal fats melted for use as fuel.
- repoussé** A method for creating designs in relief on metal by hammering on the reverse side.
- retentura** The quarters of ordinary soldiers and cavalry, placed at the rear of a Roman fort or camp.
- retiarus** Gladiator armed with a net; from the Latin for "net."
- reticulum** A pattern of stones or bricks laid into a wall in regular, rectangular blocks.
- retting** A process in which fibers that make up the stems of certain plants, such as jute and flax, are detached from their woody core by soaking the fibers in water for several days.
- reverse** The "tails" side of a coin, with a wide range of design types and images.
- revetment** A decorative thin slab of stone, or facing, on a wall.
- rhetor** In ancient Rome, a teacher of public speaking.
- rhetoric** The study of principles and techniques that aid in the effective presentation and defense of a line of reasoning; also simply eloquence in speaking.
- rhizome** An elongated, underground (or underwater) horizontal stem from which roots and shoots emerge.
- rhizotomoi** Pharmacists or herbalists (literally "root cutters") in ancient Greece.

- rites of passage** Rituals used within a community to mark the transition of individuals from one status to another, including weddings, funerals, and rituals of initiation.
- river ordeal** A method used in the ancient Near East to reach a verdict when all else failed; the accused was thrown into a river, being judged innocent if he or she survived and guilty if drowned.
- rock gong** A large rock that produces a resonant tone when struck.
- Romanitas** A sense of belonging to a great empire felt by many of the conquered peoples of the Roman Empire.
- Romanization** The process of culturally changing foreigners into Romans.
- rondo** A piece of music that has a central theme repeated between contrasting sections.
- rope stretchers** Ancient Egyptian land surveyors who used essentially modern surveying tools to remeasure individual property lines on the farmland washed free of all distinguishing features by the annual Nile inundation.
- rudder** A large paddle at the rear of a vessel that is manipulated in order to steer the vessel.
- rudus** Mixture of components such as sand, soil, clay, or concrete, which is used as a foundation for a Roman road.
- runes** Form of writing in ancient Germany and medieval Scandinavia.
- rushes** Marsh plants with hollow stems.
- rushlight** A type of early candle, consisting of the pith of a stalky plant stem soaked in oil.
- sacred barks** Boats that carried the shrines of the gods in ancient Egypt.
- sakkia** An Egyptian animal-powered waterwheel.
- salient** A segment of the wall that projects outward from the wall.
- salting** A method of drying and preserving food.
- san** An ancient Chinese jacket.
- sand-core technique** Threads of molten glass are wound around a shaped core of sand; after the glass hardens, the sand is removed.
- sapper** Engineer used to undermine or dismantle walls.
- saqiya** A waterwheel powered by a domestic animal, used to collect water in buckets and raise it to an irrigation ditch or container, used in ancient Egypt and the Near East.
- sarcophagus** A coffin made of stone, often decorated with relief sculpture.
- sari** A long, wrapped Indian garment.
- sarisa** The long Macedonian spear, an innovation of Philip of Macedon.
- sarongs** Long pieces of cloth that are wrapped around the body.
- saros cycle** A period of about 18 years after which eclipses of the sun and moon reoccur.
- sastras and sutras** Books of rules for conduct that formed the foundation for ancient Indian law.
- satire** Verse, prose, or a combination of the two that with humor, and sometimes harshness, criticizes bad behavior, hypocrisy, and other failings of society.
- satrap** A political office in the Persian Empire and later in the eastern kingdoms ruled by the successors of Alexander the Great.
- satrapy** A Persian province, administered by a royally appointed governor, who was known as a satrap.
- Saturnian** A native Roman poetic meter that was composed of two feet separated by a caesura, or pause, and that fell out of fashion in the late third century B.C.E.
- satyr play** An ancient Greek farce on a mythological subject, with a chorus representing satyrs, deities that have characteristics of horses or goats.
- satyr** A mythological creature that is usually part man and part goat, known for excessive drinking and lechery.
- savanna** A flat tropical or subtropical grassland.
- scale armor** Armor named for its resemblance to fish scales and made by sewing small oblongs of bronze or iron to a linen or felt shirt.
- scale** In music, a series of notes differing in pitch, varying with the frequency of vibration.
- scarab** A beetle used as a charm to ward off evil.
- scarification** Deliberate scarring of skin to create decorative patterns.
- schenti** A fabric loincloth or skirt.
- schistosomiasis** Parasitic infection acquired by immersion in water containing a certain species of worm; infection can result in fever, fatigue, serious anemia, and even liver damage.
- scop** Anglo-Saxon bard.
- scoria** Light volcanic ash that was used to extend concrete and make it capable of supporting longer arches and vaults.
- scribe** A man of letters in the ancient world who was capable of writing and who often worked as a teacher, a copyist, or a public official in the capacity of a clerk.
- script** A handwritten language.
- scrivener** A professional copyist or scribe.
- scutum** A rectangular or cylindrical shield.
- scytale** An encryption device consisting of rods and leather straps.
- seal** A carved piece of stone pressed into moist clay to leave an image that would be preserved when the clay was fired.
- secondary burial** Burial (or reburial) of bones from which the flesh has already decomposed. This practice implies that the corpse was originally buried elsewhere or exposed aboveground deliberately to reduce it to bones.
- sedentary pastoralism** A herding economy practiced by people living in permanent settlements.
- sedentism** A culture's shifting from living in nonpermanent settlements to living in permanent settlements.
- sediment core** A sample of layers of sediment, taken from lake bottoms or dry lands using a long cylinder, for the

- purpose of studying past environmental or human conditions
- sedimentary rock** Rock formed from sediment that has drifted down and settled in a seabed.
- seine** A fishing net that hangs vertically in the water via floats at the top and weights at the bottom.
- seismic** Relating to an earthquake.
- selvedge** Edge of a textile created by the looping of the weft around the warp.
- senator** The highest-ranking Roman class, consisting essentially of former magistrates. Their wealth lay in land, since they were banned from engaging in trade.
- senyu** In ancient Egypt, a weight in silver equal to one-half deben, or 1.75 ounces.
- sepulchre** A tomb.
- serf** A category of dependent person attached to the soil.
- sericulture** The breeding and raising of silkworms.
- serpentine** A soft, blue-green stone, sometimes used by the Olmec as an apparent substitute for more valuable jade.
- sesterti (pl. sestertii)** A Roman coin, made of silver or bronze, equal to one-fourth of a denarius.
- sexagesimal** In a mathematical system, relying on the base number 60.
- sexireme** A ship with six rows of oarsmen.
- sextant** A navigational device used measuring angles to a celestial body as a way to calculate, with a calibration of 60 degrees.
- shabiti (pl. shabitti)** Small figure placed in an Egyptian tomb used as a substitute workman in case the spirit of the deceased is called on to do work in the afterlife.
- shaduf** A tool for irrigation made of a long branch or pole on a frame, with a bucket at one end and a counterweight at the other, allowing the operator to lower the bucket into the water and then easily raise it out with the help of the counterweight.
- shaman** A person who acts as intermediary between the natural and supernatural worlds, using magic or sorcery for purposes of healing, divination, and control over natural events.
- shed rod** A stick that separates warp threads into over-and-under groups.
- sheet bronze** Bronze that has been beaten or compressed into a thin sheet, which can then be fashioned into tubular and other shapes.
- shemu** The “drought season,” one of three seasons in the Egyptian calendar, based on the stages of the Nile’s transformation.
- shinty** A game resembling field hockey and dating to ancient times in the British Isles.
- sibbe** An ancient Germanic clan.
- sickle sword** A sword with a blade that curves so that it resembles the sickle used in harvesting crops.
- sidelock of youth** A long ponytail, worn to one side by youngsters.
- sidereal** Having a relation to or based on the stars.
- silt** Sand or earth, usually fine grained, carried by flowing water and then deposited.
- singlet** A loose shirt made of one layer of cloth.
- sirocco** A warm, moist Mediterranean wind.
- sistrum** (pl. sistra) An ancient Egyptian hand-held percussive musical instrument consisting of a handle and a U-shaped frame with crossbars holding loose rings that would jangle or tinkle when the instrument was shaken.
- situla (pl. situlae)** A bronze vessel, similar to a bucket.
- skene** A rectangular building with one to three doors at the rear of the Greek stage, often representing a house, palace, military tent, cave, or other enclosure.
- skyphos (pl. skyphoi)** A deep, two-handled cup.
- slag** What remains after ore is smelted and metal is removed.
- slash-and-burn agriculture** The practice of felling and burning trees to clear land for planting.
- slip** A thick clay-based liquid coating applied to the surface of a ceramic vessel, either for decorative purposes or to make the vessel surface less porous.
- smallpox** A highly contagious and deadly viral disease that produces fever and skin eruptions.
- smelting** A method of separating metal from surrounding rock or soil through heating or mixing with chemicals; also the process of heating and transforming mineral ores into more refined and usable finished metals and alloys.
- social stratification** The division of people into classes; from the word *strata*, meaning “layers.”
- socket ax** A battle-ax with a bronze or iron head possessing a socket that slips over the end of the ax’s handle to which the head is fastened with a rivet.
- soil resistivity testing** Detecting changes in the electrical resistance of the soil in order to find the remains of structures hidden beneath the ground.
- solar calendar** A calendar that bases a year on the time it takes the earth to complete one revolution around the sun.
- solar year** A year based on the time it takes the earth to complete one revolution around the sun; a calendar year of 365 days.
- solar zenith passage** The day of the year when the sun passes directly overhead and casts no shadow on vertical objects.
- solstice** The point at which days are longest or shortest, depending on the earth’s tilt to its orbital plane. The winter solstice occurs in December in the Northern Hemisphere and in June the Southern Hemisphere, and the summer solstices are the reverse.
- sophistēs** A sophist, or professional teacher of rhetoric in ancient Greece; literally “professional wise person.”
- sorghum** A cereal grain crop.
- sound box** On a stringed instrument, the hollow shell that amplifies the sound of the strings.
- southern** Underground chambers lined with stone.

- spar** A pole used for support on a watercraft.
- speakers of the laws** Legal specialists in the Persian Empire who explained the ins and outs of the law to those involved in court cases as well as helping to conduct those cases.
- spear thrower** Also called by its Aztec name, *atlatl*, a weapon used as an extension of the thrower's arm to add force and speed to a hurled spear or dart.
- spelt** A kind of wheat (*Triticum aestivum spelta*).
- sphere of influence** and **sphere of interest** A means of reserving a portion of territory from the political interference of another state; *interest* is assumed to be a less significant claim than *influence*.
- spillway** A channel carrying water around an obstruction.
- spindle whorl** A circular object that weights a spindle for spinning to improve rotation.
- spindle** A pointed stick about 12 inches long, used for spinning.
- sprang** Stretchy fabric woven of intertwined warp threads only.
- squinch** A small arch built across the interior angle of two walls.
- stadion** A term denoting both the rectangular ground upon which the Greeks ran in competition and the name of a race covering one length of this track.
- stalactites** Mineral deposit, often shaped like a spike, hanging down from the ceiling of a cavern.
- stalagmites** Mineral deposit, often shaped like a spike, pointing up from the floor of a cavern.
- standard** A wooden pole surmounted by an image used to represent a town or province in Egypt.
- stasis** A political faction in Greece, or the strife caused by such a faction.
- statics** The branch of mechanics dealing with weights in static equilibrium.
- statumen** Mixture of stones used as a foundation for a Roman road.
- steganography** A writing system used for hidden messages; the message is literally hidden from readers other than the intended recipient.
- stela (pl. stelae)** A carved stone slab, usually installed vertically and used to commemorate an event or person.
- steppe** A vast treeless grassland
- stepped fret** A zigzag form resembling a mountain, especially the terraced mountainsides of the Andes—a prominent feature in later Andean art and a symbol of prestige.
- stereometry** The measurement of solid figures or volumes.
- stoa** A narrow hallway often found in the commercial districts of Greek towns, with an open colonnade, where merchants set up shops.
- stola** The long garment worn by married Roman women over the tunic.
- strategos** “General,” one of the few elected officials in democratic Athens, with authority that often extended beyond military matters.
- stratification** Division of people into social groups or classes
- strut** Bar used to draw weight down to a central point.
- stucco** A fine plaster used to cover walls.
- stupa** A dome-shaped mound serving as a Buddhist shrine.
- stylus** An instrument, often made of reed, used by the ancients for incising or inscribing on clay or wax tablets.
- suasaria** In Roman rhetoric, an argument made to justify or condemn a course of action.
- subligaculum** Also called a *campestre*, a garment worn under the tunic and toga as underwear and as a sports garment.
- subsistence farming** The practice of agriculture that provides enough food to eat without an excess for sale.
- suffets** Nonroyal magistrates who were granted control over a Punic city-state.
- sumptuary laws** Laws designed to limit excessive consumption or use of luxury goods.
- sunk relief** A form of stone carving where the background is left as it is and the figures are carved into the stone.
- supernova** A star's explosion, producing an exponential increase in its luminosity.
- surface mining** The process of harvesting useful stone and metals at above-ground sites, such as hillsides, and where drilling underground is not necessary or desirable.
- swastika** A pattern resembling a cross with each arm bent at a right angle, an ancient Hindu symbol (also used by Buddhists and Jains); the term is derived from the Sanskrit word for “well-being.”
- swidden** An area cleared for temporary cultivation by cutting and burning the vegetation.
- sykophantes** In the legal system of ancient Athens, a class of professional prosecutors.
- syllabary** A written set of symbols that represent syllables.
- sympathetic magic** Magic that looks to achieve its ends through imitation of the desired results.
- symposium** A drinking party for Greek aristocrats featuring wine, games, poetry, and conversation.
- synodic cycle** The lunar phase cycle of 29.5 days.
- synoecism** In ancient Greece, the amalgamation of villages and towns into a larger unit.
- synoikiai** In ancient Greece, blocks of apartment buildings.
- syntax** The grammatical arrangement of words in a sentence.
- syssitia** In ancient Greece, military-style messes or eating clubs to which every Spartan citizen belonged.
- syumuu** In ancient Egypt, the dry season from March to July, literally meaning “the drought.”
- t'un-t'ien** Military colonies set up by the ancient Chinese.
- tabby weave** A type of weave in which a single thread from the weft passes over and under one warp thread at a time.
- tablinum** A “home office” for the head of household in a Roman home.

- taboos** Practices or objects that are forbidden or banned because of social custom or religious practices.
- talent** The largest unit of weight and money in the ancient world, variously defined as a man's weight in gold or the amount of gold one man could carry; in ancient Greece, a specific weight of metal equivalent to 60 minas, or 6,000 drachmas.
- tallow** Animal fat.
- Talmud** The Jewish book of law and scriptural commentary.
- talud-tablero** A system of construction generally associated first with the city of Teotihuacán in ancient Mesoamerica; facades are formed by vertical panels alternating with sloped and diagonal ones.
- tang** A narrow projection by which a tool, typically a knife, is attached to its handle.
- tanning** The process of drying, curing, and dyeing leather for use in clothing, armor, and shoes.
- taper** A slender candle.
- taproot** A primary root that sends out offshoots.
- tarentine** A thin, almost transparent white gown worn by the ancient Greeks.
- taro** A large-leaved plant that is typically cooked as a vegetable or ground into flour.
- tartan** A cloth woven in a plaid or checked pattern.
- tebenna** A short, semicircular woolen mantle worn by the Etruscans and which was the forerunner of the Roman toga.
- techné** Greek term meaning "art," "craft," or "expertise" and the root of such words as *technical* and *technology*.
- tectonic plate** One of seven major pieces of the earth's crust that moves slowly over the mantle.
- tell** An ancient mound built up from the remains of earlier settlements.
- templum** Any sacred area (not necessarily a building) in which ancient Roman priests could conduct rituals of augury, or foretelling of the future.
- teosinte** The plant from which early Americans bred maize, or corn.
- terra sigillata** Ornate red pottery favored in and around the Roman Empire.
- terrace** A "step" cut into the slope of a hill, providing a flat place for farming or building.
- terra-cotta** A hard fired clay used in pottery, sculpture, and building decoration.
- tessera (pl. tesserae)** One of the small pieces of stone, ceramics, or glass used in making mosaics.
- tetrachord** The building block of Greek melodic theory, consisting of four notes, with the top and bottom note forming an interval of a fourth.
- tetradrachm** In ancient Greece, coin equal to four drachms, issued under several different weight standards.
- tetrarchy** Rule by four people.
- thalassocracy** Maritime dominance or supremacy.
- thatch** Roofing made of grasses or leaves.
- theocracy** A government or political system based on the rule or religious authority of a god or gods and their human representatives (such as kings and priests), as found in the ancient Near East.
- theriac** A medicine used by the ancient Romans as an antidote to poison and a cure-all or preventative against numerous diseases.
- thermae** Public bathhouses, found in all Roman cities.
- thermoluminescence** A process of measuring the age of an object, often used for ceramic objects between 10,000 and 300 years old to determine their authenticity.
- thermopolium** A shop in an ancient Roman city where people could buy hot wine and food.
- tholia** A high, pointed hat worn by ancient Greek women.
- tholos** A circular building used for religious purposes in ancient Greece.
- thronos** A solid, upright chair with armrests, usually found in ancient Greek temples or palaces.
- throwing knife** Multibladed weapon without a solid hilt and with one plain, flat side and one decorated or embossed side.
- tidal bore** A wave that travels from the ocean up a river.
- tin foil** A thin sheet of tin used as a wrapping.
- titulus crucis** The *elogium* (headboard) attached to the cross above someone who has been crucified, stating the offense the person committed; specifically, the headboard above Jesus, with the inscription *Jesus of Nazareth, King of the Jews*.
- toga** The rounded, woolen mantle worn by Roman citizens.
- Torah** The Jewish book of scripture, generally referring to the first five books of the Old Testament.
- torque** Circular bar worn around the neck as jewelry by ancient Celts and Germans.
- torsion catapult** A launching device that derives its power from the twisting of ropes or wooden elements of the frame.
- transhumant pastoralism** A system in which some members of the community migrate with herds to distant pastures on a seasonal basis while most remain sedentary and focus on agricultural activities.
- transliterate** To reproduce in English letters the sound of a word's original pronunciation in another language.
- transmigration** The movement of a dead person's soul into the body of an already existing living person.
- trapeza** A four-legged table used by the ancient Greeks.
- trappings** Clothing, jewelry, and symbols of office.
- trepanning** An ancient European medical practice that consisted of sawing or drilling a hole in the skull to treat head or psychological disorders.
- tribe** Group of people related by lineage, kin, or clan with or without centralized leadership.
- tribon** A coarse, dark-colored wrap worn by the ancient Greeks.
- tribulum** A device to thresh grain, consisting of a heavy board with flints or small wheels on its underside.

- tribunal** The raised platform at one end of a basilica from where a judge or other magistrates presided over a hearing or tried legal cases.
- tribune** An elected representative of the plebeians of Rome.
- tribute** Goods, labor, or payment offered to the ruling classes, usually by obligation, in exchange for their rulership.
- triclinium** A Roman dining room containing three couches on which men reclined to eat.
- trilithon** A megalithic structure made of two large vertical stones supporting a horizontal stone laid across the top.
- trireme** An ancient ship with three rows of oars on each side.
- trittys** Political division in Athens consisting of several contiguous demes.
- trypanosomiasis** A disease caused by parasitic single-celled organisms generally transmitted by insect bites; the form popularly known as “sleeping sickness” is transmitted by tsetse flies.
- tsetse fly** A fly that spreads diseases among cattle and humans, including sleeping sickness.
- tsunami** A giant wave or series of waves created by earthquakes, volcanic eruptions, or other major impact to an ocean.
- tubers** Rounded roots, such as the potato, that grow underground.
- tufa** Soft volcanic rock that was frequently used as a filler or as facing stone in Roman buildings.
- tumbaga** An alloy of gold and copper used by the ancient Peruvians.
- tumulus (pl. tumuli)** An artificial mound built, in ancient Europe, usually over the remains of the dead; also called a *barrow*.
- tundra** A vast, cold, treeless plain characteristic of arctic and subarctic regions.
- tunic** A T-shaped garment with openings at the top for the head and arms.
- turf** Sod; a mat of grass and its roots.
- tuyere** Nozzle through which air is delivered into a furnace.
- twill** Fabric threads interwoven to give the cloth a parallel diagonal, diamond shape or herringbone ridges on the surface.
- typhoon** A hurricane occurring in the western Pacific region.
- typology** Within the discipline of historical linguistics, the characteristic of surface structural similarity.
- tyrannos (pl. tyrannoi)** In ancient Greece, sole ruler without hereditary claim to the throne; the word sometimes has negative connotations but less so than the English word *tyrant*.
- Tyrian purple** An ancient dye made from the secretions of marine snails and very highly valued throughout the ancient Mediterranean world.
- Tzolkin** Mayan sacred calendar based on a 260-day ritual cycle.
- unguent** A medicinal or cosmetic ointment.
- univira** A matron who had the honorable distinction of having married only once in her life and not having divorced.
- untouchables** People without caste in India, the lowest social group.
- urbs** Latin word for “city.”
- ushabtis** In ancient Egypt, small figurines that were buried with the dead to accompany them into the underworld and work for them in the afterlife.
- uttariya** A scarf that covered the upper body, worn by ancient Indians.
- vallus** Ancient Roman reaping machine pulled by an animal and used to cut off the heads of wheat stalks and drop them in a container.
- varna** Associated with Hinduism; the name in India for the original social division of people into four main groups, which in turn contain thousands of subdivisions.
- vassal** A person, nation, or group that is dependent on or subordinate to another.
- vault** An arched brick or stone ceiling or roof.
- Vedic laws** Legal codes based on religious texts, such as the sacred writings of Hinduism.
- vela** A linen awning covering a Roman theater; sometimes called a *velarium*.
- vellum** A special kind of leather used to make sheets for writing. In general this was more prestigious and expensive than papyrus.
- venatio** Beast hunts that were conducted as a spectator sport in ancient Roman amphitheaters.
- venator** Hunter in a staged wild-animal hunt in the Roman arena.
- veneer** Thin strips of decorative wood applied to the surface of an object to hide a wood of less aesthetic value or to mask imperfections.
- vestal virgins** The priestesses of the Roman hearth goddess, Vesta, who were required to be virgins and entrusted with keeping a sacred flame burning in Vesta’s temple.
- vigesimal** Referring to a number system based on 20.
- vihara** In Indian architecture, a small building consisting of cubicles arranged around a central courtyard, used by monks and visitors to meditate and do penance.
- villa** A self-sufficient community, including a residential building, gardens, workshops, and cultivated fields.
- viticulture** The science of growing grapes.
- vivisection** The cutting open of a living being for the investigational or diagnostic purposes.
- vizier** In ancient Egypt, the highest-ranking government official after the pharaoh.
- volute** A type of spiral scrollwork.
- votive** Given or done in fulfillment of a vow or pledge.
- wabet** The workshop in which bodies were embalmed before burial in ancient Egypt.
- warp** In weaving, the threads that run lengthwise.

- warp-weighted loom** A rectangular, upright loom with the warp hanging from the top crossbar and anchored by weights on the free ends.
- wattle and daub** A method of building construction that involves a wooden lattice structure covered with packed mud, clay, and other materials.
- wedge** To stamp on clay to remove air pockets and impurities.
- weft** In weaving, the threads that run crosswise.
- weir trap** A cone-shaped wicker basket with an internal funnel.
- weld** A plant used to make yellow dye.
- well-field system** During the Chinese Zhou Dynasty, the territory controlled by a duke and divided into nine equal portions arranged in a square; the commoners worked all the land, but the produce of the center square belonged to the duke.
- were-jaguar** An Olmec sculptural figure combining human and jaguar traits.
- wet nurse** A woman who nurses another woman's infant in exchange for wages.
- whorl** A pulley that helps to rotate a spindle.
- wick** A short length of cloth or fiber that draws fuel oil from a reservoir by capillary action and then can be burned to provide a steady light.
- wickerwork shield** A shield made from woven reeds or twigs supported by a wooden frame.
- wisdom literature** Ancient Egyptian texts that consist of either instructions or philosophical dialogue.
- woad** A plant used to make blue dye.
- wuxing** The five elements of ancient Chinese philosophy and science: fire, earth, water, wood, and metal.
- xenia** Greek word usually denoting the relationship between host and guest.
- xenos** Greek word meaning, variously, "foreigner," "stranger," or "guest-friend."
- xoanon** One of a set of wooden cult objects venerated in ancient Greece for the deities that they represented.
- yakshi** In India, a female supernatural being who guards the earth's mineral treasures.
- yang** In Chinese philosophy, the form of energy that supposedly is hard, bright, active, and "male."
- yaws** A bacterial skin infection marked by red skin eruptions and joint pain.
- yin** In Chinese philosophy, the form of energy that supposedly is soft, dark, receptive, and "female."
- zaliths** Members of an assembly who governed an Etruscan city-state.
- zenith** The point on the celestial sphere directly above the place on which the observer stands and opposite the zenith.
- ziggurat** In ancient Mesopotamia, a pyramid-shaped tower rising in stages of decreasing size to a shrine at the top.
- zooarchaeology** A field of science that has to do with uncovering, identifying, and interpreting animal remains in archaeological contexts.
- zoomorphic** Having animal attributes or an animal form.
- zori** A Japanese sandal that resembles modern flip-flops.

prehistory – 10,000 B.C.E.

10,000 B.C.E. – 5000 B.C.E.
(continues)

AFRICA

Ca. 2 million years ago: *Homo erectus* emerges and spreads to Asia and Europe

ca. 1 million–500,000 years ago: *Homo erectus* gains the ability to make fire

ca. 200,000–100,000 years ago: *Homo sapiens* emerges and spreads to Europe and Asia.

ca. 27,500–ca. 25,000 B.C.E.: Date of the earliest-known rock art in Africa, found in eastern and southern Africa and produced by the San.

ca. 11,000 B.C.E.: Beginning of the African Humid Period, a period of warmer and wetter weather on the African continent.

ca. 9000 B.C.E.: New Stone Age begins in Egypt.

ca. 8500 B.C.E.: The harpoon is developed in present-day Sudan, allowing for the exploitation of deepwater fish.

ca. 7700 B.C.E.: Nile Valley forms part of the Fertile Crescent.

ca. 7500 B.C.E.: Egyptians first begin using reed boats; earliest-known African pottery is produced in the Sahara.

ca. 6000 B.C.E.: Onset of dry conditions begins the desertification of the Sahara.

THE MIDDLE EAST

ca. 10,000 B.C.E.: Emergence of Natufian culture in the Middle East, to the west of the Euphrates River; establishment of the town of Abu Hureyra in present-day Syria; earliest firm evidence of domesticated dogs from a grave in Palestine.

ca. 11,000 B.C.E.: As the glaciers retreat, fields of wild grain begin to appear in the Near East.

ca. 10,000 B.C.E.: Hunter-gatherers begin to domesticate the goat.

ca. 9000 B.C.E.: The New Stone Age begins in Mesopotamia.

ca. 8000 B.C.E.: Agriculture begins in the Near East; farmers use sticks to scratch up the earth to plant grains; thick beer (“drinkable bread”) first brewed in Mesopotamia by the Sumerians; clay tokens first used for counting purposes in Mesopotamia.

ca. 7700 B.C.E.: Milk from ewes (sheep) used widely as a food source in Near East.

ca. 7500 B.C.E.: Reed boats come into use in Mesopotamia.

ca. 7000 B.C.E.: Emmer wheat becomes a major food crop in portions of the Middle East.

Chronology by Region

ASIA AND THE PACIFIC

ca. 42,000 B.C.E.: The first seafaring colonists arrive in Australia from the Asian mainland.

ca. 28,500 B.C.E.: Seafaring colonists from Australia or the Asian mainland arrive in New Guinea.

ca. 27,000 B.C.E.: The first people arrive on the islands of Japan over land bridges or ice from the Asian mainland.

ca. 13,000–300 B.C.E.: Jōmon Period of Japan.

ca. 9000 B.C.E.: By this date people in Siberia and central Asia are using bones and skins from animals such as mammoths to build shelters.

ca. 7000 B.C.E.: Tropical horticulture begins in New Guinea.

ca. 6500 B.C.E.: Farming starts on the Indian subcontinent.

ca. 6400 B.C.E.: Pengtoushan in China is the oldest-known site of rice cultivation in Asia.

ca. 5500 B.C.E.: Beginning date for the earliest paintings in India, found on large stones and rock faces, mostly in central India.

ca. 5400–ca. 5200 B.C.E.: The Yellow River region in China provides the earliest evidence for the domestication of chickens in Asia.

EUROPE

ca. 1,000,000??–ca. 8,000 B.C.E.: Paleolithic Period.

ca. 34,000 B.C.E.: Beginning of the Aurignacian culture in the region of present-day Bulgaria, Hungary, and France.

ca. 25,000 B.C.E.: First human settlements in what is now Spain.

ca. 24,000 B.C.E.: First evidence of cold food storage and preservation, discovered in eastern Europe.

ca. 10,500 B.C.E.: Würm Glacial Age ends; ice withdraws so that humans can move into northern Europe.

ca. 9500 B.C.E.: Ice sheets start to melt in Europe.

ca. 8000–ca. 4000 B.C.E.: Mesolithic Period.

ca. 7200 B.C.E.: Sheep domesticated in the area of present-day Greece.

ca. 7000–ca. 2000 B.C.E.: Neolithic Period; emergence of agriculture, sometimes called the Neolithic Revolution.

ca. 6500 B.C.E.: Ancestor of cattle first domesticated in the region of present-day Yugoslavia.

THE AMERICAS

ca. 18,000–ca. 3,000 B.C.E.: The first Americans migrate from Siberia over the Bering Sea Land Bridge, now the Bering Strait, into present-day Alaska, though this date remains uncertain.

ca. 10,500 B.C.E.: Date assigned to early Clovis points (stone tools such as arrowheads, named after site in New Mexico where the first such points were found) at Monte Verde site in Chile.

ca. 10,200 B.C.E.: Dogs domesticated by earliest Americans.

ca. 9,500 B.C.E.: Date assigned to the first-discovered Clovis points in New Mexico; Clovis culture formed.

ca. 9200–ca. 8000 B.C.E.: Folsom tradition spreads across North America.

ca. 9000 B.C.E.: Bison herds cover the Great Plains of North America; first civilizations develop in the Arctic North.

ca. 8000 B.C.E.: First Americans arrive in South America; Archaic Age begins in North America, with dramatic changes in the landscape caused by receding of glaciers.

ca. 7000 B.C.E.: First cultivation of corn, or maize; agriculture begins to develop in the Americas.

<p>10,000 B.C.E. – 5000 B.C.E. (continued)</p>
<p>5000 B.C.E. – 4000 B.C.E.</p>
<p>4000 B.C.E. – 3000 B.C.E.</p>
<p>3000 B.C.E. – 2000 B.C.E. (continues)</p>

AFRICA

-
- ca. 5000 B.C.E.:** Egyptians first build canals and dikes to irrigate crops.
 - ca. 4500 B.C.E.:** Start of cattle herding in the Sahara.
 - ca. 4400 B.C.E.:** First evidence of use of horizontal loom, depicted on Egyptian pottery.

-
- ca. 4000 B.C.E.:** Beginning date for the cultivation of yam along the Niger River.
 - ca. 3600 B.C.E.:** Beginning of Bronze Age in Egypt.
 - ca. 3500 B.C.E.:** Egyptians develop complete number system.
 - ca. 3100 B.C.E.:** Egyptian hieroglyphic writing emerges.

-
- ca. 3000 B.C.E.:** Egyptians begin to mine copper and develop the first crude paper, made of papyrus; Sahara Desert begins to form in North Africa.
Berbers arrive in North Africa.
 - ca. 2920 B.C.E.:** The start of Egypt's First Dynasty, uniting Upper and Lower Egypt.
 - ca. 2650 B.C.E.:** The first pyramid, the Step Pyramid, built by Imhotep in Egypt.
 - ca. 2575 B.C.E.:** The Great Pyramid of Cheops is constructed.
 - ca. 2400–ca. 1500 B.C.E.:** Kingdom of Karmah in Nubia.

THE MIDDLE EAST

- ca. 6500 B.C.E.:** A primitive plow called the *ard* is used in the Near East.
- ca. 6000 B.C.E.:** Production of wine begins in Mesopotamia and along the eastern shore of the Mediterranean Sea.

-
- ca. 5000 B.C.E.:** People in the valleys surrounding the Tigris and Euphrates rivers domesticate cattle and begin to build irrigation systems for crops.
 - ca. 4500 B.C.E.:** Permanent settlement is established at Ur in Mesopotamia; clay tokens are first used for accounting purposes in Mesopotamia.
 - ca. 4300 B.C.E.:** Turntable for pottery making is invented in Mesopotamia.
 - ca. 4200 B.C.E.:** Copper mining begins in the area of modern-day Oman.

-
- ca. 4000 B.C.E.:** Earliest copper objects appear in the ancient Near East.
 - ca. 3500 B.C.E.:** The Sumerians begin crafting tools out of bronze, a mixture of copper and tin, initiating the Bronze Age, which begins to reach its height in about 2000 B.C.E.; Sumerians also start to use wheeled vehicles pulled by animals.
 - ca. 3400 B.C.E.:** Earliest form of cuneiform script is devised to record the language used by the ancient inhabitants of Uruk in southern Mesopotamia.

-
- ca. 2800 B.C.E.:** The sickle is invented by farmers in Sumer.
 - ca. 2750 B.C.E.:** The Phoenician city of Tyre emerges as a great sea power.
 - ca. 2500 B.C.E.:** Beginning of the Iron Age in the ancient Middle East.
 - ca. 2400 B.C.E.:** The Babylonians first use the abacus for computation; Sumerians first use "positional notation," where numbers take their value depending on their position in a numerical group.
 - ca. 2350 B.C.E.:** The Old Akkadian Empire begins rule of Mesopotamia.

ASIA AND THE PACIFIC

ca. 5000 B.C.E.: Longshan culture emerges in China.

ca. 4500 B.C.E.: China domesticates the water buffalo.

ca. 4000 B.C.E.: The people of the Indus Valley in India are cultivating a wide variety of crops, including dates, mangos, wheat, barley, and peas, using irrigation systems to water the crops.

ca. 3000 B.C.E.: People in the Indus Valley begin to weave fabric out of cotton; the Chinese begin to manufacture silk.

ca. 2900 B.C.E.: In China the mythical emperor Fu Xi develops the concept of yin and yang, fundamental to the practice of ancient Chinese medicine and the Chinese view of nature.

ca. 2700 B.C.E.: Mythical Chinese emperor Shennong develops the principles of acupuncture; tea is first used as a beverage in China.

ca. 2600 B.C.E.: Long-distance trade, particularly in luxury goods, develops among the nations of Southeast Asia; the major Indian cities of Harappa and Mohenjo Daro are founded.

ca. 2300 B.C.E.: Rice from the Indus Valley is introduced in northern China.

ca. 2296 B.C.E.: Chinese astronomers make the first recorded sighting of a comet.

EUROPE

ca. 5000 B.C.E.: Southeast European plains populated by agriculturalists.

ca. 5000–ca. 900 B.C.E.: Rock faces in Alps carved with figures of animals, warriors, and buildings.

ca. 4500–ca. 3500 B.C.E.: Europeans begin to use pottery with linear ornamentation.

ca. 4350 B.C.E.: Horses first domesticated in Europe and used for power.

ca. 3400–c. 1600 B.C.E.: Earliest evidence of wheeled vehicles in Europe (from a grave in Poland).

ca. 3200–c. 1600 B.C.E.: The “Iceman,” equipped with a cast copper ax, dies while crossing the Alps near the present-day Italian-Austrian border.

ca. 3100–c. 1600 B.C.E.: Construction of Stonehenge megaliths in England.

ca. 3000 B.C.E.: The ox-drawn plow first used in Europe

ca. 2800 B.C.E.: Emergence of the Aegean Sea civilizations on Minoan and Crete, precursors of the Greeks.

ca. 2800 B.C.E.–ca. 700 B.C.E.: Bronze Age, marked by use of bronze tools.

ca. 2500 B.C.E.: Horses are introduced to Ireland.

ca. 2400 B.C.E.: People of the Beaker culture begin migration from Spain to France, Germany, and Britain.

THE AMERICAS

ca. 6000 B.C.E.: The Coahuiltecan culture forms in Texas; North American population groups become more settled, and cultural differences begin to emerge.

ca. 5000 B.C.E.: Cochise culture forms in Arizona and New Mexico.

ca. 4800 B.C.E.: Peoples from the Central American mainland become the first inhabitants of the Caribbean.

ca. 4300 B.C.E.: A variety of cotton is produced in the area of present-day Mexico.

ca. 4000 B.C.E.: First permanent shelters constructed in the North American Midwest; corn is domesticated in Mexico; llamas and alpacas are domesticated in the region of present-day Peru.

ca. 3000 B.C.E.: Early Alaskans begin to construct permanent villages; artwork produced by Native Americans begins to appear; Andes peoples of South America first cultivate potatoes; adobe pyramids built at Caral and El Aspero in modern-day Peru.

ca. 2600 B.C.E.: First temple mounds are constructed in Peru.

ca. 2500 B.C.E.: North Americans begin to make pottery; village cultures become predominant in the Americas.

ca. 2475 B.C.E.: Maize is domesticated and becomes a staple crop.

3000 B.C.E. – 2000 B.C.E.
(continued)

2000 B.C.E. – 1000 B.C.E.

1000 B.C.E. – 500 B.C.E.

AFRICA

ca. 2000 B.C.E.: Date assigned to the remains of cities in Mauritania, Africa's oldest cities.

ca. 2000–ca. 1000 B.C.E.: Emergence of Bantu language and its spread throughout much of Africa in what is called the Bantu Migration.

ca. 1700 B.C.E.: Date of the world's oldest mathematical document, on Egyptian papyrus.

ca. 1400 B.C.E.: Africa passes directly from the Stone Age to the Iron Age, skipping the Bronze Age important in other world cultures.

ca. 1380 B.C.E.: Egyptians complete construction of a canal linking the Nile River and the Red Sea.

ca. 1323 B.C.E.: Death of Egypt's King Tutankhamen.

ca. 1000–ca. 100 B.C.E.: The kingdom of Kush flourishes in Sudan.

ca. 800 B.C.E.: North African city of Carthage founded by the Phoenicians.

ca. 600 B.C.E.: The Sahel, south of the Sahara Desert, emerges as the site of numerous cities along an east–west trading route; Phoenician seafarers circumnavigate Africa.

ca. 580 B.C.E.: Africans first produce iron, in Meroë.

THE MIDDLE EAST

ca. 2000 B.C.E.: The Epic of Gilgamesh, written in cuneiform, is the world's oldest epic poem; its story of a great flood and an ark is believed to be the origin of the story of Noah's flood narrated in the biblical book of Genesis.

ca. 1800 B.C.E.: First taboos against eating pork develop in the Near East.

ca. 1850 B.C.E.: Judaism is founded by Abraham, a Mesopotamian prince.

ca. 1750 B.C.E.: Babylon's king Hammurabi dies.

ca. 1700 B.C.E.: Syria and Palestine develop the first alphabet; windmills first used by Babylonians.

ca. 1275 B.C.E.: Beginning of the 40-year-long Israelite migration from Egypt to the Near East, commonly called the Exodus and recorded in the Old Testament book of the same name.

ca. 1141 B.C.E.: The Jewish Ark of the Covenant is seized by the Philistines.

ca. 1124 B.C.E.: Nebuchadnezzar I becomes king of Babylon.

961 B.C.E.: The Great Temple of Jerusalem is constructed under the leadership of King Solomon.

ca. 800 B.C.E.: Babylonian astronomers discover how to predict lunar eclipses.

ca. 700 B.C.E.: Cities in the Near East build aqueducts to provide water to their populations.

ca. 689 B.C.E.: The Assyrians destroy the city of Babylon, but the city is rebuilt and in the next century is one of the great cities of the world.

ca. 600 B.C.E.: The religion Zoroastrianism found by Zoroaster in Persia.

ca. 587 B.C.E.: The Great Temple of Jerusalem is destroyed by Nebuchadnezzar; temple is rebuilt ca. 516 B.C.E.

ASIA AND THE PACIFIC

ca. 2205 B.C.E.: The Chinese become the first civilization to mill grain; sheep, oxen, dogs, pigs, and goats first domesticated in China.

ca. 2000 B.C.E.: Horses are first tamed by nomads on the Asian steppes.

ca. 1750 B.C.E.: In India two major historic cities, Harappa and Mohenjo Daro, collapse.

ca. 1500 B.C.E.: Aryan nomads arrive in India from the steppes of Eurasia, bringing with them cattle and sheep; Chinese begin to use vehicles drawn by horses.

ca. 1400 B.C.E.: China domesticates first poultry, the jungle fowl from Malaya.

ca. 1300 B.C.E.: Date assigned to the first evidence of Chinese writing.

ca. 1100 B.C.E.: The Chinese invent the crossbow and the kite and begin using ice for refrigeration.

ca. 1045 B.C.E.: Zhou Dynasty founded in China; the dynasty will last until approximately 256 B.C.E.

ca. 1000 B.C.E.: Polynesian expansion across the Pacific Ocean reaches Samoa and Tonga.

ca. 876 B.C.E.: The concept of zero first introduced in India.

ca. 700 B.C.E.: China introduces the concept of crop rotation.

ca. sixth century B.C.E.: Confucianism developed in China by philosopher Confucius (Kong Fuzi).

ca. 600 B.C.E.: The Upanishads, texts of Hinduism, are compiled in India.

ca. 565 B.C.E.: The Chinese philosopher Laozi founds the religious philosophy of Daoism.

ca. 528 B.C.E.: The religion of Buddhism wins its first adherents in India.

EUROPE

ca. 2000 B.C.E.: Seafarers from Crete and Phoenicia adopt sails and masts on ships.

ca. 1600 B.C.E.: Arrival of the Greeks in the Aegean region.

ca. 1500–ca. 1000 B.C.E.: Emergence of Celtic cultures in central Europe and the Balkans.

ca. 1470 B.C.E.: Minoan civilization in the Mediterranean Sea destroyed by volcanic eruption.

ca. 1200–ca. 800 B.C.E.: Hallstatt A and B cultures, of the Bronze Age, flourish in the region around present-day Austria.

ca. 1100 B.C.E.: Collapse of Mycenaean civilization; Iron Age begins in Europe, marked by the use of iron tools.

ca. 1100–ca. 750 B.C.E.: Greek Dark Ages.

ca. Eighth–seventh centuries B.C.E.: Homer writes/compiles Greek epics *The Iliad* and *The Odyssey*.

ca. 800–ca. 500 B.C.E.: Halstatt C and D cultures, of the Iron Age, arise in the region around present-day Austria.

ca. 776 B.C.E.: First ancient Olympic Games held in Greece.

ca. 753 B.C.E.: Traditional date of the founding of Rome, although archaeologists have found graves in Rome dating to at least a century earlier.

ca. 650–ca. 500 B.C.E.: Etruscan dominance of Rome, ending with Roman rebellion against Etruscans.

ca. 600 B.C.E.: Capitoline temple built in Rome.

ca. 525 B.C.E.: The Greek philosopher Pythagoras declares that the earth is round.

ca. 509 B.C.E.–ca. first century B.C.E.: Roman Republic.

ca. 508 B.C.E.: Beginning of democracy in Greece.

THE AMERICAS

ca. 2000 B.C.E.: Arctic ancestors of the Inuit begin to use small tools, especially the harpoon.

ca. 1800 B.C.E.: People in Peru first make pottery.

ca. 1600–ca. 1300 B.C.E.: Mounds constructed by peoples along the Mississippi River; best-known mound is Poverty Point.

ca. 1500–ca. 400 B.C.E.: Olmec civilization arises and flourishes in Mesoamerica.

ca. 1200 B.C.E.: The ancient ball game, the oldest-known game in the Americas, originates with the Olmec civilization.

ca. 1000 B.C.E.: Archaic Age ends in North America; cultivation of corn is introduced to North America from Mexico.

ca. 900–ca. 200 B.C.E.: The Chavín culture thrives in Peru.

ca. 800 B.C.E.: Pottery making emerges in Alaska; the temple center of Chavín de Huántar is established in Peru.

ca. 650 B.C.E.: The Maya begin using smoke to cure diseases.

500 B.C.E. – 250 B.C.E.

250 B.C.E. – 0

0 – 250 C.E.

AFRICA

ca. 300 B.C.E.: Carthaginians attain height of power and influence as traders and shipbuilders; date assigned to Namoratunga, a cluster of stone pillars in Kenya that may have served as a calendar; museum and Great Library are founded at Alexandria, Egypt.

ca. 280 B.C.E.: Ptolemy II of Egypt completes a canal between the Mediterranean Sea and the Red Sea.

ca. 264 B.C.E.: Beginning of the Punic Wars between Rome and Carthage.

ca. 250 B.C.E.: Dromedaries are introduced into Egypt.

ca. 200 B.C.E.: Formation of kingdom of Axum in northern Ethiopia.

ca. 146 B.C.E.: Carthage falls to the Roman invaders, marking the end of the Third Punic War.

ca. 100s C.E.: The Bantu use iron utensils for cooking, iron spearheads for hunting, and iron hooks for fishing.

ca. 150 C.E.: Kingdom of Meroë goes into decline from competition with the rival kingdom of Axum.

ca. 200 C.E.: Kingdom of Ghana, a major gold producer, flourishes.

THE MIDDLE EAST

ca. 420 B.C.E.: The Nabataeans establish a kingdom at Petra, in present-day Jordan.

ca. 311 B.C.E.: The start of the Seleucid Empire, which rules Babylonia and Syria.

ca. 66–ca. 73 B.C.E.: The first great revolt of the Jews of Judea against the Romans, during which legions under Titus destroyed Jerusalem, looting and burning Herod's Temple.

37 B.C.E.: Herod the Great is made king of Judea by the Romans.

7 B.C.E.: Jesus of Nazareth born in Bethlehem; historians arrive at this date based on astronomical records.

33 C.E.: Jesus Christ is condemned to death and crucified in Jerusalem; Christian religion founded.

ca. 50: Farmers in Near East (and China) first begin using silos for grain storage.

67: The apostle Paul, the leading member of the new Christian faith, is executed on June 29.

132–135: The second (sometimes called the third) Jewish revolt against the Roman Empire; after this revolt the emperor Hadrian roots out Jews and Judaism from Judea and bars Jews from Jerusalem.

ca. 224: Sassanian Dynasty begins in Persia and will rule until 651.

ASIA AND THE PACIFIC

ca. 475 B.C.E.: Beginning of the Iron Age in China.

ca. 400 B.C.E.: The Chinese become the first to use catapults in warfare.

ca. 301 B.C.E.: Nomadic tribes invade parts of northern China; Chinese construct a massive irrigation system to relieve flooding in river basins in Sichuan.

ca. 300 B.C.E.–ca. 300 C.E.: Yayoi Period in Japan; religion called Shinto may have originated during this period, though the matter is disputed.

ca. 221 B.C.E.: Qin Dynasty founded in China; country united.

ca. 202 B.C.E.: Han Dynasty begins in China.

ca. 101 B.C.E.: Using a compass for the first time, Chinese seafarers arrive on the eastern coast of India.

ca. 6 C.E.: People in China who want jobs as government officials have to take a civil service examination.

ca. 31: Earliest description of a Chinese horizontal waterwheel.

ca. 80: A massive migration of Asians moves westward with horses and cattle to join the Iranians and Mongols to become the Huns.

ca. 100: Japan imports rice for cultivation from China.

ca. 105: China develops the first paper made from fibers.

ca. 200: Japan invades and subdues Korea.

EUROPE

ca. 500 B.C.E.: Portions of Greece become the first to use coins.

ca. 480 B.C.E.–ca. 1 C.E.: La Tène culture, a Celtic Iron Age culture, emerges in the area of modern-day Switzerland, and the Celts expand through much of Europe.

ca. 457–ca. 429 B.C.E.: The “Golden Age” of Athens under the rule of Pericles.

ca. 450 B.C.E.: Celts arrive in the British Isles.

ca. 440 B.C.E.: The first textbook of geometry written by the Greek Hippocrates of Chios.

ca. 323–ca. 31 B.C.E.: Hellenistic Period of Greece.

ca. 312 B.C.E.: Construction on Roman Appian Way begins.

ca. 270 B.C.E.: Rome brings all of Italian Peninsula under its authority.

ca. 250 B.C.E.: Greek mathematician Archimedes calculates value of pi and develops the screw for pumping water.

ca. 170 B.C.E.: Rome builds the world’s first paved streets.

58–51 B.C.E.: Julius Caesar subdues Gaul (France) in the name of the Roman Empire.

1st century B.C.E.–476 C.E.: Roman Empire.

55 B.C.E.–43 C.E.: Roman Empire invades Britain twice, and Roman domination and influence grow through trade and other interactions; city of London founded.

60s: First revolts against Roman rule by Germanic and Celtic tribes.

64: Great Fire destroys much of Rome; first persecutions of Christians.

75–77: Roman conquest of Britain is complete.

ca. 138–ca. 192: Period of the so-called Antonine plague, a series of epidemics in the Roman world, including two notable outbreaks in 165 and 180.

167: The first Barbarian attacks on Rome.

THE AMERICAS

ca. 500 B.C.E.: Adena culture of the North American Midwest reaches its peak; date of the Maya story of creation, the Popol Vuh; the Cuspisnique build roads exclusively with walls.

ca. 400 B.C.E.: The Mayans begin using jugs with spouts.

ca. 400 B.C.E.–150 C.E.: Preclassic Period of Mayan civilization.

ca. 200 B.C.E.–ca. 600 B.C.E.: The Nazca create hundreds of earth drawings, or geoglyphs, that can be seen only from the air.

ca. 100 B.C.E.: Hopewell societies, especially in Illinois and Ohio, flourish; pottery from Peru and Ecuador shows the presence of facial ulceration, scarring, and malformation of the mucous membranes among the pre-Inca, an indication of epidemic *leishmaniasis*.

ca. 1 C.E.: Hohokam culture forms in U.S. Southwest; Toltec city of Teotihuacán founded.

ca. 50 C.E.: The city of Teotihuacán establishes control in the valley of Mexico; construction of the Pyramid of the Sun begins.

ca. 100–600: The Moche people flourish in northern Peru.

ca. 150–650: Classic Period of Mayan civilization.

250 C.E. – 500 C.E.

AFRICA

343 C.E.: King Ezana of Axum is converted to Christianity by Egyptian missionaries.

ca. 350: Kingdom of Axum defeats kingdom of Kush.

439 C.E.: Vandals capture the city of Carthage and establish a kingdom.

THE MIDDLE EAST

ca. 370: The Sassanian Dynasty attains the height of its power under the leadership of Shāpūr II.

ca. 460: Famine strikes the Sassanian Empire.

ASIA AND THE PACIFIC

ca. 280 C.E.: China is reunified under the Western Jin Dynasty.

ca. 300–ca. 538: Kofun Period in Japan.

ca. 320: Northern India unified by the Gupta Dynasty.

ca. 375 C.E.: Stirrups are invented in China.

ca. 450: The Chinese invent ink, made from lampblack.

EUROPE

313: Emperor Constantine I of Rome converts to Christianity and declares it the official religion of the empire.

330: Foundation of Constantinople by Emperor Constantine I of Rome.

ca. 360: Invasion of Europe by the Huns.

391: Roman emperor Theodosius I makes Christianity the sole legal religion of the Roman Empire.

410: Rome besieged by Visigoths under the command of Alaric.

ca. 430: Angles and Saxons from Denmark invade the eastern portion of Britain; the bubonic plague strikes Europe for the first time.

455: Vandals sack Rome.

476: The Roman Empire falls when the last of the Roman emperors in the West, Romulus Augustus, is deposed and not replaced.

THE AMERICAS

ca. 400 C.E.: The sacred site of Serpent Mound is created by the Hopewell culture in present-day Ohio.
